Acknowledgments

Hundreds of people have helped the SAS System in many ways since its inception. The following individuals have been especially helpful in the development of the procedures in SAS/ETS software. Acknowledgments for the SAS System generally appear in Base SAS software documentation and SAS/ETS software documentation. The organizations listed represent these individuals' affiliations when they made their most significant or most recent contributions.

David Amick	Idaho Office of Highway Safety
Lai Cheng	Haver Analytics
David M. DeLong	Duke University
David Dickey	North Carolina State University
Douglas J. Drummond	Center for Survey Statistics
Janet Eder	Chicago Booth Center for Research in Security Prices
George Essig	Federal Reserve Bank of St. Louis
Michel Ferland	Statistics Canada
Susie Fortier	Statistics Canada
William Fortney	Boeing Computer Services
Wayne Fuller	Iowa State University
A. Ronald Gallant	Fuqua School, Duke University
Phil Hanser	Sacramento Municipal Utilities District
Maurine Haver	Haver Analytics
Marvin Jochimsen	Mississippi R&O Center
Tammer Kamel	Quandl Search Engine
Jeff Kaplan	FIS Global (formerly SunGard Data Management Solutions)
Ken Kraus	Chicago Booth Center for Research in Security Prices
Dominique Ladiray	INSEE
Derek Manning	Factset Research Systems, Inc.
George McCollister	San Diego Gas & Electric
Douglas Miller	Purdue University
Brian C. Monsell	U.S. Census Bureau
Robert Parks	Washington University
Benoit Quenneville	Statistics Canada
Gregory Sali	Idaho Office of Highway Safety
David Sheldon	FactSet Research Systems, Inc.
Artur Shepilko	Chicago Booth Center for Research in Security Prices
Bob Spatz	Chicago Booth Center for Research in Security Prices
Greg Stumpf	Cooperative Institute for Mesoscale Meteorological Studies, University of Oklahoma
Thomas J. Turnage	Science and Operations Officer, NOAA - National Weather Service
Mary Young	Salt River Project

The final responsibility for the SAS System lies with SAS alone. We hope that you will always let us know your opinions about the SAS System and its documentation. It is through your participation that SAS software is continuously improved.

Overview of SAS/ETS Software

SAS/ETS software, a component of the SAS System, provides SAS procedures and data interface engines for the following:

- econometric analysis
- time series analysis
- time series forecasting
- panel data analysis, including dynamic panels
- spatial econometric linear models
- systems modeling and simulation
- discrete choice analysis
- analysis of qualitative and limited dependent variable models
- seasonal adjustment of time series data
- financial analysis and reporting
- access to economic and financial databases
- access to global weather databases
- time series data management
- high-performance econometric analysis in symmetric multiprocessing (SMP) mode

Uses of SAS/ETS Software

SAS/ETS software provides tools for a wide variety of applications in business, government, and academia. Major uses of SAS/ETS procedures are economic analysis, forecasting, economic and financial modeling, time series analysis, financial reporting, and manipulation of time series data.

The common theme relating the many applications of the software is time series data: SAS/ETS software is useful whenever it is necessary to analyze or predict processes that take place over time or to analyze models that involve simultaneous relationships.

Although SAS/ETS software is most closely associated with business, finance, and economics, time series data also arise in many other fields. SAS/ETS software is useful whenever time dependencies, simultaneous relationships, or dynamic processes complicate data analysis. For example, an environmental quality study might use SAS/ETS software's time series analysis tools to analyze pollution emissions data. A pharmacokinetic study might use SAS/ETS software's features for nonlinear systems to model the dynamics of drug metabolism in different tissues.

The diversity of problems for which econometrics and time series analysis tools are needed is reflected in the applications reported by SAS users. The following listed items are some applications of SAS/ETS software presented by SAS users at past annual conferences of the SAS Users Groups (SUGI and SAS Global Forum):

- analyzing heart rate variability of a sleep apnea and cardiovascular patient (Wongdhamma 2016)
- seasonality and interdependence of parking meter transactions (Milhøj 2015)
- modeling operational risk in banking (Rozo, Crook, and Moreira 2015)
- estimating volatility of financial assets (LaBarr 2014)
- analyzing levels, seasonality, and trends in e-commerce (Milhøj 2012)
- early detection of epidemic outbreaks (Shtatland and Shtatland 2008)
- modeling long-run water quality trends (Ragavan and Fernandez 2006)
- neural networks and genetic algorithms for forecasting automobile demand (McNelis and Nickelsburg 2002)
- forecasting college enrollment (Calise and Earley 1997)
- fitting a pharmacokinetic model (Morelock et al. 1995)
- testing interaction effects in reducing sudden infant death syndrome (Fleming, Gibson, and Fleming 1996)
- forecasting operational indices to measure productivity changes (McCarty 1994)
- spectral decomposition and reconstruction of nuclear plant signals (Hoyer and Gross 1993)
- estimating parameters for the constant-elasticity-of-substitution translog model (Hisnanick 1993)
- applying econometric analysis for mass appraisal of real property (Amal and Weselowski 1993)
- forecasting telephone usage data (Fischetti, Heathcote, and Perry 1993)

- forecasting demand and utilization of inpatient hospital services (Hisnanick 1992)
- using conditional demand estimation to determine electricity demand (Keshani and Taylor 1992)
- estimating tree biomass for measurement of forestry yields (Parresol and Thomas 1991)
- evaluating the theory of input separability in the production function of U.S. manufacturing (Hisnanick 1991)
- forecasting dairy milk yields and composition (Benseman 1990)
- predicting the gloss of coated aluminum products subject to weathering (Khan 1990)
- learning curve analysis for predicting manufacturing costs of aircraft (LeBouton 1989)
- analyzing Dow Jones stock index trends (Earley, Sweeney, and Zekavat 1989)
- analyzing the usefulness of the composite index of leading economic indicators for forecasting the economy (Lin and Myers 1988)

Contents of SAS/ETS Software

Procedures

SAS/ETS software includes the following SAS procedures:

ARIMA	ARIMA (Box-Jenkins) and ARIMAX (Box-Tiao) modeling and forecasting
AUTOREG	regression analysis with autocorrelated or heteroscedastic errors and ARCH and GARCH modeling
COMPUTAB	spreadsheet calculations and financial report generation
COPULA	fitting and simulating multivariate distributions by using copula methods
COUNTREG	regression modeling for dependent variables that represent counts
DATASOURCE	access to financial and economic databases
ENTROPY	maximum entropy-based regression
ESM	forecasting by using exponential smoothing models with optimized smoothing weights
EXPAND	time series interpolation, frequency conversion, and transformation of time series
LOAN	loan analysis and comparison
MDC	multinomial discrete choice analysis
MODEL	nonlinear simultaneous equations regression and nonlinear systems modeling and simulation
PANEL	panel data modeling
PDLREG	polynomial distributed lag regression
QLIM	qualitative and limited dependent variable analysis
SEVERITY	modeling the statistical distribution of the severity of losses and other events

SIMILARITY	similarity analysis of time series data for time series data mining
SIMLIN	linear systems simulation
SPATIALREG	spatial econometric models for cross-sectional data
SPECTRA	spectral and cross-spectral analysis
SSM	state space modeling of time series
STATESPACE	state space modeling and automated forecasting of multivariate time series
SYSLIN	linear simultaneous equations models
TIMEDATA	analyzes time-stamped transactional data with respect to time and accumulates the data into a time series format
TIMEID	identifying the time frequency for data sets that contain time series data
TIMESERIES	analysis of time-stamped transactional data
TMODEL	nonlinear simultaneous equations regression and nonlinear systems modeling and simulation
TSCSREG	time series cross-sectional regression analysis
UCM	unobserved components analysis of time series
VARMAX	vector autoregressive and moving average with modeling and forecasting
X11	seasonal adjustment (Census X-11 and X-11 ARIMA)
X12	seasonal adjustment (Census X-12 ARIMA)
X13	seasonal adjustment (Census X-13 ARIMA-SEATS)

High-Performance (HP) Procedures

High-performance (HP) procedures are adapted to perform optimally in symmetric multiprocessing (SMP) mode, providing faster performance by making multiple CPUs available to complete individual processes simultaneously.

SAS/ETS software includes the following high-performance procedures:

HPCDM	high-performance compound distribution models
HPCOPULA	high-performance fitting and simulation of multivariate distributions by using copula methods
HPCOUNTREG	high-performance regression modeling for count dependent variables
HPPANEL	high-performance panel data modeling
HPQLIM	high-performance qualitative and limited dependent variable analysis
HPSEVERITY	high-performance modeling of the severity of losses and other events

Access Interfaces to Economic and Financial Databases

SAS/ETS software includes the following LIBNAME statement engines to provide access to financial and economic databases:

SASECRSP	LIBNAME engine for accessing time series and event data that reside in a CRSPAccess database
SASEFAME	LIBNAME engine for accessing time series or case series data that reside in a FAME database
SASEFRED	LIBNAME engine to retrieve economic data from the FRED website, which is hosted by the Economic Research Division of the Federal Reserve Bank of St. Louis
SASEHAVR	LIBNAME engine for accessing time series that reside in a Haver Analytics Data Link Express (DLX) database
SASEOECD	LIBNAME engine for accessing time series to retrieve statistical data from the Organisation for Economic Cooperation and Development (OECD) website on topics such as agriculture and fisheries, economy, education, employment, energy, environment, finance, health, industry and entrepreneurship, innovation, insurance and pensions, international migration, internet economy, investment, OECD.Stat data warehouse, regional, rural and urban development, science and technology, social and welfare issues, tax, trade, and transport
SASEQUAN	LIBNAME engine to retrieve economic data from the Quandl website, which offers access to 8 million time series data sets from 400 sources in finance, economics, society, health, energy, demography, and more
SASEXCCM	LIBNAME engine for accessing data items that reside in the CRSP US Stock (STK) Database, the CRSP US Stock and Indices (IND) Database, the CRSP US Treasury (TRS) Database, or the CRSP/Compustat Merged (CCM) Database, which is created from data delivered via Standard & Poor's Compustat Xpressfeed product
SASEXFSD	LIBNAME engine for accessing both FactSet data and FactSet-sourced data that are provided by the FactSet OnDemand service
SASEWBGO	LIBNAME engine for accessing time series to retrieve statistical data from the World Bank Group Open (WBGO) data website, hosted by the World Bank Group. The most popular is the World Development Indicators (WDI) database, which presents the most current and accurate global development data available, including national, regional, and global estimates. The SASEWBGO interface engine supports access to the WDI database, but it also provides access to time series in other WBGO databases, such as the Global Economic Monitor (GEM) and the Special Data Dissemination Standard (SDDS)

Access Interfaces to Global Weather and NOAA Severe Weather Data Inventory Databases

SAS/ETS software includes the following LIBNAME statement engines to provide access to global weather and severe weather databases:

SASENOAA	LIBNAME engine to retrieve severe weather data such as tornado vortex signatures; mesocyclone signatures; digital mesocyclone detection algorithm; hail, storm cell structure, and preliminary local storm reports; and severe thunderstorm, tornado, flash flood, and

	special marine warnings from the NOAA Severe Weather Data Inventory (SWDI) web service
SASERAIN	LIBNAME engine to retrieve global weather data such as temperature, precipitation (rainfall), weather description, weather icon, and wind speed from the World Weather Online website

Macros

SAS/ETS software includes the following SAS macros:

%AR	generates statements to define autoregressive error models for the MODEL procedure
%EQAR	defines autoregressive error models that are specified using general form equations for the MODEL procedure
%BOXCOXAR	investigates Box-Cox transformations useful for modeling and forecasting a time series
%DFPVALUE	computes probabilities for Dickey-Fuller test statistics
%DFTEST	performs Dickey-Fuller tests for unit roots in a time series process
%LOGTEST	tests to determine whether a log transformation is appropriate for modeling and forecasting a time series
%MA	generates statements to define moving-average error models for the MODEL procedure
%EQMA	defines moving-average error models that are specified using general form equations for the MODEL procedure
%PDL	generates statements to define polynomial distributed lag models for the MODEL procedure

These macros are part of the SAS AUTOCALL facility and are automatically available for use in your SAS program. For information about the SAS macro facility, see *SAS Macro Language: Reference*.

SAS/ETS High-Performance Procedures

SAS/ETS high-performance procedures provide econometric modeling tools that have been specially developed to take advantage of parallel processing in multithreaded single-machine mode. Econometric modeling methods available in high-performance environment include regression for count data, models for the severity of losses or other events, compound distribution modeling, regression models for qualitative and limited dependent variables, copula simulation, and panel data modeling.

In addition to the high-performance econometric procedures described in this book, SAS/ETS includes high-performance utility procedures, which are described in *Base SAS Procedures Guide: High-Performance Procedures*. You can run all these procedures in single-machine mode without licensing SAS High-Performance Econometrics.

Experimental Software

Experimental software is sometimes included as part of a production-release product. It is provided to customers in order to obtain feedback. All experimental features are marked Experimental in this document. Whenever an experimental procedure, statement, or option is used, a message is displayed in the SAS log to indicate that it is experimental. The design and syntax of experimental software might change before any production release. Experimental software has been tested prior to release, but it has not necessarily been tested to production-quality standards, so it should be used with care.

About This Book

This book is a user's guide to SAS/ETS software. Since SAS/ETS software is a part of the SAS System, this book assumes that you are familiar with Base SAS software and have the books *SAS Programmers Guide: Essentials* and *Base SAS Procedures Guide* available for reference. It also assumes that you are familiar with SAS data sets, the SAS DATA step, and with basic SAS procedures such as PROC PRINT and PROC SORT. Chapter 3, "Working with Time Series Data," in this book summarizes the aspects of Base SAS software that are most relevant to the use of SAS/ETS software.

Chapter Organization

This book is divided into three major parts. *Part I* contains general information to aid you in working with SAS/ETS Software. *Part II* explains the SAS procedures of SAS/ETS software. *Part III* describes the available data access interfaces for economic, financial and weather databases.

Part I contains the following chapters.

Chapter 1, the current chapter, provides an overview of SAS/ETS software and summarizes related SAS publications, products, and services.

Chapter 2, "Shared Concepts in High-Performance Computing," describes the modes in which SAS/ETS high-performance procedures can execute.

Chapter 3, "Working with Time Series Data," discusses the use of SAS data management and programming features for time series data.

Chapter 4, "Date Intervals, Formats, and Functions," summarizes the time intervals, date and datetime informats, date and datetime formats, and date and datetime functions available in the SAS System.

Chapter 5, "SAS Macros and Functions," documents SAS macros and DATA step financial functions provided with SAS/ETS software. The macros use SAS/ETS procedures to perform Dickey-Fuller tests, test for the need for log transformations, or select optimal Box-Cox transformation parameters for time series data.

Chapter 6, "Nonlinear Optimization Methods," documents the NonLinear Optimization subsystem used by some ETS procedures to perform nonlinear optimization tasks.

Part II contains chapters that explain the SAS procedures that make up SAS/ETS software. These chapters appear in alphabetical order by procedure name.

Part III contains chapters that document the ETS access interfaces to economic, financial, and weather databases.

Each of the chapters that document the SAS/ETS procedures (*Part II*) and the SAS/ETS access interfaces (*Part III*) is organized as follows:

1. The "Overview" section gives a brief description of the procedure.
2. The "Getting Started" section provides a tutorial introduction on how to use the procedure.
3. The "Syntax" section is a reference to the SAS statements and options that control the procedure.
4. The "Details" section discusses various technical details.
5. The "Examples" section contains examples of the use of the procedure.
6. The "References" section contains technical references on methodology.

Syntax Conventions

Each procedure's "Syntax" section follows the conventions that are described in this section. Consider the following statements:

CLASS *variable* < *(options)* > . . . < *variable* < *(options)* > > < / *global-options* > **;**

RANGE FROM *from* **TO** *to* **;**

<*label*:> **TEST** <'*string*'> *equation1* < *, equation2. . .* > / *test-options* **;**

These statements demonstrate the syntax conventions that are described in the following list:

UPPERCASE BOLD is used for keywords in lists of SAS statements and options in "Syntax" sections. When you type a keyword in SAS code, you type it as shown (although any mix of uppercase and lowercase is valid). In the preceding examples, the statement names (CLASS, RANGE, and TEST) are keywords. In addition, the FROM and TO are required keywords in the RANGE statement. Note that keywords are displayed only in uppercase (not bold) when they are used in text.

oblique is used in syntax definitions and in text to represent arguments for which you supply a value. The preceding CLASS statement indicates that *variable*, *options*, and *global-options* are arguments for which you can supply values. The values that you can supply are defined later in the description of the CLASS statement.

< > (angle brackets) identify optional arguments. Arguments that are not enclosed in angle brackets are required. In the preceding CLASS statement, you must supply a value for one *variable* because the first *variable* is not enclosed in angle brackets. However, supplying values for additional *variables*, *options*, and *global-options* is optional.

. . . (ellipsis dots) indicate that the preceding argument can be repeated. In the preceding CLASS statement, the ". . ." indicates that you can supply additional *variables*, (along with optional *options*). Sometimes the argument is shown again after the ". . ." to emphasize that it can be repeated.

'*value*'	(straight quotes around a *value*) indicate that the *value* must be enclosed in quotation marks (which can be single or double quotes). In the preceding TEST statement, straight quotes around *string* indicate that you must use quotation marks when you specify a string.
( )	(parentheses) indicate arguments that must be grouped together. In the preceding CLASS statement, you must type parentheses around the *options* in order to indicate which syntax elements are *options* and which are *variables*. Statements that do not require parentheses to indicate association sometimes allow you to omit the parentheses when you specify only one *option*; these cases are indicated in the statement description.
|	(vertical bar) indicates that you can choose one value from a group of values. Values that are separated by a vertical bar are mutually exclusive. A vertical bar indicates mutually exclusive values for an option or indicates aliases for an option name.
;	(semicolon) indicates the end of a statement.

Other special characters—such as an equal sign (=), tilde (~), colon (:), and slash (/)—indicate where in the syntax you must type those characters.

Typographical Conventions

This book uses several type styles for presenting information. The following list explains the meaning of the typographical conventions used in this book:

UPPERCASE ROMAN	is used for SAS statements, options, and other SAS language elements when they appear in the text. However, you can enter these elements in your own SAS programs in lowercase, uppercase, or a mixture of the two.
VariableName	is used for the names of variables and data sets when they appear in the text.
bold	is used to refer to matrices and vectors.
italic	is used for terms that are defined in the text, for emphasis, and for references to publications.
`monospace`	is used for example code. In most cases, this book uses lowercase type for SAS code.

Options Used in Examples

The HTMLBLUE style is used to create the graphs and the HTML tables that appear in the online documentation. The PEARLJ style is used to create the PDF tables that appear in the documentation. A style template controls stylistic elements such as colors, fonts, and presentation attributes. You can specify a style template in an ODS destination statement as follows:

```
ods html style=HTMLBlue;
. . .
ods html close;

ods pdf style=PearlJ;
. . .
ods pdf close;
```

Most of the PDF tables are produced by using the following SAS System option:

```
options papersize=(6.5in 9in);
```

If you run the examples, you might get slightly different output. This is a function of the SAS System options that are used and the precision that your computer uses for floating-point calculations.

Where to Turn for More Information

This section describes other sources of information about SAS/ETS software.

SAS Short Courses

The SAS Education Division offers a number of training courses that might be of interest to SAS/ETS users. Please check the SAS web site for the current list of available training courses.

SAS Technical Support Services

As with all SAS products, the SAS Technical Support staff is available to respond to problems and answer technical questions regarding the use of SAS/ETS software. Go to `http://support.sas.com/techsup` for more information.

Major Features of SAS/ETS Software

The following sections summarize major features of SAS/ETS software. For more information, see the chapters on individual procedures.

ARIMA (Box-Jenkins) and ARIMAX (Box-Tiao) Modeling and Forecasting

The ARIMA procedure provides the identification, parameter estimation, and forecasting of autoregressive integrated moving-average (Box-Jenkins) models, seasonal ARIMA models, transfer function models, and intervention models. The ARIMA procedure includes the following features:

- complete ARIMA (Box-Jenkins) modeling with no limits on the order of autoregressive or moving-average processes
- model identification diagnostics, including the following:
  - autocorrelation function
  - partial autocorrelation function
  - inverse autocorrelation function
  - cross-correlation function
  - extended sample autocorrelation function
  - minimum information criterion for model identification
  - squared canonical correlations
- stationarity tests
- outlier detection
- intervention analysis
- regression with ARMA errors
- transfer function modeling with fully general rational transfer functions
- seasonal ARIMA models
- ARIMA model-based interpolation of missing values
- several parameter estimation methods, including the following:
  - exact maximum likelihood
  - conditional least squares
  - exact nonlinear unconditional least squares (ELS or ULS)
- prewhitening transformations
- forecasts and confidence limits for all models

- forecasting tied to parameter estimation methods: finite memory forecasts for models estimated by maximum likelihood or exact nonlinear least squares methods and infinite memory forecasts for models estimated by conditional least squares
- diagnostic statistics to help judge the adequacy of the model, including the following:
  - Akaike's information criterion (AIC)
  - Schwarz's Bayesian criterion (SBC or BIC)
  - Box-Ljung chi-square test statistics for white-noise residuals
  - autocorrelation function of residuals
  - partial autocorrelation function of residuals
  - inverse autocorrelation function of residuals
  - automatic outlier detection

Structural Time Series Modeling and Forecasting

The UCM procedure provides a flexible environment for analyzing time series data using structural time series models, also called unobserved components models (UCM). These models represent the observed series as a sum of suitably chosen components such as trend, seasonal, cyclical, and regression effects. You can use the UCM procedure to formulate comprehensive models that bring out all the salient features of the series under consideration. Structural models are applicable in the same situations where Box-Jenkins ARIMA models are applicable; however, the structural models tend to be more informative about the underlying stochastic structure of the series. The UCM procedure includes the following features:

- general unobserved components modeling where the models can include trend, multiple seasons and cycles, and regression effects
- maximum-likelihood estimation of the model parameters
- model diagnostics that include a variety of goodness-of-fit statistics, and extensive graphical diagnosis of the model residuals
- forecasts and confidence limits for the series and all the model components
- Model-based seasonal decomposition
- extensive plotting capability that includes the following:
  - forecast and confidence interval plots for the series and model components such as trend, cycles, and seasons
  - diagnostic plots such as residual plot, residual autocorrelation plots, and so on
  - seasonal decomposition plots such as trend, trend plus cycles, trend plus cycles plus seasons, and so on
- model-based interpolation of series missing values
- full sample (also called smoothed) estimates of the model components

Regression with Autocorrelated and Heteroscedastic Errors

The AUTOREG procedure provides regression analysis and forecasting of linear models with autocorrelated or heteroscedastic errors. The AUTOREG procedure includes the following features:

- estimation and prediction of linear regression models with autoregressive errors
- autoregressive or subset autoregressive processes of any order
- optional stepwise selection of autoregressive parameters
- choice of the following estimation methods:
  - exact maximum likelihood
  - exact nonlinear least squares
  - Yule-Walker
  - iterated Yule-Walker
- tests for any linear hypothesis that involves the structural coefficients
- restrictions for any linear combination of the structural coefficients
- forecasts with confidence limits
- estimation and forecasting for A of ARCH (autoregressive conditional heteroscedasticity), and the following variations:
  - GARCH (generalized autoregressive conditional heteroscedasticity)
  - IGARCH (integrated GARCH)
  - EGARCH (exponential GARCH)
  - QGARCH (quadratic GARCH)
  - TGARCH (threshold GARCH)
  - PGARCH (power GARCH)
  - GARCH-M (GARCH-in-mean)
- combination of ARCH and GARCH models with autoregressive models, with or without regressors
- estimation and testing of general heteroscedasticity models
- variety of model diagnostic information, including the following:
  - autocorrelation plots
  - partial autocorrelation plots
  - Durbin-Watson test statistic and generalized Durbin-Watson tests of any order
  - Durbin *h* and Durbin *t* statistics
  - Godfrey LM test
  - Ramsey's RESET test

  - McLeod-Li portmanteau Q test for ARCH disturbances
  - Engle's LM test for ARCH disturbances
  - Lee and King's for ARCH disturbances
  - Wong and Li's test for ARCH disturbances
  - Chow test
  - Bai-Perron supF, UDmaxF, WDmaxF, and supF($l + 1|l$) tests
  - Akaike's information criterion
  - Schwarz information criterion
  - Phillips-Perron stationarity test
  - Phillips-Ouliaris cointegration test
  - Kwiatkowski-Phillips-Schmidt-Shin (KPSS) test
  - Shin cointegration test
  - augmented Dickey-Fuller test
  - Engle-Granger cointegration test
  - Elliot, Rothenberg, and Stock test
  - Ng and Perron test
  - tests for statistical independence
  - Jarque-Bera test for normality
  - CUSUM and CUMSUMSQ statistics
- exact significance levels (p-values) for the Durbin-Watson statistic
- embedded missing values

Count Data Models

The COUNTREG procedure provides regression models in which the dependent variable takes nonnegative integer count values. The COUNTREG procedure supports the following features:

- Poisson regression
- Conway-Maxwell-Poisson regression
- negative binomial regression with quadratic and linear variance functions
- zero-inflated Poisson (ZIP) regression
- zero-inflated Conway-Maxwell-Poisson regression
- zero-inflated negative binomial (ZINB) regression
- fixed- and random-effects Poisson panel data models

- fixed- and random-effects NB (negative binomial) panel data models
- variable selection
- Bayesian estimation and inference, including diagnostic plots

Multinomial Discrete Choice Analysis

The MDC procedure provides maximum likelihood (ML) or simulated maximum likelihood estimates of multinomial discrete choice models in which the choice set consists of unordered multiple alternatives. The decision makers can be people, households, firms, or any other decision-making units, and the alternatives are a set of competing options. Unordered multiple choices are observed in many settings, including choices of housing location, occupation, political party affiliation, and mode of transportation.

The MDC procedure supports the following models and features:

- intuitive
- conditional logit
- nested logit
- heteroscedastic extreme value
- multinomial probit
- mixed logit
- pseudorandom or quasi-random numbers for simulated maximum likelihood estimation
- bounds imposed on the parameter estimates
- linear restrictions imposed on the parameter estimates
- SAS data set containing predicted probabilities and linear predictor ($\mathbf{x}'\boldsymbol{\beta}$) values
- decision tree and nested logit
- model fit and goodness-of-fit measures, including the following:
  - likelihood ratio
  - Aldrich-Nelson
  - Cragg-Uhler 1
  - Cragg-Uhler 2
  - Estrella
  - adjusted Estrella
  - McFadden's LRI
  - Veall-Zimmermann
  - Akaike's information criterion (AIC)
  - Schwarz criterion or Bayesian information criterion (BIC)

Panel Data Linear Models

The PANEL procedure deals with panel data sets that consist of time series observations on each of several cross-sectional units. The PANEL procedure includes the following features:

- one-way and two-way fixed effects
- one-way and two-way random effects
- variance component estimation by the following methods:
  - Fuller and Battese method (variance component model)
  - Wansbeek and Kapteyn method
  - Wallace and Hussain method
  - Nerlove method
- Parks method (autoregressive model)
- Da Silva method (mixed variance component moving-average model)
- Hausman-Taylor and Amemiya-MaCurdy estimation
- dynamic-panel estimation one-step, two-step, or iterative generalized method of moments (GMM)
- support for unbalanced panel data for all methods
- model specification tests
- panel data unit-root tests
- automatic generation of lagged variables
- model comparison tables
- model specification tests
- variety of estimates and statistics, including the following:
  - underlying error components estimates
  - regression parameter estimates
  - standard errors of estimates
  - *t* tests
  - R-square statistic
  - correlation matrix of estimates
  - covariance matrix of estimates
  - autoregressive parameter estimate
  - cross-sectional components estimates
  - autocovariance estimates
  - *F* tests of linear hypotheses about the regression parameters
  - specification tests, including the Hausman test

Qualitative and Limited Dependent Variable Analysis

The QLIM procedure analyzes univariate and multivariate limited dependent variable models where dependent variables take discrete values or dependent variables are observed only in a limited range of values. This procedure includes logit, probit, Tobit, and general simultaneous equations models. The QLIM procedure includes the following features:

- linear regression with heteroscedasticity
- probit models with heteroscedasticity
- logit models with heteroscedasticity
- Tobit models (censored and truncated) with heteroscedasticity
- Box-Cox regression with heteroscedasticity
- bivariate probit models
- bivariate Tobit models
- ordered logit and ordered probit models
- sample selection models, including the Heckman model
- multivariate limited dependent models
- stochastic frontier models
- random effects and random coefficients
- Bayesian estimation and inference, including diagnostic plots
- residual plots, predictive plots, marginal-effects plots, and so on

Spatial Econometric Models

The SPATIALREG procedure analyzes spatial econometric models for cross-sectional data where observations are spatially referenced or georeferenced. The SPATIALREG procedure includes the following features:

- linear models with spatial log of X (SLX) effects
- spatial autoregressive (SAR) model
- spatial Durbin model (SDM)
- spatial error model (SEM)
- spatial Durbin error model (SDEM)

- spatial moving average (SMA) model
- spatial Durbin moving average (SDMA) model
- spatial autoregressive moving average (SARMA) model
- spatial Durbin autoregressive moving average (SDARMA) model
- spatial autoregressive confused (SAC) model
- spatial Durbin autoregressive confused (SDAC) model
- *k*-order binary contiguity spatial weight matrices
- *k*-order nearest neighbor spatial weight matrices
- compact representations of spatial weight matrices
- Taylor and Chebyshev approximations for large data sets

Vector Time Series Analysis

The VARMAX procedure enables you to model the dynamic relationship both between the dependent variables and between the dependent and independent variables. The VARMAX procedure includes the following features:

- several modeling features:
  - vector autoregressive model (VAR)
  - vector autoregressive model with exogenous variables (VARX)
  - vector autoregressive and moving-average model (VARMA)
  - vector autoregressive and moving-average model with exogenous variables (VARMAX)
  - vector autoregressive fractionally integrated moving-average model (VARFIMA)
  - vector autoregressive fractionally integrated moving-average model with exogenous variables (VARFIMAX)
  - Bayesian vector autoregressive model (BVAR)
  - vector error correction model (VECM)
  - Bayesian vector error correction model (BVECM)
  - GARCH-type multivariate conditional heteroscedasticity models (BEKK, CCC, DCC)
  - vector error correction model in ARMA-GARCH form
- criteria for automatically determining AR and MA orders:
  - Akaike's information criterion (AIC)
  - corrected AIC (AICC)
  - Hannan-Quinn (HQ) criterion

  - final prediction error (FPE)
  - Schwarz Bayesian criterion (SBC), also known as Bayesian information criterion (BIC)
- AR order identification aids:
  - partial cross-correlations
  - Yule-Walker estimates
  - partial autoregressive coefficients
  - partial canonical correlations
- testing the presence of unit roots and cointegration:
  - Dickey-Fuller tests
  - Johansen cointegration test for nonstationary vector processes of integrated order one
  - Stock-Watson common trends test for the possibility of cointegration among nonstationary vector processes of integrated order one
  - Johansen cointegration test for nonstationary vector processes of integrated order two
- model parameter estimation methods:
  - least squares (LS)
  - maximum likelihood (ML)
  - conditional maximum likelihood (CML)
- model checks and residual analysis using the following tests:
  - Durbin-Watson (DW) statistics
  - F test for autoregressive conditional heteroscedastic (ARCH) disturbance
  - F test for AR disturbances
  - Jarque-Bera normality test
  - portmanteau test
- seasonal deterministic terms
- subset models
- multiple regression with distributed lags
- dead-start model that does not have present values of the exogenous variables
- Granger-causal relationships between two distinct groups of variables
- infinite order AR representation
- impulse response function (or infinite order MA representation)
- decomposition of the predicted error covariances
- roots of the characteristic functions for both the AR and MA parts to evaluate the proximity of the roots to the unit circle

- contemporaneous relationships among the components of the vector time series
- forecasts
- conditional covariances for GARCH models
- log-likelihood output
- specification of initial parameter values for optimization
- constraints and bounds on parameters for optimization
- Wald tests

Simultaneous Systems Linear Regression

The SYSLIN and ENTROPY procedures provide regression analysis of a simultaneous system of linear equations.

The SYSLIN procedure includes the following features:

- estimation of parameters in simultaneous systems of linear equations
- full range of estimation methods including the following:
  - ordinary least squares (OLS)
  - two-stage least squares (2SLS)
  - three-stage least squares (3SLS)
  - iterated 3SLS (IT3SLS)
  - seemingly unrelated regression (SUR)
  - iterated SUR (ITSUR)
  - limited-information maximum likelihood (LIML)
  - full-information maximum likelihood (FIML)
  - minimum expected loss (MELO)
  - general K-class estimators
- weighted regression
- any number of restrictions for any linear combination of coefficients, within a single model or across equations
- tests for any linear hypothesis, for the parameters of a single model or across equations
- wide range of model diagnostics and statistics including the following:
  - usual ANOVA tables and R-square statistics
  - Durbin-Watson statistics

  - standardized coefficients
  - test for overidentifying restrictions
  - residual plots
  - standard errors and *t* tests
  - covariance and correlation matrices of parameter estimates and equation errors
- predicted values, residuals, parameter estimates, and variance-covariance matrices saved in output SAS data sets
- other features of the SYSLIN procedure that enable you to do the following:
  - impose linear restrictions on the parameter estimates
  - test linear hypotheses about the parameters
  - write predicted and residual values to an output SAS data set
  - write parameter estimates to an output SAS data set
  - write the crossproducts matrix (SSCP) to an output SAS data set
  - use raw data, correlations, covariances, or cross products as input

The ENTROPY procedure supports the following models and features:

- generalized maximum entropy (GME) estimation
- generalized cross entropy (GCE) estimation
- normed moment generalized maximum entropy
- maximum entropy-based seemingly unrelated regression (MESUR) estimation
- pure inverse estimation
- estimation of parameters in simultaneous systems of linear equations
- Markov models
- unordered multinomial choice problems
- weighted regression
- any number of restrictions for any linear combination of coefficients, within a single model or across equations
- tests for any linear hypothesis, for the parameters of a single model or across equations

Linear Systems Simulation

The SIMLIN procedure performs simulation and multiplier analysis for simultaneous systems of linear regression models. The SIMLIN procedure includes the following features:

- reduced form coefficients
- interim multipliers
- total multipliers
- dynamic multipliers
- multipliers for higher-order lags
- dynamic forecasts and simulations
- goodness-of-fit statistics
- acceptance of the equation system coefficients estimated by the SYSLIN procedure as input

Polynomial Distributed Lag Regression

The PDLREG procedure provides regression analysis for linear models with polynomial distributed (Almon) lags. The PDLREG procedure includes the following features:

- entry of any number of regressors as a polynomial lag distribution and the use of any number of covariates
- use of any order lag length and degree polynomial for lag distribution
- optional upper and lower endpoint restrictions
- specification of any number of linear restrictions on covariates
- option to repeat analysis over a range of degrees for the lag distribution polynomials
- support for autoregressive errors to any lag
- forecasts with confidence limits

Nonlinear Systems Regression and Simulation

The MODEL and TMODEL procedures provide parameter estimation, simulation, and forecasting of dynamic nonlinear simultaneous equation models. The TMODEL procedure is a newer, multithreaded version of the MODEL procedure. The MODEL and TMODEL procedures include the following features:

- nonlinear regression analysis for systems of simultaneous equations, including weighted nonlinear regression
- full range of parameter estimation methods including the following:
  - nonlinear ordinary least squares (OLS)
  - nonlinear seemingly unrelated regression (SUR)
  - nonlinear two-stage least squares (2SLS)
  - nonlinear three-stage least squares (3SLS)
  - iterated SUR
  - iterated 3SLS
  - generalized method of moments (GMM)
  - nonlinear full-information maximum likelihood (FIML)
  - simulated method of moments (SMM)
- supports dynamic multi-equation nonlinear models of any size or complexity
- uses the full power of the SAS programming language for model definition, including left-hand-side expressions
- hypothesis tests of nonlinear functions of the parameter estimates
- linear and nonlinear restrictions of the parameter estimates
- bounds imposed on the parameter estimates
- computation of estimates and standard errors of nonlinear functions of the parameter estimates
- estimation and simulation of ordinary differential equations (ODEs), and differential algebraic equations (DAEs)
- vector autoregressive error processes and polynomial lag distributions easily specified for the nonlinear equations
- variance modeling (ARCH, GARCH, and others)
- computation of goal-seeking solutions of nonlinear systems to find input values needed to produce target outputs
- dynamic, static, or *n*-period-ahead forecast simulation modes
- simultaneous solution or single equation solution modes

- Monte Carlo simulation using parameter estimate covariance and across-equation residuals covariance matrices or user-specified random functions
- Monte Carlo simulation of multidimensional systems using copulas
- a variety of diagnostic statistics including the following
  - model R-square statistics
  - general Durbin-Watson statistics and exact *p*-values
  - asymptotic standard errors and *t* tests
  - first-stage R-square statistics
  - covariance estimates
  - collinearity diagnostics
  - simulation goodness-of-fit statistics
  - Theil inequality coefficient decompositions
  - Theil relative change forecast error measures
  - heteroscedasticity tests
  - Godfrey test for serial correlation
  - Hausman specification test
  - Chow tests
- block structure and dependency structure analysis for the nonlinear system
- listing and cross-reference of fitted model
- automatic calculation of needed derivatives by using exact analytic formula
- efficient sparse matrix methods used for model solution; choice of other solution methods

Model definition, parameter estimation, simulation, and forecasting can be performed interactively in a single SAS session, or models can be stored in files and reused and combined in later runs.

State Space Modeling and Forecasting

The SSM procedure provides state space modeling of univariate and multivariate time series and longitudinal data. State space models encompass an alternative general formulation of multivariate ARIMA models. The SSM procedure includes the following features:

- general linear state space models (SSMs)
- expressive language to specify an SSM, including flexible and intuitive specification of transition and covariance matrices
- easy specification of commonly used SSMs by using only a few keywords
- restricted maximum likelihood estimation computed using the (diffuse) Kalman filter algorithm

- forecasts, residuals, and full-sample estimations of any linear combination of state variables
- residual diagnostics plots
- plots for detecting structural breaks

Spectral Analysis

The SPECTRA procedure provides spectral analysis and cross-spectral analysis of time series. The SPECTRA procedure includes the following features:

- efficient calculation of periodogram and smoothed periodogram using fast finite Fourier transform and Chirp-Z algorithms
- multiple spectral analysis, including raw and smoothed spectral and cross-spectral function estimates, with user-specified window weights
- choice of kernel for smoothing
- output of the following spectral estimates to a SAS data set:
  - Fourier sine and cosine coefficients
  - periodogram
  - smoothed periodogram
  - cospectrum
  - quadrature spectrum
  - amplitude
  - phase spectrum
  - squared coherency
- Fisher's Kappa and Bartlett's Kolmogorov-Smirnov test statistic for testing a null hypothesis of white noise

Distribution of the Severity

The SEVERITY procedure estimates parameters of any probability distribution that is used to model the magnitude (severity) of a continuous-valued event of interest. The SEVERITY procedure includes the following features:

- parameter estimation of predefined distribution models, including the following:
  - Burr distribution
  - exponential distribution
  - gamma distribution
  - generalized Pareto distribution
  - inverse Gaussian (Wald) distribution
  - lognormal distribution
  - Pareto distribution
  - Tweedie distribution
  - Weibull distribution
- parameter estimation of arbitrarily defined parametric distribution models
- fitting distributions to data by either truncation or censoring
- group estimation
- several fit statistics, including the following:
  - log likelihood
  - Akaike's information criterion (AIC)
  - corrected Akaike's information criterion (AICC)
  - Schwarz Bayesian information criterion (BIC)
  - Kolmogorov-Smirnov statistic (KS)
  - Anderson-Darling statistic (AD)
  - Cramér–von Mises statistic (CvM)
- regression effects
- scoring functions
- multithreaded computation
- ability to specify the objective function for optimization
- plots of the estimated cumulative distribution function (CDF), the estimated empirical distribution function (EDF), and the estimated probability density function (PDF)

Compound Distribution Models

The HPCDM procedure computes an estimate of the compound distribution model, given the distributions of the parameters. For example, PROC HPCDM can estimate the distribution of the aggregate loss during a time period of interest, given the distribution models of the frequency (count) and of the severity of loss.

The HPCDM procedure includes the following features:

- accepts severity models estimated by the SEVERITY procedure and frequency models estimated by the COUNTREG procedure
- scenario analysis with regression effects
- group scenario analysis with classification and interaction effects
- support for externally simulated counts
- parameter perturbation analysis that assesses the effect of parameter uncertainty associated with frequency and severity models
- ability to compute the distribution of aggregate *adjusted* loss

Similarity Analysis

The SIMILARITY procedure computes similarity measures associated with time-stamped data, time series, and other sequentially ordered numeric data. The SIMILARITY procedure includes the following features:

- ability to accumulate time-stamped data into a time series
- missing value interpretation
- zero value interpretation
- functional transformations of time series, including the following:
  - log (LOG)
  - square-root (SQRT)
  - logistic (LOGISTIC)
  - Box-Cox (BOXCOX)
  - user-defined transformations
- simple differencing and seasonal differencing
- time series missing value trimming
- time warping by compressing or expanding the input sequence with respect to the target sequence
- sequence normalizations, including the following:

  - standard (STANDARD)
  - absolute (ABSOLUTE)
  - user-defined normalizations
- sequence scaling, including the following:
  - standard (STANDARD)
  - absolute (ABSOLUTE)
  - user-defined scaling
- ability to compute similarity measures, including the following:
  - squared deviation (SQRDEV)
  - absolute deviation (ABSDEV)
  - mean square deviation (MSQRDEV)
  - mean absolute deviation (MABSDEV)
  - user-defined similarity measures
- sliding similarity measures analysis with three types of sequence sliding:
  - no sliding
  - slide by time index
  - slide by season index
- support for large data sets

Seasonal Adjustment

The X13 procedure provides seasonal adjustment of time series by using the US Bureau of the Census X-13ARIMA-SEATS seasonal adjustment program. The X-13ARIMA-SEATS program was developed by the Time Series Staff of the Statistical Research Division, US Census Bureau, by incorporating the SEATS method into the X-12-ARIMA seasonal adjustment program.

The X13 procedure generalizes the older X11 and X12 procedures and includes the following features:

- US Bureau of the Census X-13ARIMA-SEATS seasonal adjustment program
- support for the X-12 ARIMA method
- support for the X-11 ARIMA method
- all the features of the Census Bureau program
- processing of any number of variables at once with no maximum length for a series
- decomposition of monthly or quarterly series into seasonal, trend, trading day, and irregular components

- multiplicative, additive, pseudo-additive, and log additive forms of the decomposition
- support for regARIMA modeling
- automatic identification of outliers
- support for TRAMO-based automatic model selection
- support for sliding spans analysis
- use of regressors to process missing values within the span of the series
- computation of tests for stable, moving, and combined seasonality
- spectral analysis of original, seasonally adjusted, and irregular series
- ability to project seasonal component one year ahead, which enables reintroduction of seasonal factors for an extrapolated series
- full control over what is printed or output

Automatic Time Series Forecasting

The ESM procedure provides a quick way to generate forecasts for many time series or transactional data in one step by using exponential smoothing methods. All parameters associated with the forecasting model are optimized based on the data.

You can use the following smoothing models:

- simple
- double
- linear
- damped trend
- seasonal
- Winters method (additive and multiplicative)

Additionally, PROC ESM can transform the data before applying the smoothing methods using any of these transformations:

- log
- square root
- logistic
- Box-Cox

In addition to forecasting, the ESM procedure can also produce graphic output.

The ESM procedure can forecast both time series data, whose observations are equally spaced at a specific time interval (for example, monthly, weekly), or transactional data, whose observations are not spaced with respect to any particular time interval. (Internet, inventory, sales, and similar data are typical examples of transactional data. For transactional data, the data are accumulated based on a specified time interval to form a time series.)

Time Series Interpolation and Frequency Conversion

The EXPAND procedure provides time interval conversion and missing value interpolation for time series. The EXPAND procedure includes the following features:

- conversion of time series frequency; for example, constructing quarterly estimates from annual series or aggregating quarterly values to annual values
- conversion of irregular observations to periodic observations
- interpolation of missing values in time series
- conversion of observation types; for example, estimate stocks from flows and vice versa. All possible conversions are supported between any of the following:
  - beginning of period
  - end of period
  - period midpoint
  - period total
  - period average
- conversion of time series phase shift; for example, conversion between fiscal years and calendar years
- identifying observations including the following:
  - identification of the time interval of the input values
  - validation of the input data set observations
  - computation of the ID values for the observations in the output data set
- choice of four interpolation methods:
  - cubic splines
  - linear splines
  - step functions
  - simple aggregation
- ability to perform extrapolation by a linear projection of the trend of the cubic spline curve fit to the input data

- ability to transform series before and after interpolation (or without interpolation) by using any of the following:
  - constant shift or scale
  - sign change or absolute value
  - logarithm, exponential, square root, square, logistic, inverse logistic
  - lags, leads, differences
  - classical decomposition
  - bounds, trims, reverse series
  - centered moving, cumulative, or backward moving average
  - centered moving, cumulative, or backward moving range
  - centered moving, cumulative, or backward moving geometric mean
  - centered moving, cumulative, or backward moving maximum
  - centered moving, cumulative, or backward moving median
  - centered moving, cumulative, or backward moving minimum
  - centered moving, cumulative, or backward moving product
  - centered moving, cumulative, or backward moving corrected sum of squares
  - centered moving, cumulative, or backward moving uncorrected sum of squares
  - centered moving, cumulative, or backward moving rank
  - centered moving, cumulative, or backward moving standard deviation
  - centered moving, cumulative, or backward moving sum
  - centered moving, cumulative, or backward moving median
  - centered moving, cumulative, or backward moving *t*-value
  - centered moving, cumulative, or backward moving variance
- support for a wide range of time series frequencies:
  - YEAR
  - SEMIYEAR
  - QUARTER
  - MONTH
  - SEMIMONTH
  - TENDAY
  - WEEK
  - WEEKDAY
  - DAY
  - HOUR
  - MINUTE
  - SECOND

- support for repeating of shifting the basic interval types to define a great variety of different frequencies, such as fiscal years, biennial periods, work shifts, and so forth

For more information about time series data transformations, see Chapter 3, "Working with Time Series Data," and Chapter 4, "Date Intervals, Formats, and Functions."

Trend and Seasonal Analysis on Transaction Databases

The TIMESERIES procedure can accumulate transactional data to time series and perform trend and seasonal analysis on the accumulated time series.

Time series analyses performed by the TIMESERIES procedure include the follows:

- descriptive statistics relevant for time series data
- seasonal decomposition and seasonal adjustment analysis
- correlation analysis
- cross-correlation analysis

The TIMESERIES procedure includes the following features:

- ability to process large amounts of time-stamped transactional data
- statistical methods useful for large-scale time series analysis or (temporal) data mining
- output data sets stored in either a time series format (default) or a coordinate format (transposed)

The TIMESERIES procedure is normally used to prepare data for subsequent analysis that uses other SAS/ETS procedures or other parts of the SAS system. The time series format is most useful when the data are to be analyzed with SAS/ETS procedures. The coordinate format is most useful when the data are to be analyzed with SAS/STAT procedures.

Endogeneity and Instrumental Variables

SAS/ETS software provides several procedures that estimate models that have endogeneity. Endogeneity usually occurs for three reasons: omitted variables, measurement error in regressors, and simultaneity. In dynamic models, endogeneity is even more relevant, because regressors might be correlated with the error term not only from the current time period but from preceding periods as well. The following procedures support models that have endogeneity.

The MODEL and TMODEL procedures include the following features related to endogeneity:

- nonlinear regression analysis of single equations
- nonlinear regression analysis of systems of simultaneous equations

- support for general-form models that have endogeneity
- a variety of estimation methods to handle endogeneity, including the following:
  - (nonlinear) two-stage least squares (2SLS)
  - iterated two-stage least squares (IT2SLS)
  - (nonlinear) three-stage least squares (3SLS)
  - iterated three-stage least squares (IT3SLS)
  - generalized method of moments (GMM)
  - iterated generalized method of moments (ITGMM)
  - full-information maximum likelihood (FIML)

The SYSLIN procedure includes the following features related to endogeneity:

- linear regression analysis of single equations
- linear regression analysis of systems of simultaneous equations
- a variety of estimation methods to handle endogeneity, including the following:
  - (nonlinear) two-stage least squares (2SLS)
  - (nonlinear) three-stage least squares (3SLS)
  - iterated three-stage least squares (IT3SLS)
  - limited-information maximum likelihood (LIML)
  - minimum expected loss (MELO)
  - general K-class estimators
  - full-information maximum likelihood (FIML)

The SIMLIN procedure performs simulation and multiplier analysis of simultaneous systems of linear regression models that have endogeneity.

The QLIM procedure includes the following features related to endogeneity:

- test of endogeneity for a list of regressors in the model
- overidentification test for the validity of instrumental variables
- ability to estimate models that have endogeneity by adding regressions of endogenous regressors on exogenous regressors and instrumental variables
- ability to estimate structural models that contain one endogenous variable by using full-information maximum likelihood (FIML)
- ability to estimate structural models that contain multiple endogenous variables by using simulated maximum likelihood

The PANEL procedure uses instrumental variable regressions to estimate both static and dynamic panel models that have endogeneity:

- Hausman-Taylor and Amemiya-MaCurdy estimation for static panel models
- One-step, two-step, or iterative generalized method of moments (GMM) for dynamic panel models

Access to Financial and Economic Databases

The DATASOURCE procedure and the SAS/ETS data access interface LIBNAME engines (SASECRSP, SASEFAME, SASEFRED, SASEHAVR, SASEOECD, SASEQUAN, SASEWBGO, SASEXCCM and SASEXFSD) provide seamless, efficient access to time series data from data files supplied by a variety of commercial and governmental data vendors.

The DATASOURCE procedure includes the following features:

- support for data files distributed by the following data vendors:
  - DRI/McGraw-Hill
  - FAME Information Services
  - Haver Analytics
  - Standard & Poor's Compustat Service
  - Center for Research in Security Prices (CRSP)
  - International Monetary Fund
  - US Bureau of Labor Statistics
  - US Bureau of Economic Analysis
  - Organization for Economic Cooperation and Development (OECD)
- ability to select the series, frequency, time range, and cross sections of extracted data
- ability to create an output data set containing descriptive information about the series available in the data file
- ability to read EBCDIC data on ASCII systems and vice versa

The SASECRSP interface LIBNAME engine includes the following features:

- enables random access to time series data residing in CRSPAccess databases
- provides a seamless interface between CRSP and SAS data processing
- uses the LIBNAME statement to enable you to specify which time series you want to read from the CRSPAccess database and how you want to perform selection
- enables you access to CRSP Stock, CRSP/COMPUSTAT Merged (CCM), or CRSP Indices Data

- provides convenient formats, informats, and functions for CRSP and SAS datetime conversions

The SASEFAME interface LIBNAME engine includes the following features:

- provides SAS and FAME users with flexibility in accessing and processing time series data, case series, and formulas that reside in either a FAME database or a SAS data set
- uses the LIBNAME statement to enable you to specify which time series you want to read from the FAME database
- enables you to convert the selected time series to the same time scale
- works with the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set
- performs more analysis if desired in either the same SAS session or a later session
- supports the FAME CROSSLIST function for subsetting via BY groups
- supports the use of FAME in a client/server environment
- enables access to your FAME remote data when you specify the port number of the TCP/IP service that is defined for your FAME Master server and the node name of your FAME master server in your SASEFAME libref's physical path

The SASEFRED interface LIBNAME engine includes the following features:

- enables SAS users to retrieve economic data from the FRED website, which is hosted by the Economic Research Division of the Federal Reserve Bank of St. Louis
- provides access to various sources of FRED data, including those from Dow Jones & Company and the Federal Reserve System
- provides query options that allow you to request information by date, series, source, release, tag, or category
- enables selection of time series variables that you want to read into SAS based on a list of IDs that name the index or series
- defines the range of observations based on a specified date range or a specified offset and limit (cutoff)
- aggregates the selected time series to a specified aggregation frequency and specified aggregation method
- supports TLS connectivity by obtaining a secure connection using the CONNECT method (if necessary) and a PROXY
- creates an XML map of the data for dynamic, flexible association of SAS formats and informats for all variables
- supports various data transformations, including rates of change

- enables you to select the vintage dates you want to use when accessing archival (ALFRED) time series

The SASEHAVR interface LIBNAME engine includes the following features:

- gives Windows users random access to economic and financial data residing in a Haver Analytics Data Link Express (DLX) database
- provides the following types of Haver data sets:
  - US Economic Indicators
  - Specialized Databases
  - Financial Indicators
  - Industry
  - Industrial Countries
  - Emerging Markets
  - International Organizations
  - Forecasts and As Reported Data
  - United States Regional
- enables you to limit the range of data that is read from the time series
- enables you to specify a desired conversion frequency. Start dates are recommended in the LIBNAME statement to help you save resources when processing large databases or when processing a large number of observations.
- enables you to use the WHERE, KEEP, or DROP statement in your DATA step to further subset your data
- supports use of the SQL procedure to create a view of your resulting SAS data set

The SASEOECD interface LIBNAME engine includes the following features:

- enables SAS users to retrieve time series data from the Organization for Economic Cooperation and Development (OECD) web site which offers access to statistical data on topics such as agriculture and fisheries, economy, education, employment, energy, environment, finance, health, industry and entrepreneurship, innovation, insurance and pensions, international migration, internet economy, investment, OECD.Stat data warehouse, regional, rural and urban development, science and technology, social and welfare issues, tax, trade, and transport
- uses the LIBNAME statement to enable you to specify which time series you want to retrieve based on the data set id and the key sets that you specify
- enables you to limit the time range of data that is retrieved by specifying a start date and an end date
- reads the JSON data into a SAS data set, and automatically maps the JSON data for dynamic, flexible association of SAS formats and informats for all variables

- works with the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set

The SASEQUAN interface LIBNAME engine includes the following features:

- enables SAS users to retrieve economic and other time series data from the Quandl website, which offers access to over 8 million time series data sets from 400 sources in finance, economics, society, health, energy, demography, and more
- provides various sources of QUANDL data, including those from NASDAQ, Merrill Lynch, Nikkei Group, the Wall Street Journal, Google Finance, Yahoo Finance, and various foreign and domestic stock and commodity exchanges
- uses the LIBNAME statement to enable you to specify which time series you want to read from QUANDL
- enables selection of time series variables that you want to read into SAS based on a list of QUANDL codes that name the index or series
- defines the range of observations based on a specified date range
- sorts the order of observation in either ascending or descending time order
- enables you to collapse the selected time series to the same frequency
- supports various data transformations, including those that accumulate or difference the series
- works with the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set
- supports TLS connectivity by obtaining a secure connection using the CONNECT method (if necessary) and a PROXY
- creates an XML map of the data for dynamic, flexible association of SAS formats and informats for all variables

The SASEWBGO interface LIBNAME engine includes the following features:

- enables SAS programmers to retrieve time series data from the World Bank Group Open (WBGO) data website, hosted by the World Bank Group
- uses the LIBNAME statement to enable you to specify how to retrieve your WBGO data
- enables selection of time series data that you want to read into SAS based on a list of country codes that name the countries whose data you want to read
- enables selection of time series variables that you want to read into SAS based on a list of time series indicator codes that name the series
- defines the range of observations based on a range of years, and an optional page number and number of observations per page to report

- sorts the order of observations in ascending or descending time order
- provides a utility data set, XWBGOTPU, containing useful information (downloaded from a specified URL) about countries based on income level, time series indicators based on source ID, or time series indicators based on topic ID
- works with the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set
- creates an XML map of the data for dynamic, flexible association of SAS formats and informats for all variables

The SASEXCCM interface LIBNAME engine includes the following features:

- enables random access to time series data residing in CRSPAccess databases
- provides a seamless interface between CRSP, Compustat XpressFeed, and SAS data processing
- uses the LIBNAME statement to enable you to specify which data items, data groups, and time series you want to read from the CRSPAccess database and how you want to perform selection
- supports data-item-handling access methods to CRSP Stock (STK), CRSP/COMPUSTAT Merged (CCM), CRSP Indices (IND), or CRSP Treasury (TRS) DData
- provides selection based on keys such as GVKEY, PERMNO, INDNO, TREASNO, and TCUSIP for efficient access to data items

The SASEXFSD interface LIBNAME engine includes the following features:

- enables SAS users to access both FactSet data and FactSet-sourced data that are provided by the FactSet OnDemand service (formerly known as FASTFetch)
- uses the LIBNAME statement to specify which factlet (provided by FactSet) to use to open a FactSet database and to select the desired access method for subsetting and selecting data
- provides updated access to various sources of FactSet OnDemand offerings for financial data, including commodity benchmarks, banking data, and broker research
- works with the SAS DATA step to write the selected FactSet data to a SAS data set
- enables you to specify a range of dates for time series selection by either relative or absolute dates
- enables you to specify a FactSet frequency for displaying the data by using any of over 20 available codes
- provides TLS connectivity by obtaining a secure connection using the CONNECT method (if necessary) and a PROXY
- allows for ECON_EXPR_DATA and FQL (FactSet Query Language) syntax for function returns from FactSet
- allows for SPEC_ID_DATA and FQL economic download syntax
- creates an XML map of the data for dynamic, flexible association of SAS formats and informats for all variables

Access to World Weather and NOAA Severe Weather Inventory Databases

The SAS/ETS data access interface LIBNAME engines (SASERAIN and SASENOAA) provide seamless, efficient access to weather events and weather time series data supplied by World Weather Online and the NOAA Severe Weather Data Inventory web services.

The SASENOAA interface LIBNAME engine includes the following features:

- enables SAS users to access severe weather data sets, such as those for tornado vortex signatures (NX3TVS), storm cell structure (NX3STRUCTURE), and preliminary local storm reports (PLSR)
- works with the SAS DATA step to write the selected NOAA data to a SAS data set
- selects data based on geospatial limits, such as by a bounding box or a centerpoint-radius combination
- selects data based on a date range
- returns data in these formats:
  - XML; data are returned in XML format
  - KMZ; data are returned in zipped KML format for Google My Maps (plot data on a map)
  - SHP; mapping data are returned in zipped Esri format (four files returned inside ZIP file)
- works with the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set
- supports TLS connectivity by obtaining a secure connection using the CONNECT method (if necessary) and a PROXY
- creates an XML map of the data for dynamic, flexible association of SAS formats and informats for all variables

The SASERAIN interface LIBNAME engine includes the following features:

- enables SAS users to retrieve weather data from the World Weather Online website
- uses the LIBNAME statement to enable you to download World Weather Online data and to specify which weather data time series you want to retrieve based on up to nine locations
- works with the SAS DATA step to write the selected weather data to a SAS data set
- selects past weather data based on a date range that starts no earlier than July 1, 2008
- selects local forecast data based on a range defined by number of days (starts today), returns up to 15 days of premium local weather forecast data.
- enables you to select the frequency of data, whether daily, hourly, every three hours, or otherwise
- maintains the sort order, so the locations (q-codes) are sorted in the resulting SAS data set by the order specified in the QUERY= option, by date (time ID), and by variable (time series item name)

- works with the SAS DATA step to perform further subsetting and to store weather data in a SAS data set
- supports TLS connectivity by obtaining a secure connection using the CONNECT method (if necessary) and a PROXY
- creates an XML map of the data for dynamic, flexible association of SAS formats and informats for all variables

Spreadsheet Calculations and Financial Report Generation

The COMPUTAB procedure generates tabular reports using a programmable data table.

The COMPUTAB procedure is especially useful when you need both the power of a programmable spreadsheet and a report-generation system and you want to set up a program to run in batch mode and generate routine reports. The COMPUTAB procedure includes the following features:

- report generation facility for creating tabular reports such as income statements, balance sheets, and other row and column reports for analyzing business or time series data
- ability to tailor report format to almost any desired specification
- use of the SAS programming language to provide complete control of the calculation and format of each item of the report
- ability to report definition in terms of a data table on which programming statements operate
- ability for a single reference to a row or column to bring the entire row or column into a calculation
- ability to create new rows and columns (such as totals, subtotals, and ratios) with a single programming statement
- access to individual table values when needed
- built-in features to provide consolidation reports over summarization variables

Loan Analysis, Comparison, and Amortization

The LOAN procedure provides analysis and comparison of mortgages and other installment loans; it includes the following features:

- ability to specify contract terms for any number of different loans and ability to analyze and compare various financing alternatives
- analysis of four different types of loan contracts including the following:
  - fixed rate
  - adjustable rate
  - buy-down rate
  - balloon payment
- full control over adjustment terms for adjustable rate loans: life caps, adjustment frequency, and maximum and minimum rates
- support for a wide variety of payment and compounding intervals
- ability to incorporate initialization costs, discount points, down payments, and prepayments (uniform or lump-sum) in loan calculations
- analysis of different rate adjustment scenarios for variable rate loans including the following:
  - worst case
  - best case
  - fixed rate case
  - estimated case
- ability to make loan comparisons at different points in time
- ability to make loan comparisons at each analysis date on the basis of five different economic criteria:
  - present worth of cost (net present value of all payments to date)
  - true interest rate (internal rate of return to date)
  - current periodic payment
  - total interest paid to date
  - outstanding balance
- ability to base loan comparisons on either after-tax or before-tax analysis
- report of the best alternative when loans of equal amount are compared
- amortization schedules for each loan contract
- output that shows payment dates, rather than just payment sequence numbers, when starting date is specified

- optional printing or output of the amortization schedules, loan summaries, and loan comparison information to SAS data sets
- ability to specify rounding of payments to any number of decimal places

ODS Graphics

Many SAS/ETS procedures produce graphical output using the SAS Output Delivery System (ODS). The ODS Graphics system provides several advantages:

- Plots and graphs are output objects in the Output Delivery System (ODS) and can be manipulated with ODS commands.
- There is no need to write SAS/GRAPH statements or use special plotting macros.
- There are multiple formats to choose from: html, gif, and rtf.
- Templates control the appearance of plots.
- Styles control the color scheme.
- You can edit or create templates and styles for all graphs.

To enable graphical output from SAS/ETS procedures, you must use the following statement in your SAS program.

```
ods graphics on;
```

The graphical output produced by many SAS/ETS procedures can be controlled using the PLOTS= option in the PROC statement.

For more information about the features of the ODS Graphics system, including the many ways that you can control or customize the plots produced by SAS procedures, see Chapter 24, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*). For more information about the SAS Output Delivery system, see the *SAS Output Delivery System: User’s Guide*.

Related SAS Software

Many features not found in SAS/ETS software are available in other parts of the SAS System, such as Base SAS, SAS Forecast Server, SAS/STAT software, SAS/OR software, SAS/QC software, and SAS/IML software.

If you do not find something you need in SAS/ETS software, you might be able to find it in SAS/STAT software and in Base SAS software. If you still do not find it, look in other SAS software products or contact SAS Technical Support staff.

The following subsections summarize the features of other SAS products that might be of interest to users of SAS/ETS software.

Base SAS Software

The features provided by SAS/ETS software are extensions to the features provided by Base SAS software. Many data management and reporting capabilities you need are part of Base SAS software. For documentation of Base SAS software, see *SAS Programmers Guide: Essentials* and *Base SAS Procedures Guide*. In particular, for information about statistical analysis features included with Base SAS, see *Base SAS Procedures Guide: Statistical Procedures*.

The following sections summarize Base SAS software features of interest to users of SAS/ETS software. For further discussion of some of these topics as they relate to time series data and SAS/ETS software, see Chapter 3, "Working with Time Series Data."

SAS DATA Step

The DATA step is your primary tool for reading and processing data in the SAS System. The DATA step provides a powerful general purpose programming language that enables you to perform all kinds of data processing tasks. The DATA step is documented in *Base SAS Procedures Guide*.

Base SAS Procedures

Base SAS software includes many useful SAS procedures, which are documented in *Base SAS Procedures Guide* and *Base SAS Procedures Guide: Statistical Procedures*. The following is a list of Base SAS procedures you might find useful:

CATALOG	for managing SAS catalogs
CHART	for printing charts and histograms
COMPARE	for comparing SAS data sets
CONTENTS	for displaying the contents of SAS data sets
COPY	for copying SAS data sets
CORR	for computing correlations
CPORT	for moving SAS data libraries between computer systems
DATASETS	for deleting or renaming SAS data sets

FCMP	for compiling functions for use in SAS programs. The SAS Function Compiler Procedure (FCMP) enables you to create, test, and store SAS functions and subroutines before you use them in other SAS procedures. PROC FCMP accepts slight variations of DATA step statements, and most features of the SAS programing language can be used in functions and subroutines that are processed by PROC FCMP.
FREQ	for computing frequency crosstabulations
MEANS	for computing descriptive statistics and summarizing or collapsing data over cross sections
PLOT	for printing scatter plots
PRINT	for printing SAS data sets
PROTO	for accessing external functions from the SAS system. The PROTO procedure enables you to register external functions that are written in the C or C++ programming languages. You can use these functions in SAS as well as in C-language structures and types. After the C-language functions are registered in PROC PROTO, they can be called from any SAS function or subroutine that is declared in the FCMP procedure, as well as from any SAS function, subroutine, or method block that is declared in the COMPILE procedure.
RANK	for computing rankings or order statistics
SORT	for sorting SAS data sets
SQL	for processing SAS data sets with Structured Query Language
STANDARD	for standardizing variables to a fixed mean and variance
TABULATE	for printing descriptive statistics in tabular format
TIMEPLOT	for plotting variables over time
TRANSPOSE	for transposing SAS data sets
UNIVARIATE	for computing descriptive statistics

Global Statements

Global statements can be specified anywhere in your SAS program, and they remain in effect until changed. Global statements are documented in *Base SAS Procedures Guide*. You may find the following SAS global statements useful:

FILENAME	for accessing data files
FOOTNOTE	for printing footnote lines at the bottom of each page
%INCLUDE	for including files of SAS statements
LIBNAME	for accessing SAS data libraries
OPTIONS	for setting various SAS system options
QUIT	for ending an interactive procedure step
RUN	for executing the preceding SAS statements
TITLE	for printing title lines at the top of each page

Some Base SAS statements can be used with any SAS procedure, including SAS/ETS procedures. These statements are not global, and they affect only the SAS procedure they are used with. These statements are documented in *Base SAS Procedures Guide*.

The following Base SAS statements are useful with SAS/ETS procedures:

BY	for computing separate analyses for groups of observations
FORMAT	for assigning formats to variables
LABEL	for assigning descriptive labels to variables
WHERE	for subsetting data to restrict the range of data processed or to select or exclude observations from the analysis

SAS Functions

SAS functions can be used in DATA step programs and in the COMPUTAB, MODEL, and TMODEL procedures. The following kinds of functions are available:

- character functions for manipulating character strings
- date and time functions for performing date and calendar calculations
- financial functions for performing financial calculations such as depreciation, net present value, periodic savings, and internal rate of return
- lagging and differencing functions for computing lags and differences
- mathematical functions for computing data transformations and other mathematical calculations
- probability functions for computing quantiles of statistical distributions and the significance of test statistics
- random number functions for simulation experiments
- sample statistics functions for computing means, standard deviations, kurtosis, and so forth

SAS functions are documented in *Base SAS Procedures Guide*. Chapter 3, "Working with Time Series Data," discusses the use of date, time, lagging, and differencing functions. Chapter 4, "Date Intervals, Formats, and Functions," contains a reference list of date and time functions.

Formats, Informats, and Time Intervals

Base SAS software provides formats to control the printing of data values, informats to read data values, and time intervals to define the frequency of time series. For more information, see Chapter 4, "Date Intervals, Formats, and Functions."

SAS/STAT Software

SAS/STAT software is of interest to users of SAS/ETS software because many econometric and other statistical methods not included in SAS/ETS software are provided in SAS/STAT software.

SAS/STAT software includes procedures for a wide range of statistical methodologies including the following:

- logistic regression
- censored regression
- principal component analysis
- structural equation models using covariance structure analysis
- factor analysis
- survival analysis
- discriminant analysis
- cluster analysis
- categorical data analysis; log-linear and conditional logistic models
- general linear models
- mixed linear and nonlinear models
- generalized linear models
- response surface analysis
- kernel density estimation
- LOESS regression
- spline regression
- two-dimensional kriging
- multiple imputation for missing values
- survey data analysis

SAS/IML Software

SAS/IML software gives you access to a powerful and flexible programming language (Interactive Matrix Language) in a dynamic, interactive environment. The fundamental object of the language is a data matrix. You can use SAS/IML software interactively (at the statement level) to see results immediately, or you can store statements in a module and execute them later. The programming is dynamic because necessary activities such as memory allocation and dimensioning of matrices are done automatically.

You can access built-in operators and call routines to perform complex tasks such as matrix inversion or eigenvector generation. You can define your own functions and subroutines using SAS/IML modules. You can perform operations on an entire data matrix. You have access to a wide choice of data management commands. You can read, create, and update SAS data sets from inside SAS/IML software without ever using the DATA step.

SAS/IML software is of interest to users of SAS/ETS software because it enables you to program your own econometric and time series methods in the SAS System. It contains subroutines for time series operators and for general function optimization. If you need to perform a statistical calculation not provided as an automated feature by SAS/ETS or other SAS software, you can use SAS/IML software to program the matrix equations for the calculation.

Kalman Filtering and Time Series Analysis in SAS/IML

SAS/IML software includes CALL routines and functions for Kalman filtering and time series analysis, which perform the following:

- generate univariate, multivariate, and fractional time series
- compute likelihood function of ARMA, VARMA, and ARFIMA models
- compute an autocovariance function of ARMA, VARMA, and ARFIMA models
- check the stationarity of ARMA and VARMA models
- filter and smooth time series models using Kalman method
- fit AR, periodic AR, time-varying coefficient AR, VAR, and ARFIMA models
- handle Bayesian seasonal adjustment models

SAS/OR Software

SAS/OR software provides SAS procedures for operations research and project planning and includes a menu driven system for project management. SAS/OR software has features for the following:

- solving transportation problems
- linear, integer, and mixed-integer programming
- nonlinear programming and optimization
- scheduling projects
- plotting Gantt charts
- drawing network diagrams
- solving optimal assignment problems
- network flow programming

SAS/OR software might be of interest to users of SAS/ETS software for its mathematical programming features. In particular, the NLP and OPTMODEL procedures in SAS/OR software solve nonlinear programming problems and can be used for constrained and unconstrained maximization of user-defined likelihood functions.

For more information, see *SAS/OR User's Guide: Mathematical Programming*.

SAS/QC Software

SAS/QC software provides a variety of procedures for statistical quality control and quality improvement. SAS/QC software includes procedures for the following:

- Shewhart control charts
- cumulative sum control charts
- moving average control charts
- process capability analysis
- Ishikawa diagrams
- Pareto charts
- experimental design

MLE for User-Defined Likelihood Functions

There are several SAS procedures that enable you to do maximum likelihood estimation of parameters in an arbitrary model with a likelihood function that you define: PROC MODEL, PROC TMODEL, PROC NLP, PROC OPTMODEL and PROC IML.

The MODEL and TMODEL procedures in SAS/ETS software enable you to minimize general log-likelihood functions for the error term of a model.

The NLP and OPTMODEL procedures in SAS/OR software are general nonlinear programming procedures that can maximize a general function subject to linear equality or inequality constraints. You can use PROC NLP or OPTMODEL to maximize a user-defined nonlinear likelihood function.

You can use the IML procedure in SAS/IML software for maximum likelihood problems. The optimization routines used by PROC NLP are available through IML subroutines. You can write the likelihood function in the SAS/IML matrix language and call the constrained and unconstrained nonlinear programming subroutines to maximize the likelihood function with respect to the parameter vector.

JMP Software

JMP software uses a flexible graphical interface to display and analyze data. JMP dynamically links statistics and graphics so you can easily explore data, make discoveries, and gain the knowledge you need to make better decisions. JMP provides a comprehensive set of statistical tools as well as design of experiments (DOE) and advanced quality control (QC and SPC) tools for Six Sigma in a single package. JMP is software for interactive statistical graphics and includes the following:

- a data table window for editing, entering, and manipulating data
- a broad range of graphical and statistical methods for data analysis
- a facility for grouping data and computing summary statistics
- JMP scripting language (JSL)—a scripting language for saving and creating frequently used routines
- JMP automation
- Formula Editor—a formula editor for each table column to compute values as needed
- linear models, correlations, and multivariate
- design of experiments module
- options to highlight and display subsets of data
- statistical quality control and variability charts—special plots, charts, and communication capability for quality-improvement techniques
- survival analysis
- time series analysis, which includes the following:

  - Box-Jenkins ARIMA forecasting
  - seasonal ARIMA forecasting
  - transfer function modeling
  - smoothing models: Winters method, single, double, linear, damped trend linear, and seasonal exponential smoothing
  - diagnostic charts (autocorrelation, partial autocorrelation, and variogram) and statistics of fit
  - a model comparison table to compare all forecasts generated
  - spectral density plots and white noise tests
- tools for printing and for moving analyses results between applications

SAS Add-In for Microsoft Office

The main time series tasks in SAS Add-In for Microsoft Office (AMO) are as follows:

- Prepare Time Series Data
- Basic Forecasting
- ARIMA Modeling and Forecasting
- Regression Analysis with Autoregressive Errors
- Regression Analysis of Panel Data
- Create Time Series Data

Chapter 2
Shared Concepts in High-Performance Computing

Contents

Overview 57
Single-Machine Mode 57
Single-Machine Data Access Mode 58
Output Data Sets 58
Working with Formats 58
PERFORMANCE Statement 59

Overview

This chapter describes common concepts that are used by SAS/ETS high-performance procedures. It also provides the syntax for the PERFORMANCE statement, which is common to all high-performance analytical procedures.

Single-Machine Mode

Single-machine mode is a computing model in which multiple processors or multiple cores are controlled by a single operating system and can access shared resources, such as disks and memory. In this book, single-machine mode refers to an application running multiple concurrent threads on a multicore machine in order to take advantage of parallel execution on multiple processing units. More simply, single-machine mode for high-performance analytical procedures means multithreading on the client machine.

All high-performance analytical procedures run in single-machine mode. The procedure uses the number of CPUs (cores) on the machine to determine the number of concurrent threads. High-performance analytical procedures use different methods to map core count to the number of concurrent threads, depending on the analytic task. Using one thread per core is not uncommon for the procedures that implement data-parallel algorithms.

Single-Machine Data Access Mode

When high-performance analytical procedures run in single-machine mode, they access data in the same way as traditional SAS procedures. They use Base SAS to access input and output SAS data sets.

Output Data Sets

Many procedures in SAS software add the variables from the input data set when an observationwise output data set is created. The assumption of high-performance analytical procedures is that the input data sets can be large and contain many variables. For performance reasons, the output data set contains the following:

- variables that are explicitly created by the statement
- variables that are listed in the ID statement, as described in Chapter 22, "Shared Concepts and Topics in High-Performance Statistical Procedures" (*SAS/STAT User's Guide*)
- distribution keys or hash keys that are transferred from the input data set

Including this information enables you to add to the output data set information necessary for subsequent SQL joins without copying the entire input data set to the output data set.

Working with Formats

You can use SAS formats and user-defined formats with high-performance analytical procedures as you can with other procedures in the SAS System.

High-performance analytical procedures examine the variables that are used in an analysis for association with user-defined formats. If you are running multiple high-performance analytical procedures in a SAS session and the analysis variables depend on user-defined formats, you can preprocess the formats. This step involves generating an XML stream (a file) of the formats and passing the stream to the high-performance analytical procedures.

Suppose that the following formats are defined in your SAS program:

```
proc format;
     value YesNo        1='Yes'        0='No';
     value checkThis    1='ThisisOne'  2='ThisisTwo';
     value $cityChar    1='Portage'    2='Kinston';
run;
```

The next group of SAS statements create the XML stream for the formats in the file *Myfmt.xml*, associate that file with the file reference myxml, and pass the file reference with the FMTLIBXML= option in the PROC HPLOGISTIC statement:

```
filename myxml 'Myfmt.xml';
libname  myxml XML92 xmltype=sasfmt tagset=tagsets.XMLsuv;
proc format cntlout=myxml.allfmts;
run;

proc hplogistic data=six fmtlibxml=myxml;
   class wheeze cit age;
   format wheeze best4. cit $cityChar.;
   model wheeze = cit age;
run;
```

Generation and destruction of the stream can be wrapped in convenience macros:

```
%macro Make_XMLStream(name=tempxml);
    filename &name 'fmt.xml';
    libname  &name XML92 xmltype=sasfmt tagset=tagsets.XMLsuv;
    proc format cntlout=&name..allfmts;
    run;
%mend;

%macro Delete_XMLStream(fref);
    %let rc=%sysfunc(fdelete(&fref));
%mend;
```

If you do not pass an XML stream to a high-performance analytical procedure that supports the FMTLIBXML= option, the procedure generates an XML stream as needed when it is invoked.

PERFORMANCE Statement

PERFORMANCE < *performance-options* > **;**

The PERFORMANCE statement defines performance parameters for multithreaded computing, and requests detailed results about the performance characteristics of a high-performance analytical procedure.

You can specify the following *performance-options* in the PERFORMANCE statement:

BPC=*n*

specifies the number of bytes per character that is used in processing character strings in multibyte encodings. The default is the bytes per character of the encoding. The number of characters in a string is calculated as the byte length of the string divided by the bytes per character of the encoding. This will be incorrect when the strings in the multibyte encoding contain one or more single byte characters. In such cases, setting BPC=1 enables appropriate byte lengths to be used in processing such strings.

DETAILS

requests a table that shows a timing breakdown of the procedure steps.

NTHREADS=*n*

THREADS=*n*

specifies the number of threads for analytic computations and overrides the SAS system option THREADS | NOTHREADS. If you do not specify the NTHREADS= option, the number of threads is determined based on the number of CPUs on the host on which the analytic computations execute. The algorithm by which a CPU count is converted to a thread count is specific to the high-performance analytical procedure. Most procedures create one thread per CPU for the analytic computations.

By default, high-performance analytical procedures run in multiple concurrent threads unless multithreading has been turned off by the NOTHREADS system option or you force single-threaded execution by specifying NTHREADS=1. The largest number that can be specified for *n* is 256. Individual high-performance analytical procedures can impose more stringent limits if called for by algorithmic considerations.

Overview

This chapter discusses working with time series data in the SAS System. The following topics are included:

- dating time series and working with SAS date and datetime values
- subsetting data and selecting observations
- storing time series data in SAS data sets
- specifying time series periodicity and time intervals
- plotting time series
- using calendar and time interval functions
- computing lags and other functions across time

- transforming time series
- transposing time series data sets
- interpolating time series
- reading time series data recorded in different ways

In general, this chapter focuses on using features of the SAS programming language and not on features of SAS/ETS software. However, since SAS/ETS procedures are used to analyze time series, understanding how to use the SAS programming language to work with time series data is important for the effective use of SAS/ETS software.

You do not need to read this chapter to use SAS/ETS procedures. If you are already familiar with SAS programming you might want to skip this chapter, or you can refer to sections of this chapter for help on specific time series data processing questions.

Time Series and SAS Data Sets

Introduction

To analyze data with the SAS System, data values must be stored in a SAS data set. A SAS data set is a matrix (or table) of data values organized into variables and observations.

The *variables* in a SAS data set label the columns of the data matrix, and the *observations* in a SAS data set are the rows of the data matrix. You can also think of a SAS data set as a kind of file, with the observations representing records in the file and the variables representing fields in the records. (For more information about SAS data sets, see *SAS Programmers Guide: Essentials*.)

Usually, each observation represents the measurement of one or more variables for the individual subject or item observed. Often, the values of some of the variables in the data set are used to identify the individual subjects or items that the observations measure. These identifying variables are referred to as *ID variables*.

For many kinds of statistical analysis, only relationships among the variables are of interest, and the identity of the observations does not matter. ID variables might not be relevant in such a case.

However, for time series data the identity and order of the observations are crucial. A time series is a set of observations made at a succession of equally spaced points in time.

For example, if the data are monthly sales of a company's product, the variable measured is sales of the product and the unit observed is the operation of the company during each month. These observations can be identified by year and month. If the data are quarterly gross national product, the variable measured is final goods production and the unit observed is the economy during each quarter. These observations can be identified by year and quarter.

For time series data, the observations are identified and related to each other by their position in time. Since SAS does not assume any particular structure to the observations in a SAS data set, there are some special considerations needed when storing time series in a SAS data set.

The main considerations are how to associate dates with the observations and how to structure the data set so that SAS/ETS procedures and other SAS procedures recognize the observations of the data set as constituting time series. These issues are discussed in the following sections.

Reading a Simple Time Series

Time series data can be recorded in many different ways. The section "Reading Time Series Data" on page 113 discusses some of the possibilities. The example that follows shows a simple case.

The following SAS statements read monthly values of the U.S. Consumer Price Index (CPI) for June 1990 through July 1991. The data set USCPI is shown in Figure 3.1.

```
data uscpi;
   input year month cpi;
datalines;
1990  6 129.9
1990  7 130.4
1990  8 131.6

   ... more lines ...

proc print data=uscpi;
run;
```

Figure 3.1 Time Series Data

Obs	year	month	cpi
1	1990	6	129.9
2	1990	7	130.4
3	1990	8	131.6
4	1990	9	132.7
5	1990	10	133.5
6	1990	11	133.8
7	1990	12	133.8
8	1991	1	134.6
9	1991	2	134.8
10	1991	3	135.0
11	1991	4	135.2
12	1991	5	135.6
13	1991	6	136.0
14	1991	7	136.2

When a time series is stored in the manner shown by this example, the terms *series* and *variable* can be used interchangeably. There is one observation per row and one series/variable per column.

Dating Observations

The SAS System supports special date, datetime, and time values, which make it easy to represent dates, perform calendar calculations, and identify the time period of observations in a data set.

The preceding example uses the ID variables YEAR and MONTH to identify the time periods of the observations. For a quarterly data set, you might use YEAR and QTR as ID variables. A daily data set might have the ID variables YEAR, MONTH, and DAY. Clearly, it would be more convenient to have a single ID variable that could be used to identify the time period of observations, regardless of their frequency.

The following section, "SAS Date, Datetime, and Time Values" on page 65, discusses how the SAS System represents dates and times internally and how to specify date, datetime, and time values in a SAS program. The section "Reading Date and Datetime Values with Informats" on page 67 discusses how to read in date and time values from data records and how to control the display of date and datetime values in SAS output. Later sections discuss other issues concerning date and datetime values, specifying time intervals, data periodicity, and calendar calculations.

SAS date and datetime values and the other features discussed in the following sections are also described in *SAS Programmers Guide: Essentials*. Reference documentation on these features is also provided in Chapter 4, "Date Intervals, Formats, and Functions."

SAS Date, Datetime, and Time Values

SAS Date Values

SAS software represents dates as the number of days since a reference date. The reference date, or date zero, used for SAS date values is 1 January 1960. For example, 3 February 1960 is represented by SAS as 33. The SAS date for 17 October 1991 is 11612.

SAS software correctly represents dates from the year 1582 to the year 20,000.

Dates represented in this way are called SAS *date values*. Any numeric variable in a SAS data set whose values represent dates in this way is called a SAS *date variable*.

Representing dates as the number of days from a reference date makes it easy for the computer to store them and perform calendar calculations, but these numbers are not meaningful to users. However, you never have to use SAS date values directly, since SAS automatically converts between this internal representation and ordinary ways of expressing dates, provided that you indicate the format with which you want the date values to be displayed. (Formatting of date values is explained in the section "Formatting Date and Datetime Values" on page 67.)

Century of Dates Represented with Two-Digit Year Values

SAS software informats, functions, and formats can process dates that are represented with two-digit year values. The century assumed for a two-digit year value can be controlled with the YEARCUTOFF= option in the OPTIONS statement. The YEARCUTOFF= system option controls how dates with two-digit year values are interpreted by specifying the first year of a 100-year span. The default value for the YEARCUTOFF= option is 1920. Thus by default the year '17' is interpreted as 2017, while the year '25' is interpreted as 1925. (For more information about the YEARCUTOFF= option, see *SAS Programmers Guide: Essentials*.)

SAS Date Constants

SAS date values are written in a SAS program by placing the dates in single quotes followed by a D. The date is represented by the day of the month, the three letter abbreviation of the month name, and the year.

For example, SAS reads the value '17OCT1991'D the same as 11612, the SAS date value for 17 October 1991. Thus, the following SAS statements print DATE=11612:

```
data _null_;
  date = '17oct1991'd;
  put date=;
run;
```

The year value can be given with two or four digits, so '17OCT91'D is the same as '17OCT1991'D.

SAS Datetime Values and Datetime Constants

To represent both the time of day and the date, SAS uses *datetime values*. SAS datetime values represent the date and time as the number of seconds the time is from a reference time. The reference time, or time zero, used for SAS datetime values is midnight, 1 January 1960. Thus, for example, the SAS datetime value for 17 October 1991 at 2:45 in the afternoon is 1003329900.

To specify datetime constants in a SAS program, write the date and time in single quotes followed by DT. To write the date and time in a SAS datetime constant, write the date part using the same syntax as for date constants, and follow the date part with the hours, the minutes, and the seconds, separating the parts with colons. The seconds are optional.

For example, in a SAS program you would write 17 October 1991 at 2:45 in the afternoon as '17OCT91:14:45'DT. SAS reads this as 1003329900. Table 3.1 shows some other examples of datetime constants.

Table 3.1 Examples of Datetime Constants

Datetime Constant	Time
'17OCT1991:14:45:32'DT	32 seconds past 2:45 p.m., 17 October 1991
'17OCT1991:12:5'DT	12:05 p.m., 17 October 1991
'17OCT1991:2:0'DT	2:00 a.m., 17 October 1991
'17OCT1991:0:0'DT	Midnight, 17 October 1991

SAS Time Values

The SAS System also supports *time values*. SAS time values are just like datetime values, except that the date part is not given. To write a time value in a SAS program, write the time the same as for a datetime constant, but use T instead of DT. For example, 2:45:32 p.m. is written '14:45:32'T. Time values are represented by a number of seconds since midnight, so SAS reads '14:45:32'T as 53132.

SAS time values are not very useful for identifying time series, since usually both the date and the time of day are needed. Time values are not discussed further in this book.

Reading Date and Datetime Values with Informats

SAS provides a selection of *informats* for reading SAS date and datetime values from date and time values recorded in ordinary notations.

A SAS informat is an instruction that converts the values from a character-string representation into the internal numerical value of a SAS variable. Date informats convert dates from ordinary notations used to enter them to SAS date values; datetime informats convert date and time from ordinary notation to SAS datetime values.

For example, the following SAS statements read monthly values of the U.S. Consumer Price Index. Since the data are monthly, you could identify the date with the variables YEAR and MONTH, as in the previous example. Instead, in this example the time periods are coded as a three-letter month abbreviation followed by the year. The informat MONYY. is used to read month-year dates coded this way and to express them as SAS date values for the first day of the month, as follows:

```
data uscpi;
   input date : monyy7. cpi;
   format date monyy7.;
   label cpi = "US Consumer Price Index";
datalines;
jun1990 129.9
jul1990 130.4
aug1990 131.6

   ... more lines ...
```

The SAS System provides informats for most common notations for dates and times. For more information about the date and datetime informats available, see Chapter 4.

Formatting Date and Datetime Values

SAS provides *formats* to convert the internal representation of date and datetime values used by SAS to ordinary notations for dates and times. Several different formats are available for displaying dates and datetime values in most of the commonly used notations.

A SAS format is an instruction that converts the internal numerical value of a SAS variable to a character string that can be printed or displayed. Date formats convert SAS date values to a readable form; datetime formats convert SAS datetime values to a readable form.

In the preceding example, the variable DATE was set to the SAS date value for the first day of the month for each observation. If the data set USCPI were printed or otherwise displayed, the values shown for DATE would be the number of days since 1 January 1960. (See the "DATE with no format" column in Figure 3.2.) To display date values appropriately, use the FORMAT statement.

The following example processes the data set USCPI to make several copies of the variable DATE and uses a FORMAT statement to give different formats to these copies. The format cases shown are the MONYY7. format (for the DATE variable), the DATE9. format (for the DATE1 variable), and no format (for the DATE0 variable). The PROC PRINT output in Figure 3.2 shows the effect of the different formats on how the date values are printed.

```
data fmttest;
   set uscpi;
   date0 = date;
   date1 = date;
   label date  = "DATE with MONYY7. format"
         date1 = "DATE with DATE9. format"
         date0 = "DATE with no format";
   format date monyy7. date1 date9.;
run;

proc print data=fmttest label;
run;
```

Figure 3.2 SAS Date Values Printed with Different Formats

Obs	DATE with MONYY7. format	US Consumer Price Index	DATE with no format	DATE with DATE9. format
1	JUN1990	129.9	11109	01JUN1990
2	JUL1990	130.4	11139	01JUL1990
3	AUG1990	131.6	11170	01AUG1990
4	SEP1990	132.7	11201	01SEP1990
5	OCT1990	133.5	11231	01OCT1990
6	NOV1990	133.8	11262	01NOV1990
7	DEC1990	133.8	11292	01DEC1990
8	JAN1991	134.6	11323	01JAN1991
9	FEB1991	134.8	11354	01FEB1991
10	MAR1991	135.0	11382	01MAR1991
11	APR1991	135.2	11413	01APR1991
12	MAY1991	135.6	11443	01MAY1991
13	JUN1991	136.0	11474	01JUN1991
14	JUL1991	136.2	11504	01JUL1991

The appropriate format to use for SAS date or datetime valued ID variables depends on the sampling frequency or periodicity of the time series. Table 3.2 shows recommended formats for common data sampling frequencies and shows how the date '17OCT1991'D or the datetime value '17OCT1991:14:45:32'DT is displayed by these formats.

Table 3.2 Formats for Different Sampling Frequencies

ID Values	Periodicity	FORMAT	Example
SAS date	Annual	YEAR4.	1991
	Quarterly	YYQC6.	1991:4
	Monthly	MONYY7.	OCT1991
	Weekly	WEEKDATX23.	Thursday, 17 Oct 1991
	Daily	DATE9.	17OCT1991
SAS datetime	Hourly	DATETIME10.	17OCT91:14
	Minutes	DATETIME13.	17OCT91:14:45
	Seconds	DATETIME16.	17OCT91:14:45:32

For more information about the date and datetime formats available, see Chapter 4, "Date Intervals, Formats, and Functions."

The Variables DATE and DATETIME

SAS/ETS procedures enable you to identify time series observations in many different ways to suit your needs. As discussed in preceding sections, you can use a combination of several ID variables, such as YEAR and MONTH for monthly data.

However, using a single SAS date or datetime ID variable is more convenient and enables you to take advantage of some features SAS/ETS procedures provide for processing ID variables. One such feature is automatic extrapolation of the ID variable to identify forecast observations. These features are discussed in the following sections.

Thus, it is a good practice to include a SAS date or datetime ID variable in all the time series SAS data sets you create. It is also a good practice to always give the date or datetime ID variable a format appropriate for the data periodicity. (For information about creating SAS date and datetime values from multiple ID variables, see the section "Computing Dates from Calendar Variables" on page 86.)

You can assign a SAS date- or datetime-valued ID variable any name that conforms to SAS variable name requirements. However, you might find working with time series data in SAS easier and less confusing if you adopt the practice of always using the same name for the SAS date or datetime ID variable.

This book always names the date- or datetime-values ID variable DATE if it contains SAS date values or DATETIME if it contains SAS datetime values. This makes it easy to recognize the ID variable and also makes it easy to recognize whether this ID variable uses SAS date or datetime values.

Sorting by Time

Many SAS/ETS procedures assume the data are in chronological order. If the data are not in time order, you can use the SORT procedure to sort the data set. For example:

```
proc sort data=a;
   by date;
run;
```

There are many ways of coding the time ID variable or variables, and some ways do not sort correctly. If you use SAS date or datetime ID values as suggested in the preceding section, you do not need to be concerned with this issue. But if you encode date values in nonstandard ways, you need to consider whether your ID variables will sort.

SAS date and datetime values always sort correctly, as do combinations of numeric variables such as YEAR, MONTH, and DAY used together. Julian dates also sort correctly. (Julian dates are numbers of the form *yyddd*, where *yy* is the year and *ddd* is the day of the year. For example, 17 October 1991 has the Julian date value 91290.)

Calendar dates such as numeric values coded as *mmddyy* or *ddmmyy* do not sort correctly. Character variables that contain display values of dates, such as dates in the notation produced by SAS date formats, generally do not sort correctly.

Subsetting Data and Selecting Observations

It is often necessary to subset data for analysis. You might need to subset data to do the following:

- restrict the time range. For example, you want to perform a time series analysis using only recent data and ignoring observations from the distant past.
- select cross sections of the data. (See the section "Cross-Sectional Dimensions and BY Groups" on page 76.) For example, you have a data set with observations over time for each of several states, and you want to analyze the data for a single state.
- select particular kinds of time series from an interleaved-form data set. (See the section "Interleaved Time Series" on page 77.)
- exclude particular observations. For example, you have an outlier in your time series, and you want to exclude this observation from the analysis.

You can subset data either by using the DATA step to create a subset data set or by using a WHERE statement with the SAS procedure that analyzes the data.

A typical WHERE statement used in a procedure has the following form:

```
proc arima data=full;
   where '31dec1993'd < date < '26mar1994'd;
   identify var=close;
run;
```

For complete reference documentation on the WHERE statement, see *SAS DATA Step Statements: Reference*.

Subsetting SAS Data Sets

To create a subset data set, specify the name of the subset data set in the DATA statement, bring in the full data set with a SET statement, and specify the subsetting criteria with either subsetting IF statements or WHERE statements.

For example, suppose you have a data set that contains time series observations for each of several states. The following DATA step uses a WHERE statement to exclude observations with dates before 1970 and uses a subsetting IF statement to select observations for North Carolina (NC):

```
data subset;
   set full;
   where date >= '1jan1970'd;
   if state = 'NC';
run;
```

In this case, it makes no difference logically whether the WHERE statement or the IF statement is used, and you can combine several conditions in one subsetting statement. The following statements produce the same results as the previous example:

```
data subset;
   set full;
   if date >= '1jan1970'd & state = 'NC';
run;
```

The WHERE statement acts on the input data sets specified in the SET statement before observations are processed by the DATA step program, whereas the IF statement is executed as part of the DATA step program. If the input data set is indexed, using the WHERE statement can be more efficient than using the IF statement. However, the WHERE statement can refer only to variables in the input data set, not to variables computed by the DATA step program.

To subset the variables of a data set, use KEEP or DROP statements or use KEEP= or DROP= data set options. For more information about KEEP and DROP statements and SAS data set options, see *SAS DATA Step Statements: Reference*.

For example, suppose you want to subset the data set as in the preceding example, but you want to include in the subset data set only the variables DATE, X, and Y. You could use the following statements:

```
data subset;
   set full;
   if date >= '1jan1970'd & state = 'NC';
   keep date x y;
run;
```

Using the WHERE Statement with SAS Procedures

Use the WHERE statement with SAS procedures to process only a subset of the input data set. For example, suppose you have a data set that contains monthly observations for each of several states, and you want to use the AUTOREG procedure to analyze data since 1970 for North Carolina (NC). You could use the following statements:

```
proc autoreg data=full;
   where date >= '1jan1970'd & state = 'NC';
  ... additional statements ...
run;
```

You can specify any number of conditions in the WHERE statement. For example, suppose that a strike created an outlier in May 1975, and you want to exclude that observation. You could use the following statements:

```
proc autoreg data=full;
   where date >= '1jan1970'd & state = 'NC'
       & date ^= '1may1975'd;
  ... additional statements ...
run;
```

Using SAS Data Set Options

You can use the OBS= and FIRSTOBS= data set options to subset the input data set.

For example, the following statements print observations 20 through 25 of the data set FULL:

```
proc print data=full(firstobs=20 obs=25);
run;
```

Figure 3.3 Partial Listing of Data Set FULL

You can use KEEP= and DROP= data set options to exclude variables from the input data set. For information about SAS data set options, see *SAS DATA Step Statements: Reference*.

Storing Time Series in a SAS Data Set

This section discusses aspects of storing time series in SAS data sets. The topics discussed are the standard form of a time series data set, storing several series with different time ranges in the same data set, omitted observations, cross-sectional dimensions and BY groups, and interleaved time series.

Any number of time series can be stored in a SAS data set. Normally, each time series is stored in a separate variable. For example, the following statements augment the USCPI data set read in the previous example with values for the producer price index (PPI):

```
data usprice;
   input date : monyy7. cpi ppi;
   format date monyy7.;
   label cpi = "Consumer Price Index"
         ppi = "Producer Price Index";
datalines;
jun1990 129.9 114.3
jul1990 130.4 114.5
aug1990 131.6 116.5

   ... more lines ...

proc print data=usprice;
run;
```

Standard Form of a Time Series Data Set

The simple way the CPI and PPI time series are stored in the USPRICE data set in the preceding example is termed the *standard form* of a time series data set. A time series data set in standard form has the following characteristics:

- The data set contains one variable for each time series.
- The data set contains exactly one observation for each time period.
- The data set contains an ID variable or variables that identify the time period of each observation.
- The data set is sorted by the ID variables associated with date time values, so the observations are in time sequence.
- The data are equally spaced in time. That is, successive observations are a fixed time interval apart, so the data set can be described by a single sampling interval such as hourly, daily, monthly, quarterly, yearly, and so forth. This means that time series with different sampling frequencies are not mixed in the same SAS data set.

Most SAS/ETS procedures that process time series expect the input data set to contain time series in this standard form, and this is the simplest way to store time series in SAS data sets. (The EXPAND and TIMESERIES procedures can be helpful in converting your data to this standard form.) There are more complex ways to represent time series in SAS data sets.

You can incorporate cross-sectional dimensions with BY groups, so that each BY group is like a standard form time series data set. This method is discussed in the section "Cross-Sectional Dimensions and BY Groups" on page 76.

You can interleave time series, with several observations for each time period identified by another ID variable. Interleaved time series data sets are used to store several series in the same SAS variable. Interleaved time

series data sets can be used to store series of actual values, predicted values, and residuals, or series of forecast values and confidence limits for the forecasts. This is discussed in the section "Interleaved Time Series" on page 77.

Several Series with Different Ranges

Different time series can have values recorded over different time ranges. Since a SAS data set must have the same observations for all variables, when time series with different ranges are stored in the same data set, missing values must be used for the periods in which a series is not available.

Suppose that in the previous example you did not record values for CPI before August 1990 and did not record values for PPI after June 1991. The USPRICE data set could be read with the following statements:

```
data usprice;
   input date : monyy7. cpi ppi;
   format date monyy7.;
datalines;
jun1990     . 114.3
jul1990     . 114.5
aug1990 131.6 116.5
sep1990 132.7 118.4
oct1990 133.5 120.8
nov1990 133.8 120.1
dec1990 133.8 118.7
jan1991 134.6 119.0
feb1991 134.8 117.2
mar1991 135.0 116.2
apr1991 135.2 116.0
may1991 135.6 116.5
jun1991 136.0 116.3
jul1991 136.2     .
;
```

The decimal points with no digits in the data records represent missing data and are read by SAS as missing value codes.

In this example, the time range of the USPRICE data set is June 1990 through July 1991, but the time range of the CPI variable is August 1990 through July 1991, and the time range of the PPI variable is June 1990 through June 1991.

SAS/ETS procedures ignore missing values at the beginning or end of a series. That is, the series is considered to begin with the first nonmissing value and end with the last nonmissing value.

Missing Values and Omitted Observations

Missing data can also occur within a series. Missing values that appear after the beginning of a time series and before the end of the time series are called *embedded missing values*.

Suppose that in the preceding example you did not record values for CPI for November 1990 and did not record values for PPI for both November 1990 and March 1991. The USPRICE data set could be read with the following statements:

```
data usprice;
   input date : monyy. cpi ppi;
   format date monyy.;
datalines;
jun1990     . 114.3
jul1990     . 114.5
aug1990 131.6 116.5
sep1990 132.7 118.4
oct1990 133.5 120.8
nov1990     .     .
dec1990 133.8 118.7
jan1991 134.6 119.0
feb1991 134.8 117.2
mar1991 135.0     .
apr1991 135.2 116.0
may1991 135.6 116.5
jun1991 136.0 116.3
jul1991 136.2     .
;
```

In this example, the series CPI has one embedded missing value, and the series PPI has two embedded missing values. The ranges of the two series are the same as before.

Note that the observation for November 1990 has missing values for both CPI and PPI; there are no data for this period. This is an example of a *missing observation*.

You might ask why the data record for this period is included in the example at all, since the data record contains no data. However, deleting the data record for November 1990 from the example would cause an *omitted observation* in the USPRICE data set. SAS/ETS procedures expect input data sets to contain observations for a contiguous time sequence. If you omit observations from a time series data set and then try to analyze the data set with SAS/ETS procedures, the omitted observations will cause errors. When all data are missing for a period, a missing observation should be included in the data set to preserve the time sequence of the series.

If observations are omitted from the data set, the EXPAND procedure can be used to fill in the gaps with missing values (or to interpolate nonmissing values) for the time series variables and with the appropriate date or datetime values for the ID variable.

Cross-Sectional Dimensions and BY Groups

Often, time series in a collection are related by a cross sectional dimension. For example, the national average U.S. consumer price index data shown in the previous example can be disaggregated to show price indexes for major cities. In this case, there are several related time series: CPI for New York, CPI for Chicago, CPI for Los Angeles, and so forth. When these time series are considered as one data set, the city whose price level is measured is a cross sectional dimension of the data.

There are two basic ways to store such related time series in a SAS data set. The first way is to use a standard form time series data set with a different variable for each series.

For example, the following statements read CPI series for three major U.S. cities:

```
data citycpi;
   input date : monyy7. cpiny cpichi cpila;
   format date monyy7.;
datalines;
nov1989  133.200  126.700  130.000
dec1989  133.300  126.500  130.600
jan1990  135.100  128.100  132.100

   ... more lines ...
```

The second way is to store the data in a time series cross-sectional form. In this form, the series for all cross sections are stored in one variable and a cross section ID variable is used to identify observations for the different series. The observations are sorted by the cross section ID variable and by time within each cross section.

The following statements indicate how to read the CPI series for U.S. cities in time series cross-sectional form:

```
data cpicity;
   length city $11;
   input city $11. date : monyy. cpi;
   format date monyy.;
datalines;
New York       JAN1990   135.100
New York       FEB1990   135.300
New York       MAR1990   136.600

   ... more lines ...

proc sort data=cpicity;
   by city date;
run;
```

When processing a time series cross sectional form data set with most SAS/ETS procedures, use the cross section ID variable in a BY statement to process the time series separately. The data set must be sorted by the cross section ID variable and sorted by date within each cross section. The PROC SORT step in the preceding example ensures that the CPICITY data set is correctly sorted.

When the cross section ID variable is used in a BY statement, each BY group in the data set is like a standard form time series data set. Thus, SAS/ETS procedures that expect a standard form time series data set can process time series cross sectional data sets when a BY statement is used, producing an independent analysis for each cross section.

It is also possible to analyze time series cross-sectional data jointly. The PANEL procedure (and the older TSCSREG procedure) expects the input data to be in the time series cross-sectional form described here. For more information, see Chapter 25, "The PANEL Procedure."

Interleaved Time Series

Normally, a time series data set has only one observation for each time period, or one observation for each time period within a cross section for a time series cross-sectional-form data set. However, it is sometimes useful to store several related time series in the same variable when the different series do not correspond to levels of a cross-sectional dimension of the data.

In this case, the different time series can be interleaved. An interleaved time series data set is similar to a time series cross-sectional data set, except that the observations are sorted differently, and the ID variable that distinguishes the different time series does not represent a cross-sectional dimension.

The interleaved time series form is a convenient way to store data when the results consist of several different kinds of time series for each of numerous independent variables. For example, the MODEL procedure, which can fit and simulate dynamic systems of equations, in which many inter-related endogenous variables evolve over time, produces an interleaved time series output data set. For each time period, the MODEL procedure output includes observations for the actual, predicted, and residual values for each of the endogenous variables. These observations are identified by values of the variable _TYPE_. The observations are interleaved in the output data set with observations for the same date grouped together.

Using Interleaved Data Sets as Input to SAS/ETS Procedures

Interleaved time series data sets are not directly accepted as input by SAS/ETS procedures. However, it is easy to use a WHERE statement with a DATA step or with any procedure to subset the input data and select one of the interleaved time series as the input. For example, to analyze the residual series contained in a PROC MODEL output data set using another SAS/ETS procedure, include a WHERE _TYPE_='RESIDUAL' statement. The following statements show how to extract the residuals from an output data set produced by PROC MODEL.

```
data residuals_only;
   set output_dataset;
   where _type_='RESIDUAL';
run;
```

Combined Cross Sections and Interleaved Time Series Data Sets

Interleaved time series output data sets produced from BY-group processing of time series cross-sectional input data sets have a complex structure that combines a cross-sectional dimension, a time dimension, and the values of the _TYPE_ variable.

Output Data Sets of SAS/ETS Procedures

Most SAS/ETS procedures produce standard form time series output data sets, which contain variables for the predicted, actual, residual, and other values. In some cases variables names for the output variables are constructed automatically. In other cases you must specify names for the output variables in an OUTPUT statement. The MODEL procedure is an exception: it produces and interleaved output data sets, in which the different output values for each endogenous variable in the model is identified by the variable _TYPE_, and multiple observations with different _TYPE_ values are output for each time period.

For example, the ARIMA procedure can output actual series, forecast series, residual series, and confidence limit series. The following statements show the use of the ARIMA procedure to produce a forecast of the USCPI data set. Figure 3.5 shows part of the output data set that is produced by the ARIMA procedure's FORECAST statement. (The printed output from PROC ARIMA is not shown.)

```
title "PROC ARIMA Output Data Set";

proc arima data=uscpi;
   identify var=cpi(1);
   estimate q=1;
   forecast id=date interval=month
                    lead=12 out=arimaout;
run;

proc print data=arimaout(obs=6);
run;
```

Figure 3.5 Partial Listing of Output Data Set Produced by PROC ARIMA

PROC ARIMA Output Data Set

Obs	date	cpi	FORECAST	STD	L95	U95	RESIDUAL
1	JUN1990	129.9	.	.	.	.	.
2	JUL1990	130.4	130.368	0.36160	129.660	131.077	0.03168
3	AUG1990	131.6	130.881	0.36160	130.172	131.590	0.71909
4	SEP1990	132.7	132.354	0.36160	131.645	133.063	0.34584
5	OCT1990	133.5	133.306	0.36160	132.597	134.015	0.19421
6	NOV1990	133.8	134.046	0.36160	133.337	134.754	-0.24552

The output data set produced by the ARIMA procedure's FORECAST statement stores the actual values in a variable with the same name as the response series, stores the forecast series in a variable named FORECAST, stores the residuals in a variable named RESIDUAL, stores the 95% confidence limits in variables named L95 and U95, and stores the standard error of the forecast in the variable STD.

This method of storing several different result series as a standard form time series data set is simple and convenient. However, it works well only for a single input series. The forecast of a single series can be stored in the variable FORECAST. But if two series are forecast, two different FORECAST variables are needed.

The STATESPACE procedure handles this problem by generating forecast variable names FOR1, FOR2, and so forth. The SPECTRA procedure uses a similar method. Names such as FOR1, FOR2, RES1, RES2, and so forth require you to remember the order in which the input series are listed.

Other SAS/ETS procedures store output time series in standard form (as PROC ARIMA does) but require an OUTPUT statement to give names to the result series.

Time Series Periodicity and Time Intervals

A fundamental characteristic of time series data is how frequently the observations are spaced in time. How often the observations of a time series occur is called the *sampling frequency* or the *periodicity* of the series. For example, a time series with one observation each month has a monthly sampling frequency or monthly periodicity and so is called a monthly time series.

In SAS, data periodicity is described by specifying periodic *time intervals* into which the dates of the observations fall. For example, the SAS time interval MONTH divides time into calendar months.

Many SAS/ETS procedures enable you to specify the periodicity of the input data set with the INTERVAL= option. For example, specifying INTERVAL=MONTH indicates that the procedure should expect the ID variable to contain SAS date values, and that the date value for each observation should fall in a separate calendar month. The EXPAND procedure uses interval name values with the FROM= and TO= options to control the interpolation of time series from one periodicity to another.

SAS also uses time intervals in several other ways. In addition to indicating the periodicity of time series data sets, time intervals are used with the interval functions INTNX and INTCK and for controlling the plot axis and reference lines for plots of data over time.

Specifying Time Intervals

Intervals are specified in SAS by using *interval names* such as YEAR, QTR, MONTH, DAY, and so forth. Table 3.3 summarizes the basic types of intervals.

Table 3.3 Basic Interval Types

Name	Periodicity
YEAR	Yearly
SEMIYEAR	Semiannual
QTR	Quarterly
MONTH	Monthly
SEMIMONTH	1st and 16th of each month
TENDAY	1st, 11th, and 21st of each month
WEEK	Weekly
WEEKDAY	Daily, ignoring weekend days
DAY	Daily
HOUR	Hourly
MINUTE	Every minute
SECOND	Every second

Interval names can be abbreviated in various ways. For example, you could specify monthly intervals as MONTH, MONTHS, MONTHLY, or just MON. SAS accepts all these forms as equivalent.

Interval names can also be qualified with a multiplier to indicate multiperiod intervals. For example, biennial intervals are specified as YEAR2.

Interval names can also be qualified with a shift index to indicate intervals with different starting points. For example, fiscal years starting in July are specified as YEAR.7.

Intervals are classified as either date or datetime intervals. Date intervals are used with SAS date values, while datetime intervals are used with SAS datetime values. The interval types YEAR, SEMIYEAR, QTR, MONTH, SEMIMONTH, TENDAY, WEEK, WEEKDAY, and DAY are date intervals. HOUR, MINUTE, and SECOND are datetime intervals. Date intervals can be turned into datetime intervals for use with datetime values by prefixing the interval name with 'DT'. Thus DTMONTH intervals are like MONTH intervals but are used with datetime ID values instead of date ID values.

For more information about specifying time intervals and for a detailed reference to the different kinds of intervals available, see Chapter 4, "Date Intervals, Formats, and Functions."

Using Intervals with SAS/ETS Procedures

SAS/ETS procedures use the date or datetime interval and the ID variable in the following ways:

- to validate the data periodicity. The ID variable is used to check the data and verify that successive observations have valid ID values that correspond to successive time intervals.
- to check for gaps in the input observations. For example, if INTERVAL=MONTH and an input observation for January 1990 is followed by an observation for April 1990, there is a gap in the input data with two omitted observations.
- to label forecast observations in the output data set. The values of the ID variable for the forecast observations after the end of the input data set are extrapolated according to the frequency specifications of the INTERVAL= option.

Plotting Time Series

This section discusses SAS procedures that are available for plotting time series data, but it covers only certain aspects of the use of these procedures with time series data.

The SGPLOT procedure produces high resolution color graphics plots. For more information, see *SAS ODS Graphics: Procedures Guide*.

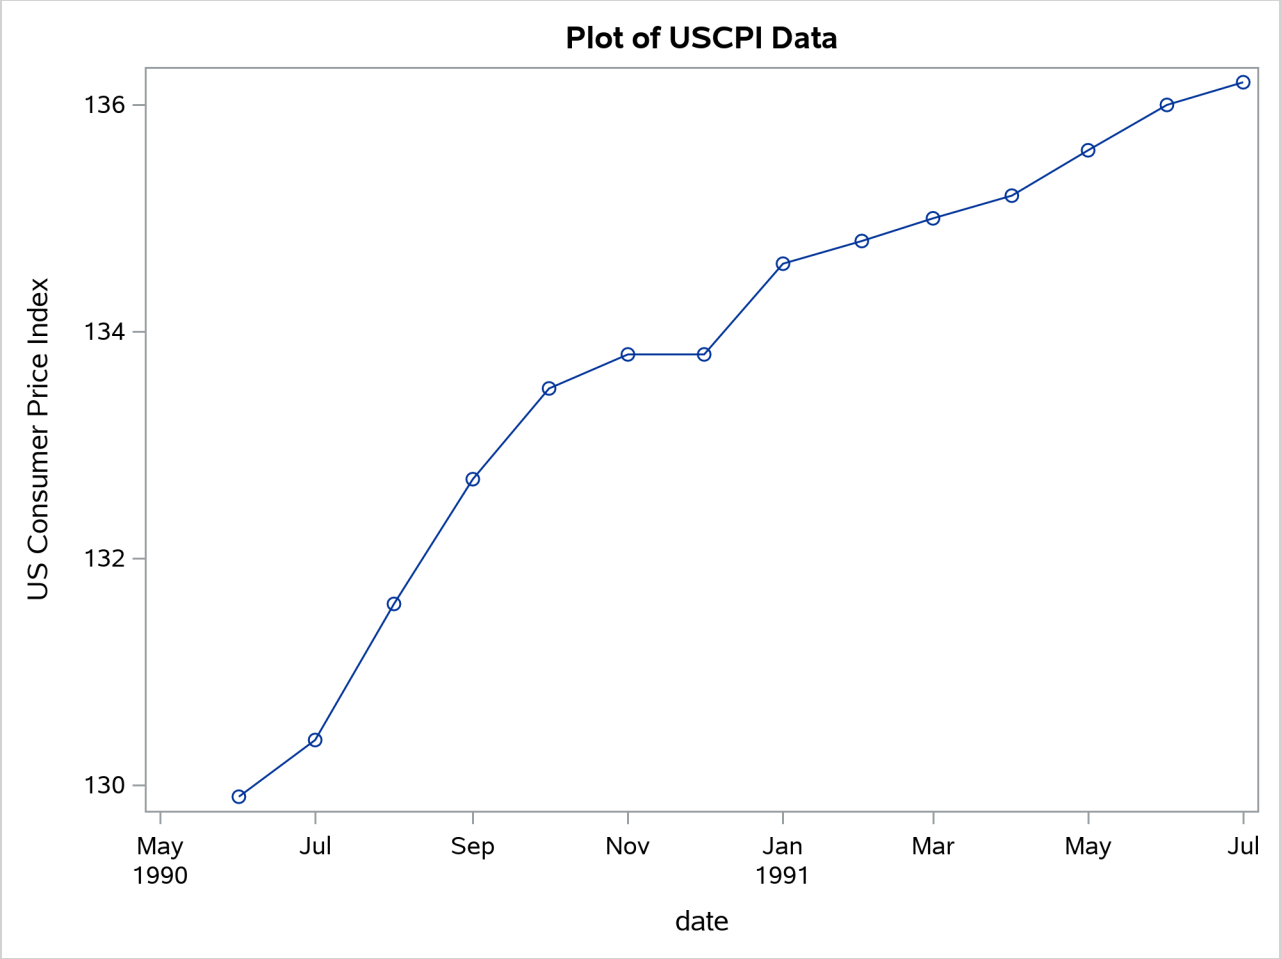
Using PROC SGPLOT

The following statements use the SGPLOT procedure to plot CPI in the USCPI data set against DATE. (The USCPI data set was shown in a previous example; the data set plotted in the following example contains more observations than shown previously.)

```
title "Plot of USCPI Data";
proc sgplot data=uscpi;
   series x=date y=cpi / markers;
run;
```

The plot is shown in Figure 3.6.

Figure 3.6 Plot of Monthly CPI over Time



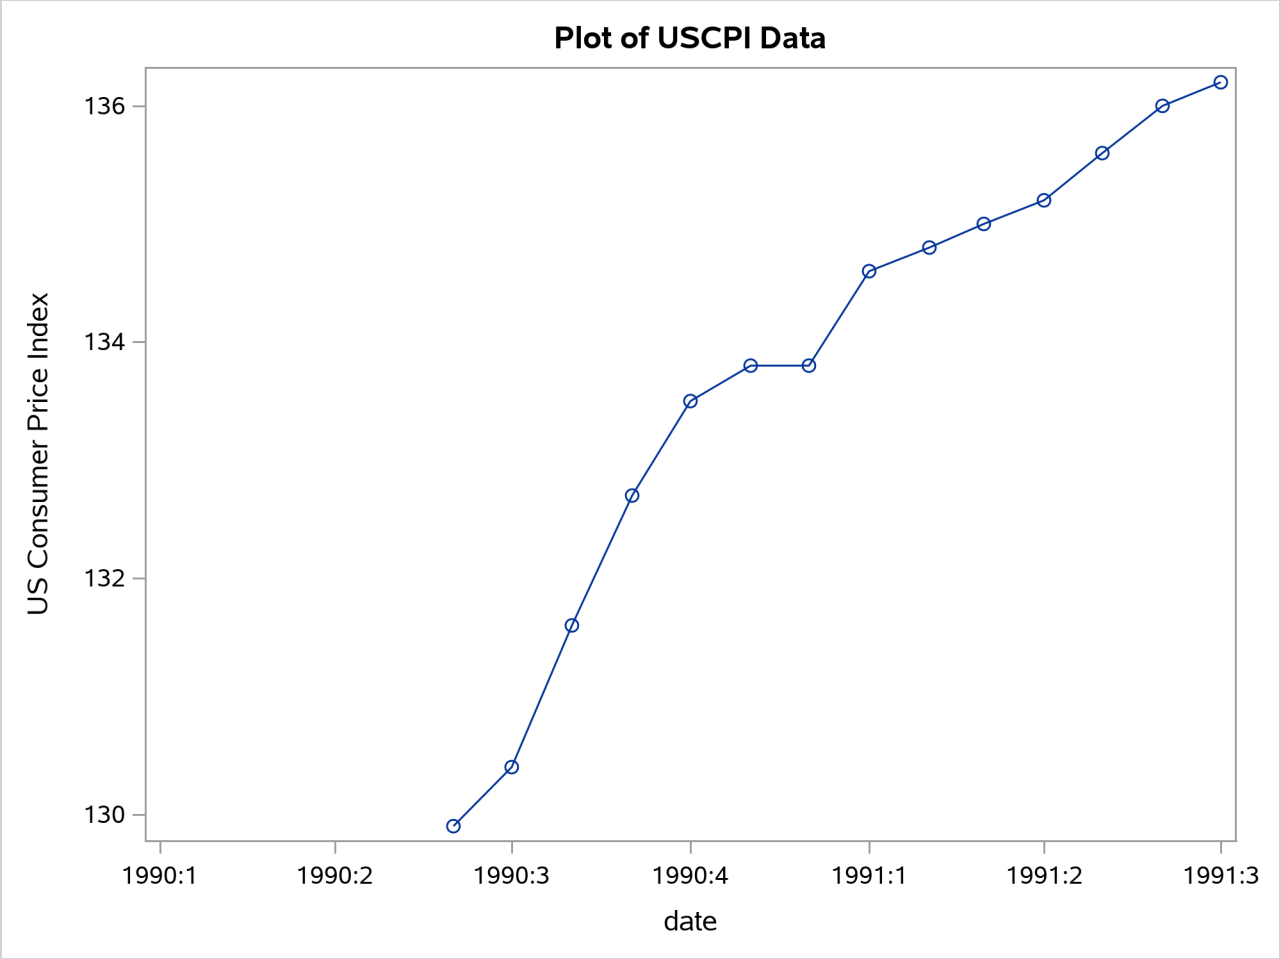
Controlling the Time Axis: Tick Marks and Reference Lines

It is possible to control the spacing of the tick marks on the time axis. The following statements use the XAXIS statement to tell PROC SGPLOT to mark the axis at the start of each quarter:

```
proc sgplot data=uscpi;
   series x=date y=cpi / markers;
   format date yyqc.;
   xaxis values=('1jan90'd to '1jul91'd by qtr);
run;
```

The plot is shown in Figure 3.7.

Figure 3.7 Plot of Monthly CPI over Time



Overlay Plots of Different Variables

You can plot two or more series stored in different variables on the same graph by specifying multiple plot requests in one SGPLOT statement.

For example, the following statements plot the CPI, FORECAST, L95, and U95 variables produced by PROC ARIMA in a previous example. A reference line is drawn to mark the start of the forecast period. Quarterly tick marks with YYQC format date values are used.

```
title "ARIMA Forecasts of CPI";

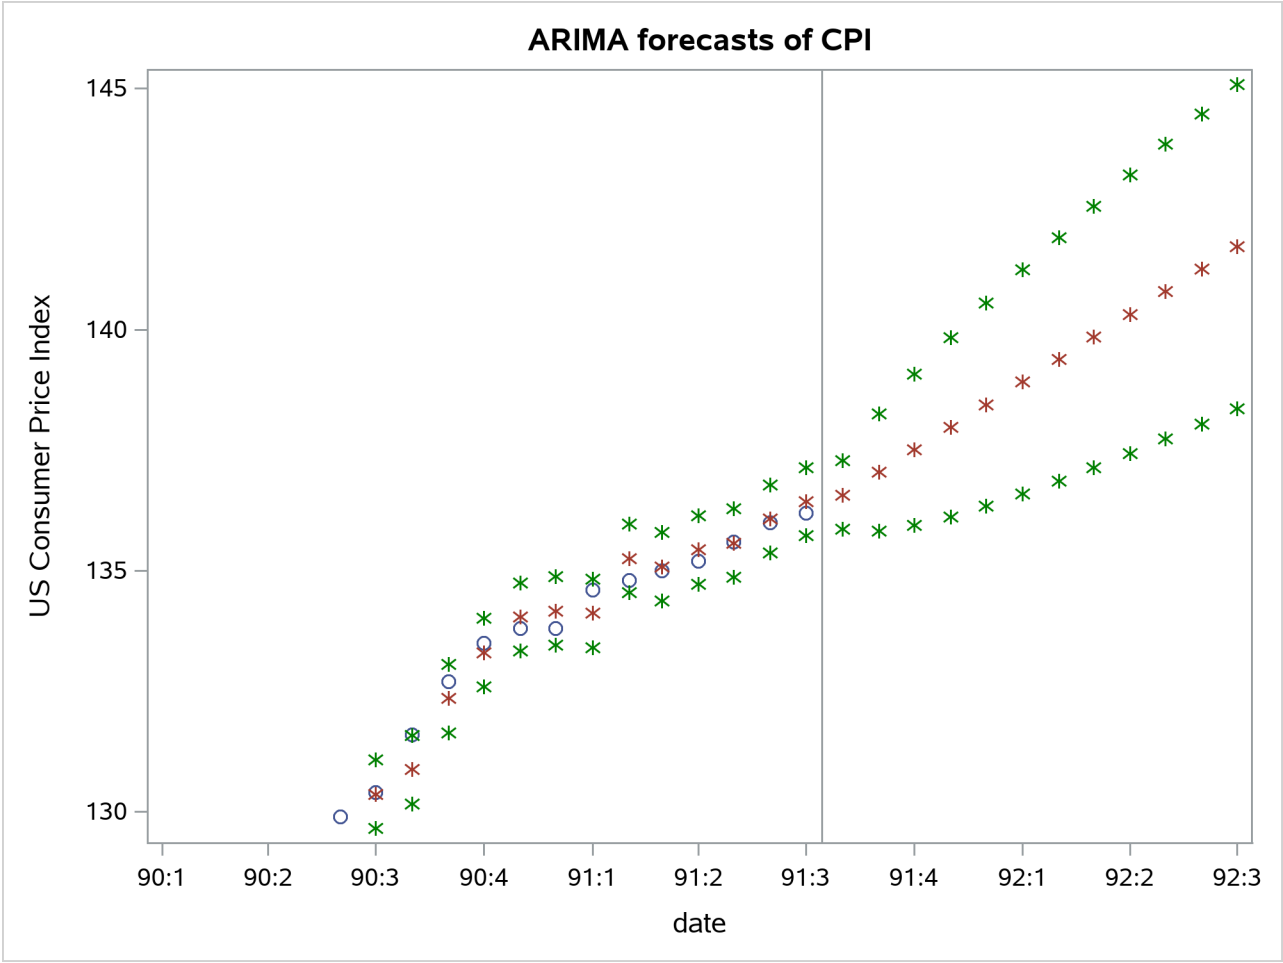
proc arima data=uscpi;
   identify var=cpi(1);
   estimate q=1;
   forecast id=date interval=month lead=12 out=arimaout;
run;

title "ARIMA forecasts of CPI";
proc sgplot data=arimaout noautolegend;
   scatter x=date y=cpi;
```

```
    scatter x=date y=forecast / markerattrs=(symbol=asterisk);
    scatter x=date y=l95 / markerattrs=(symbol=asterisk color=green);
    scatter x=date y=u95 / markerattrs=(symbol=asterisk color=green);
    format date yyqc4.;
    xaxis values=('1jan90'd to '1jul92'd by qtr);
    refline '15jul91'd / axis=x;
run;
```

The plot is shown in Figure 3.8.

Figure 3.8 Plot of ARIMA Forecast



Overlay Plots of Interleaved Series

You can also plot several series on the same graph when the different series are stored in the same variable in interleaved form. Plot interleaved time series by specifying the series identifying variable (_TYPE_, for example) in the GROUP= option on the SCATTER statement of the SGPLOT procedure to distinguish the different series.

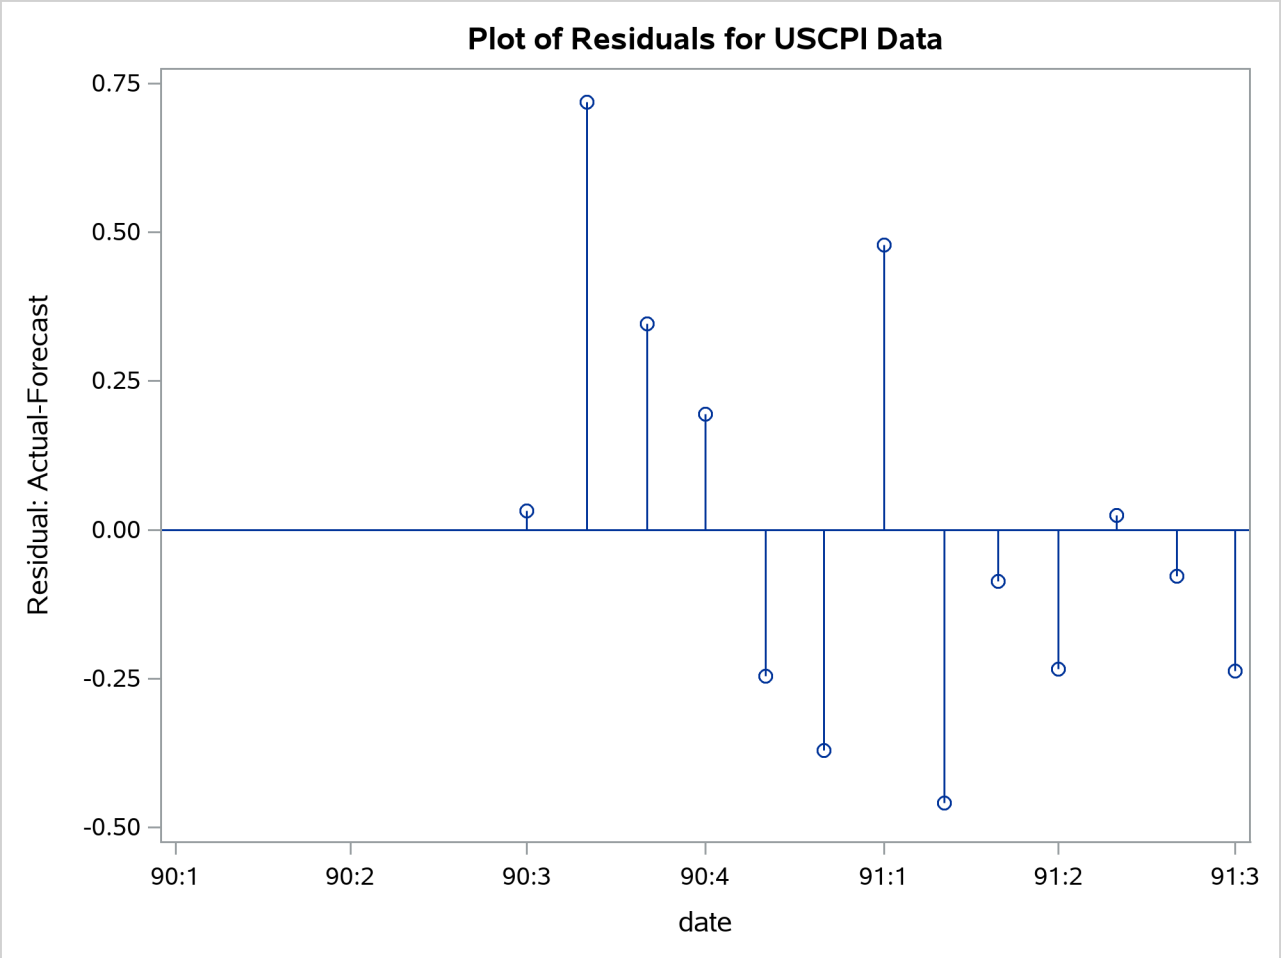
Residual Plots

The following example plots the residuals series from the forecast data set used in the previous example. The NEEDLE statement specifies a needle plot, so that each residual point is plotted as a vertical line showing deviation from zero.

```
title "Plot of Residuals for USCPI Data";
proc sgplot data=arimaout;
   needle x=date y=residual / markers;
   format date yyqc4.;
   xaxis values=('1jan90'd to '1jul91'd by qtr);
run;
```

The plot is shown in Figure 3.9.

Figure 3.9 Plot of Residuals



Calendar and Time Functions

Calendar and time functions convert calendar and time variables such as YEAR, MONTH, DAY, and HOUR, MINUTE, SECOND into SAS date or datetime values, and vice versa.

The SAS calendar and time functions are DATEJUL, DATEPART, DAY, DHMS, HMS, HOUR, JULDATE, MDY, MINUTE, MONTH, QTR, SECOND, TIMEPART, WEEKDAY, YEAR, and YYQ. For more information about these functions, see *SAS Functions and CALL Routines: Reference*.

Computing Dates from Calendar Variables

The MDY function converts MONTH, DAY, and YEAR values to a SAS date value. For example, MDY(2010,17,91) returns the SAS date value '17OCT2010'D.

The YYQ function computes the SAS date for the first day of a quarter. For example, YYQ(2010,4) returns the SAS date value '1OCT2010'D.

The DATEJUL function computes the SAS date for a Julian date. For example, DATEJUL(91290) returns the SAS date '17OCT2010'D.

The YYQ and MDY functions are useful for creating SAS date variables when the ID values recorded in the data are year and quarter; year and month; or year, month, and day.

For example, the following statements read quarterly data from records in which dates are coded as separate year and quarter values. The YYQ function is used to compute the variable DATE.

```
data usecon;
   input year qtr gnp;
   date = yyq( year, qtr );
   format date yyqc.;
datalines;
1990 1 5375.4
1990 2 5443.3
1990 3 5514.6

   ... more lines ...
```

The monthly USCPI data shown in a previous example contained time ID values represented in the MONYY format. If the data records instead contain separate year and month values, the data can be read in and the DATE variable computed with the following statements:

```
data uscpi;
   input month year cpi;
   date = mdy( month, 1, year );
   format date monyy.;
datalines;
 6 90 129.9
 7 90 130.4
 8 90 131.6
```

```
... more lines ...
```

Computing Calendar Variables from Dates

The functions YEAR, MONTH, DAY, WEEKDAY, and JULDATE compute calendar variables from SAS date values.

Returning to the example of reading the USCPI data from records that contain date values represented in the MONYY format, you can find the month and year of each observation from the SAS dates of the observations by using the following statements:

```
data uscpi;
   input date monyy7. cpi;
   format date monyy7.;
   year  = year( date );
   month = month( date );
datalines;
jun1990 129.9
jul1990 130.4
aug1990 131.6

   ... more lines ...
```

Converting between Date, Datetime, and Time Values

The DATEPART function computes the SAS date value for the date part of a SAS datetime value. The TIMEPART function computes the SAS time value for the time part of a SAS datetime value.

The HMS function computes SAS time values from HOUR, MINUTE, and SECOND time variables. The DHMS function computes a SAS datetime value from a SAS date value and HOUR, MINUTE, and SECOND time variables.

For more information about these functions, see the section "SAS Date, Time, and Datetime Functions" on page 136.

Computing Datetime Values

To compute datetime ID values from calendar and time variables, first compute the date and then compute the datetime with DHMS.

For example, suppose you read tri-hourly temperature data with time recorded as YEAR, MONTH, DAY, and HOUR. The following statements show how to compute the ID variable DATETIME:

```
data weather;
   input year month day hour temp;
   datetime = dhms( mdy( month, day, year ), hour, 0, 0 );
   format datetime datetime10.;
datalines;
91 10 16 21  61
91 10 17  0  56
91 10 17  3  53
91 10 17  6  54

   ... more lines ...
```

Computing Calendar and Time Variables

The functions HOUR, MINUTE, and SECOND compute time variables from SAS datetime values. The DATEPART function and the date-to-calendar variables functions can be combined to compute calendar variables from datetime values.

For example, suppose the date and time of the tri-hourly temperature data in the preceding example were recorded as datetime values in the datetime format. The following statements show how to compute the YEAR, MONTH, DAY, and HOUR of each observation and include these variables in the SAS data set:

```
data weather;
   input datetime : datetime13. temp;
   format datetime datetime10.;
   hour = hour( datetime );
   date = datepart( datetime );
   year = year( date );
   month = month( date );
   day = day( date );
datalines;
16oct91:21:00  61
17oct91:00:00  56
17oct91:03:00  53
17oct91:06:00  54

   ... more lines ...
```

Interval Functions INTNX and INTCK

The SAS interval functions INTNX and INTCK perform calculations with date values, datetime values, and time intervals. They can be used for calendar calculations with SAS date values to increment date values or datetime values by intervals and to count time intervals between dates.

The INTNX function increments dates by intervals. INTNX computes the date or datetime of the start of the interval a specified number of intervals from the interval that contains a given date or datetime value.

The form of the INTNX function is

INTNX *(interval, from, n < , alignment >)* **;**

The arguments to the INTNX function are as follows:

interval
is a character constant or variable that contains an interval name

from
is a SAS date value (for date intervals) or datetime value (for datetime intervals)

n
is the number of intervals to increment from the interval that contains the *from* value

alignment
controls the alignment of SAS dates, within the interval, used to identify output observations. Allowed values are BEGINNING, MIDDLE, END, and SAMEDAY.

The number of intervals to increment, *n*, can be positive, negative, or zero.

For example, the statement NEXTMON=INTNX('MONTH',DATE,1) assigns to the variable NEXTMON the date of the first day of the month following the month that contains the value of DATE. Thus INTNX('MONTH','21OCT2007'D,1) returns the date 1 November 2007.

The INTCK function counts the number of interval boundaries between two date values or between two datetime values.

The form of the INTCK function is

INTCK *(interval, from, to)* **;**

The arguments of the INTCK function are as follows:

interval
is a character constant or variable that contains an interval name.

from
is the starting date value (for date intervals) or datetime value (for datetime intervals).

to
is the ending date value (for date intervals) or datetime value (for datetime intervals).

For example, the statement NEWYEARS=INTCK('YEAR',DATE1,DATE2) assigns to the variable NEWYEARS the number of New Year's Days between the two dates.

Incrementing Dates by Intervals

Use the INTNX function to increment dates by intervals. For example, suppose you want to know the date of the start of the week that is six weeks from the week of 17 October 1991. The function INTNX('WEEK','17OCT91'D,6) returns the SAS date value '24NOV1991'D.

One practical use of the INTNX function is to generate periodic date values. For example, suppose the monthly U.S. Consumer Price Index data in a previous example were recorded without any time identifier on the data records. Given that you know the first observation is for June 1990, the following statements use the INTNX function to compute the ID variable DATE for each observation:

```
data uscpi;
   input cpi;
   date = intnx( 'month', '1jun1990'd, _n_-1 );
   format date monyy7.;
datalines;
129.9
130.4
131.6

   ... more lines ...
```

The automatic variable _N_ counts the number of times the DATA step program has executed; in this case _N_ contains the observation number. Thus _N_–1 is the increment needed from the first observation date. Alternatively, you could increment from the month before the first observation, in which case the INTNX function in this example would be written INTNX('MONTH','1MAY1990'D,_N_).

Alignment of SAS Dates

Any date within the time interval that corresponds to an observation of a periodic time series can serve as an ID value for the observation. For example, the USCPI data in a previous example might have been recorded with dates at the 15th of each month. The person recording the data might reason that since the CPI values are monthly averages, midpoints of the months might be the appropriate ID values.

However, as far as SAS/ETS procedures are concerned, what is important about monthly data is the month of each observation, not the exact date of the ID value. If you indicate that the data are monthly (with an INTERVAL=MONTH) option, SAS/ETS procedures ignore the day of the month in processing the ID variable. The MONYY format also ignores the day of the month.

Thus, you could read in the monthly USCPI data with mid-month DATE values by using the following statements:

```
data uscpi;
   input date : date9. cpi;
   format date monyy7.;
datalines;
15jun1990 129.9
15jul1990 130.4
15aug1990 131.6

   ... more lines ...
```

The results of using this version of the USCPI data set for analysis with SAS/ETS procedures would be the same as with first-of-month values for DATE. Although you can use any date within the interval as an ID value for the interval, you might find working with time series in SAS less confusing if you always use date ID values normalized to the start of the interval.

For some applications it might be preferable to use end of period dates, such as 31Jan1994, 28Feb1994, 31Mar1994, . . . , 31Dec1994. For other applications, such as plotting time series, it might be more convenient to use interval midpoint dates to identify the observations.

(Some SAS/ETS procedures provide an ALIGN= option to control the alignment of dates for output time series observations. In addition, the INTNX library function supports an optional argument to specify the alignment of the returned date value.)

To normalize date values to the start of intervals, use the INTNX function with a 0 increment. The INTNX function with an increment of 0 computes the date of the first day of the interval (or the first second of the interval for datetime values).

For example, INTNX('MONTH','17OCT1991'D,0,'BEG') returns the date '1OCT1991'D.

The following statements show how the preceding example can be changed to normalize the mid-month DATE values to first-of-month and end-of-month values. For exposition, the first-of-month value is transformed back into a middle-of-month value.

```
data uscpi;
   input date : date9. cpi;
   format date monyy7.;
   monthbeg = intnx( 'month', date, 0, 'beg' );
   midmonth = intnx( 'month', monthbeg, 0, 'mid' );
   monthend = intnx( 'month', date, 0, 'end' );
datalines;
15jun1990 129.9
15jul1990 130.4
15aug1990 131.6

   ... more lines ...
```

If you want to compute the date of a particular day within an interval, you can use calendar functions, or you can increment the starting date of the interval by a number of days. The following example shows three ways to compute the seventh day of the month:

```
data test;
   set uscpi;
   mon07_1 = mdy( month(date), 7, year(date) );
   mon07_2 = intnx( 'month', date, 0, 'beg' ) + 6;
   mon07_3 = intnx( 'day', date, 6 );
run;
```

Computing the Width of a Time Interval

To compute the width of a time interval, subtract the ID value of the start of the next interval from the ID value of the start of the current interval. If the ID values are SAS dates, the width is in days. If the ID values are SAS datetime values, the width is in seconds.

For example, the following statements show how to add a variable WIDTH to the USCPI data set that contains the number of days in the month for each observation:

```
data uscpi;
   input date : date9. cpi;
   format date monyy7.;
   width = intnx( 'month', date, 1 ) - intnx( 'month', date, 0 );
datalines;
15jun1990 129.9
15jul1990 130.4
15aug1990 131.6
15sep1990 132.7

   ... more lines ...
```

Computing the Ceiling of an Interval

To shift a date to the start of the next interval if it is not already at the start of an interval, subtract 1 from the date and use INTNX to increment the date by 1 interval.

For example, the following statements add the variable NEWYEAR to the monthly USCPI data set. The variable NEWYEAR contains the date of the next New Year's Day. NEWYEAR contains the same value as DATE when the DATE value is the start of year and otherwise contains the date of the start of the next year.

```
data test;
   set uscpi;
   newyear = intnx( 'year', date - 1, 1 );
   format newyear date.;
run;
```

Counting Time Intervals

Use the INTCK function to count the number of interval boundaries between two dates.

Note that the INTCK function counts the number of times the beginning of an interval is reached in moving from the first date to the second. It does not count the number of complete intervals between two dates. Following are two examples:

- The function INTCK('MONTH','1JAN1991'D,'31JAN1991'D) returns 0, since the two dates are within the same month.
- The function INTCK('MONTH','31JAN1991'D,'1FEB1991'D) returns 1, since the two dates lie in different months that are one month apart.

When the first date is later than the second date, INTCK returns a negative count. For example, the function INTCK('MONTH','1FEB1991'D,'31JAN1991'D) returns –1.

The following example shows how to use the INTCK function with shifted interval specifications to count the number of Sundays, Mondays, Tuesdays, and so forth, in each month. The variables NSUNDAY, NMONDAY, NTUESDAY, and so forth, are added to the USCPI data set.

```
data uscpi;
   set uscpi;
   d0 = intnx( 'month', date, 0 ) - 1;
   d1 = intnx( 'month', date, 1 ) - 1;
   nSunday    = intck( 'week.1', d0, d1 );
   nMonday    = intck( 'week.2', d0, d1 );
   nTuesday   = intck( 'week.3', d0, d1 );
   nWednesday = intck( 'week.4', d0, d1 );
   nThursday  = intck( 'week.5', d0, d1 );
   nFriday    = intck( 'week.6', d0, d1 );
   nSaturday  = intck( 'week.7', d0, d1 );
   drop d0 d1;
run;
```

Since the INTCK function counts the number of interval beginning dates between two dates, the number of Sundays is computed by counting the number of week boundaries between the last day of the previous month and the last day of the current month. To count Mondays, Tuesdays, and so forth, shifted week intervals are used. The interval type WEEK.2 specifies weekly intervals starting on Mondays, WEEK.3 specifies weeks starting on Tuesdays, and so forth.

Checking Data Periodicity

Suppose you have a time series data set and you want to verify that the data periodicity is correct, the observations are dated correctly, and the data set is sorted by date. You can use the INTCK function to compare the date of the current observation with the date of the previous observation and verify that the dates fall into consecutive time intervals.

For example, the following statements verify that the data set USCPI is a correctly dated monthly data set. The RETAIN statement is used to hold the date of the previous observation, and the automatic variable _N_ is used to start the verification process with the second observation.

```
data _null_;
   set uscpi;
   retain prevdate;
   if _n_ > 1 then
      if intck( 'month', prevdate, date ) ^= 1 then
         put "Bad date sequence at observation number " _n_;
   prevdate = date;
run;
```

Filling In Omitted Observations in a Time Series Data Set

Most SAS/ETS procedures expect input data to be in the standard form, with no omitted observations in the sequence of time periods. When data are missing for a time period, the data set should contain a missing observation, in which all variables except the ID variables have missing values.

You can replace omitted observations in a time series data set with missing observations with the EXPAND procedure.

The following statements create a monthly data set, OMITTED, from data lines that contain records for an intermittent sample of months. (Data values are not shown.) The OMITTED data set is sorted to make sure it is in time order.

```
data omitted;
   input date : monyy7. x y z;
   format date monyy7.;
datalines;
jan1991  ...
mar1991  ...
apr1991  ...
jun1991  ...
 ... etc. ...
;

proc sort data=omitted;
   by date;
run;
```

This data set is converted to a standard form time series data set by the following PROC EXPAND step. The TO= option specifies that monthly data is to be output, while the METHOD=NONE option specifies that no

interpolation is to be performed, so that the variables X, Y, and Z in the output data set STANDARD will have missing values for the omitted time periods that are filled in by the EXPAND procedure.

```
proc expand data=omitted
            out=standard
            to=month
            method=none;
   id date;
run;
```

Using Interval Functions for Calendar Calculations

With a little thought, you can come up with a formula that involves INTNX and INTCK functions and different interval types to perform almost any calendar calculation.

For example, suppose you want to know the date of the third Wednesday in the month of October 1991. The answer can be computed as

```
intnx( 'week.4', '1oct91'd - 1, 3 )
```

which returns the SAS date value '16OCT91'D.

Consider this more complex example: how many weekdays are there between 17 October 1991 and the second Friday in November 1991, inclusive? The following formula computes the number of weekdays between the date value contained in the variable DATE and the second Friday of the following month (including the ending dates of this period):

```
n = intck( 'weekday', date - 1,
    intnx( 'week.6', intnx( 'month', date, 1 ) - 1, 2 ) + 1 );
```

Setting DATE to '17OCT91'D and applying this formula produces the answer, N=17.

Lags, Leads, Differences, and Summations

When working with time series data, you sometimes need to refer to the values of a series in previous or future periods. For example, the usual interest in the consumer price index series shown in previous examples is how fast the index is changing, rather than the actual level of the index. To compute a percent change, you need both the current and the previous values of the series. When you model a time series, you might want to use the previous values of other series as explanatory variables.

This section discusses how to use the DATA step to perform operations over time: lags, differences, leads, summations over time, and percent changes.

The EXPAND procedure can also be used to perform many of these operations; for more information, see Chapter 15, "The EXPAND Procedure." See also the section "Transforming Time Series" on page 104.

The LAG and DIF Functions

The DATA step provides two functions, LAG and DIF, for accessing previous values of a variable or expression. These functions are useful for computing lags and differences of series.

For example, the following statements add the variables CPI_LAG and CPI_DIF to the USCPI data set. The variable CPI_LAG contains lagged values of the CPI series. The variable CPI_DIF contains the changes of the CPI series from the previous period; that is, CPI_DIF is CPI minus CPI_LAG. The new data set is shown in part in Figure 3.10.

```
data uscpi;
   set uscpi;
   cpi_lag = lag( cpi );
   cpi_dif = dif( cpi );
run;

proc print data=uscpi;
run;
```

Figure 3.10 USCPI Data Set with Lagged and Differenced Series

Plot of Residuals for USCPI Data

Obs	date	cpi	cpi_lag	cpi_dif
1	JUN1990	129.9	.	.
2	JUL1990	130.4	129.9	0.5

13	JUN1991	136.0	135.6	0.4
14	JUL1991	136.2	136.0	0.2

Understanding the DATA Step LAG and DIF Functions

When used in this simple way, LAG and DIF act as lag and difference functions. However, it is important to keep in mind that, despite their names, the LAG and DIF functions available in the DATA step are not true lag and difference functions.

Rather, LAG and DIF are queuing functions that remember and return argument values from previous calls. The LAG function remembers the value you pass to it and returns as its result the value you passed to it on the previous call. The DIF function works the same way but returns the difference between the current argument and the remembered value. (LAG and DIF return a missing value the first time the function is called.)

A true lag function does not return the value of the argument for the "previous call," as do the DATA step LAG and DIF functions. Instead, a true lag function returns the value of its argument for the "previous observation," regardless of the sequence of previous calls to the function. Thus, for a true lag function to be possible, it must be clear what the "previous observation" is.

If the data are sorted chronologically, then LAG and DIF act as true lag and difference functions. If in doubt, use PROC SORT to sort your data before using the LAG and DIF functions. Beware of missing observations, which can cause LAG and DIF to return values that are not the actual lag and difference values.

The DATA step is a powerful tool that can read any number of observations from any number of input files or data sets, can create any number of output data sets, and can write any number of output observations to any of the output data sets, all in the same program. Thus, in general, it is not clear what "previous observation" means in a DATA step program. In a DATA step program, the "previous observation" exists only if you write the program in a simple way that makes this concept meaningful.

Since, in general, the previous observation is not clearly defined, it is not possible to make true lag or difference functions for the DATA step. Instead, the DATA step provides queuing functions that make it easy to compute lags and differences.

Pitfalls of DATA Step LAG and DIF Functions

The LAG and DIF functions compute lags and differences provided that the sequence of calls to the function corresponds to the sequence of observations in the output data set. However, any complexity in the DATA step that breaks this correspondence causes the LAG and DIF functions to produce unexpected results.

For example, suppose you want to add the variable CPI_LAG to the USCPI data set, as in the previous example, and you also want to subset the series to 1991 and later years. You might use the following statements:

```
data subset;
   set uscpi;
   if date >= '1jan1991'd;
   cpi_lag = lag( cpi );  /* WRONG PLACEMENT! */
run;
```

If the subsetting IF statement comes before the LAG function call, the value of CPI_LAG will be missing for January 1991, even though a value for December 1990 is available in the USCPI data set. To avoid losing this value, you must rearrange the statements to ensure that the LAG function is actually executed for the December 1990 observation.

```
data subset;
   set uscpi;
   cpi_lag = lag( cpi );
   if date >= '1jan1991'd;
run;
```

In other cases, the subsetting statement should come before the LAG and DIF functions. For example, suppose you have a data set STATECPI which contains consumer price index data over time for each state in the United States, in which the data for each state is identified by the values of the BY variable STATE. You want to extract the data for a single state, North Carolina, which has the STATE code "NC", and also compute the lagged cpi values. The following statements subset the STATECPI data set to select only the North Carolina observations, and also to compute the variable CPI_LAG:

```
set statecpi;
by state;
if state= "NC";
cpi_lag = lag( cpi );
```

Another pitfall of LAG and DIF functions arises when they are used to process time series cross-sectional data sets. For example, suppose you want to add the variable CPI_LAG to the CPICITY data set shown in a previous example. You might use the following statements:

```
data cpicity;
   set cpicity;
   cpi_lag = lag( cpi );
run;
```

However, these statements do not yield the desired result. In the data set produced by these statements, the value of CPI_LAG for the first observation for the first city is missing (as it should be), but in the first observation for all later cities, CPI_LAG contains the last value for the previous city. To correct this, set the lagged variable to missing at the start of each cross section, as follows:

```
data cpicity;
   set cpicity;
   by city date;
   cpi_lag = lag( cpi );
   if first.city then cpi_lag = .;
run;
```

Alternatives to LAG and DIF Functions

You can also use the EXPAND procedure to compute lags and differences. For example, the following statements compute lag and difference variables for CPI:

```
proc expand data=uscpi out=uscpi method=none;
   id date;
   convert cpi=cpi_lag / transform=( lag 1 );
   convert cpi=cpi_dif / transform=( dif 1 );
run;
```

You can also calculate lags and differences in the DATA step without using LAG and DIF functions. For example, the following statements add the variables CPI_LAG and CPI_DIF to the USCPI data set:

```
data uscpi;
   set uscpi;
   retain cpi_lag;
   cpi_dif = cpi - cpi_lag;
   output;
   cpi_lag = cpi;
run;
```

The RETAIN statement prevents the DATA step from reinitializing CPI_LAG to a missing value at the start of each iteration and thus allows CPI_LAG to retain the value of CPI assigned to it in the last statement. The OUTPUT statement causes the output observation to contain values of the variables before CPI_LAG is reassigned the current value of CPI in the last statement. This is the approach that must be used if you want to build a variable that is a function of its previous lags.

LAG and DIF Functions in PROC MODEL

The preceding discussion of LAG and DIF functions applies to LAG and DIF functions available in the DATA step. However, LAG and DIF functions are also used in the MODEL procedure.

The MODEL procedure LAG and DIF functions do not work like the DATA step LAG and DIF functions. The LAG and DIF functions supported by PROC MODEL are true lag and difference functions, not queuing functions.

Unlike the DATA step, the MODEL procedure processes observations from a single input data set, so the "previous observation" is always clearly defined in a PROC MODEL program. Therefore, PROC MODEL is able to define LAG and DIF as true lagging functions that operate on values from the previous observation. For more information about LAG and DIF functions in the MODEL procedure, see Chapter 24, "The MODEL Procedure."

Multiperiod Lags and Higher-Order Differencing

To compute lags at a lagging period greater than 1, add the lag length to the end of the LAG keyword to specify the lagging function needed. For example, the LAG2 function returns the value of its argument two calls ago, the LAG3 function returns the value of its argument three calls ago, and so forth.

To compute differences at a lagging period greater than 1, add the lag length to the end of the DIF keyword. For example, the DIF2 function computes the differences between the value of its argument and the value of its argument two calls ago. (The maximum lagging period is 100.)

The following statements add the variables CPI_LAG12 and CPI_DIF12 to the USCPI data set. CPI_LAG12 contains the value of CPI from the same month one year ago. CPI_DIF12 contains the change in CPI from the same month one year ago. (In this case, the first 12 values of CPI_LAG12 and CPI_DIF12 are missing.)

```
data uscpi;
   set uscpi;
   cpi_lag12 = lag12( cpi );
   cpi_dif12 = dif12( cpi );
run;
```

To compute second differences, take the difference of the difference. To compute higher-order differences, nest DIF functions to the order needed. For example, the following statements compute the second difference of CPI:

```
data uscpi;
   set uscpi;
   cpi_2dif = dif( dif( cpi ) );
run;
```

Multiperiod lags and higher-order differencing can be combined. For example, the following statements compute monthly changes in the inflation rate, with inflation rate computed as percent change in CPI from the same month one year ago:

```
data uscpi;
   set uscpi;
   infchng = dif( 100 * dif12( cpi ) / lag12( cpi ) );
run;
```

Percent Change Calculations

There are several common ways to compute the percent change in a time series. This section illustrates the use of LAG and DIF functions by showing SAS statements for various kinds of percent change calculations.

Computing Period-to-Period Change

To compute percent change from the previous period, divide the difference of the series by the lagged value of the series and multiply by 100.

```
data uscpi;
   set uscpi;
   pctchng = dif( cpi ) / lag( cpi ) * 100;
   label pctchng = "Monthly Percent Change, At Monthly Rates";
run;
```

Often, changes from the previous period are expressed at annual rates. This is done by exponentiation of the current-to-previous period ratio to the number of periods in a year and expressing the result as a percent change. For example, the following statements compute the month-over-month change in CPI as a percent change at annual rates:

```
data uscpi;
   set uscpi;
   pctchng = ( ( cpi / lag( cpi ) ) ** 12 - 1 ) * 100;
   label pctchng = "Monthly Percent Change, At Annual Rates";
run;
```

Computing Year-over-Year Change

To compute percent change from the same period in the previous year, use LAG and DIF functions with a lagging period equal to the number of periods in a year. (For quarterly data, use LAG4 and DIF4. For monthly data, use LAG12 and DIF12.)

For example, the following statements compute monthly percent change in CPI from the same month one year ago:

```
data uscpi;
   set uscpi;
   pctchng = dif12( cpi ) / lag12( cpi ) * 100;
   label pctchng = "Percent Change from One Year Ago";
run;
```

To compute year-over-year percent change measured at a given period within the year, subset the series of percent changes from the same period in the previous year to form a yearly data set. Use an IF or WHERE statement to select observations for the period within each year on which the year-over-year changes are based.

For example, the following statements compute year-over-year percent change in CPI from December of the previous year to December of the current year:

```
data annual;
   set uscpi;
   pctchng = dif12( cpi ) / lag12( cpi ) * 100;
   label pctchng = "Percent Change: December to December";
   if month( date ) = 12;
   format date year4.;
run;
```

Computing Percent Change in Yearly Averages

To compute changes in yearly averages, first aggregate the series to an annual series by using the EXPAND procedure, and then compute the percent change of the annual series. (For more information about PROC EXPAND, see Chapter 15, "The EXPAND Procedure.")

For example, the following statements compute percent changes in the annual averages of CPI:

```
proc expand data=uscpi out=annual from=month to=year;
   convert cpi / observed=average method=aggregate;
run;

data annual;
   set annual;
   pctchng = dif( cpi ) / lag( cpi ) * 100;
   label pctchng = "Percent Change in Yearly Averages";
run;
```

It is also possible to compute percent change in the average over the most recent yearly span. For example, the following statements compute monthly percent change in the average of CPI over the most recent 12 months from the average over the previous 12 months:

```
data uscpi;
   retain sum12 0;
   drop sum12 ave12 cpi_lag12;
   set uscpi;
   sum12 = sum12 + cpi;
   cpi_lag12 = lag12( cpi );
   if cpi_lag12 ^= . then sum12 = sum12 - cpi_lag12;
   if lag11( cpi ) ^= . then ave12 = sum12 / 12;
   pctchng = dif12( ave12 ) / lag12( ave12 ) * 100;
   label pctchng = "Percent Change in 12 Month Moving Ave.";
run;
```

This example is a complex use of LAG and DIF functions that requires care in handling the initialization of the moving-window averaging process. The LAG12 of CPI is checked for missing values to determine when more than 12 values have been accumulated, and older values must be removed from the moving sum. The LAG11 of CPI is checked for missing values to determine when at least 12 values have been accumulated; AVE12 will be missing when LAG11 of CPI is missing. The DROP statement prevents temporary variables from being added to the data set.

Note that the DIF and LAG functions must execute for every observation, or the queues of remembered values will not operate correctly. The CPI_LAG12 calculation must be separate from the IF statement. The PCTCHNG calculation must not be conditional on the IF statement.

The EXPAND procedure provides an alternative way to compute moving averages.

Leading Series

Although the SAS System does not provide a function to look ahead at the "next" value of a series, there are a couple of ways to perform this task.

The most direct way to compute leads is to use the EXPAND procedure. For example:

```
proc expand data=uscpi out=uscpi method=none;
   id date;
   convert cpi=cpi_lead1 / transform=( lead 1 );
   convert cpi=cpi_lead2 / transform=( lead 2 );
run;
```

Another way to compute lead series in SAS software is by lagging the time ID variable, renaming the series, and merging the result data set back with the original data set.

For example, the following statements add the variable CPI_LEAD to the USCPI data set. The variable CPI_LEAD contains the value of CPI in the following month. (The value of CPI_LEAD is missing for the last observation, of course.)

```
data temp;
   set uscpi;
   keep date cpi;
   rename cpi = cpi_lead;
   date = lag( date );
   if date ^= .;
run;

data uscpi;
   merge uscpi temp;
   by date;
run;
```

To compute leads at different lead lengths, you must create one temporary data set for each lead length. For example, the following statements compute CPI_LEAD1 and CPI_LEAD2, which contain leads of CPI for 1 and 2 periods, respectively:

```
data temp1(rename=(cpi=cpi_lead1))
     temp2(rename=(cpi=cpi_lead2));
   set uscpi;
   keep date cpi;
   date = lag( date );
   if date ^= . then output temp1;
   date = lag( date );
   if date ^= . then output temp2;
run;

data uscpi;
   merge uscpi temp1 temp2;
   by date;
run;
```

Summing Series

Simple cumulative sums are easy to compute using SAS sum statements. The following statements show how to compute the running sum of variable X in data set A, adding XSUM to the data set:

```
data a;
   set a;
   xsum + x;
run;
```

The SAS sum statement automatically retains the variable XSUM and initializes it to 0, and the sum statement treats missing values as 0. The sum statement is equivalent to using a RETAIN statement and the SUM function. The previous example could also be written as follows:

```
data a;
   set a;
   retain xsum;
   xsum = sum( xsum, x );
run;
```

You can also use the EXPAND procedure to compute summations. For example:

```
proc expand data=a out=a method=none;
   convert x=xsum / transform=( sum );
run;
```

Like differencing, summation can be done at different lags and can be repeated to produce higher-order sums. To compute sums over observations separated by lags greater than 1, use the LAG and SUM functions together, and use a RETAIN statement that initializes the summation variable to zero.

For example, the following statements add the variable XSUM2 to data set A. XSUM2 contains the sum of every other observation, with even-numbered observations containing a cumulative sum of values of X from even observations, and odd-numbered observations containing a cumulative sum of values of X from odd observations.

```
data a;
   set a;
   retain xsum2 0;
   xsum2 = sum( lag( xsum2 ), x );
run;
```

Assuming that A is a quarterly data set, the following statements compute running sums of X for each quarter. XSUM4 contains the cumulative sum of X for all observations for the same quarter as the current quarter. Thus, for a first-quarter observation, XSUM4 contains a cumulative sum of current and past first-quarter values.

```
data a;
   set a;
   retain xsum4 0;
   xsum4 = sum( lag3( xsum4 ), x );
run;
```

To compute higher-order sums, repeat the preceding process and sum the summation variable. For example, the following statements compute the first and second summations of X:

```
data a;
   set a;
   xsum + x;
   x2sum + xsum;
run;
```

The following statements compute the second order four-period sum of X:

```
data a;
   set a;
   retain xsum4 x2sum4 0;
   xsum4 = sum( lag3( xsum4 ), x );
   x2sum4 = sum( lag3( x2sum4 ), xsum4 );
run;
```

You can also use PROC EXPAND to compute cumulative statistics and moving window statistics. For more information, see Chapter 15, "The EXPAND Procedure."

Transforming Time Series

It is often useful to transform time series for analysis or forecasting. Many time series analysis and forecasting methods are most appropriate for time series with an unrestricted range, a linear trend, and a constant variance. Series that do not conform to these assumptions can often be transformed to series for which the methods are appropriate.

Transformations can be useful for the following:

- range restrictions. Many time series cannot have negative values or can be limited to a maximum possible value. You can often create a transformed series with an unbounded range.
- nonlinear trends. Many economic time series grow exponentially. Exponential growth corresponds to linear growth in the logarithms of the series.
- series variability that changes over time. Various transformations can be used to stabilize the variance.
- nonstationarity. The %DFTEST macro can be used to test a series for nonstationarity which can then be removed by differencing.

Log Transformation

The logarithmic transformation is often useful for series that must be greater than zero and that grow exponentially. For example, Figure 3.11 shows a plot of an airline passenger miles series. Notice that the series has exponential growth and the variability of the series increases over time. Airline passenger miles must also be zero or greater.

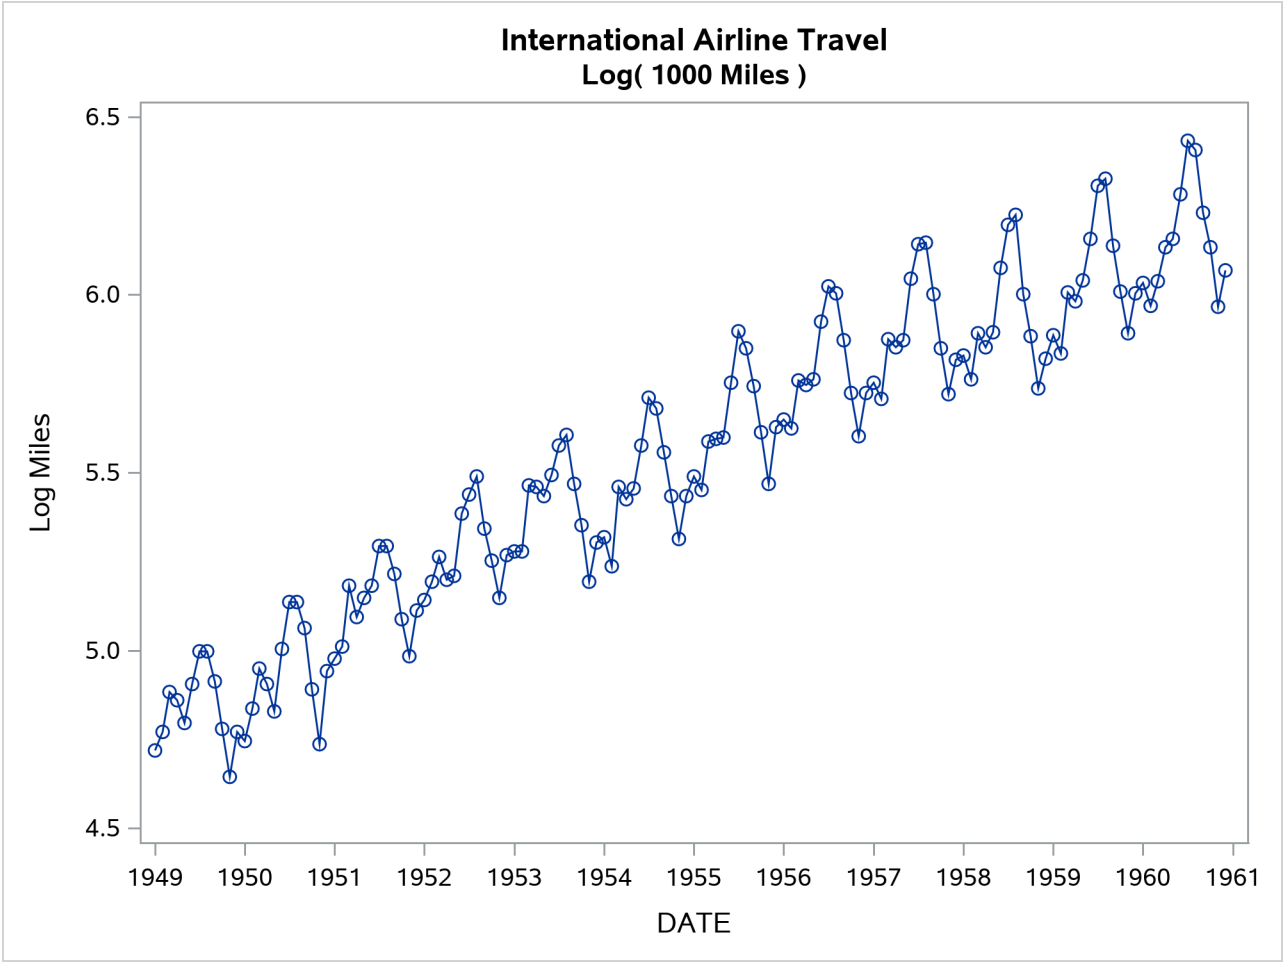
Figure 3.11 Airline Series

The following statements compute the logarithms of the airline series:

```
data lair;
   set sashelp.air;
   logair = log( air );
run;
```

Figure 3.12 shows a plot of the log-transformed airline series. Notice that the log series has a linear trend and constant variance.

Figure 3.12 Log Airline Series



The %LOGTEST macro can help you decide if a log transformation is appropriate for a series. For more information about the %LOGTEST macro, see Chapter 5, "SAS Macros and Functions."

Other Transformations

The Box-Cox transformation is a general class of transformations that includes the logarithm as a special case. The %BOXCOXAR macro can be used to find an optimal Box-Cox transformation for a time series. For more information about the %BOXCOXAR macro, see Chapter 5.

The logistic transformation is useful for variables with both an upper and a lower bound, such as market shares. The logistic transformation is useful for proportions, percent values, relative frequencies, or probabilities. The logistic function transforms values between 0 and 1 to values that can range from $-\infty$ to $+\infty$.

For example, the following statements transform the variable SHARE from percent values to an unbounded range:

```
data a;
   set a;
   lshare = log( share / ( 100 - share ) );
run;
```

Many other data transformation can be used. You can create virtually any desired data transformation using DATA step statements.

The EXPAND Procedure and Data Transformations

The EXPAND procedure provides a convenient way to transform series. For example, the following statements add variables for the logarithm of AIR and the logistic of SHARE to data set A:

```
proc expand data=a out=a method=none;
   convert air=logair   / transform=( log );
   convert share=lshare / transform=( / 100 logit );
run;
```

For a complete list of transformations supported by PROC EXPAND, see Table 15.2 in Chapter 15, "The EXPAND Procedure."

Manipulating Time Series Data Sets

This section discusses merging, splitting, and transposing time series data sets and interpolating time series data to a higher or lower sampling frequency.

Splitting and Merging Data Sets

In some cases, you might want to separate several time series that are contained in one data set into different data sets. In other cases, you might want to combine time series from different data sets into one data set.

To split a time series data set into two or more data sets that contain subsets of the series, use a DATA step to create the new data sets and use the KEEP= data set option to control which series are included in each new data set. The following statements split the USPRICE data set shown in a previous example into two data sets, USCPI and USPPI:

```
data uscpi(keep=date cpi)
   usppi(keep=date ppi);
   set usprice;
run;
```

If the series have different time ranges, you can subset the time ranges of the output data sets accordingly. For example, if you know that CPI in USPRICE has the range August 1990 through the end of the data set, while PPI has the range from the beginning of the data set through June 1991, you could write the previous example as follows:

```
data uscpi(keep=date cpi)
   usppi(keep=date ppi);
   set usprice;
   if date >= '1aug1990'd then output uscpi;
   if date <= '1jun1991'd then output usppi;
run;
```

To combine time series from different data sets into one data set, list the data sets to be combined in a MERGE statement and specify the dating variable in a BY statement. The following statements show how to combine the USCPI and USPPI data sets to produce the USPRICE data set. It is important to use the BY DATE statement so that observations are matched by time before merging.

```
data usprice;
   merge uscpi usppi;
   by date;
run;
```

Transposing Data Sets

The TRANSPOSE procedure is used to transpose data sets from one form to another. The TRANSPOSE procedure can transpose variables and observations, or transpose variables and observations within BY groups. This section discusses some applications of the TRANSPOSE procedure relevant to time series data sets. For more information about PROC TRANSPOSE, see *Base SAS Procedures Guide*.

Transposing Cross-Sectional Dimensions

The following statements transpose the variable CPI in the CPICITY data set shown in a previous example from time series cross-sectional form to a standard form time series data set. (Only a subset of the data shown in the previous example is used here.) Note that the method shown in this example works only for a single variable.

```
title "Original Data Set";
proc print data=cpicity;
run;

proc sort data=cpicity out=temp;
   by date city;
run;

proc transpose data=temp out=citycpi(drop=_name_);
   var cpi;
   id city;
   by date;
run;

title "Transposed Data Set";
proc print data=citycpi;
run;
```

The names of the variables in the transposed data sets are taken from the city names in the ID variable CITY. The original and the transposed data sets are shown in Figure 3.13 and Figure 3.14.

Figure 3.14 Transposed Data Sets

Transposed Data Set

Obs	date	Chicago	Los_Angeles	New_York
1	JAN90	128.1	132.1	135.1
2	FEB90	129.2	133.6	135.3
3	MAR90	129.5	134.5	136.6
4	APR90	130.4	134.2	137.3
5	MAY90	130.4	134.6	137.2
6	JUN90	131.7	135.0	137.1
7	JUL90	132.0	135.6	138.4

The following statements transpose the CITYCPI data set back to the original form of the CPICITY data set. The variable _NAME_ is added to the data set to tell PROC TRANSPOSE the name of the variable in which to store the observations in the transposed data set. (If the (DROP=_NAME_ _LABEL_) option were omitted from the first PROC TRANSPOSE step, this would not be necessary. PROC TRANSPOSE assumes ID _NAME_ by default.)

The NAME=CITY option in the PROC TRANSPOSE statement causes PROC TRANSPOSE to store the names of the transposed variables in the variable CITY. Because PROC TRANSPOSE recodes the values of the CITY variable to create valid SAS variable names in the transposed data set, the values of the variable

CITY in the retransposed data set are not the same as in the original. The retransposed data set is shown in Figure 3.15.

```
data temp;
   set citycpi;
   _name_ = 'CPI';
run;

proc transpose data=temp out=retrans name=city;
   by date;
run;

proc sort data=retrans;
   by city date;
run;

title "Retransposed Data Set";
proc print data=retrans;
run;
```

Time Series Interpolation

The EXPAND procedure interpolates time series. This section provides a brief summary of the use of PROC EXPAND for different kinds of time series interpolation problems. Most of the issues discussed in this section are explained in greater detail in Chapter 15.

By default, the EXPAND procedure performs interpolation by first fitting cubic spline curves to the available data and then computing needed interpolating values from the fitted spline curves. Other interpolation methods can be requested.

Note that interpolating values of a time series does not add any real information to the data because the interpolation process is not the same process that generated the other (nonmissing) values in the series. While time series interpolation can sometimes be useful, great care is needed in analyzing time series that contain interpolated values.

Interpolating Missing Values

To use the EXPAND procedure to interpolate missing values in a time series, specify the input and output data sets in the PROC EXPAND statement, and specify the time ID variable in an ID statement. For example, the following statements cause PROC EXPAND to interpolate values for missing values of all numeric variables in the data set USPRICE:

```
proc expand data=usprice out=interpl;
   id date;
run;
```

Interpolated values are computed only for embedded missing values in the input time series. Missing values before or after the range of a series are ignored by the EXPAND procedure.

In the preceding example, PROC EXPAND assumes that all series are measured at points in time given by the value of the ID variable. In fact, the series in the USPRICE data set are monthly averages. PROC EXPAND can produce a better interpolation if this is taken into account. The following example uses the FROM=MONTH option to tell PROC EXPAND that the series is monthly and uses the CONVERT statement with the OBSERVED=AVERAGE to specify that the series values are averages over each month:

```
proc expand data=usprice out=interpl
            from=month;
   id date;
   convert cpi ppi / observed=average;
run;
```

Interpolating to a Higher or Lower Frequency

You can use PROC EXPAND to interpolate values of time series at a higher or lower sampling frequency than the input time series. To change the periodicity of time series, specify the time interval of the input data set with the FROM= option, and specify the time interval for the desired output frequency with the TO= option. For example, the following statements compute interpolated weekly values of the monthly CPI and PPI series:

```
proc expand data=usprice out=interpl
            from=month to=week;
   id date;
   convert cpi ppi / observed=average;
run;
```

Interpolating between Stocks and Flows, Levels and Rates

A distinction is made between variables that are measured at points in time and variables that represent totals or averages over an interval. Point-in-time values are often called *stocks* or *levels*. Variables that represent totals or averages over an interval are often called *flows* or *rates*.

For example, the annual series Gross National Product represents the final goods production of over the year and also the yearly average rate of that production. However, the monthly variable Inventory represents the cost of a stock of goods at the end of the month.

The EXPAND procedure can convert between point-in-time values and period average or total values. To convert observation characteristics, specify the input and output characteristics with the OBSERVED= option in the CONVERT statement. For example, the following statements use the monthly average price index values in USPRICE to compute interpolated estimates of the price index levels at the midpoint of each month:

```
proc expand data=usprice out=midpoint
            from=month;
   id date;
   convert cpi ppi / observed=(average,middle);
run;
```

Reading Time Series Data

Time series data can be coded in many different ways. The SAS System can read time series data recorded in almost any form. Earlier sections of this chapter show how to read time series data coded in several commonly used ways. This section shows how to read time series data from data records coded in two other commonly used ways not previously introduced.

Several time series databases distributed by major data vendors can be read into SAS data sets by the DATASOURCE procedure. For more information, see Chapter 12, "The DATASOURCE Procedure."

The SASECRSP, SASEFAME, and SASEHAVR interface engines enable SAS users to access and process time series data in CRSPAccess data files, FAME databases, and Haver Analytics Data Link Express (DLX) databases, respectively. For more information, see Chapter 46, "The SASECRSP Interface Engine," Chapter 47, "The SASEFAME Interface Engine," and Chapter 49, "The SASEHAVR Interface Engine."

Reading a Simple List of Values

Time series data can be coded as a simple list of values without dating information and with an arbitrary number of observations on each data record. In this case, the INPUT statement must use the trailing "@@" option to retain the current data record after reading the values for each observation, and the time ID variable must be generated with programming statements.

For example, the following statements read the USPRICE data set from data records that contain pairs of values for CPI and PPI. This example assumes you know that the first pair of values is for June 1990.

```
data usprice;
   input cpi ppi @@;
   date = intnx( 'month', '1jun1990'd, _n_-1 );
   format date monyy7.;
datalines;
129.9 114.3  130.4 114.5  131.6 116.5
132.7 118.4  133.5 120.8  133.8 120.1 133.8 118.7
134.6 119.0  134.8 117.2  135.0 116.2 135.2 116.0
135.6 116.5  136.0 116.3  136.2 116.0
;
```

Reading Fully Described Time Series in Transposed Form

Data for several time series can be coded with separate groups of records for each time series. Data files coded this way are transposed from the form required by SAS procedures. Time series data can also be coded with descriptive information about the series included with the data records.

The following example reads time series data for the USPRICE data set coded with separate groups of records for each series. The data records for each series consist of a series description record and one or more value records. The series description record gives the series name, starting month and year of the series, number of values in the series, and a series label. The value records contain the observations of the time series.

The data are first read into a temporary data set that contains one observation for each value of each series.

```
data temp;
   length _name_ $8 _label_ $40;
   keep _name_ _label_ date value;
   format date monyy.;
   input _name_ month year nval _label_ &;
   date = mdy( month, 1, year );
   do i = 1 to nval;
      input value @;
      output;
      date = intnx( 'month', date, 1 );
   end;
datalines;
cpi      8 90  12  Consumer Price Index
131.6 132.7 133.5 133.8 133.8 134.6 134.8 135.0
135.2 135.6 136.0 136.2
ppi      6 90  13  Producer Price Index
114.3 114.5 116.5 118.4 120.8 120.1 118.7 119.0
117.2 116.2 116.0 116.5 116.3
;
```

The following statements sort the data set by date and series name, and the TRANSPOSE procedure is used to transpose the data into a standard form time series data set:

```
proc sort data=temp;
   by date _name_;
run;

proc transpose data=temp out=usprice(drop=_name_);
   by date;
   var value;
run;

proc contents data=usprice;
run;

proc print data=usprice;
run;
```

The final data set is shown in Figure 3.17.

Overview

This chapter summarizes the time intervals, date and datetime informats, date and datetime formats, and date, time, and datetime functions available in SAS software. The use of these features is explained in Chapter 3, "Working with Time Series Data." The material in this chapter is also contained in *SAS Programmers Guide: Essentials* and *Base SAS Procedures Guide*. Because these features are useful for work with time series data, documentation of these features is consolidated and repeated here for easy reference.

Time Intervals

This section provides a reference for the different kinds of time intervals supported by SAS software, but it does not cover how they are used. For an introduction to the use of time intervals, see Chapter 3, "Working with Time Series Data."

Some interval names are used with SAS date values, while other interval names are used with SAS date-time values. The interval names used with SAS date values are YEAR, SEMIYEAR, QTR, MONTH, SEMIMONTH, TENDAY, WEEK, WEEKDAY, DAY, YEARV, R445YR, R454YR, R544YR, R445QTR, R454QTR, R544QTR, R445MON, R454MON, R544MON, and WEEKV. The interval names used with SAS datetime or time values are HOUR, MINUTE, and SECOND. Various abbreviations of these names are also allowed, as described in the section "Summary of Interval Types" on page 121.

Interval names for use with SAS date values can be prefixed with 'DT' to construct interval names for use with SAS datetime values. The interval names DTYEAR, DTSEMIYEAR, DTQTR, DTMONTH, DTSEMIMONTH, DTTENDAY, DTWEEK, DTWEEKDAY, DTDAY, DTYEARV, DTR445YR, DTR454YR, DTR544YR, DTR445QTR, DTR454QTR, DTR544QTR, DTR445MON, DTR454MON, DTR544MON, and DTWEEKV are used with SAS datetime values.

Constructing Interval Names

Multipliers and shift indexes can be used with the basic interval names to construct more complex interval specifications. The general form of an interval name is as follows:

NAMEn.s

The three parts of the interval name are as follows:

NAME	the name of the basic interval type. For example, YEAR specifies yearly intervals.
n	an optional multiplier that specifies that the interval is a multiple of the period of the basic interval type. For example, the interval YEAR2 consists of two-year (biennial) periods.
s	an optional starting subperiod index that specifies that the intervals are shifted to later starting points. For example, YEAR.3 specifies yearly periods shifted to start on the first of March of each calendar year and to end in February of the following year.

Both the multiplier *n* and the shift index *s* are optional and default to 1. For example, YEAR, YEAR1, YEAR.1, and YEAR1.1 are all equivalent ways of specifying ordinary calendar years.

To test for a valid interval specification, use the INTTEST function:

```
interval = 'MONTH3.2';
valid = INTTEST( interval );
valid = INTTEST( 'YEAR4');
```

INTTEST returns a value of 0 if the argument is not a valid interval specification and 1 if the argument is a valid interval specification. The INTTEST function can also be used in a DATA step to test an interval before calling an interval function:

```
valid = INTTEST( interval );
if ( valid = 1 ) then do;
    end_date = INTNX( interval, date, 0, 'E' );
    Status = 'Success';
end;
if ( valid = 0 ) then Status = 'Failure';
```

For more information about the INTTEST function, see the *SAS Functions and CALL Routines: Reference*.

Shifted Intervals

Different kinds of intervals are shifted by different subperiods:

- YEAR, SEMIYEAR, QTR, and MONTH intervals are shifted by calendar months.
- WEEK and DAY intervals are shifted by days.
- SEMIMONTH intervals are shifted by semimonthly periods.
- TENDAY intervals are shifted by 10-day periods.
- YEARV intervals are shifted by WEEKV intervals.
- R445YR, R445QTR, and R445MON intervals are shifted by R445MON intervals.
- R454YR, R454QTR, and R454MON intervals are shifted by R454MON intervals.
- R544YR, R544QTR, and R544MON intervals are shifted by R544MON intervals.
- WEEKV intervals are shifted by days.
- WEEKDAY intervals are shifted by weekdays.
- HOUR intervals are shifted by hours.
- MINUTE intervals are shifted by minutes.
- SECOND intervals are shifted by seconds.

The INTSHIFT function returns the shift interval:

```
interval = 'MONTH3.2';
shift_interval = INTSHIFT( interval );
```

In this example, the value of shift_interval is 'MONTH'. For more information about the INTSHIFT function, see the *SAS Functions and CALL Routines: Reference*.

If a subperiod is specified, the shift index cannot be greater than the number of subperiods in the whole interval. For example, you can use YEAR2.24, but YEAR2.25 is an error because there is no 25th month in a two-year interval.

For interval types that shift by subperiods that are the same as the basic interval type, only multiperiod intervals can be shifted. For example, MONTH type intervals shift by MONTH subintervals; thus, monthly intervals cannot be shifted because there is only one month in MONTH. However, bimonthly intervals can be shifted because there are two MONTH intervals in each MONTH2 interval. The interval name MONTH2.2 specifies bimonthly periods that start on the first day of even-numbered months.

Beginning Dates and Datetimes of Intervals

Intervals that represent divisions of a year begin with the start of the year (1 January). YEARV, R445YR, R454YR, and R544YR intervals begin with the first week of the International Organization for Standardization (ISO) year, the Monday on or immediately preceding January 4th. R445QTR, R454QTR, and R544QTR intervals begin with the 1st, 14th, 27th, and 40th weeks of the ISO year. MONTH2 periods begin with odd-numbered months (January, March, May, and so on).

Likewise, intervals that represent divisions of a day begin with the start of the day (midnight). Thus, HOUR8.7 intervals divide the day into the periods 06:00 to 14:00, 14:00 to 22:00, and 22:00 to 06:00.

Intervals that do not nest within years or days begin relative to the SAS date or datetime value 0. The arbitrary reference time of midnight on January 1, 1960, is used as the origin for nonshifted intervals, and shifted intervals are defined relative to that reference point. For example, MONTH13 defines the intervals that begin January 1, 1960, February 1, 1961, March 1, 1962, and so on, in addition to the intervals that begin December 1, 1958, November 1, 1957, and so on before the base date January 1, 1960.

Similarly, the WEEK2 interval begins relative to the Sunday of the week of January 1, 1960. The interval specification WEEK6.13 defines six-week periods that start on second Fridays, and the convention of counting relative to the period that contains January 1, 1960, indicates the starting date or datetime of the interval closest to January 1, 1960, that corresponds to the second Fridays of six-week intervals.

Intervals always begin on the date or datetime defined by the base interval name, the multiplier, and the shift value. The end of the interval immediately precedes the beginning of the next interval. However, an interval can be identified by any date or datetime value between its starting and ending values, inclusive. For more information about generating identifying dates for intervals, see the section “Alignment of SAS Dates” on page 136.

Summary of Interval Types

The interval types are summarized as follows:

YEAR
specifies yearly intervals. Abbreviations are YEAR, YEARS, YEARLY, YR, ANNUAL, ANNUALLY, and ANNUALS. The starting subperiod *s* is in months (MONTH).

YEARV
specifies ISO 8601 yearly intervals. The ISO 8601 year starts on the Monday on or immediately preceding January 4th. Note that it is possible for the ISO 8601 year to start in December of the preceding year. Also, some ISO 8601 years contain a leap week. For further discussion of ISO weeks, see Technical Committee ISO/TC 154 (Processes, Data Elements, and Documents in Commerce, Industry, and Administration) (2004). The starting subperiod *s* is in ISO 8601 weeks (WEEKV).

R445YR
is the same as YEARV except that the starting subperiod *s* is in retail 4-4-5 months (R445MON).

R454YR
is the same as YEARV except that the starting subperiod *s* is in retail 4-5-4 months (R454MON). For a discussion of the retail 4-5-4 calendar, see National Retail Federation (2007).

R544YR
is the same as YEARV except that the starting subperiod *s* is in retail 5-4-4 months (R544MON).

SEMIYEAR
specifies semiannual intervals (every six months). Abbreviations are SEMIYEAR, SEMIYEARS, SEMIYEARLY, SEMIYR, SEMIANNUAL, and SEMIANN.

The starting subperiod *s* is in months (MONTH). For example, SEMIYEAR.3 intervals are March–August and September–February.

QTR
specifies quarterly intervals (every three months). Abbreviations are QTR, QUARTER, QUARTERS, QUARTERLY, QTRLY, and QTRS. The starting subperiod *s* is in months (MONTH).

R445QTR
specifies retail 4-4-5 quarterly intervals (every 13 ISO 8601 weeks). Some fourth quarters contain a leap week. The starting subperiod *s* is in retail 4-4-5 months (R445MON).

R454QTR
specifies retail 4-5-4 quarterly intervals (every 13 ISO 8601 weeks). Some fourth quarters contain a leap week. For a discussion of the retail 4-5-4 calendar, see National Retail Federation (2007). The starting subperiod *s* is in retail 4-5-4 months (R454MON).

R544QTR
specifies retail 5-4-4 quarterly intervals (every 13 ISO 8601 weeks). Some fourth quarters contain a leap week. The starting subperiod *s* is in retail 5-4-4 months (R544MON).

MONTH
specifies monthly intervals. Abbreviations are MONTH, MONTHS, MONTHLY, and MON. The starting subperiod *s* is in months (MONTH). For example, MONTH2.2 intervals are February–March, April–May, June–July, August–September, October–November, and December–January of the following year.

R445MON
specifies retail 4-4-5 monthly intervals. The 3rd, 6th, 9th, and 12th months are five ISO 8601 weeks long with the exception that some 12th months contain leap weeks. All other months are four ISO 8601 weeks long. R445MON intervals begin with the 1st, 5th, 9th, 14th, 18th, 22nd, 27th, 31st, 35th, 40th, 44th, and 48th weeks of the ISO year. The starting subperiod *s* is in retail 4-4-5 months (R445MON).

R454MON
specifies retail 4-5-4 monthly intervals. The 2nd, 5th, 8th, and 11th months are five ISO 8601 weeks long. All other months are four ISO 8601 weeks long with the exception that some 12th months contain leap weeks. R454MON intervals begin with the 1st, 5th, 10th, 14th, 18th, 23rd, 27th, 31st, 36th, 40th, 44th, and 49th weeks of the ISO year. For a discussion of the retail 4-5-4 calendar, see National Retail Federation (2007). The starting subperiod *s* is in retail 4-5-4 months (R454MON).

R544MON
specifies retail 5-4-4 monthly intervals. The 1st, 4th, 7th, and 10th months are five ISO 8601 weeks long. All other months are four ISO 8601 weeks long with the exception that some 12th months contain leap weeks. R544MON intervals begin with the 1st, 6th, 10th, 14th, 19th, 23rd, 27th, 32nd, 36th, 40th, 45th, and 49th weeks of the ISO year. The starting subperiod *s* is in retail 5-4-4 months (R544MON).

SEMIMONTH
specifies semimonthly intervals. SEMIMONTH breaks each month into two periods, starting on the 1st and 16th days. Abbreviations are SEMIMONTH, SEMIMONTHS, SEMIMONTHLY, and SEMIMON. The starting subperiod *s* is in SEMIMONTH periods. For example, SEMIMONTH2.2 specifies intervals from the 16th of one month through the 15th of the next month.

TENDAY
specifies 10-day intervals. TENDAY breaks the month into three periods, the 1st through the 10th day of the month, the 11th through the 20th day of the month, and the remainder of the month. (TENDAY is a special interval typically used for reporting automobile sales data.) The starting subperiod *s* is in TENDAY periods. For example, TENDAY4.2 defines 40-day periods that start at the second TENDAY period.

WEEK
specifies weekly intervals of seven days. Abbreviations are WEEK, WEEKS, and WEEKLY. The starting subperiod *s* is in days (DAY), with the days of the week numbered as 1=Sunday, 2=Monday, 3=Tuesday, 4=Wednesday, 5=Thursday, 6=Friday, and 7=Saturday. For example, WEEK.7 means weekly with Saturday as the first day of the week.

WEEKV
specifies ISO 8601 weekly intervals of seven days. Each week starts on Monday. The starting subperiod *s* is in days (DAY). Note that WEEKV differs from WEEK in that WEEKV.1 starts on Monday, WEEKV.2 starts on Tuesday, and so forth.

WEEKDAY

WEEKDAY*d*W

WEEKDAY*dd*W

WEEKDAY*ddd*W

specifies daily intervals with weekend days included in the preceding weekday. Note that for a five-day work week that starts on Monday, the appropriate interval is WEEKDAY5.2. Abbreviations are WEEKDAY and WEEKDAYS. The starting subperiod *s* is in weekdays (WEEKDAY).

The WEEKDAY interval is the same as DAY except that weekend days are absorbed into the preceding weekday. Thus, there are five WEEKDAY intervals in a calendar week: Monday, Tuesday, Wednesday, Thursday, and the three-day period Friday-Saturday-Sunday.

The default weekend days are Saturday and Sunday, but any one to six weekend days can be listed after the WEEKDAY string and followed by a W. Weekend days are specified as '1' for Sunday, '2' for Monday, and so forth. For example, WEEKDAY67W specifies a Friday-Saturday weekend. WEEKDAY1W specifies a six-day work week with a Sunday weekend. WEEKDAY17W is the same as WEEKDAY.

DAY

specifies daily intervals. Abbreviations are DAY, DAYS, and DAILY. The starting subperiod *s* is in days (DAY).

HOUR

specifies hourly intervals. Aliases are HOUR, DTHOUR, HOURS, DTHOURS, HOURLY, DTHOURLY, HR, and DTHR. The starting subperiod *s* is in hours (HOUR).

MINUTE

specifies minute intervals. Aliases are MINUTE, DTMINUTE, MINUTES, DTMINUTES, MIN, and DTMIN. The starting subperiod *s* is in minutes (MINUTE).

SECOND

specifies second intervals. Aliases are SECOND, DTSECOND, SECONDS, DTSECONDS, SEC and DTSEC. The starting subperiod *s* is in seconds (SECOND).

Examples of Interval Specifications

Table 4.1 shows examples of different kinds of interval specifications.

Table 4.1 Examples of Intervals

Name	Description of Interval
YEAR	Years that start in January
YEAR.10	Years that start in October
YEAR2.7	Biennial intervals that start in July of even years
YEAR2.19	Biennial intervals that start in July of odd years
YEAR4.11	Four-year intervals that start in November of leap years (frequency of U.S. presidential elections)

Table 4.1 *continued*

Name	Description of Interval
YEAR4.35	Four-year intervals that start in November of even years between leap years (frequency of U.S. midterm elections)
YEARV	Years that start on the Monday on or immediately preceding January 4th
YEARV.2	Years that start on the Monday immediately following January 4th
R445MON	Months that start on the 1st, 5th, 9th, 14th, 18th, 22nd, 27th, 31st, 35th, 40th, 44th, and 48th Monday of the year. The 1st Monday is the Monday on or immediately preceding January 4th
R445MON3	Three-month intervals that start on the 1st, 14th, 27th, and 40th Monday of the year. This is equivalent to R445QTR
R445MON3.2	Three-month intervals that start on the 5th, 18th, 31th, and 44th Monday of the year. This is equivalent to R445QTR.2
WEEK	Weekly intervals that start on Sundays
WEEK2	Biweekly intervals that start on first Sundays
WEEK1.1	Same as WEEK
WEEK.2	Weekly intervals that start on Mondays
WEEK6.3	Six-week intervals that start on first Tuesdays
WEEK6.11	Six-week intervals that start on second Wednesdays
WEEKDAY	Daily with Friday-Saturday-Sunday counted as the same day (five-day work week with a Saturday-Sunday weekend)
WEEKDAY17W	Same as WEEKDAY
WEEKDAY5.2	Five weekdays that start on Monday. If WEEKDAY data are accumulated into weekly data, the interval of the accumulated data is WEEKDAY5.2
WEEKDAY67W	Daily with Thursday-Friday-Saturday counted as the same day (five-day work week with a Friday-Saturday weekend)
WEEKDAY1W	Daily with Saturday-Sunday counted as the same day (six-day work week with a Sunday weekend)
WEEKDAY3.2	Three-weekday intervals (with Friday-Saturday-Sunday counted as one weekday) with the cycle three-weekday periods aligned to Monday, January 4, 1960
HOUR8.7	Eight-hour intervals that start at 6 a.m., 2 p.m., and 10 p.m. (might be used for work shifts)

Custom Time Intervals

The standard time intervals described in the previous sections do not always fit the data. For example, you might want to use fiscal months that begin on the 10th of each month, but the MONTH interval begins on the 1st of each month. Or you might collect data hourly for a business that is closed at night, but using the DTHOUR interval results in gaps in the data that can cause problems in standard time series analysis. In another case, you might wish to calculate the number of business days between dates, excluding holidays and weekends, but holidays are counted when you use the INTCK function with the WEEKDAY interval. For more information about the INTCK function, see "Interval Functions INTNX and INTCK" on page 89.

Time series can be analyzed using observation numbers as the identifying reference. However, it is often desirable to maintain the time stamp for other types of modeling such as regression variables based on time or reconciliation.

To address these issues, you can define custom intervals within a given SAS program. The use of custom intervals requires the following two steps for each interval:

1 Associate a data set name with a custom interval name by using the INTERVALDS= system option. For more information about the INTERVALDS= option, see the *SAS System Options: Reference*. The following example associates the data set StoreHoursDS with the custom interval StoreHours:

```
options intervalds=(StoreHours=StoreHoursDS);
```

2 Create a data set that describes the custom interval. The data set must contain a BEGIN variable. It can also contain an END and a SEASON variable. It should contain a FORMAT statement for the BEGIN variable that specifies a SAS date, SAS datetime, or numeric format that matches the BEGIN variable data. If the END variable is present, it should also be included in the FORMAT statement. A numeric format that is not a SAS date or SAS datetime format indicates that the values are observation numbers. If the END variable is not present, then the implied value of END at each observation is one less than the value of BEGIN at the next observation.

   The span of the custom interval data set should include any dates or times that are necessary for performing calculations on the time series, including backcasting, forecasting, and other operations that might extend beyond the series (such as filters).

After the two preceding steps have been completed, the custom interval can be specified in SAS procedures and functions where a standard time interval can be specified.

The following DATA step creates the StoreHoursDS data set, which is appropriate for a business that is open 9 a.m. to 6 p.m. Monday through Friday and 9 a.m. to 1 p.m. Saturday:

```
options intervalds=(StoreHours=StoreHoursDS);
data StoreHoursDS(keep=BEGIN END);
   start = '01JAN2009'D;
   stop  = '31DEC2009'D;
   do date = start to stop;
      dow = WEEKDAY(date);
      datetime=dhms(date,0,0,0);
```

```
      if dow not in (1,7) then
         do hour = 9 to 17;
            begin=intnx('hour',datetime,hour,'b');
            end=intnx('hour',datetime,hour,'e');
            output;
         end;
      else if dow = 7 then
         do hour = 9 to 12;
            begin=intnx('hour',datetime,hour,'b');
            end=intnx('hour',datetime,hour,'e');
            output;
         end;
   end;
   format BEGIN END DATETIME.;
run;

title 'Store Hours Custom Interval';
proc print data=StoreHoursDS(obs=18);
run;
```

The first 18 observations of the custom interval data set are shown in Figure 4.1.

Figure 4.1 Store Hours Custom Interval

Store Hours Custom Interval

Obs	begin	end
1	01JAN09:09:00:00	01JAN09:09:59:59
2	01JAN09:10:00:00	01JAN09:10:59:59
3	01JAN09:11:00:00	01JAN09:11:59:59
4	01JAN09:12:00:00	01JAN09:12:59:59
5	01JAN09:13:00:00	01JAN09:13:59:59
6	01JAN09:14:00:00	01JAN09:14:59:59
7	01JAN09:15:00:00	01JAN09:15:59:59
8	01JAN09:16:00:00	01JAN09:16:59:59
9	01JAN09:17:00:00	01JAN09:17:59:59
10	02JAN09:09:00:00	02JAN09:09:59:59
11	02JAN09:10:00:00	02JAN09:10:59:59
12	02JAN09:11:00:00	02JAN09:11:59:59
13	02JAN09:12:00:00	02JAN09:12:59:59
14	02JAN09:13:00:00	02JAN09:13:59:59
15	02JAN09:14:00:00	02JAN09:14:59:59
16	02JAN09:15:00:00	02JAN09:15:59:59
17	02JAN09:16:00:00	02JAN09:16:59:59
18	02JAN09:17:00:00	02JAN09:17:59:59

The following DATA step creates the FMDS data set to define a custom interval FiscalMonth, which is appropriate for a business that uses fiscal months that start on the 10th of each month. The SAME alignment option of the INTNX function specifies that the dates generated by the INTNX function are the same day of the month as the date in the start variable. For more information about the INTNX function, see "SAS Date, Time, and Datetime Functions" on page 136. The MONTH function assigns the month of the BEGIN variable to the SEASON variable. This specifies monthly seasonality.

```
options intervalds=(FiscalMonth=FMDS);
data FMDS(keep=BEGIN SEASON);
   start = '10JAN1999'D;
   stop  = '10JAN2001'D;
   nmonths = INTCK('MONTH',start,stop);
   do i=0 to nmonths;
      BEGIN = INTNX('MONTH',start,i,'S');
      SEASON = MONTH(BEGIN);
      output;
   end;
   format BEGIN DATE.;
run;
```

The difference between the custom FiscalMonth interval and a standard interval can be seen in the following example. The output shown in Figure 4.2 compares how the data are accumulated. For the FiscalMonth interval, values in the first nine days of the month are accumulated with the interval that begins in the previous month. For the standard MONTH interval, values in the first nine days of the month are accumulated with the calendar month.

```
data sales(keep=DATE sales);
   do date = '01JAN2000'D to '31DEC2000'D;
      month = MONTH(date);
      dayofmonth = DAY(date);
      sales = 0;
      if ( dayofmonth lt 10 ) then sales = month/9;
      output;
   end;
   format date monyy.;
run;

proc timeseries data=sales out=dataInFiscalMonths;
   id DATE interval=FiscalMonth accumulate=total;
   var sales;
run;

proc timeseries data=sales out=dataInStdMonths;
   id DATE interval=Month accumulate=total;
   var sales;
run;

data compare;
     merge dataInFiscalMonths(rename=(sales=FM_sales))
           dataInStdMonths(rename=(sales=SM_sales));
     by DATE;
run;

title 'Standard Monthly Data vs. Fiscal Month Data';
proc print data=compare;
run;
```

Figure 4.2 Fiscal Months Custom Interval

Standard Monthly Data vs. Fiscal Month Data

Obs	date	FM_sales	SM_sales
1	10-DEC-1999	1	.
2	01-JAN-2000	.	1
3	10-JAN-2000	2	.
4	01-FEB-2000	.	2
5	10-FEB-2000	3	.
6	01-MAR-2000	.	3
7	10-MAR-2000	4	.
8	01-APR-2000	.	4
9	10-APR-2000	5	.
10	01-MAY-2000	.	5
11	10-MAY-2000	6	.
12	01-JUN-2000	.	6
13	10-JUN-2000	7	.
14	01-JUL-2000	.	7
15	10-JUL-2000	8	.
16	01-AUG-2000	.	8
17	10-AUG-2000	9	.
18	01-SEP-2000	.	9
19	10-SEP-2000	10	.
20	01-OCT-2000	.	10
21	10-OCT-2000	11	.
22	01-NOV-2000	.	11
23	10-NOV-2000	12	.
24	01-DEC-2000	.	12
25	10-DEC-2000	0	.

The next example uses custom intervals in the time function INTCK to omit holidays when counting business days. The result is shown in Figure 4.3.

```
options intervalds=(BankingDays=BankDayDS);
data BankDayDS(keep=BEGIN);
   start = '15DEC1998'D;
   stop  = '15JAN2002'D;
   nwkdays = INTCK('WEEKDAY',start,stop);
   do i = 0 to nwkdays;
      BEGIN = INTNX('WEEKDAY',start,i);
      year = YEAR(BEGIN);
      if BEGIN ne HOLIDAY("NEWYEAR",year) and
         BEGIN ne HOLIDAY("MLK",year) and
         BEGIN ne HOLIDAY("USPRESIDENTS",year) and
         BEGIN ne HOLIDAY("MEMORIAL",year) and
         BEGIN ne HOLIDAY("USINDEPENDENCE",year) and
         BEGIN ne HOLIDAY("LABOR",year) and
         BEGIN ne HOLIDAY("COLUMBUS",year) and
         BEGIN ne HOLIDAY("VETERANS",year) and
         BEGIN ne HOLIDAY("THANKSGIVING",year) and
```

```
         BEGIN ne HOLIDAY("CHRISTMAS",year) then
      output;
   end;
   format BEGIN DATE.;
run;

data CountDays;
   start = '01JAN1999'D;
   stop  = '31DEC2001'D;
   ActualDays = INTCK('DAYS',start,stop);
   Weekdays   = INTCK('WEEKDAYS',start,stop);
   BankDays   = INTCK('BankingDays',start,stop);
   format start stop DATE.;
run;

title 'Methods of Counting Days';
proc print data=CountDays;
run;
```

Figure 4.3 Bank Days Custom Interval

Methods of Counting Days

Obs	start	stop	ActualDays	Weekdays	BankDays
1	01JAN99	31DEC01	1095	781	757

Date and Datetime Informats

Table 4.2 lists some of the SAS date and datetime informats available to read date, time, and datetime values. For a discussion of the use of date and datetime informats, see Chapter 3, "Working with Time Series Data." For a complete description of these informats, see *SAS Programmers Guide: Essentials*.

For each informat, Table 4.2 shows an example of a date or datetime value written in the style that the informat is designed to read. You can specify the width of each informat by adding *w*. For informats that include second values, you can specify the number of decimal digits for seconds by adding *d*. Table 4.2 shows the width range allowed by the informat and the default width. The date 17 October 1991 and the time 2:25:32 p.m. are used for the example in all cases.

Table 4.2 Frequently Used SAS Date and Datetime Informats

Informat	Example	Description	Width Range	Default Width
ANYDTDTE*w.*		Reads and extracts the date value from any of the following: DATE, DATETIME, DDMMYY, JULIAN, MDYAMPM, MMDDYY, MMxYY*, MONYY, TIME, YMDDTTM, YYMMDD, YYQ, YYxMM*, month-day-year	5–32	9

Table 4.2 *continued*

Informat	Example	Description	Width Range	Default Width
ANYDTDTM*w.*		Reads and extracts the datetime value from any of the following: DATE, DATETIME, DDMMYY, JULIAN, MMDDYY, MMxYY*, MONYY, TIME, YYMMDD, YYQ, YYxMM*, month-day-year	1–32	19
ANYDTTME*w.*		Reads and extracts the time value from any of the following: DATE, DATETIME, DDMMYY, JULIAN, MMDDYY, MONYY, TIME, YYMMDD, YYQ, month-day-year	1–32	8
DATE*w.*	17oct91	Day, month abbreviation, and year: *ddmonyy*	7–32	7
DATETIME*w.d*	17oct91:14:45:32	Date and time: *ddmonyy*:*hh*:*mm*:*ss*	13–40	18
DDMMYY*w.*	17/10/91	Day, month, year: *ddmmyy*, *dd*/*mm*/*yy*, *dd-mm-yy*, or *dd mm yy*	6–32	6
JULIAN*w.*	91290	Year and day of year (Julian dates): *yyddd*	5–32	5
MMDDYY*w.*	10/17/91	Month, day, year: *mmddyy*, *mm*/*dd*/*yy*, *mm-dd-yy*, or *mm dd yy*	6–32	6
MONYY*w.*	Oct91	Month abbreviation and year: *monyy*	5–32	5
NENGO*w.*	H.03/10/17	Japanese Nengo notation	7–32	10
TIME*w.d*	14:45:32	Hours, minutes, seconds: *hh*:*mm*:*ss* or hours, minutes: *hh*:*mm*	5–32	8
WEEKV*w.*	1991-W42-04	ISO 8601 year, week, day of week: *yyyy*-W*ww*-*dd*	3–200	11
YYMMDD*w.*	91/10/17	Year, month, day: *yymmdd*, *yy*/*mm*/*dd*, *yy-mm-dd*, or *yy mm dd*	6–32	6
YYQ*w.*	91Q4	Year and quarter of year: *yy*Q*q*	4–32	4

Date, Time, and Datetime Formats

Some of the commonly used SAS date and datetime formats are listed in Table 4.3 and Table 4.4. You can specify the width value for each format by adding *w*. The tables list the range of width values allowed and the default width value for each format.

The notation used by a format is abbreviated in different ways depending on the width option used. For example, the format MMDDYY8. writes the date 17 October 1991 as 10/17/91, while the format MMDDYY6. writes this date as 101791. In particular, formats that display the year show two-digit or four-digit year values depending on the width option. The examples shown in the tables use the default width.

The interval function INTFMT returns a recommended format for time ID values based on the interval that describes the frequency of the values. The following example uses INTFMT to select a format to display the quarterly time ID variable qtrDate. In this example, INTFMT returns the format YYQC6., which displays the year in four digits and the quarter in a single digit. This selected format is stored in a macro variable that is created by the CALL SYMPUT statement. The second argument to INTFMT controls the width of the year for date formats; it can take the value 'long' or 'l' to indicate 4 for the year width or the value 'short' or 's' to indicate 2 for the year width. For more information about the INTFMT function, see the . For more information about the CALL SYMPUT statement, see the *SAS DATA Step Statements: Reference*.

The macro variable &FMT is then used in the FORMAT statement in the PROC PRINT step as follows:

```
data b(keep=qtrDate);
   interval = 'QTR';
   form = INTFMT( interval, 'long' );
   call symput('fmt',form);
   do i=1 to 4;
      qtrDate = INTNX( interval, '01jan00'd, i-1 );
      output;
   end;
run;

proc print;
   format qtrDate &fmt;
run;
```

It is also possible to display date and datetime values as strings by using the format that is identified by INTFMT. In the following example, INTFIT is used to identify the intervals of the sashelp.citiwk and sashelp.air data sets. Then INTFMT is used to identify formats that are based on the intervals. The formats are then used to convert the first SAS date value of each data set to a string. The START variable displays the date of the first observation of each data set. This method assumes that the interval of the data set can be identified by examining the first two observations. This is often the case for output data sets and data sets that have been properly prepared for input by using a procedure such as the TIMESERIES procedure. More than two observations might be required to identify the difference between a DAY interval and a WEEKDAY interval. This example would need to be modified if the DATE variable contained SAS datetime values.

```
data a(keep=DATE0 DATE INTERVAL FMT START);
   length START INTERVAL FMT $32;
   format date0 date DATE.;
   set sashelp.citiwk(obs=2) sashelp.air(obs=2);
   DATE0 = lag(date);
```

```
   if ( mod(_n_,2) eq 1 ) then delete;
   if ( mod(_n_,2) eq 0 ) then INTERVAL = intfit( DATE0, date, 'D' );
   if ( mod(_n_,2) eq 0 ) then FMT = INTFMT( interval, 'l' );
   START = putn( DATE0, FMT );
run;

proc print;
run;
```

For a complete description of these formats, including the variations of the formats produced by different width options, see *SAS Programmers Guide: Essentials*. For a discussion of the use of date and datetime formats, see Chapter 3, "Working with Time Series Data,".

Date Formats

Table 4.3 lists some of the available SAS date formats. For each format, an example is shown of a date value in the notation produced by the format. The date '17OCT91'D is used as the example.

Table 4.3 Frequently Used SAS Date Formats

Format	Example	Description	Width Range	Default Width
DATE*w.*	17OCT91	Day, month abbreviation, year: *ddmonyy*	5–9	7
DAY*w.*	17	Day of month	2–32	2
DDMMYY*w.*	17/10/91	Day, month, year: *dd*/*mm*/*yy*	2–8	8
DOWNAME*w.*	Thursday	Name of day of the week	1–32	9
JULDAY*w.*	290	Day of year	3–32	3
JULIAN*w.*	91290	Year and day of year: *yyddd*	5–7	5
MMDDYY*w.*	10/17/91	Month, day, year: *mm*/*dd*/*yy*	2–8	8
MMYY*w.*	10M1991	Month and year: *mm*M*yyyy*	5–32	7
MMYYC*w.*	10:1991	Month and year: *mm*:*yyyy*	5–32	7
MMYYD*w.*	10-1991	Month and year: *mm*-*yyyy*	5–32	7
MMYYP*w.*	10.1991	Month and year: *mm*.*yyyy*	5–32	7
MMYYS*w.*	10/1991	Month and year: *mm*/*yyyy*	5–32	7

Table 4.3 *continued*

Format	Example	Description	Width Range	Default Width
MMYYN*w.*	101991	Month and year: *mmyyyy*	5–32	6
MONNAME*w.*	October	Name of month	1–32	9
MONTH*w.*	10	Month of year	1–32	2
MONYY*w.*	OCT91	Month abbreviation and year: *monyy*	5–7	5
QTR*w.*	4	Quarter of year	1–32	1
QTRR*w.*	IV	Quarter in roman numerals	3–32	3
NENGO*w.*	H.03/10/17	Japanese Nengo notation	2–10	10
WEEKDATE*w.*	Thursday, October 17, 1991	*day-of-week*, *month-name dd*, *yyyy*	3–37	29
WEEKDATX*w.*	Thursday, 17 October 1991	*day-of-week*, *dd month-name yyyy*	3–37	29
WEEKDAY*w.*	5	Day of week	1–32	1
WEEKV*w.*	1991-W42-04	ISO 8601 year, week, day of week: *yyyy*-W*ww*-*dd*	3–200	11
WORDDATE*w.*	October 17, 1991	*month-name dd*, *yyyy*	3–32	18
WORDDATX*w.*	17 October 1991	*dd month-name yyyy*	3–32	18
YEAR*w.*	1991	Year: *yyyy*	2–32	4

YYQRP*w.*	1991.IV	Year and quarter in roman numerals: *yyyy*.*rr*	6–32	8
YYQRS*w.*	1991/IV	Year and quarter in roman numerals: *yyyy*/*rr*	6–32	8
YYQRN*w.*	1991IV	Year and quarter in roman numerals: *yyyyrr*	6–32	8

Datetime and Time Formats

Table 4.4 lists some of the available SAS datetime and time formats. For each format, the example shows the formatted value. The value of the variable dt is '17OCT91:14:25:32'DT. You can specify the width of each format by adding *w*. For formats that allow a decimal value, you can specify the number of decimal digits by adding *d*.

Table 4.4 Frequently Used SAS Datetime and Time Formats

Format	Value	Example	Description	Width Range	Default Width
DATETIME*w.d*	dt	17OCT91:14:25:32	*ddmonyy*: *hh*:*mm*:*ss.ss*	7–40	16
DTWKDATX*w*.	dt	Thursday, 17 October 1991	*day-of-week*, *dd month yyyy*	3–37	29
HHMM*w.d*	TIMEPART(dt)	14:26	Hour and minute: *hh*:*mm.mm*	2–20	5
HOUR*w.d*	TIMEPART(dt)	14	Hour: *hh.hh*	2–20	2
MMSS*w.d*	HMS(0, MINUTE(dt), SECOND(dt))	25:32	Minutes and seconds: *mm*:*ss.ss*	2–20	5
TIME*w.d*	TIMEPART(dt)	14:25:32	Time of day: *hh*:*mm*:*ss.ss*	2–20	8
TOD*w.d*	dt	14:25:32	Time of day: *hh*:*mm*:*ss.ss*	2–20	8

Alignment of SAS Dates

SAS date values that are used to identify time series observations produced by SAS/ETS and SAS High-Performance Forecasting procedures are normally aligned with the beginning of the time intervals that correspond to the observations. For example, for monthly data for 1994, the date values that identify the observations are 1Jan94, 1Feb94, 1Mar94, . . . , 1Dec94.

However, for some applications it might be preferable to use end-of-period dates, such as 31Jan94, 28Feb94, 31Mar94, . . . , 31Dec94. For other applications, such as plotting time series, it might be more convenient to use interval midpoint dates to identify the observations.

Many SAS/ETS and SAS High-Performance Forecasting procedures provide an ALIGN= option to control the alignment of dates for outputting time series observations. SAS/ETS procedures that support the ALIGN= option are ARIMA, DATASOURCE, ESM, EXPAND, SIMILARITY, TIMESERIES, UCM, and VARMAX. SAS High-Performance Forecasting procedures that support the ALIGN= option are HPFRECONCILE, HPF, HPFDIAGNOSE, HPFENGINE, and HPFEVENTS.

ALIGN=

The ALIGN= option can have the following values:

BEGINNING	specifies that dates be aligned to the start of the interval. This is the default. BEGINNING can be abbreviated as BEGIN, BEG, or B.
MIDDLE	specifies that dates be aligned to the interval midpoint, the average of the beginning and ending values. MIDDLE can be abbreviated as MID or M.
ENDING	specifies that dates be aligned to the end of the interval. ENDING can be abbreviated as END or E.

For information about the calculation of the beginning and ending values of intervals, see the section "Beginning Dates and Datetimes of Intervals" on page 120.

SAS Date, Time, and Datetime Functions

SAS date, time, and datetime functions are used to perform the following tasks:

- compute date, time, and datetime values from calendar and time-of-day values
- compute calendar and time-of-day values from date and datetime values
- convert between date, time, and datetime values
- perform calculations that involve time intervals
- provide information about time intervals
- provide information about seasonality

For all interval functions, you can supply the intervals and other character arguments either directly as a quoted string or as a SAS character variable. When you use a character variable, you should set the length of the character variable to at least the length of the longest string for that variable that is used in the DATA step.

Also, to ensure correct results when using interval functions, use date intervals with date values and datetime intervals with datetime values.

For a complete description of these functions, see *SAS Functions and CALL Routines: Reference*.

The following list shows SAS date, time, and datetime functions in alphabetical order:

DATE()
returns today's date as a SAS date value.

DATEJUL(*yyddd* **)**
returns the SAS date value when given the Julian date in *yyddd* or *yyyyddd* format. For example, `DATE = DATEJUL(99001);` assigns the SAS date value '01JAN99'D to DATE, and `DATE = DATEJUL(1999365);` assigns the SAS date value '31DEC1999'D to DATE.

DATEPART(*datetime* **)**
returns the date part of a SAS datetime value as a date value.

DATETIME()
returns the current date and time of day as a SAS datetime value.

DAY(*date* **)**
returns the day of the month from a SAS date value.

DHMS(*date, hour, minute, second* **)**
returns a SAS datetime value for date, hour, minute, and second values.

FMTINFO('*format-name***', '***information-type***')**
returns the information specified by *information-type* for *format-name*. This function is useful for determining the category of a variable if the variable has a format. Specifying the *information-type* as 'cat' returns the category of the format. Examples of categories are date, datetime, time, and num. For example, `FMTINFO('MMDDYY','cat')` returns 'date'.

HMS(*hour, minute, second* **)**
returns a SAS time value for hour, minute, and second values.

HOLIDAY('*holiday***',** *year* **)**
returns a SAS date value for the holiday and year specified. Valid values for holiday are 'BOXING', 'CANADA', 'CANADAOBSERVED', 'CHRISTMAS', 'COLUMBUS', 'EASTER', 'FATHERS', 'HALLOWEEN', 'JUNETEENTH', 'JUNETEENTHUSG', 'JUNETEENTHUSPS', 'LABOR', 'MLK', 'MEMORIAL', 'MOTHERS', 'NEWYEAR','THANKSGIVING', 'THANKSGIVINGCANADA', 'USINDEPENDENCE', 'USPRESIDENTS', 'VALENTINES', 'VETERANS', 'VETERANSUSG', 'VETERANSUSPS', and 'VICTORIA'. For example: `EASTER2000 = HOLIDAY('EASTER', 2000);`

HOUR(*datetime* **)**
returns the hour from a SAS datetime or time value.

INTCINDEX('*date-interval***',** *date* **)**

INTCINDEX('*datetime-interval***',** *datetime* **)**
returns the index of the seasonal cycle when given an interval and an appropriate SAS date, datetime, or time value. For example, the seasonal cycle for INTERVAL='DAY' is 'WEEK', so `INTCINDEX('DAY','01SEP78'D);` returns 35 because September 1, 1978, is the sixth day of the 35th week of the year. For correct results, date intervals should be used with date values, and datetime intervals should be used with datetime values.

INTCK('*date-interval***',** *date1, date2* **<,** *'method'* **>)**

INTCK('*datetime-interval***',** *datetime1, datetime2* **<,** *'method'* **>)**
returns the number of boundaries of intervals of the given kind that lie between the two date or datetime values. The optional method argument specifies that the intervals are counted using either a discrete or a continuous method. The default DISCRETE (or DISC or D) method uses discrete time intervals. For the DISCRETE method, the distance in MONTHS between January 31, 2000, and February 1, 2000, is one month. The CONTINUOUS (or CONT or C) method uses continuous time intervals. For the CONTINUOUS method, the distance in MONTHS between January 15, 2000, and February 14, 2000, is zero, but the distance in MONTHS between January 15, 2000, and February 15, 2000, is one month.

INTCYCLE('*interval***' <,** *seasonality* **>)**
returns the interval of the seasonal cycle, given a date, time, or datetime interval. For example, INTCYCLE('MONTH') returns 'YEAR' because the months January, February, . . . , December constitute a yearly cycle. INTCYCLE('DAY') returns 'WEEK' because Sunday, Monday, . . . , Saturday constitute a weekly cycle.

You can specify the optional *seasonality* argument to construct a cycle other than the default seasonal cycle. For example, INTCYCLE('MONTH', 3) returns 'QTR'. The optional second argument is the seasonal frequency.

INTFIT(*date1, date2***, '***D***')**

INTFIT(*datetime1, datetime2***, '***DT***')**

INTFIT(*obs1, obs2***, '***OBS***')**
returns an interval that fits exactly between two SAS date, datetime, or observation values. That is, if the interval result of the INTFIT function is used with *date1*, 1, and SAMEDAY alignment in the INTNX function, then the result is *date2*. This concept is illustrated in the following example, where result1 is the same as date1 and result2 is the same as date2:

```
FitInterval = INTFIT( date1, date2, 'D' );
result1 = INTNX( FitInterval, date1, 0, 'SAMEDAY');
result2 = INTNX( FitInterval, date1, 1, 'SAMEDAY');
```

More than one interval can fit the preceding definition. For example, two SAS date values that are seven days apart could be fit with either 'DAY7' or 'WEEK'. The INTFIT function chooses the more common interval, so 'WEEK' is the result when the dates are seven days apart. The INTFIT function can be used to detect the possible frequency of the time series or to analyze frequencies of other events in a time series, such as outliers or missing values.

INTFMT('*interval***' ,'***size***')**

returns a recommended format when given a date, time, or datetime interval for displaying the time ID values associated with a time series of the given interval. The second argument to INTFMT controls the width of the year for date formats; it can take the value 'long' or 'l' to specify that the returned format display a four-digit year or the value 'short' or 's' to specify that the returned format display a two-digit year.

INTGET(*date1, date2, date3* **)**

INTGET(*datetime1, datetime2, datetime3* **)**

returns an interval that fits three consecutive SAS date or datetime values. The INTGET function examines two intervals: the first interval between *date1* and *date2*, and the second interval between *date2* and *date3*. In order for an interval to be detected, either the two intervals must be the same or one interval must be an integer multiple of the other interval. That is, INTGET assumes that at least two of the dates are consecutive points in the time series, and that the other two dates are also consecutive or represent the points before and after missing observations. The INTGET function assumes that large values are SAS datetime values, which are measured in seconds, and that smaller values are SAS date values, which are measured in days. The INTGET function can be used to detect the possible frequency of the time series or to analyze frequencies of other events in a time series, such as outliers or missing values.

INTINDEX('*date-interval***',** *date* **<,** *seasonality* **>)**

INTINDEX('*datetime-interval***',** *datetime* **<,** *seasonality* **>)**

returns the seasonal index for the specified date or datetime interval and an appropriate date or datetime value. The seasonal index is a number that represents the position of the date or datetime value in the seasonal cycle of the specified interval. For example, `INTINDEX('MONTH','01DEC2000'D);` returns 12 because monthly data is yearly periodic and DECEMBER is the 12th month of the year. However, `INTINDEX('DAY','01DEC2000'D);` returns 6 because daily data is weekly periodic and December 01, 2000, is a Friday, the sixth day of the week. To correctly identify the seasonal index, the interval specification should agree with the date or datetime value. For example, `INTINDEX('DTMONTH','01DEC2000'D);` and `INTINDEX('MONTH','01DEC2000:00:00:00'DT);` do not return the expected value of 12. However, both `INTINDEX('MONTH','01DEC2000'D);` and `INTINDEX('DTMONTH','01DEC2000:00:00:00'DT);` return the expected value of 12.

You can specify the optional *seasonality* argument to use a seasonal cycle other than the default seasonal cycle. For example, `INTINDEX('MONTH','01APR2000'D);` returns the value 4, to indicate the fourth month of the year. However, `INTINDEX('MONTH','01APR2000'D,3);` and `INTINDEX('MONTH','01APR2000'D,'QTR');` return the value 1 to indicate the first month of the quarter. Specifying either 3 or 'QTR' for the third argument uses a quarterly seasonal cycle instead of the default yearly seasonal cycle.

INTNEST('*interval***', '***interval***')**

An interval is said to *nest* within another interval if a whole number of the first interval spans the same time period as the second interval for all time periods. For example, DAY is nested within WEEK because there are exactly seven DAY periods within each WEEK for every span of time. However, WEEK is not nested in MONTH because a MONTH period is not consistently a multiple of 7 days. In order to nest, the two intervals must also generate beginning and ending dates that align. For example, WEEK.2 will not nest within WEEK because WEEK begins on Sundays and WEEK.2 begins on Mondays.

The INTNEST function calculates the number of whole periods of the smaller interval that will fit into the period of the larger interval. If the first interval specified spans a larger time period than the second interval specified, then the number returned is positive. If the second interval specified spans a larger period than the first interval specified, then the number returned is negative. For example, `INTNEST('WEEK','DAY')` returns 7, and `INTNEST('DAY','WEEK')` returns –7. A missing value is returned if neither interval nests into the other. Table 4.5 lists the types of results returned by INTNEST and describes how to interpret each result.

Table 4.5 Results Returned by the INTNEST Function

Result	Description	Explanation Example
0	Same	The two input intervals define the same time periods for all time periods. INTNEST('MONTH12','YEAR')
1	Variable number	The first interval contains a whole number of periods of the second interval, but the number varies over time. INTNEST('MONTH','DAY')
-1	Variable number	The second interval contains a whole number of periods of periods of the first interval, but the number varies over time. INTNEST('DAY','YEAR')
$n > 1$	Fixed number	The first interval contains a whole number n periods of the second interval, and that is fixed for all time. INTNEST('WEEK', 'DAY')
$n < -1$	Fixed number	The second interval contains a whole number $-n$ periods of the first interval, and that is fixed for all time. INTNEST('DTHOUR', 'DAY')
Missing value of M	Multiple mismatch	Neither interval will nest into other interval. However, intervals of these types can nest for some multiple values. INTNEST('SEMIMONTH3', 'MONTH')
Missing value of S	Shift mismatch	Neither interval will nest into other interval. However, if a shift value were changed, then the intervals would be the same or one would nest into the other. INTNEST('SEMIMONTH2.2', 'MONTH')
Missing value of B	Base mismatch	The interval bases define time periods that are so different that nesting is not possible for any multiple or shift. For example, YEAR always begins on January 1st of each year, and is shifted by months. However, YEARV always begins on the Monday on or immediately preceding January 4th, and YEARV is shifted by ISO 8601 weeks that begin on Monday. Since January 1st is only a Monday for some years, the intervals will not consistently start on the same day. The same problem exists if the YEAR interval is shifted by months, since the first of a month would not be a Monday for all years. INTNEST('YEAR', 'YEARV')

The result returned by the INTNEST function is of interest when performing the following tasks related to time series:

accumulation	when one interval nests into another interval, even with a variable number, accumulation from the smaller time periods into the larger time periods can be accomplished with a simple rule. If the intervals do not nest, you should consider transforming a time series from one frequency to another with a more complex rule, for example an interpolation.
seasonality	many seasonal models require the higher frequency interval nest into the lower frequency seasonal interval with a fixed number of periods.
time reconciliation	time reconciliation requires that the higher frequency interval nest into the lower frequency interval.

The following example illustrates the relationship between two intervals that nest and both intervals are either date intervals or both intervals are datetime intervals. In this example, for each observation, the value calculated for begin1 is the same as begin2 and the value calculated for end1 is the same as end2:

```
/* interval1 and interval2 are any 2 valid intervals */
nest=INTNEST(interval1,interval2);
/* If interval1 and interval2 are date intervals, then start and end are any
   SAS date values. If interval1 and interval2 are datetime intervals,
   then start and end are SAS datetime values.
   This algorithm would need to be modified if a SAS date interval is
   compared to a SAS datetime interval. */
do date=start to end;
   if ( ( nest = .B ) or
        ( nest = .M ) or
        ( nest = .S )    ) then do;
      /* skip this case as the rule does not apply */
      end;
   else if ( nest = 0 ) then do;
      begin1=INTNX(interval1,date,0);
      begin2=INTNX(interval2,date,0);
      end1=INTNX(interval1,date,nest,'E');
      end2=INTNX(interval2,date,nest,'E');
      end;
   else if ( nest = 1 ) then do;
      begin1=INTNX(interval1,date,0);
      end1=INTNX(interval1,date,0,'E');
      n=INTCK(interval2,begin1,end1);
      begin2=INTNX(interval2,begin1,0);
      end2=INTNX(interval2,begin2,n,'E');
      end;
   else if ( nest = -1 ) then do;
      begin2=INTNX(interval2,date,0);
      end2=INTNX(interval2,date,0,'E');
      n=INTCK(interval1,begin2,end2);
      begin1=INTNX(interval1,begin2,0);
```

```
      end1=INTNX(interval1,begin1,n,'E');
      end;
   else if ( nest > 1 ) then do;
      begin1=INTNX(interval1,date,0);
      begin2=INTNX(interval2,begin1,0);
      end1=INTNX(interval1,date,0,'E');
      end2=INTNX(interval2,begin2,nest-1,'E');
      end;
   else if ( nest < 1 ) then do;
      begin2=INTNX(interval2,date,0);
      begin1=INTNX(interval1,begin2,0);
      end1=INTNX(interval1,begin1,(-nest)-1,'E');
      end2=INTNX(interval2,date,0,'E');
      end;
   output;
end;
```

INTNX('*date-interval***', *date*, *n* < , '*alignment*' >)**

INTNX('*datetime-interval***', *datetime*, *n* < , '*alignment*' >)**

returns the date or datetime value of the beginning of the interval that is *n* intervals from the interval that contains the given date or datetime value. The optional *alignment* argument specifies that the returned date is aligned to the beginning, middle, or end of the interval. Beginning is the default. In addition, you can specify SAME (S) alignment. The SAME alignment bases the alignment of the calculated date or datetime value on the alignment of the input date or datetime value. As illustrated in the following example, the SAME alignment can be used to calculate the meaning of "same day next year" or "same day two weeks from now":

```
nextYear = INTNX( 'YEAR', '15Apr2007'D, 1, 'S' );
TwoWeeks = INTNX( 'WEEK', '15Apr2007'D, 2, 'S' );
```

The preceding example returns '15Apr2008'D for nextYear and '29Apr2007'D for TwoWeeks.

For all values of alignment, the number of discrete intervals *n* between the input date and the resulting date agrees with the input value. In the following example, the result is always that n2 = n1:

```
date2 = INTNX( interval, date1, n1, align );
n2 = INTCK( interval, date1, date2 );
```

The preceding example uses the DISCRETE method of the INTCK function by default. The result n2 = n1 does not always apply when the CONTINUOUS method of the INTCK function is specified.

INTSEAS('*interval***' < , *seasonality* >)**

returns the length of the seasonal cycle for the specified date or datetime interval. The length of a seasonal cycle is the number of intervals in a seasonal cycle. For example, when the interval for a time series is described as monthly, many procedures use the option INTERVAL=MONTH to indicate that each observation in the data corresponds to a particular month. Monthly data are considered to be periodic for a one-year seasonal cycle. There are 12 months in one year, so the number of intervals (months) in a seasonal cycle (year) is 12. For quarterly data, there are 4 quarters in one year, so the number of intervals in a seasonal cycle is 4. The periodicity is not always one year. For example,

INTERVAL=DAY is considered to have a seasonal cycle of one week, and because there are 7 days in a week, the number of intervals in a seasonal cycle is 7.

You can specify the optional *seasonality* argument to use a seasonal cycle other than the default seasonal cycle. For example, INTSEAS('MONTH', 3) and INTSEAS('MONTH', 'QTR') both specify a quarterly seasonal cycle and return the value 3. If the optional *seasonality* argument is numeric, it is the seasonal frequency. If the optional *seasonality* argument is character, it is the seasonal cycle.

INTSHIFT('*interval***')**
returns the shift interval that applies to the shift index if a subperiod is specified. For example, YEAR intervals are shifted by MONTH, so INTSHIFT('YEAR') returns 'MONTH'.

INTTEST('*interval***')**
returns 1 if the interval name is valid, 0 otherwise. For example, `VALID = INTTEST('MONTH');` should set VALID to 1, while `VALID = INTTEST('NOTANINTERVAL');` should set VALID to 0. The INTTEST function can be useful in verifying which values of multiplier *n* and the shift index *s* are valid in constructing an interval name.

JULDATE(*date* **)**
returns the Julian date from a SAS date value. The format of the Julian date is either *yyddd* or *yyyyddd* depending on the value of the system option YEARCUTOFF=. For example, using the default system option values, `JULDATE('31DEC1999'D );` returns 99365, while `JULDATE('31DEC1899'D);` returns 1899365.

MDY(*month, day, year* **)**
returns a SAS date value for month, day, and year values.

MINUTE(*datetime* **)**
returns the minute from a SAS time or datetime value.

MONTH(*date* **)**
returns the numerical value for the month of the year from a SAS date value. For example, `MONTH=MONTH('01JAN2000'D);` returns 1, the numerical value for January.

NWKDOM(*n, weekday, month, year* **)**
returns a SAS date value for the *n*th weekday of the month and year specified. For example, Thanksgiving is always the fourth (*n*=4) Thursday (*weekday*=5) in November (*month*=11). Thus `THANKS2000 = NWKDOM( 4, 5, 11, 2000);` returns the SAS date value for Thanksgiving in the year 2000. The last weekday of a month can be specified by using *n*=5. Memorial Day in the United States is the last (*n*=5) Monday (*weekday*=2) in May (*month*=5), and so `MEMORIAL2002 = NWKDOM( 5, 2, 5, 2002);` returns the SAS date value for Memorial Day in 2002. Because *n*=5 always specifies the last occurrence of the month and most months have only 4 instances of each day, the result for *n*=5 is often the same as the result for *n*=4. NWKDOM is useful for calculating the SAS date values of holidays that are defined in this manner.

QTR(*date* **)**
returns the quarter of the year from a SAS date value.

SECOND(*date* **)**
returns the second from a SAS time or datetime value.

TIME()
returns the current time of day.

TIMEPART(*datetime* **)**
returns the time part of a SAS datetime value.

TODAY()
returns the current date as a SAS date value. (TODAY is another name for the DATE function.)

WEEK(*date* < , '*descriptor*' > **)**
returns the week of year from a SAS date value. The algorithm used to calculate the week depends on the *descriptor*, which can take the value 'U', 'V', or 'W'.

If the descriptor is 'U,' weeks start on Sunday and the range is 0 to 53. If weeks 0 and 53 exist, they are only partial weeks. Week 52 can be a partial week.

If the descriptor is 'V', the result is equivalent to the ISO 8601 week of year definition. The range is 1 to 53. Week 53 is a leap week. The first week of the year, Week 1, and the last week of the year, Week 52 or 53, can include days in another Gregorian calendar year.

If the descriptor is 'W', weeks start on Monday and the range is 0 to 53. If weeks 0 and 53 exist, they are only partial weeks. Week 52 can be a partial week.

WEEKDAY(*date* **)**
returns the day of the week from a SAS date value. The WEEKDAY function produces an integer that represents the day of the week, where 1=Sunday, 2=Monday, ..., 7=Saturday. For example `WEEKDAY=WEEKDAY('17OCT1991'D);` returns 5, the numerical value for Thursday.

YEAR(*date* **)**
returns the year from a SAS date value.

YYQ(*year, quarter* **)**
returns a SAS date value for year and quarter values.

SAS Macros

This chapter describes several SAS macros and the SAS function PROBDF that are provided with SAS/ETS software. A SAS macro is a program that generates SAS statements. Macros make it easy to produce and execute complex SAS programs that would be time-consuming to write yourself.

SAS/ETS software includes the following macros:

%AR	generates statements to define autoregressive error models for the MODEL procedure.
%BOXCOXAR	investigates Box-Cox transformations useful for modeling and forecasting a time series.
%DFPVALUE	computes probabilities for Dickey-Fuller test statistics.
%DFTEST	performs Dickey-Fuller tests for unit roots in a time series process.
%LOGTEST	tests to see if a log transformation is appropriate for modeling and forecasting a time series.
%MA	generates statements to define moving-average error models for the MODEL procedure.
%PDL	generates statements to define polynomial-distributed lag models for the MODEL procedure.

These macros are part of the SAS AUTOCALL facility and are automatically available for use in your SAS program. For information about the SAS macro facility, see *SAS Macro Language: Reference*.

Since the %AR, %MA, and %PDL macros are used only with PROC MODEL, they are documented with the MODEL procedure. For more information about these macros, see the sections about the %AR, %MA, and %PDL macros in Chapter 24, "The MODEL Procedure." The %BOXCOXAR, %DFPVALUE, %DFTEST, and %LOGTEST macros are described in the following sections.

BOXCOXAR Macro

The %BOXCOXAR macro finds the optimal Box-Cox transformation for a time series.

Transformations of the dependent variable are a useful way of dealing with nonlinear relationships or heteroscedasticity. For example, the logarithmic transformation is often used for modeling and forecasting time series that show exponential growth or that show variability proportional to the level of the series.

The Box-Cox transformation is a general class of power transformations that include the log transformation and no transformation as special cases. The Box-Cox transformation is

$$Y_t = \begin{cases} \frac{(X_t+c)^{\lambda}-1}{\lambda} & \text{for } \lambda \neq 0 \\ \ln(X_t + c) & \text{for } \lambda = 0 \end{cases}$$

The parameter λ controls the shape of the transformation. For example, λ=0 produces a log transformation, while λ=0.5 results in a square root transformation. When λ=1, the transformed series differs from the original series by $c - 1$.

The constant c is optional. It can be used when some X_t values are negative or 0. You choose c so that the series X_t is always greater than $-c$.

The %BOXCOXAR macro tries a range of λ values and reports which of the values tried produces the optimal Box-Cox transformation. To evaluate different λ values, the %BOXCOXAR macro transforms the series with each λ value and fits an autoregressive model to the transformed series. It is assumed that this autoregressive model is a reasonably good approximation to the true time series model appropriate for the transformed series. The likelihood of the data under each autoregressive model is computed, and the λ value that produces the maximum likelihood over the values tried is reported as the optimal Box-Cox transformation for the series.

The %BOXCOXAR macro prints and optionally writes to a SAS data set all of the λ values tried, the corresponding log-likelihood value, and related statistics for the autoregressive model.

You can control the range and number of λ values tried. You can also control the order of the autoregressive models fit to the transformed series. You can difference the transformed series before the autoregressive model is fit.

Note that the Box-Cox transformation might be appropriate when the data have a common distribution (apart from heteroscedasticity) but not when groups of observations for the variable are quite different. Thus the %BOXCOXAR macro is more often appropriate for time series data than for cross-sectional data.

Syntax

The form of the %BOXCOXAR macro is

%BOXCOXAR *(SAS-data-set, variable < , options >)* **;**

The first argument, *SAS-data-set*, specifies the name of the SAS data set that contains the time series to be analyzed. The second argument, *variable*, specifies the time series variable name to be analyzed. The first two arguments are required.

The following options can be used with the %BOXCOXAR macro. Options must follow the required arguments and are separated by commas.

AR=*n*
specifies the order of the autoregressive model fit to the transformed series. The default is AR=5.

CONST=*value*
specifies a constant *c* to be added to the series before transformation. Use the CONST= option when some values of the series are 0 or negative. The default is CONST=0.

DIF=*(differencing-list)*
specifies the degrees of differencing to apply to the transformed series before the autoregressive model is fit. The *differencing-list* is a list of positive integers separated by commas and enclosed in parentheses. For example, DIF=(1,12) specifies that the transformed series be differenced once at lag 1 and once at lag 12. For more information, see the section "IDENTIFY Statement" on page 217 in Chapter 7, "The ARIMA Procedure."

LAMBDAHI=*value*
specifies the maximum value of lambda for the grid search. The default is LAMBDAHI=1. A large (in magnitude) LAMBDAHI= value can result in problems with floating point arithmetic.

LAMBDALO=*value*
specifies the minimum value of lambda for the grid search. The default is LAMBDALO=0. A large (in magnitude) LAMBDALO= value can result in problems with floating point arithmetic.

NLAMBDA=*value*
specifies the number of lambda values considered, including the LAMBDALO= and LAMBDAHI= option values. The default is NLAMBDA=2.

OUT=*SAS-data-set*
writes the results to an output data set. The output data set includes the lambda values tried (LAMBDA), and for each lambda value, the log likelihood (LOGLIK), the residual mean squared error (RMSE), Akaike's information criterion (AIC), and Schwarz's Bayesian criterion (SBC).

PRINT=YES | NO
specifies whether results are printed. The default is PRINT=YES. The printed output contains the lambda values, log likelihoods, residual mean square errors, Akaike's information criterion (AIC), and Schwarz's Bayesian criterion (SBC).

Results

The value of λ that produces the maximum log likelihood is returned in the macro variable &BOXCOXAR. The value of the variable &BOXCOXAR is "ERROR" if the %BOXCOXAR macro is unable to compute the best transformation due to errors. This might be the result of large lambda values. The Box-Cox transformation parameter involves exponentiation of the data, so that large lambda values can cause floating-point overflow.

Results are printed unless the PRINT=NO option is specified. Results are also stored in SAS data sets when the OUT= option is specified.

Details

Assume that the transformed series Y_t is a stationary pth-order autoregressive process generated by independent normally distributed innovations.

$$(1 - \Theta(B))(Y_t - \mu) = \epsilon_t$$

$$\epsilon_t \sim iid\,\mathrm{N}(0, \sigma^2)$$

Given these assumptions, the log-likelihood function of the transformed data Y_t is

$$\begin{aligned} l_Y(\cdot) = & -\frac{n}{2}\ln(2\pi) - \frac{1}{2}\ln(|\Sigma|) - \frac{n}{2}\ln(\sigma^2) \\ & -\frac{1}{2\sigma^2}(\mathbf{Y} - \mathbf{1}\mu)'\Sigma^{-1}(\mathbf{Y} - \mathbf{1}\mu) \end{aligned}$$

In this equation, n is the number of observations, μ is the mean of Y_t, $\mathbf{1}$ is the n-dimensional column vector of 1s, σ^2 is the innovation variance, $\mathbf{Y} = (Y_1, \ldots, Y_n)'$, and Σ is the covariance matrix of Y.

The log-likelihood function of the original data $X_1, \ldots, X_n$ is

$$l_X(\cdot) = l_Y(\cdot) + (\lambda - 1)\sum_{t=1}^{n}\ln(X_t + c)$$

where c is the value of the CONST= option.

For each value of λ, the maximum log-likelihood of the original data is obtained from the maximum log-likelihood of the transformed data given the maximum likelihood estimate of the autoregressive model.

The maximum log-likelihood values are used to compute Akaike's information criterion (AIC) and Schwarz's Bayesian criterion (SBC) for each λ value. The residual mean squared error based on the maximum likelihood estimator is also produced. To compute the mean squared error, the predicted values from the model are transformed again to the original scale (Pankratz 1983, pp. 256–258; Taylor 1986).

After differencing as specified by the DIF= option, the process is assumed to be a stationary autoregressive process. You can check for stationarity of the series with the %DFTEST macro. If the process is not stationary, differencing with the DIF= option is recommended. For a process with moving-average terms, a large value for the AR= option might be appropriate.

DFPVALUE Macro

The %DFPVALUE macro computes the significance of the Dickey-Fuller test. The %DFPVALUE macro evaluates the *p*-value for the Dickey-Fuller test statistic τ for the test of H_0: "The time series has a unit root" versus H_a: "The time series is stationary" using tables published by Dickey (1976); Dickey, Hasza, and Fuller (1984).

The %DFPVALUE macro can compute *p*-values for tests of a simple unit root with lag 1 or for seasonal unit roots at lags 2, 4, or 12. The %DFPVALUE macro takes into account whether an intercept or deterministic time trend is assumed for the series.

The %DFPVALUE macro is used by the %DFTEST macro described later in this chapter.

Note that the %DFPVALUE macro has been superseded by the PROBDF function described later in this chapter. It remains for compatibility with past releases of SAS/ETS.

Syntax

The %DFPVALUE macro has the following form:

%DFPVALUE *(tau, nobs < , options >)* **;**

The first argument, *tau,* specifies the value of the Dickey-Fuller test statistic.

The second argument, *nobs,* specifies the number of observations on which the test statistic is based.

The first two arguments are required. The following options can be used with the %DFPVALUE macro. Options must follow the required arguments and are separated by commas.

DLAG=1 | 2 | 4 | 12
specifies the lag period of the unit root to be tested. DLAG=1 specifies a one-period unit root test. DLAG=2 specifies a test for a seasonal unit root with lag 2. DLAG=4 specifies a test for a seasonal unit root with lag 4. DLAG=12 specifies a test for a seasonal unit root with lag 12. The default is DLAG=1.

TREND=0 | 1 | 2
specifies the degree of deterministic time trend included in the model. TREND=0 specifies no trend and assumes the series has a zero mean. TREND=1 includes an intercept term. TREND=2 specifies both an intercept and a deterministic linear time trend term. The default is TREND=1. TREND=2 is not allowed with DLAG=2, 4, or 12.

Results

The computed *p*-value is returned in the macro variable &DFPVALUE. If the *p*-value is less than 0.01 or larger than 0.99, the macro variable &DFPVALUE is set to 0.01 or 0.99, respectively.

Minimum Observations

The minimum number of observations required by the %DFPVALUE macro depends on the value of the DLAG= option. The minimum observations are as follows:

DLAG=	Minimum Observations
1	9
2	6
4	4
12	12

DFTEST Macro

The %DFTEST macro performs the Dickey-Fuller unit root test. You can use the %DFTEST macro to decide whether a time series is stationary and to determine the order of differencing required for the time series analysis of a nonstationary series.

Most time series analysis methods require that the series to be analyzed is stationary. However, many economic time series are nonstationary processes. The usual approach to this problem is to difference the series. A time series that can be made stationary by differencing is said to have a *unit root*. For more information, see the discussion of this issue in the section "Getting Started: ARIMA Procedure" on page 183 of Chapter 7, "The ARIMA Procedure."

The Dickey-Fuller test is a method for testing whether a time series has a unit root. The %DFTEST macro tests the hypothesis H_0: "The time series has a unit root" versus H_a: "The time series is stationary" based on tables provided in Dickey (1976); Dickey, Hasza, and Fuller (1984). The test can be applied for a simple unit root with lag 1, or for seasonal unit roots at lag 2, 4, or 12.

Note that the %DFTEST macro has been superseded by the PROC ARIMA stationarity tests. For more information, see Chapter 7, "The ARIMA Procedure."

Syntax

The %DFTEST macro has the following form:

%DFTEST *(SAS-data-set, variable < , options >)* **;**

The first argument, *SAS-data-set,* specifies the name of the SAS data set that contains the time series variable to be analyzed.

The second argument, *variable,* specifies the time series variable name to be analyzed.

The first two arguments are required. The following options can be used with the %DFTEST macro. Options must follow the required arguments and are separated by commas.

AR=*n*

specifies the order of autoregressive model fit after any differencing specified by the DIF= and DLAG= options. The default is AR=3.

DIF=*(differencing-list)*

specifies the degrees of differencing to be applied to the series. The differencing list is a list of positive integers separated by commas and enclosed in parentheses. For example, DIF=(1,12) specifies that the series be differenced once at lag 1 and once at lag 12. For more information, see the section "IDENTIFY Statement" on page 217 in Chapter 7, "The ARIMA Procedure."

If the option DIF=$(d_1, \ldots, d_k)$ is specified, the series analyzed is $(1 - B^{d_1}) \cdots (1 - B^{d_k}) Y_t$, where Y_t is the variable specified, and B is the backshift operator defined by $BY_t = Y_{t-1}$.

DLAG=1 | 2 | 4 | 12

specifies the lag to be tested for a unit root. The default is DLAG=1.

OUT=*SAS-data-set*

writes residuals to an output data set.

OUTSTAT=*SAS-data-set*

writes the test statistic, parameter estimates, and other statistics to an output data set.

TREND=0 | 1 | 2

specifies the degree of deterministic time trend included in the model. TREND=0 includes no deterministic term and assumes the series has a zero mean. TREND=1 includes an intercept term. TREND=2 specifies an intercept and a linear time trend term. The default is TREND=1. TREND=2 is not allowed with DLAG=2, 4, or 12.

Results

The computed p-value is returned in the macro variable &DFTEST. If the p-value is less than 0.01 or larger than 0.99, the macro variable &DFTEST is set to 0.01 or 0.99, respectively. (The same value is given in the macro variable &DFPVALUE returned by the %DFPVALUE macro, which is used by the %DFTEST macro to compute the p-value.)

Results can be stored in SAS data sets with the OUT= and OUTSTAT= options.

Minimum Observations

The minimum number of observations required by the %DFTEST macro depends on the value of the DLAG= option. Let s be the sum of the differencing orders specified by the DIF= option, let t be the value of the TREND= option, and let p be the value of the AR= option. The minimum number of observations required is as follows:

DLAG=	Minimum Observations
1	$1 + p + s + \max(9, p + t + 2)$
2	$2 + p + s + \max(6, p + t + 2)$
4	$4 + p + s + \max(4, p + t + 2)$
12	$12 + p + s + \max(12, p + t + 2)$

Observations are not used if they have missing values for the series or for any lag or difference used in the autoregressive model.

LOGTEST Macro

The %LOGTEST macro tests whether a logarithmic transformation is appropriate for modeling and forecasting a time series. The logarithmic transformation is often used for time series that show exponential growth or variability proportional to the level of the series.

The %LOGTEST macro fits an autoregressive model to a series and fits the same model to the log of the series. Both models are estimated by the maximum-likelihood method, and the maximum log-likelihood values for both autoregressive models are computed. These log-likelihood values are then expressed in terms of the original data and compared.

You can control the order of the autoregressive models. You can also difference the series and the log-transformed series before the autoregressive model is fit.

You can print the log-likelihood values and related statistics (AIC, SBC, and MSE) for the autoregressive models for the series and the log-transformed series. You can also output these statistics to a SAS data set.

Syntax

The %LOGTEST macro has the following form:

%LOGTEST *(SAS-data-set, variable,* < *options* > *)* **;**

The first argument, *SAS-data-set,* specifies the name of the SAS data set that contains the time series variable to be analyzed. The second argument, *variable,* specifies the time series variable name to be analyzed.

The first two arguments are required. The following options can be used with the %LOGTEST macro. Options must follow the required arguments and are separated by commas.

AR=*n*

specifies the order of the autoregressive model fit to the series and the log-transformed series. The default is AR=5.

CONST=*value*

specifies a constant to be added to the series before transformation. Use the CONST= option when some values of the series are 0 or negative. The series analyzed must be greater than the negative of the CONST= value. The default is CONST=0.

DIF=(*differencing-list* **)**

specifies the degrees of differencing applied to the original and log-transformed series before fitting the autoregressive model. The *differencing-list* is a list of positive integers separated by commas and enclosed in parentheses. For example, DIF=(1,12) specifies that the transformed series be differenced once at lag 1 and once at lag 12. For more information, see the section "IDENTIFY Statement" on page 217 in Chapter 7, "The ARIMA Procedure."

OUT=*SAS-data-set*
writes the results to an output data set. The output data set includes a variable TRANS that identifies the transformation (LOG or NONE), the log-likelihood value (LOGLIK), the residual mean squared error (RMSE), Akaike's information criterion (AIC), and Schwarz's Bayesian criterion (SBC) for the log-transformed and untransformed cases.

PRINT=YES | NO
specifies whether the results are printed. The default is PRINT=NO. The printed output shows the log-likelihood value, the residual mean squared error, Akaike's information criterion (AIC), and Schwarz's Bayesian criterion (SBC) for the log-transformed and untransformed cases.

Results

The result of the test is returned in the macro variable &LOGTEST. The value of the &LOGTEST variable is 'LOG' if the model fit to the log-transformed data has a larger log likelihood than the model fit to the untransformed series. The value of the &LOGTEST variable is 'NONE' if the model fit to the untransformed data has a larger log likelihood. The variable &LOGTEST is set to 'ERROR' if the %LOGTEST macro is unable to compute the test due to errors.

Results are printed when the PRINT=YES option is specified. Results are stored in SAS data sets when the OUT= option is specified.

Details

Assume that a time series X_t is a stationary pth-order autoregressive process with normally distributed white noise innovations. That is,

$$(1 - \Theta(B))(X_t - \mu_{\mathbf{x}}) = \epsilon_t$$

where $\mu_{\mathbf{x}}$ is the mean of X_t.

The log likelihood function of X_t is

$$\begin{aligned} l_1(\cdot) = &-\frac{n}{2}\ln(2\pi) - \frac{1}{2}\ln(|\Sigma_{\mathbf{xx}}|) - \frac{n}{2}\ln(\sigma_{\mathbf{e}}^2) \\ &- \frac{1}{2\sigma_{\mathbf{e}}^2}(\mathbf{X} - \mathbf{1}\mu_{\mathbf{x}})'\Sigma_{\mathbf{xx}}^{-1}(\mathbf{X} - \mathbf{1}\mu_{\mathbf{x}}) \end{aligned}$$

where n is the number of observations, $\mathbf{1}$ is the n-dimensional column vector of 1s, $\sigma_{\mathbf{e}}^2$ is the variance of the white noise, $\mathbf{X} = (X_1, \ldots, X_n)'$, and $\Sigma_{\mathbf{xx}}$ is the covariance matrix of $\mathbf{X}$.

On the other hand, if the log-transformed time series $Y_t = \ln(X_t + c)$ is a stationary pth-order autoregressive process, the log-likelihood function of X_t is

$$\begin{aligned} l_0(\cdot) = &-\frac{n}{2}\ln(2\pi) - \frac{1}{2}\ln(|\Sigma_{\mathbf{yy}}|) - \frac{n}{2}\ln(\sigma_{\mathbf{e}}^2) \\ &- \frac{1}{2\sigma_{\mathbf{e}}^2}(\mathbf{Y} - \mathbf{1}\mu_{\mathbf{y}})'\Sigma_{\mathbf{yy}}^{-1}(\mathbf{Y} - \mathbf{1}\mu_{\mathbf{y}}) - \sum_{t=1}^{n}\ln(X_t + c) \end{aligned}$$

where $\mu_{\mathbf{y}}$ is the mean of Y_t, $\mathbf{Y} = (Y_1, \ldots, Y_n)'$, and $\Sigma_{\mathbf{yy}}$ is the covariance matrix of $\mathbf{Y}$.

The %LOGTEST macro compares the maximum values of $l_1(\cdot)$ and $l_0(\cdot)$ and determines which is larger.

The %LOGTEST macro also computes Akaike's information criterion (AIC), Schwarz's Bayesian criterion (SBC), and the residual mean squared error based on the maximum likelihood estimator for the autoregressive model. For the mean squared error, retransformation of forecasts is based on Pankratz (1983, pp. 256–258).

After differencing as specified by the DIF= option, the process is assumed to be a stationary autoregressive process. You might want to check for stationarity of the series using the %DFTEST macro. If the process is not stationary, differencing with the DIF= option is recommended. For a process with moving average terms, a large value for the AR= option might be appropriate.

Functions

PROBDF Function for Dickey-Fuller Tests

The PROBDF function calculates significance probabilities for Dickey-Fuller tests for unit roots in time series. The PROBDF function can be used wherever SAS library functions can be used, including DATA step programs, SCL programs, and PROC MODEL programs.

Syntax

PROBDF(*x, n* < *, d* < *, type* > > **)**

x is the test statistic.

n is the sample size. The minimum value of *n* allowed depends on the value specified for the third argument, *d*. For *d* in the set (1,2,4,6,12), *n* must be an integer greater than or equal to $\max(2d, 5)$; for other values of *d* the minimum value of *n* is 24.

d is an optional integer giving the degree of the unit root tested for. Specify *d*=1 for tests of a simple unit root $(1 - \mathrm{B})$. Specify *d* equal to the seasonal cycle length for tests for a seasonal unit root $(1 - \mathrm{B}^d)$. The default value of *d* is 1; that is, a test for a simple unit root $(1 - \mathrm{B})$ is assumed if *d* is not specified. The maximum value of *d* allowed is 12.

type is an optional character argument that specifies the type of test statistic used. The values of *type* are the following:

SZM studentized test statistic for the zero mean (no intercept) case

RZM regression test statistic for the zero mean (no intercept) case

SSM studentized test statistic for the single mean (intercept) case

RSM regression test statistic for the single mean (intercept) case

STR studentized test statistic for the deterministic time trend case

RTR regression test statistic for the deterministic time trend case

The values STR and RTR are allowed only when *d*=1. The default value of *type* is SZM.

Details

Theoretical Background

When a time series has a unit root, the series is nonstationary and the ordinary least squares (OLS) estimator is not normally distributed. The limiting distribution of the OLS estimator of autoregressive models for time series with a simple unit root was studied by Dickey (1976); Dickey and Fuller (1979). Dickey, Hasza, and Fuller (1984) obtained the limiting distribution for time series with seasonal unit roots. We will mainly introduce the nonseasonal tests in the following and list references for the nonseasonal tests.

Consider the Dickey-Fuller regression first. The null hypothesis is that there is an autoregressive unit root $H_0 : \alpha = 1$, and the alternative is $H_a : |\alpha| < 1$, where α is the autoregressive coefficient of the time series

$$y_t = \alpha y_{t-1} + \epsilon_t$$

This is referred to as the zero mean (ZM) model. The standard Dickey-Fuller (DF) test assumes that errors ϵ_t are white noise. There are two other types of regression models that include a constant or a time trend as follows:

$$y_t = \mu + \alpha y_{t-1} + \epsilon_t$$
$$y_t = \mu + \beta t + \alpha y_{t-1} + \epsilon_t$$

These two models are referred to as the constant mean model (SM) and the trend model (TR), respectively. The constant mean model includes a constant mean μ of the time series. However, the interpretation of μ depends on the stationarity in the following sense: the mean in the stationary case when $\alpha < 1$ is the trend in the integrated case when $\alpha = 1$. Therefore, the null hypothesis should be the joint hypothesis that $\alpha = 1$ and $\mu = 0$. However for the unit root tests, the test statistics are concerned with the null hypothesis of $\alpha = 1$. The joint null hypothesis is not commonly used. This issue is address in Bhargava (1986) with a different nesting model.

Under the null of I(1) of the Dickey-Fuller test, the differenced process is not serially correlated. There is a great need for the generalization of this specification. The augmented Dickey-Fuller (ADF) test, originally proposed in Dickey and Fuller (1979), adjusts for the serial correlation in the time series by adding lagged first differences to the autoregressive model as follows. Consider the $(p + 1)$th-order autoregressive time series

$$y_t = \alpha_1 y_{t-1} + \alpha_2 y_{t-2} + \cdots + \alpha_{p+1} y_{t-p-1} + e_t$$

and its characteristic equation

$$m^{p+1} - \alpha_1 m^p - \alpha_2 m^{p-1} - \cdots - \alpha_{p+1} = 0$$

If all the characteristic roots are less than 1 in absolute value, y_t is stationary. y_t is nonstationary if there is a unit root. If there is a unit root, the sum of the autoregressive parameters is 1, and hence you can test for a unit root by testing whether the sum of the autoregressive parameters is 1 or not. The no-intercept model is parameterized as

$$\nabla y_t = \delta y_{t-1} + \theta_1 \nabla y_{t-1} + \cdots + \theta_p \nabla y_{t-p} + e_t$$

where $\nabla y_t = y_t - y_{t-1}$ and

$$\delta = \alpha_1 + \cdots + \alpha_{p+1} - 1$$

$$\theta_k = -\alpha_{k+1} - \cdots - \alpha_{p+1}$$

The estimators are obtained by regressing ∇y_t on $y_{t-1}, \nabla y_{t-1}, \ldots, \nabla y_{t-p}$. The t statistic of the ordinary least squares estimator of δ is the test statistic for the unit root test.

If the *type* argument value specifies a test for a nonzero mean (intercept case), the autoregressive model includes a mean term α_0. If the *type* argument value specifies a test for a time trend, the model also includes a time trend term and the model is as follows:

$$\nabla y_t = \alpha_0 + \gamma t + \delta y_{t-1} + \theta_1 \nabla y_{t-1} + \cdots + \theta_p \nabla y_{t-p} + e_t$$

For testing for a seasonal unit root, consider the multiplicative model

$$(1 - \alpha_d B^d)(1 - \theta_1 B - \cdots - \theta_p B^p) y_t = e_t$$

Let $\nabla^d y_t \equiv y_t - y_{t-d}$. The test statistic is calculated in the following steps:

1. Regress $\nabla^d y_t$ on $\nabla^d y_{t-1} \cdots \nabla^d y_{t-p}$ to obtain the initial estimators $\hat{\theta}_i$ and compute residuals $\hat{e}_t$. Under the null hypothesis that $\alpha_d = 1$, $\hat{\theta}_i$ are consistent estimators of θ_i.
2. Regress $\hat{e}_t$ on $(1 - \hat{\theta}_1 B - \cdots - \hat{\theta}_p B^p) y_{t-d}, \nabla^d y_{t-1}, \ldots, \nabla^d y_{t-p}$ to obtain estimates of $\delta = \alpha_d - 1$ and $\theta_i - \hat{\theta}_i$.

The t ratio for the estimate of δ produced by the second step is used as a test statistic for testing for a seasonal unit root. The estimates of θ_i are obtained by adding the estimates of $\theta_i - \hat{\theta}_i$ from the second step to $\hat{\theta}_i$ from the first step.

The series $(1 - B^d) y_t$ is assumed to be stationary, where d is the value of the third argument to the PROBDF function.

If the series is an ARMA process, a large value of p might be desirable in order to obtain a reliable test statistic. To determine an appropriate value for *p,* see Said and Dickey (1984).

Test Statistics

The Dickey-Fuller test is used to test the null hypothesis that the time series exhibits a lag d unit root against the alternative of stationarity. The PROBDF function computes the probability of observing a test statistic more extreme than x under the assumption that the null hypothesis is true. You should reject the unit root hypothesis when PROBDF returns a small (significant) probability value.

Consider the Dickey-Fuller regression first. There are several different versions of the Dickey-Fuller test. The PROBDF function supports six versions, as selected by the *type* argument. Specify the *type* value that corresponds to the way that you calculated the test statistic x.

The last two characters of the *type* value specify the kind of regression model used to compute the Dickey-Fuller test statistic. The meaning of the last two characters of the *type* value are as follows:

ZM zero mean or no-intercept case. The test statistic x is assumed to be computed from the regression model

$$y_t = \alpha y_{t-1} + e_t$$

SM single mean or intercept case. The test statistic x is assumed to be computed from the regression model

$$y_t = \mu + \alpha y_{t-1} + e_t$$

TR intercept and deterministic time trend case. The test statistic x is assumed to be computed from the regression model

$$y_t = \mu + \gamma t + \alpha y_{t-1} + e_t$$

The first character of the *type* value specifies whether the regression test statistic or the studentized test statistic is used. Let $\hat{\alpha}$ be the estimated regression coefficient for the lag of the series, and let $\mathrm{se}_{\hat{\alpha}}$ be the standard error of $\hat{\alpha}$. The meaning of the first character of the *type* value is as follows:

R the regression-coefficient-based test statistic. The test statistic is

$$\rho = n(\hat{\alpha} - 1)$$

S the studentized test statistic. The test statistic is

$$DF_\tau = \frac{(\hat{\alpha} - 1)}{\mathrm{se}_{\hat{\alpha}}}$$

The first one is also called ρ-test and the second is called τ-test. For the zero mean model, the asymptotic distributions of the Dickey-Fuller test statistics are

$$n(\hat{\alpha} - 1) \Rightarrow \left(\int_0^1 W(r)dW(r)\right)\left(\int_0^1 W(r)^2 dr\right)^{-1}$$
$$DF_\tau \Rightarrow \left(\int_0^1 W(r)dW(r)\right)\left(\int_0^1 W(r)^2 dr\right)^{-1/2}$$

For the constant mean model, the asymptotic distributions are

$$n(\hat{\alpha} - 1) \Rightarrow \left([W(1)^2 - 1]/2 - W(1)\int_0^1 W(r)dr\right)\left(\int_0^1 W(r)^2 dr - \left(\int_0^1 W(r)dr\right)^2\right)^{-1}$$
$$DF_\tau \Rightarrow \left([W(1)^2 - 1]/2 - W(1)\int_0^1 W(r)dr\right)\left(\int_0^1 W(r)^2 dr - \left(\int_0^1 W(r)dr\right)^2\right)^{-1/2}$$

For the trend model, the asymptotic distributions are

$$n(\hat{\alpha} - 1) \Rightarrow \left[W(r)dW + 12\left(\int_0^1 rW(r)dr - \frac{1}{2}\int_0^1 W(r)dr\right)\left(\int_0^1 W(r)dr - \frac{1}{2}W(1)\right) - W(1)\int_0^1 W(r)dr\right]D^{-1}$$
$$DF_\tau \Rightarrow \left[W(r)dW + 12\left(\int_0^1 rW(r)dr - \frac{1}{2}\int_0^1 W(r)dr\right)\left(\int_0^1 W(r)dr - \frac{1}{2}W(1)\right) - W(1)\int_0^1 W(r)dr\right]D^{1/2}$$

where

$$D = \int_0^1 W(r)^2 dr - 12\left(\int_0^1 r(W(r)dr\right)^2 + 12\int_0^1 W(r)dr\int_0^1 rW(r)dr - 4\left(\int_0^1 W(r)dr\right)^2$$

For more information about the Dickey-Fuller test null distribution see: Dickey and Fuller (1979); Dickey, Hasza, and Fuller (1984); Hamilton (1994). The preceding formulas are for the basic Dickey-Fuller test. The PROBDF function can also be used for the augmented Dickey-Fuller test, in which the error term e_t is modeled as an autoregressive process; however, the test statistic is computed somewhat differently for the augmented Dickey-Fuller test. For the nonseasonal augmented Dickey-Fuller test, the test statistics can take one of the two forms similar to Dickey-Fuller test. One is the OLS t value

$$\frac{\hat{\alpha} - 1}{sd(\hat{\alpha})}$$

and the other is given by

$$\frac{n(\hat{\alpha} - 1)}{1 - \hat{\alpha}_1 - \cdots - \hat{\alpha}_p}$$

The asymptotic distributions of the test statistics are the same as those of the standard Dickey-Fuller test statistics. For information about seasonal and nonseasonal augmented Dickey-Fuller tests see Dickey, Hasza, and Fuller (1984); Hamilton (1994).

The PROBDF function is calculated from approximating functions fit to empirical quantiles that are produced by a Monte Carlo simulation that employs 10^8 replications for each simulation. Separate simulations were performed for selected values of n and for $d = 1, 2, 4, 6, 12$ (where n and d are the second and third arguments to the PROBDF function).

The maximum error of the PROBDF function is approximately $\pm 10^{-3}$ for d in the set (1,2,4,6,12) and can be slightly larger for other d values. Because the number of simulation replications used to produce the PROBDF function is much greater than the 60,000 replications used by Dickey and colleagues (Dickey and Fuller 1979; Dickey, Hasza, and Fuller 1984), the PROBDF function can be expected to produce results that are substantially more accurate than the critical values reported in those papers.

Examples

Suppose the data set TEST contains 104 observations of the time series variable Y, and you want to test the null hypothesis that there exists a lag 4 seasonal unit root in the Y series. The following statements illustrate how to perform the single-mean Dickey-Fuller regression coefficient test using PROC REG and PROBDF:

```
data test1;
   set test;
   y4 = lag4(y);
run;

proc reg data=test1 outest=alpha;
   model y = y4 / noprint;
run;

data _null_;
   set alpha;
   x = 100 * ( y4 - 1 );
```

```
   p = probdf( x, 100, 4, "RSM" );
   put p= pvalue5.3;
run;
```

To perform the augmented Dickey-Fuller test, regress the differences of the series on lagged differences and on the lagged value of the series, and compute the test statistic from the regression coefficient for the lagged series. The following statements illustrate how to perform the single-mean augmented Dickey-Fuller studentized test for a simple unit root using PROC REG and PROBDF:

```
data test1;
   set test;
   yl  = lag(y);
   yd  = dif(y);
   yd1 = lag1(yd); yd2 = lag2(yd);
   yd3 = lag3(yd); yd4 = lag4(yd);
run;

proc reg data=test1 outest=alpha covout;
   model yd = yl yd1-yd4 / noprint;
run;

data _null_;
   set alpha;
   retain a;
   if _type_ = 'PARMS' then a = yl ;
   if _type_ = 'COV' & _NAME_ = 'Y1' then do;
      x = a / sqrt(yl);
      p = probdf( x, 99, 1, "SSM" );
      put p= pvalue5.3;
      end;
run;
```

The %DFTEST macro provides an easier way to perform Dickey-Fuller tests. The following statements perform the same tests as the preceding example:

```
%dftest( test, y, ar=4 );
%put p=&dftest;
```

Overview

Several SAS/ETS procedures (COUNTREG, ENTROPY, MDC, QLIM, UCM, and VARMAX) use the nonlinear optimization (NLO) subsystem to perform nonlinear optimization. This chapter describes the options of the NLO system and some technical details of the available optimization methods. Note that not all options have been implemented for all procedures that use the NLO subsystem. You should check each procedure chapter for more information about which options are available.

Options

Table 6.1 summarizes the options available in the NLO system.

Table 6.1 NLO Options

Option	Description
Optimization Specifications	
TECHNIQUE=	Minimization technique
UPDATE=	Update technique
LINESEARCH=	Line-search method
LSPRECISION=	Line-search precision
HESCAL=	Type of Hessian scaling
INHESSIAN=	Start for approximated Hessian
RESTART=	Iteration number for update restart

Table 6.1 *continued*

Option	Description
Termination Criteria Specifications	
MAXFUNC=	Maximum number of function calls
MAXITER=	Maximum number of iterations
MINITER=	Minimum number of iterations
MAXTIME=	Upper limit seconds of CPU time
ABSCONV=	Absolute function convergence criterion
ABSFCONV=	Absolute function convergence criterion
ABSGCONV=	Absolute gradient convergence criterion
ABSXCONV=	Absolute parameter convergence criterion
FCONV=	Relative function convergence criterion
FCONV2=	Relative function convergence criterion
GCONV=	Relative gradient convergence criterion
XCONV=	Relative parameter convergence criterion
FSIZE=	Used in FCONV, GCONV criterion
XSIZE=	Used in XCONV criterion
Step Length Options	
DAMPSTEP=	Damped steps in line search
MAXSTEP=	Maximum trust region radius
INSTEP=	Initial trust region radius
Printed Output Options	
PALL	Display (almost) all printed optimization-related output
PHISTORY	Display optimization history
PHISTPARMS	Display parameter estimates in each iteration
PSHORT	Reduce some default optimization-related output
PSUMMARY	Reduce most default optimization-related output
NOPRINT	Suppress all printed optimization-related output

These options are described in alphabetical order.

ABSCONV=*r*

ABSTOL=*r*

specifies an absolute function convergence criterion. For minimization, termination requires $f(\theta^{(k)}) \leq r$. The default value of r is the negative square root of the largest double-precision value, which serves only as a protection against overflows.

ABSFCONV=*r***[***n***]**

ABSFTOL=*r***[***n***]**

specifies an absolute function convergence criterion. For all techniques except NMSIMP, termination requires a small change of the function value in successive iterations:

$$|f(\theta^{(k-1)}) - f(\theta^{(k)})| \leq r$$

The same formula is used for the NMSIMP technique, but $\theta^{(k)}$ is defined as the vertex with the lowest function value, and $\theta^{(k-1)}$ is defined as the vertex with the highest function value in the simplex. The

default value is *r*=0. The optional integer value *n* specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSGCONV=*r*[*n*]

ABSGTOL=*r*[*n*]

specifies an absolute gradient convergence criterion. Termination requires the maximum absolute gradient element to be small:

$$\max_j |g_j(\theta^{(k)})| \leq r$$

This criterion is not used by the NMSIMP technique. The default value is $r = 1\mathrm{E}-5$. The optional integer value *n* specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

ABSXCONV=*r*[*n*]

ABSXTOL=*r*[*n*]

specifies an absolute parameter convergence criterion. For all techniques except NMSIMP, termination requires a small Euclidean distance between successive parameter vectors,

$$\| \theta^{(k)} - \theta^{(k-1)} \|_2 \leq r$$

For the NMSIMP technique, termination requires either a small length $\alpha^{(k)}$ of the vertices of a restart simplex,

$$\alpha^{(k)} \leq r$$

or a small simplex size,

$$\delta^{(k)} \leq r$$

where the simplex size $\delta^{(k)}$ is defined as the L1 distance from the simplex vertex $\xi^{(k)}$ with the smallest function value to the other *n* simplex points $\theta_l^{(k)} \neq \xi^{(k)}$:

$$\delta^{(k)} = \sum_{\theta_l \neq y} \| \theta_l^{(k)} - \xi^{(k)} \|_1$$

The default is $r = 1\mathrm{E}-8$ for the NMSIMP technique and *r*=0 otherwise. The optional integer value *n* specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

DAMPSTEP[=*r*]

specifies that the initial step length value $\alpha^{(0)}$ for each line search (used by the QUANEW, HYQUAN, CONGRA, or NEWRAP technique) cannot be larger than *r* times the step length value used in the former iteration. If the DAMPSTEP option is specified but *r* is not specified, the default is *r*=2. The DAMPSTEP=*r* option can prevent the line-search algorithm from repeatedly stepping into regions where some objective functions are difficult to compute or where they could lead to floating point overflows during the computation of objective functions and their derivatives. The DAMPSTEP=*r* option can save time-costly function calls during the line searches of objective functions that result in very small steps.

FCONV=*r*[*n*]

FTOL=*r*[*n*]

specifies a relative function convergence criterion. For all techniques except NMSIMP, termination requires a small relative change of the function value in successive iterations,

$$\frac{|f(\theta^{(k)}) - f(\theta^{(k-1)})|}{\max(|f(\theta^{(k-1)})|, \text{FSIZE})} \leq r$$

where FSIZE is defined by the FSIZE= option. The same formula is used for the NMSIMP technique, but $\theta^{(k)}$ is defined as the vertex with the lowest function value, and $\theta^{(k-1)}$ is defined as the vertex with the highest function value in the simplex. The default value may depend on the procedure. In most cases, you can use the PALL option to find it.

FCONV2=*r*[*n*]

FTOL2=*r*[*n*]

specifies another function convergence criterion.

For all techniques except NMSIMP, termination requires a small predicted reduction

$$df^{(k)} \approx f(\theta^{(k)}) - f(\theta^{(k)} + s^{(k)})$$

of the objective function. The predicted reduction

$$\begin{aligned} df^{(k)} &= -g^{(k)T} s^{(k)} - \frac{1}{2} s^{(k)T} H^{(k)} s^{(k)} \\ &= -\frac{1}{2} s^{(k)T} g^{(k)} \\ &\leq r \end{aligned}$$

is computed by approximating the objective function f by the first two terms of the Taylor series and substituting the Newton step

$$s^{(k)} = -[H^{(k)}]^{-1} g^{(k)}$$

For the NMSIMP technique, termination requires a small standard deviation of the function values of the $n+1$ simplex vertices $\theta_l^{(k)}$, $l = 0, \ldots, n$, $\sqrt{\frac{1}{n+1} \sum_l \left[f(\theta_l^{(k)}) - \overline{f}(\theta^{(k)}) \right]^2} \leq r$, where $\overline{f}(\theta^{(k)}) = \frac{1}{n+1} \sum_l f(\theta_l^{(k)})$. If there are n_{act} boundary constraints active at $\theta^{(k)}$, the mean and standard deviation are computed only for the $n + 1 - n_{act}$ unconstrained vertices.

The default value is $r = 1\text{E} - 6$ for the NMSIMP technique and *r*=0 otherwise. The optional integer value *n* specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

FSIZE=*r*

specifies the FSIZE parameter of the relative function and relative gradient termination criteria. The default value is *r*=0. For more information, see the FCONV= and GCONV= options.

GCONV=*r*[*n*]

GTOL=*r*[*n*]

specifies a relative gradient convergence criterion. For all techniques except CONGRA and NMSIMP, termination requires that the normalized predicted function reduction be small,

$$\frac{g(\theta^{(k)})^T [H^{(k)}]^{-1} g(\theta^{(k)})}{\max(|f(\theta^{(k)})|, \text{FSIZE})} \leq r$$

where FSIZE is defined by the FSIZE= option. For the CONGRA technique (where a reliable Hessian estimate H is not available), the following criterion is used:

$$\frac{\| g(\theta^{(k)}) \|_2^2 \quad \| s(\theta^{(k)}) \|_2}{\| g(\theta^{(k)}) - g(\theta^{(k-1)}) \|_2 \max(|f(\theta^{(k)})|, \text{FSIZE})} \leq r$$

This criterion is not used by the NMSIMP technique. The default value is $r = 1\text{E} - 8$. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

HESCAL=0|1|2|3

HS=0|1|2|3

specifies the scaling version of the Hessian matrix used in NRRIDG, TRUREG, NEWRAP, or DBLDOG optimization.

If HS is not equal to 0, the first iteration and each restart iteration sets the diagonal scaling matrix $D^{(0)} = \text{diag}(d_i^{(0)})$,

$$d_i^{(0)} = \sqrt{\max(|H_{i,i}^{(0)}|, \epsilon)}$$

where $H_{i,i}^{(0)}$ are the diagonal elements of the Hessian. In every other iteration, the diagonal scaling matrix $D^{(0)} = \text{diag}(d_i^{(0)})$ is updated depending on the HS option:

HS=0 specifies that no scaling is done.

HS=1 specifies the Moré (1978) scaling update:

$$d_i^{(k+1)} = \max\left[d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}\right]$$

HS=2 specifies the Dennis, Gay, and Welsch (1981) scaling update:

$$d_i^{(k+1)} = \max\left[0.6 * d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}\right]$$

HS=3 specifies that d_i is reset in each iteration:

$$d_i^{(k+1)} = \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}$$

In each scaling update, ϵ is the relative machine precision. The default value is HS=0. Scaling of the Hessian can be time-consuming in the case where general linear constraints are active.

INHESSIAN[=*r*]

INHESS[=*r*]

specifies how the initial estimate of the approximate Hessian is defined for the quasi-Newton techniques QUANEW and DBLDOG. There are two alternatives:

- If you do not use the *r* specification, the initial estimate of the approximate Hessian is set to the Hessian at $\theta^{(0)}$.
- If you do use the *r* specification, the initial estimate of the approximate Hessian is set to the multiple of the identity matrix rI.

By default, if you do not specify the option INHESSIAN=*r*, the initial estimate of the approximate Hessian is set to the multiple of the identity matrix rI, where the scalar r is computed from the magnitude of the initial gradient.

INSTEP=*r*

reduces the length of the first trial step during the line search of the first iterations. For highly nonlinear objective functions, such as the EXP function, the default initial radius of the trust-region algorithm TRUREG or DBLDOG or the default step length of the line-search algorithms can result in arithmetic overflows. If this occurs, you should specify decreasing values of $0 < r < 1$ such as INSTEP=1E–1, INSTEP=1E–2, INSTEP=1E–4, and so on, until the iteration starts successfully.

- For trust-region algorithms (TRUREG, DBLDOG), the INSTEP= option specifies a factor $r > 0$ for the initial radius $\Delta^{(0)}$ of the trust region. The default initial trust-region radius is the length of the scaled gradient. This step corresponds to the default radius factor of $r = 1$.
- For line-search algorithms (NEWRAP, CONGRA, QUANEW), the INSTEP= option specifies an upper bound for the initial step length for the line search during the first five iterations. The default initial step length is $r = 1$.
- For the Nelder-Mead simplex algorithm, using TECH=NMSIMP, the INSTEP=*r* option defines the size of the start simplex.

LINESEARCH=*i*

LIS=*i*

specifies the line-search method for the CONGRA, QUANEW, and NEWRAP optimization techniques. For an introduction to line-search techniques, see Fletcher (1987). The value of *i* can be $1, \ldots, 8$. For CONGRA, QUANEW and NEWRAP, the default value is $i = 2$.

LIS=1 specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is similar to one used by the Harwell subroutine library.

LIS=2 specifies a line-search method that needs more function than gradient calls for quadratic and cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.

LIS=3 specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.

LIS=4 specifies a line-search method that needs the same number of function and gradient calls for stepwise extrapolation and cubic interpolation.

LIS=5 specifies a line-search method that is a modified version of LIS=4.

LIS=6 specifies golden section line search (Polak 1971), which uses only function values for linear approximation.

LIS=7 specifies bisection line search (Polak 1971), which uses only function values for linear approximation.

LIS=8 specifies the Armijo line-search technique (Polak 1971), which uses only function values for linear approximation.

LSPRECISION=*r*

LSP=*r*

specifies the degree of accuracy that should be obtained by the line-search algorithms LIS=2 and LIS=3. Usually an imprecise line search is inexpensive and successful. For more difficult optimization problems, a more precise and expensive line search may be necessary (Fletcher 1987). The second line-search method (which is the default for the NEWRAP, QUANEW, and CONGRA techniques) and the third line-search method approach exact line search for small LSPRECISION= values. If you have numerical problems, you should try to decrease the LSPRECISION= value to obtain a more precise line search. The default values are shown in Table 6.2.

Table 6.2 Line Search Precision Defaults

TECH=	UPDATE=	LSP Default
QUANEW	DBFGS, BFGS	$r = 0.4$
QUANEW	DDFP, DFP	$r = 0.06$
CONGRA	All	$r = 0.1$
NEWRAP	No update	$r = 0.9$

For more information, see Fletcher (1987).

MAXFUNC=*i*

MAXFU=*i*

specifies the maximum number *i* of function calls in the optimization process. The default values are

- TRUREG, NRRIDG, NEWRAP: 125
- QUANEW, DBLDOG: 500
- CONGRA: 1000
- NMSIMP: 3000

Note that the optimization can terminate only after completing a full iteration. Therefore, the number of function calls that is actually performed can exceed the number that is specified by the MAXFUNC= option.

MAXITER=*i*

MAXIT=*i*

specifies the maximum number *i* of iterations in the optimization process. The default values are

- TRUREG, NRRIDG, NEWRAP: 50
- QUANEW, DBLDOG: 200
- CONGRA: 400
- NMSIMP: 1000

These default values are also valid when *i* is specified as a missing value.

MAXSTEP=*r***[***n***]**

specifies an upper bound for the step length of the line-search algorithms during the first *n* iterations. By default, *r* is the largest double-precision value and *n* is the largest integer available. Setting this option can improve the speed of convergence for the CONGRA, QUANEW, and NEWRAP techniques.

MAXTIME=*r*

specifies an upper limit of *r* seconds of CPU time for the optimization process. The default value is the largest floating-point double representation of your computer. Note that the time specified by the MAXTIME= option is checked only once at the end of each iteration. Therefore, the actual running time can be much longer than that specified by the MAXTIME= option. The actual running time includes the rest of the time needed to finish the iteration and the time needed to generate the output of the results.

MINITER=*i*

MINIT=*i*

specifies the minimum number of iterations. The default value is 0. If you request more iterations than are actually needed for convergence to a stationary point, the optimization algorithms can behave strangely. For example, the effect of rounding errors can prevent the algorithm from continuing for the required number of iterations.

NOPRINT

suppresses the output. (See procedure documentation for availability of this option.)

PALL

displays all optional output for optimization. (See procedure documentation for availability of this option.)

PHISTORY

displays the optimization history. (See procedure documentation for availability of this option.)

PHISTPARMS

display parameter estimates in each iteration. (See procedure documentation for availability of this option.)

PINIT
displays the initial values and derivatives (if available). (See procedure documentation for availability of this option.)

PSHORT
restricts the amount of default output. (See procedure documentation for availability of this option.)

PSUMMARY
restricts the amount of default displayed output to a short form of iteration history and notes, warnings, and errors. (See procedure documentation for availability of this option.)

RESTART=*i* > 0

REST=*i* > 0
specifies that the QUANEW or CONGRA algorithm is restarted with a steepest descent/ascent search direction after, at most, *i* iterations. Default values are as follows:

- CONGRA
  UPDATE=PB: restart is performed automatically, *i* is not used.
- CONGRA
  UPDATE≠PB: $i = \min(10n, 80)$, where *n* is the number of parameters.
- QUANEW
  i is the largest integer available.

TECHNIQUE=*value*

TECH=*value*
specifies the optimization technique. Valid values are as follows:

CONGRA performs a conjugate-gradient optimization, which can be more precisely specified with the UPDATE= option and modified with the LINESEARCH= option. When you specify this option, UPDATE=PB by default.

DBLDOG performs a version of double-dogleg optimization, which can be more precisely specified with the UPDATE= option. When you specify this option, UPDATE=DBFGS by default.

NMSIMP performs a Nelder-Mead simplex optimization.

NONE does not perform any optimization. This option can be used as follows:

- to perform a grid search without optimization
- to compute estimates and predictions that cannot be obtained efficiently with any of the optimization techniques

NEWRAP performs a Newton-Raphson optimization that combines a line-search algorithm with ridging. The line-search algorithm LIS=2 is the default method.

NRRIDG performs a Newton-Raphson optimization with ridging.

QUANEW performs a quasi-Newton optimization, which can be defined more precisely with the UPDATE= option and modified with the LINESEARCH= option. This is the default estimation method.

TRUREG performs a trust region optimization.

UPDATE=*method*

UPD=*method*

specifies the update method for the QUANEW, DBLDOG, or CONGRA optimization technique. Not every update method can be used with each optimizer.

Valid *methods* are as follows:

BFGS	performs the original Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the inverse Hessian matrix.
DBFGS	performs the dual BFGS update of the Cholesky factor of the Hessian matrix. This is the default update method.
DDFP	performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
DFP	performs the original DFP update of the inverse Hessian matrix.
PB	performs the automatic restart update method of Powell (1977); Beale (1972).
FR	performs the Fletcher-Reeves update (Fletcher 1987).
PR	performs the Polak-Ribiere update (Fletcher 1987).
CD	performs a conjugate-descent update of Fletcher (1987).

XCONV=*r***[***n***]**

XTOL=*r***[***n***]**

specifies the relative parameter convergence criterion. For all techniques except NMSIMP, termination requires a small relative parameter change in subsequent iterations.

$$\frac{\max_j |\theta_j^{(k)} - \theta_j^{(k-1)}|}{\max(|\theta_j^{(k)}|, |\theta_j^{(k-1)}|, \text{XSIZE})} \leq r$$

For the NMSIMP technique, the same formula is used, but $\theta_j^{(k)}$ is defined as the vertex with the lowest function value and $\theta_j^{(k-1)}$ is defined as the vertex with the highest function value in the simplex. The default value is $r = 1\text{E} - 8$ for the NMSIMP technique and $r = 0$ otherwise. The optional integer value n specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

XSIZE=*r* > 0

specifies the XSIZE parameter of the relative parameter termination criterion. The default value is $r = 0$. For more information, see the XCONV= option.

Details of Optimization Algorithms

Overview

There are several optimization techniques available, as shown in Table 6.3. You can choose a particular optimizer with the TECH=*name* option in the PROC statement or NLOPTIONS statement.

Table 6.3 Optimization Techniques

Algorithm	TECH=
Trust region method	TRUREG
Newton-Raphson method with line search	NEWRAP
Newton-Raphson method with ridging	NRRIDG
Quasi-Newton methods (DBFGS, DDFP, BFGS, DFP)	QUANEW
Double-dogleg method (DBFGS, DDFP)	DBLDOG
Conjugate gradient methods (PB, FR, PR, CD)	CONGRA
Nelder-Mead simplex method	NMSIMP

No algorithm for optimizing general nonlinear functions exists that always finds the global optimum for a general nonlinear minimization problem in a reasonable amount of time. Since no single optimization technique is invariably superior to others, NLO provides a variety of optimization techniques that work well in various circumstances. However, you can devise problems for which none of the techniques in NLO can find the correct solution. Moreover, nonlinear optimization can be computationally expensive in terms of time and memory, so you must be careful when matching an algorithm to a problem.

All optimization techniques in NLO use $O(n^2)$ memory except the conjugate gradient methods, which use only $O(n)$ of memory and are designed to optimize problems with many parameters. These iterative techniques require repeated computation of the following:

- the function value (optimization criterion)
- the gradient vector (first-order partial derivatives)
- for some techniques, the (approximate) Hessian matrix (second-order partial derivatives)

However, since each of the optimizers requires different derivatives, some computational efficiencies can be gained. Table 6.4 shows, for each optimization technique, which derivatives are required. (FOD means that first-order derivatives or the gradient is computed; SOD means that second-order derivatives or the Hessian is computed.)

Table 6.4 Optimization Computations

Algorithm	FOD	SOD
TRUREG	x	x

Table 6.4 *continued*

Algorithm	FOD	SOD
NEWRAP	x	x
NRRIDG	x	x
QUANEW	x	-
DBLDOG	x	-
CONGRA	x	-
NMSIMP	-	-

Each optimization method employs one or more convergence criteria that determine when it has converged. The various termination criteria are listed and described in the previous section. An algorithm is considered to have converged when any one of the convergence criterion is satisfied. For example, under the default settings, the QUANEW algorithm will converge if $\mathrm{ABSGCONV} < 1\mathrm{E}-5$, $\mathrm{FCONV} < 10^{-\mathrm{FDIGITS}}$, or $\mathrm{GCONV} < 1\mathrm{E}-8$.

Choosing an Optimization Algorithm

The factors that go into choosing a particular optimization technique for a particular problem are complex and might involve trial and error.

For many optimization problems, computing the gradient takes more computer time than computing the function value, and computing the Hessian sometimes takes *much* more computer time and memory than computing the gradient, especially when there are many decision variables. Unfortunately, optimization techniques that do not use some kind of Hessian approximation usually require many more iterations than techniques that do use a Hessian matrix, and as a result the total run time of these techniques is often longer. Techniques that do not use the Hessian also tend to be less reliable. For example, they can more easily terminate at stationary points rather than at global optima.

A few general remarks about the various optimization techniques follow.

- The second-derivative methods TRUREG, NEWRAP, and NRRIDG are best for small problems where the Hessian matrix is not expensive to compute. Sometimes the NRRIDG algorithm can be faster than the TRUREG algorithm, but TRUREG can be more stable. The NRRIDG algorithm requires only one matrix with $n(n+1)/2$ double words; TRUREG and NEWRAP require two such matrices.
- The first-derivative methods QUANEW and DBLDOG are best for medium-sized problems where the objective function and the gradient are much faster to evaluate than the Hessian. The QUANEW and DBLDOG algorithms, in general, require more iterations than TRUREG, NRRIDG, and NEWRAP, but each iteration can be much faster. The QUANEW and DBLDOG algorithms require only the gradient to update an approximate Hessian, and they require slightly less memory than TRUREG or NEWRAP (essentially one matrix with $n(n+1)/2$ double words). QUANEW is the default optimization method.
- The first-derivative method CONGRA is best for large problems where the objective function and the gradient can be computed much faster than the Hessian and where too much memory is required to store the (approximate) Hessian. The CONGRA algorithm, in general, requires more iterations than

QUANEW or DBLDOG, but each iteration can be much faster. Since CONGRA requires only a factor of n double-word memory, many large applications can be solved only by CONGRA.

- The no-derivative method NMSIMP is best for small problems where derivatives are not continuous or are very difficult to compute.

Algorithm Descriptions

Some details about the optimization techniques are as follows.

Trust Region Optimization (TRUREG)

The trust region method uses the gradient $g(\theta_{(k)})$ and the Hessian matrix $H(\theta_{(k)})$; thus, it requires that the objective function $f(\theta)$ have continuous first- and second-order derivatives inside the feasible region.

The trust region method iteratively optimizes a quadratic approximation to the nonlinear objective function within a hyperelliptic trust region with radius Δ that constrains the step size that corresponds to the quality of the quadratic approximation. The trust region method is implemented using Dennis, Gay, and Welsch (1981); Gay (1983); Moré and Sorensen (1983).

The trust region method performs well for small- to medium-sized problems, and it does not need many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms may be more efficient.

Newton-Raphson Optimization with Line Search (NEWRAP)

The NEWRAP technique uses the gradient $g(\theta_{(k)})$ and the Hessian matrix $H(\theta_{(k)})$; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region. If second-order derivatives are computed efficiently and precisely, the NEWRAP method can perform well for medium-sized to large problems, and it does not need many function, gradient, and Hessian calls.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. Otherwise, a combination of ridging and line search is performed to compute successful steps. If the Hessian is not positive definite, a multiple of the identity matrix is added to the Hessian matrix to make it positive definite.

In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation (LIS=2).

Newton-Raphson Ridge Optimization (NRRIDG)

The NRRIDG technique uses the gradient $g(\theta_{(k)})$ and the Hessian matrix $H(\theta_{(k)})$; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. If at least one of these two conditions is not satisfied, a multiple of the identity matrix is added to the Hessian matrix.

The NRRIDG method performs well for small- to medium-sized problems, and it does not require many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms might be more efficient.

Since the NRRIDG technique uses an orthogonal decomposition of the approximate Hessian, each iteration of NRRIDG can be slower than that of the NEWRAP technique, which works with Cholesky decomposition. Usually, however, NRRIDG requires fewer iterations than NEWRAP.

Quasi-Newton Optimization (QUANEW)

The (dual) quasi-Newton method uses the gradient $g(\theta_{(k)})$, and it does not need to compute second-order derivatives since they are approximated. It works well for medium to moderately large optimization problems where the objective function and the gradient are much faster to compute than the Hessian; but, in general, it requires more iterations than the TRUREG, NEWRAP, and NRRIDG techniques, which compute second-order derivatives. QUANEW is the default optimization algorithm because it provides an appropriate balance between the speed and stability required for most nonlinear mixed model applications.

The QUANEW technique is one of the following, depending upon the value of the UPDATE= option:

- the original quasi-Newton algorithm, which updates an approximation of the inverse Hessian
- the dual quasi-Newton algorithm, which updates the Cholesky factor of an approximate Hessian (default)

You can specify four update formulas with the UPDATE= option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- BFGS performs the original BFGS update of the inverse Hessian matrix.
- DFP performs the original DFP update of the inverse Hessian matrix.

In each iteration, a line search is performed along the search direction to find an approximate optimum. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size α satisfying the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit of the step size. Violating the left-side Goldstein condition can affect the positive definiteness of the quasi-Newton update. In that case, either the update is skipped or the iterations are restarted with an identity matrix, resulting in the steepest descent or ascent search direction. You can specify line-search algorithms other than the default with the LIS= option.

The QUANEW algorithm performs its own line-search technique. All options and parameters (except the INSTEP= option) that control the line search in the other algorithms do not apply here. In several applications, large steps in the first iterations are troublesome. You can use the INSTEP= option to impose an upper bound for the step size α during the first five iterations. You can also use the INHESSIAN[=*r*] option to specify a different starting approximation for the Hessian. If you specify only the INHESSIAN option, the Cholesky factor of a (possibly ridged) finite difference approximation of the Hessian is used to initialize the quasi-Newton update process. The values of the LCSINGULAR=, LCEPSILON=, and LCDEACT= options, which control the processing of linear and boundary constraints, are valid only for the quadratic programming subroutine used in each iteration of the QUANEW algorithm.

Double-Dogleg Optimization (DBLDOG)

The double-dogleg optimization method combines the ideas of the quasi-Newton and trust region methods. In each iteration, the double-dogleg algorithm computes the step $s^{(k)}$ as the linear combination of the steepest descent or ascent search direction $s_1^{(k)}$ and a quasi-Newton search direction $s_2^{(k)}$.

$$s^{(k)} = \alpha_1 s_1^{(k)} + \alpha_2 s_2^{(k)}$$

The step is requested to remain within a prespecified trust region radius; see Fletcher (1987, p. 107). Thus, the DBLDOG subroutine uses the dual quasi-Newton update but does not perform a line search. You can specify two update formulas with the UPDATE= option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell update of the Cholesky factor of the Hessian matrix.

The double-dogleg optimization technique works well for medium to moderately large optimization problems where the objective function and the gradient are much faster to compute than the Hessian. The implementation is based on Dennis and Mei (1979); Gay (1983). However, this implementation is extended to deal with boundary and linear constraints. The DBLDOG technique generally requires more iterations than the TRUREG, NEWRAP, or NRRIDG technique, which requires second-order derivatives; however, each of the DBLDOG iterations is computationally cheap. Furthermore, the DBLDOG technique requires only gradient calls for the update of the Cholesky factor of an approximate Hessian.

Conjugate Gradient Optimization (CONGRA)

Second-order derivatives are not required by the CONGRA algorithm and are not even approximated. The CONGRA algorithm can be expensive in function and gradient calls, but it requires only $O(n)$ memory for unconstrained optimization. In general, many iterations are required to obtain a precise solution, but each of the CONGRA iterations is computationally cheap. You can specify four different update formulas for generating the conjugate directions by using the UPDATE= option:

- PB performs the automatic restart update method of Powell (1977); Beale (1972). This is the default.
- FR performs the Fletcher-Reeves update (Fletcher 1987).
- PR performs the Polak-Ribiere update (Fletcher 1987).
- CD performs a conjugate-descent update of Fletcher (1987).

The default, UPDATE=PB, behaved best in most test examples. You are advised to avoid the option UPDATE=CD, which behaved worst in most test examples.

The CONGRA subroutine should be used for optimization problems with large n. For the unconstrained or boundary constrained case, CONGRA requires only $O(n)$ bytes of working memory, whereas all other optimization methods require order $O(n^2)$ bytes of working memory. During n successive iterations, uninterrupted by restarts or changes in the working set, the conjugate gradient algorithm computes a cycle of n conjugate search directions. In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic

interpolation and cubic extrapolation to obtain a step size α satisfying the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit for the step size. Other line-search algorithms can be specified with the LIS= option.

Nelder-Mead Simplex Optimization (NMSIMP)

The Nelder-Mead simplex method does not use any derivatives and does not assume that the objective function has continuous derivatives. The objective function itself needs to be continuous. This technique is quite expensive in the number of function calls, and it might be unable to generate precise results for n much greater than 40.

The original Nelder-Mead simplex algorithm is implemented and extended to boundary constraints. This algorithm does not compute the objective for infeasible points, but it changes the shape of the simplex by adapting to the nonlinearities of the objective function, which contributes to an increased speed of convergence. It uses a special termination criteria.

ODS Table Names

The NLO subsystem assigns a name to each table it creates. You can use these names when using the Output Delivery System (ODS) to select tables and create output data sets. Not all tables are created by all SAS/ETS procedures that use the NLO subsystem. You should check the procedure chapter for more information. The names are listed in Table 6.5.

Table 6.5 ODS Tables Produced by the NLO Subsystem

ODS Table Name	Description
ConvergenceStatus	Convergence status
InputOptions	Input options
IterHist	Iteration history
IterStart	Iteration start
IterStop	Iteration stop
Lagrange	Lagrange multipliers at the solution
LinCon	Linear constraints
LinConDel	Deleted linear constraints
LinConSol	Linear constraints at the solution
ParameterEstimatesResults	Estimates at the results
ParameterEstimatesStart	Estimates at the start of the iterations
ProblemDescription	Problem description
ProjGrad	Projected gradients

Overview: ARIMA Procedure

The ARIMA procedure analyzes and forecasts equally spaced univariate time series data, transfer function data, and intervention data by using the autoregressive integrated moving-average (ARIMA) or autoregressive moving-average (ARMA) model. An ARIMA model predicts a value in a response time series as a linear combination of its own past values, past errors (also called shocks or innovations), and current and past values of other time series.

The ARIMA approach was first popularized by Box and Jenkins, and ARIMA models are often referred to as Box-Jenkins models. The general transfer function model employed by the ARIMA procedure was discussed by Box and Tiao (1975). When an ARIMA model includes other time series as input variables, the model is sometimes referred to as an ARIMAX model. Pankratz (1991) refers to the ARIMAX model as *dynamic regression*.

The ARIMA procedure provides a comprehensive set of tools for univariate time series model identification, parameter estimation, and forecasting, and it offers great flexibility in the kinds of ARIMA or ARIMAX models that can be analyzed. The ARIMA procedure supports seasonal, subset, and factored ARIMA models; intervention or interrupted time series models; multiple regression analysis with ARMA errors; and rational transfer function models of any complexity.

The design of PROC ARIMA closely follows the Box-Jenkins strategy for time series modeling with features for the identification, estimation and diagnostic checking, and forecasting steps of the Box-Jenkins method.

Before you use PROC ARIMA, you should be familiar with Box-Jenkins methods, and you should exercise care and judgment when you use the ARIMA procedure. The ARIMA class of time series models is complex and powerful, and some degree of expertise is needed to use them correctly.

Getting Started: ARIMA Procedure

This section outlines the use of the ARIMA procedure and gives a cursory description of the ARIMA modeling process for readers who are less familiar with these methods.

The Three Stages of ARIMA Modeling

The analysis performed by PROC ARIMA is divided into three stages, corresponding to the stages described by Box and Jenkins (1976):

1. In the *identification* stage, you use the IDENTIFY statement to specify the response series and identify candidate ARIMA models for it. The IDENTIFY statement reads time series that are to be used in later statements, possibly differencing them, and computes autocorrelations, inverse autocorrelations, partial autocorrelations, and cross-correlations. Stationarity tests can be performed to determine if differencing is necessary. The analysis of the IDENTIFY statement output usually suggests one or more ARIMA models that could be fit. Options enable you to test for stationarity and tentative ARMA order identification.

2. In the *estimation and diagnostic checking* stage, you use the ESTIMATE statement to specify the ARIMA model to fit to the variable specified in the previous IDENTIFY statement and to estimate the parameters of that model. The ESTIMATE statement also produces diagnostic statistics to help you judge the adequacy of the model.

   Significance tests for parameter estimates indicate whether some terms in the model might be unnecessary. Goodness-of-fit statistics aid in comparing this model to others. Tests for white noise residuals indicate whether the residual series contains additional information that might be used by a more complex model. The OUTLIER statement provides another useful tool to check whether the currently estimated model accounts for all the variation in the series. If the diagnostic tests indicate problems with the model, you try another model and then repeat the estimation and diagnostic checking stage.

3. In the *forecasting* stage, you use the FORECAST statement to forecast future values of the time series and to generate confidence intervals for these forecasts from the ARIMA model produced by the preceding ESTIMATE statement.

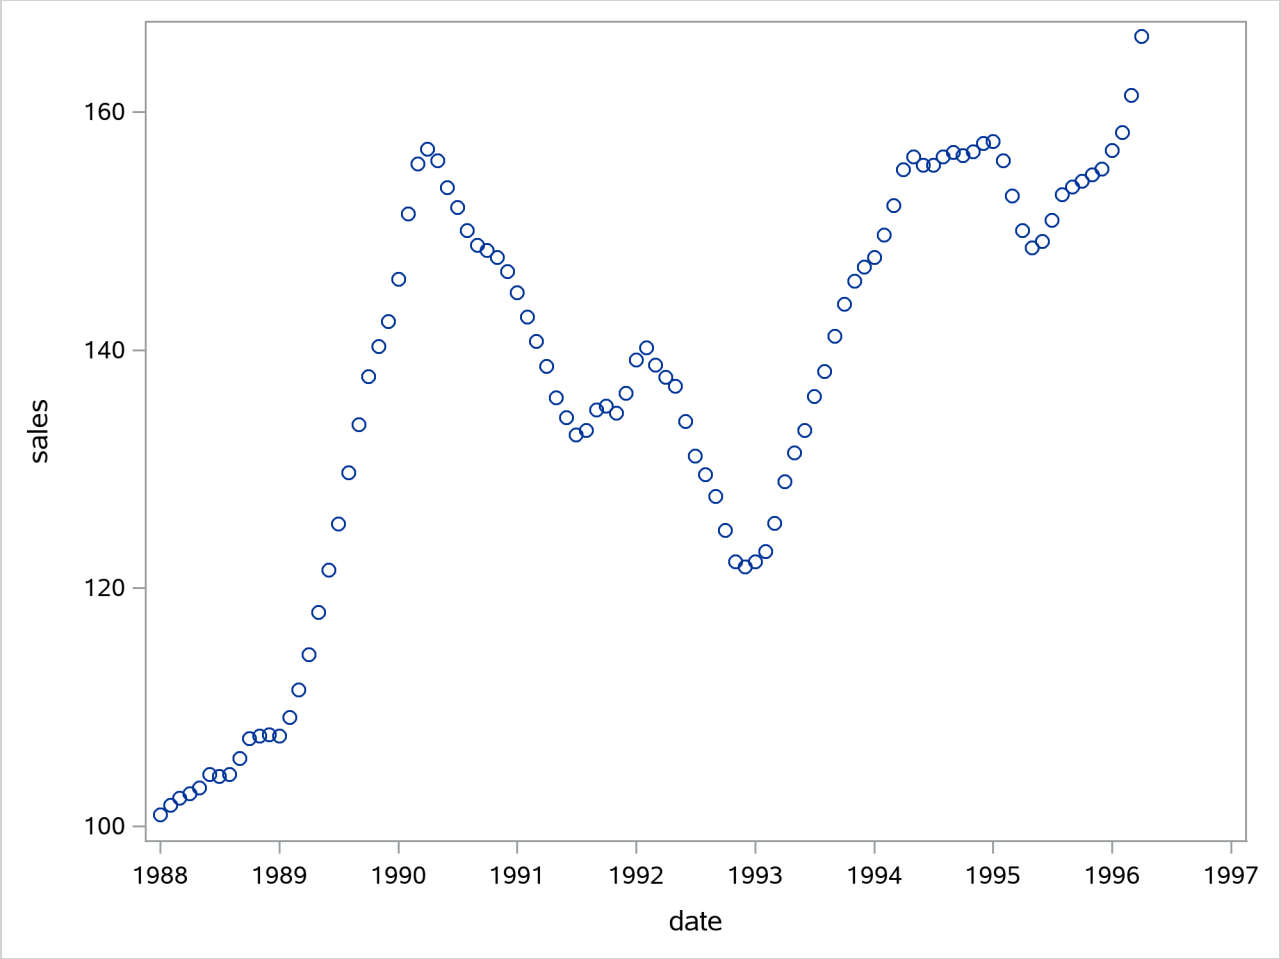
These three steps are explained further and illustrated through an extended example in the following sections.

Identification Stage

Suppose you have a variable called SALES that you want to forecast. The following example illustrates ARIMA modeling and forecasting by using a simulated data set TEST that contains a time series SALES generated by an ARIMA(1,1,1) model. The output produced by this example is explained in the following sections. The simulated SALES series is shown in Figure 7.1.

```
proc sgplot data=test;
   scatter y=sales x=date;
run;
```

Figure 7.1 Simulated ARIMA(1,1,1) Series SALES



Using the IDENTIFY Statement

You first specify the input data set in the PROC ARIMA statement. Then, you use an IDENTIFY statement to read in the SALES series and analyze its correlation properties. You do this by using the following statements:

```
proc arima data=test ;
   identify var=sales nlag=24;
run;
```

Descriptive Statistics

The IDENTIFY statement first prints descriptive statistics for the SALES series. This part of the IDENTIFY statement output is shown in Figure 7.2.

Figure 7.2 IDENTIFY Statement Descriptive Statistics Output

The ARIMA Procedure

Name of Variable = sales	
Mean of Working Series	137.3662
Standard Deviation	17.36385
Number of Observations	100

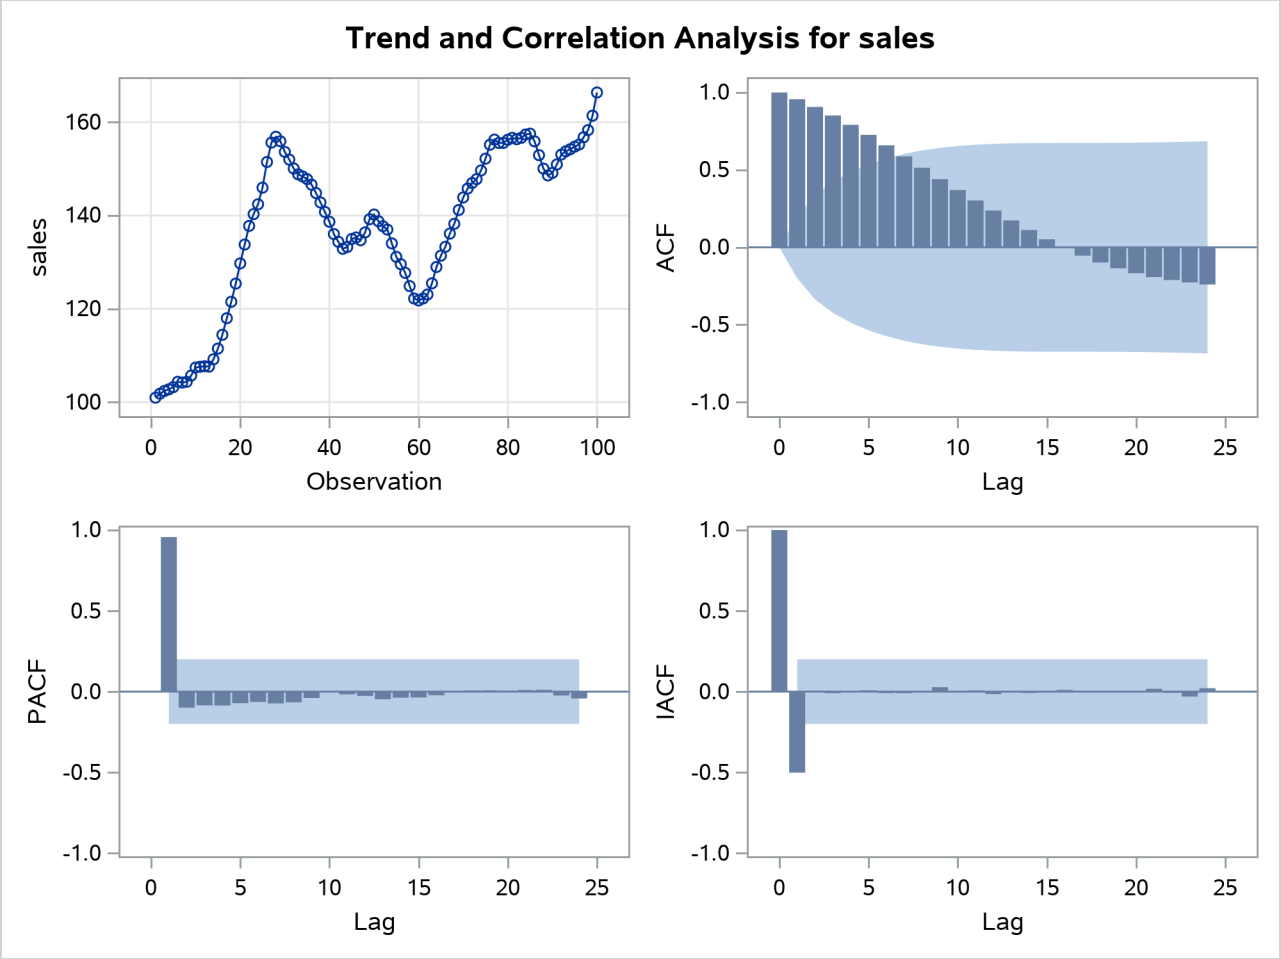
Autocorrelation Function Plots

The IDENTIFY statement next produces a panel of plots used for its autocorrelation and trend analysis. The panel contains the following plots:

- the time series plot of the series
- the sample autocorrelation function plot (ACF)
- the sample inverse autocorrelation function plot (IACF)
- the sample partial autocorrelation function plot (PACF)

This correlation analysis panel is shown in Figure 7.3.

Figure 7.3 Correlation Analysis of SALES



These autocorrelation function plots show the degree of correlation with past values of the series as a function of the number of periods in the past (that is, the lag) at which the correlation is computed.

The NLAG= option controls the number of lags for which the autocorrelations are shown. By default, the autocorrelation functions are plotted to lag 24.

Most books on time series analysis explain how to interpret the autocorrelation and the partial autocorrelation plots. For information about the inverse autocorrelation plots, see the section "The Inverse Autocorrelation Function" on page 228.

By examining these plots, you can judge whether the series is *stationary* or *nonstationary*. In this case, a visual inspection of the autocorrelation function plot indicates that the SALES series is nonstationary, since the ACF decays very slowly. For more formal stationarity tests, use the STATIONARITY= option. (See the section "Stationarity" on page 201.)

White Noise Test

The last part of the default IDENTIFY statement output is the check for white noise. This is an approximate statistical test of the hypothesis that none of the autocorrelations of the series up to a given lag are significantly different from 0. If this is true for all lags, then there is no information in the series to model, and no ARIMA model is needed for the series.

The autocorrelations are checked in groups of six, and the number of lags checked depends on the NLAG= option. The check for white noise output is shown in Figure 7.4.

Figure 7.4 IDENTIFY Statement Check for White Noise

Autocorrelation Check for White Noise									
To Lag	Chi-Square	DF	Pr > ChiSq	Autocorrelations					
6	426.44	6	<.0001	0.957	0.907	0.852	0.791	0.726	0.659
12	547.82	12	<.0001	0.588	0.514	0.440	0.370	0.303	0.238
18	554.70	18	<.0001	0.174	0.112	0.052	-0.004	-0.054	-0.098
24	585.73	24	<.0001	-0.135	-0.167	-0.192	-0.211	-0.227	-0.240

In this case, the white noise hypothesis is rejected very strongly, which is expected since the series is nonstationary. The *p*-value for the test of the first six autocorrelations is printed as <0.0001, which means the *p*-value is less than 0.0001.

Identification of the Differenced Series

Since the series is nonstationary, the next step is to transform it to a stationary series by differencing. That is, instead of modeling the SALES series itself, you model the change in SALES from one period to the next. To difference the SALES series, use another IDENTIFY statement and specify that the first difference of SALES be analyzed, as shown in the following statements:

```
proc arima data=test;
   identify var=sales(1);
run;
```

The second IDENTIFY statement produces the same information as the first, but for the change in SALES from one period to the next rather than for the total SALES in each period. The summary statistics output from this IDENTIFY statement is shown in Figure 7.5. Note that the period of differencing is given as 1, and one observation was lost through the differencing operation.

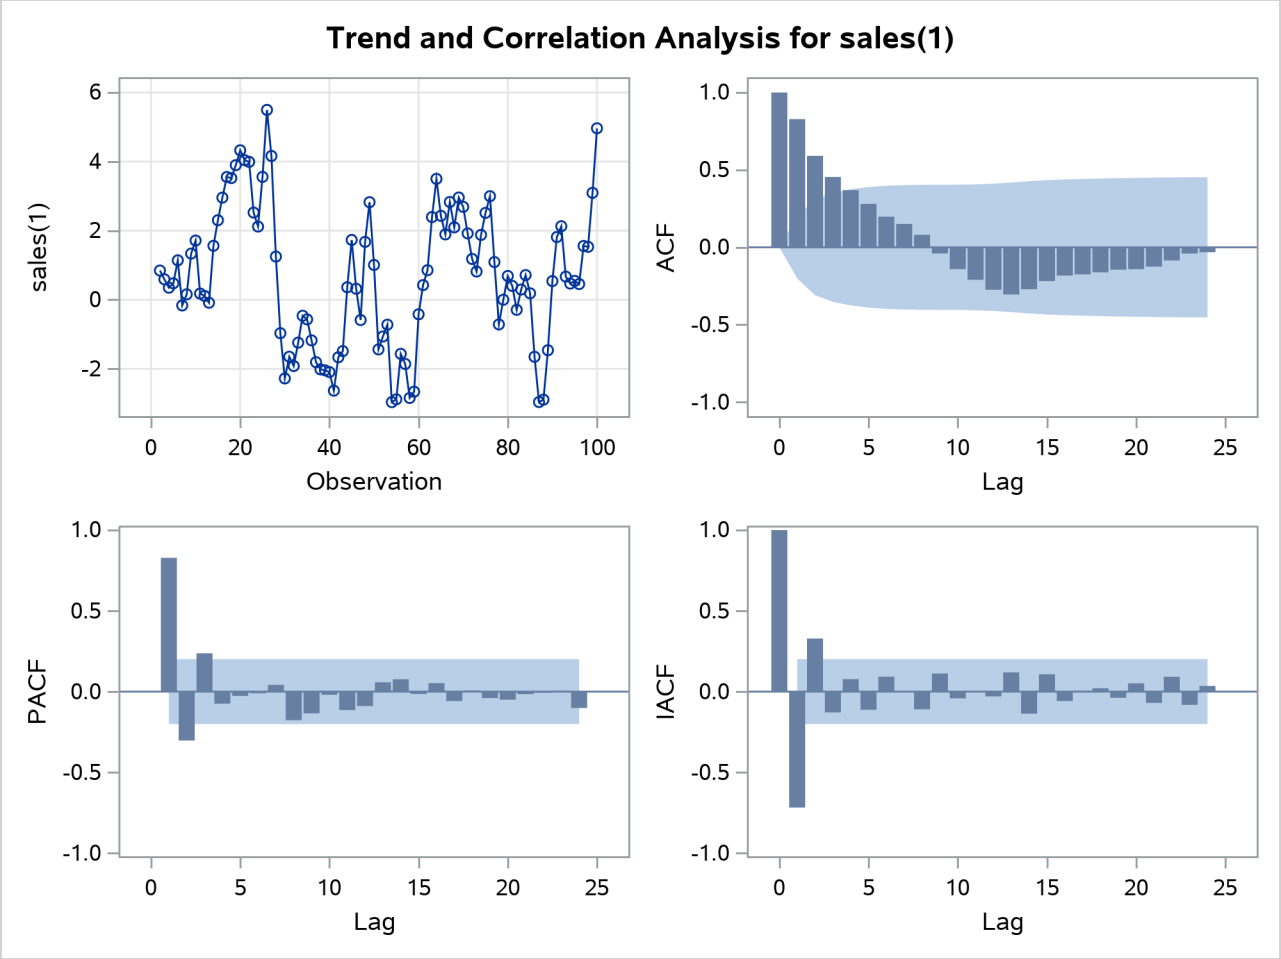
Figure 7.5 IDENTIFY Statement Output for Differenced Series

The ARIMA Procedure

Name of Variable = sales	
Period(s) of Differencing	1
Mean of Working Series	0.660589
Standard Deviation	2.011543
Number of Observations	99
Observation(s) eliminated by differencing	1

The autocorrelation plots for the differenced series are shown in Figure 7.6.

Figure 7.6 Correlation Analysis of the Change in SALES



The autocorrelations decrease rapidly in this plot, indicating that the change in SALES is a stationary time series.

The next step in the Box-Jenkins methodology is to examine the patterns in the autocorrelation plot to choose candidate ARMA models to the series. The partial and inverse autocorrelation function plots are also useful aids in identifying appropriate ARMA models for the series.

In the usual Box-Jenkins approach to ARIMA modeling, the sample autocorrelation function, inverse autocorrelation function, and partial autocorrelation function are compared with the theoretical correlation functions expected from different kinds of ARMA models. This matching of theoretical autocorrelation functions of different ARMA models to the sample autocorrelation functions computed from the response series is the heart of the identification stage of Box-Jenkins modeling. Most textbooks on time series analysis, such as Pankratz (1983), discuss the theoretical autocorrelation functions for different kinds of ARMA models.

Since the input data are only a limited sample of the series, the sample autocorrelation functions computed from the input series only approximate the true autocorrelation function of the process that generates the series. This means that the sample autocorrelation functions do not exactly match the theoretical autocorrelation functions for any ARMA model and can have a pattern similar to that of several different ARMA models. If the series is white noise (a purely random process), then there is no need to fit a model. The check for

white noise, shown in Figure 7.7, indicates that the change in SALES is highly autocorrelated. Thus, an autocorrelation model, for example an AR(1) model, might be a good candidate model to fit to this process.

Figure 7.7 IDENTIFY Statement Check for White Noise

Autocorrelation Check for White Noise

To Lag	Chi-Square	DF	Pr > ChiSq	Autocorrelations					
6	154.44	6	<.0001	0.828	0.591	0.454	0.369	0.281	0.198
12	173.66	12	<.0001	0.151	0.081	-0.039	-0.141	-0.210	-0.274
18	209.64	18	<.0001	-0.305	-0.271	-0.218	-0.183	-0.174	-0.161
24	218.04	24	<.0001	-0.144	-0.141	-0.125	-0.085	-0.040	-0.032

Estimation and Diagnostic Checking Stage

The autocorrelation plots for this series, as shown in the previous section, suggest an AR(1) model for the change in SALES. You should check the diagnostic statistics to see if the AR(1) model is adequate. Other candidate models include an MA(1) model and low-order mixed ARMA models. In this example, the AR(1) model is tried first.

Estimating an AR(1) Model

The following statements fit an AR(1) model (an autoregressive model of order 1), which predicts the change in SALES as an average change, plus some fraction of the previous change, plus a random error. To estimate an AR model, you specify the order of the autoregressive model with the P= option in an ESTIMATE statement:

```
estimate p=1;
run;
```

The ESTIMATE statement fits the model to the data and prints parameter estimates and various diagnostic statistics that indicate how well the model fits the data. The first part of the ESTIMATE statement output, the table of parameter estimates, is shown in Figure 7.8.

Figure 7.8 Parameter Estimates for AR(1) Model

The ARIMA Procedure

Conditional Least Squares Estimation

Parameter	Estimate	Standard Error	t Value	Approx Pr > |t|	Lag
MU	0.90280	0.65984	1.37	0.1744	0
AR1,1	0.86847	0.05485	15.83	<.0001	1

The table of parameter estimates is titled “Conditional Least Squares Estimation,” which indicates the estimation method used. You can request different estimation methods with the METHOD= option.

The table of parameter estimates lists the parameters in the model; for each parameter, the table shows the estimated value and the standard error and *t* value for the estimate. The table also indicates the lag at which the parameter appears in the model.

In this case, there are two parameters in the model. The mean term is labeled MU; its estimated value is 0.90280. The autoregressive parameter is labeled AR1,1; this is the coefficient of the lagged value of the change in SALES, and its estimate is 0.86847.

The *t* values provide significance tests for the parameter estimates and indicate whether some terms in the model might be unnecessary. In this case, the *t* value for the autoregressive parameter is 15.83, so this term is highly significant. The *t* value for MU indicates that the mean term adds little to the model.

The standard error estimates are based on large sample theory. Thus, the standard errors are labeled as approximate, and the standard errors and *t* values might not be reliable in small samples.

The next part of the ESTIMATE statement output is a table of goodness-of-fit statistics, which aid in comparing this model to other models. This output is shown in Figure 7.9.

Figure 7.9 Goodness-of-Fit Statistics for AR(1) Model

Constant Estimate	0.118749
Variance Estimate	1.15794
Std Error Estimate	1.076076
AIC	297.4469
SBC	302.6372
Number of Residuals	99

The "Constant Estimate" is a function of the mean term MU and the autoregressive parameters. This estimate is computed only for AR or ARMA models, but not for strictly MA models. For an explanation of the constant estimate, see the section "General Notation for ARIMA Models" on page 199.

The "Variance Estimate" is the variance of the residual series, which estimates the innovation variance. The item labeled "Std Error Estimate" is the square root of the variance estimate. In general, when you are comparing candidate models, smaller AIC and SBC statistics indicate the better fitting model. The section "Estimation Details" on page 238 explains the AIC and SBC statistics.

The ESTIMATE statement next prints a table of correlations of the parameter estimates, as shown in Figure 7.10. This table can help you assess the extent to which collinearity might have influenced the results. If two parameter estimates are very highly correlated, you might consider dropping one of them from the model.

Figure 7.10 Correlations of the Estimates for AR(1) Model

Correlations of Parameter Estimates		
Parameter	**MU**	**AR1,1**
MU	1.000	0.114
AR1,1	0.114	1.000

The next part of the ESTIMATE statement output is a check of the autocorrelations of the residuals. This output has the same form as the autocorrelation check for white noise that the IDENTIFY statement prints for the response series. The autocorrelation check of residuals is shown in Figure 7.11.

Figure 7.11 Check for White Noise Residuals for AR(1) Model

Autocorrelation Check of Residuals									
To Lag	Chi-Square	DF	Pr > ChiSq	Autocorrelations					
6	19.09	5	0.0019	0.327	-0.220	-0.128	0.068	-0.002	-0.096
12	22.90	11	0.0183	0.072	0.116	-0.042	-0.066	0.031	-0.091
18	31.63	17	0.0167	-0.233	-0.129	-0.024	0.056	-0.014	-0.008
24	32.83	23	0.0841	0.009	-0.057	-0.057	-0.001	0.049	-0.015

The χ^2 test statistics for the residuals series indicate whether the residuals are uncorrelated (white noise) or contain additional information that might be used by a more complex model. In this case, the test statistics reject the no-autocorrelation hypothesis at a high level of significance ($p = 0.0019$ for the first six lags.) This means that the residuals are not white noise, and so the AR(1) model is not a fully adequate model for this series. The ESTIMATE statement output also includes graphical analysis of the residuals. It is not shown here. The graphical analysis also reveals the inadequacy of the AR(1) model.

The final part of the ESTIMATE statement output is a listing of the estimated model, using the backshift notation. This output is shown in Figure 7.12.

Figure 7.12 Estimated ARIMA(1, 1, 0) Model for SALES

Model for variable sales	
Estimated Mean	0.902799
Period(s) of Differencing	1

Autoregressive Factors	
Factor 1:	1 - 0.86847 B**(1)

This listing combines the differencing specification given in the IDENTIFY statement with the parameter estimates of the model for the change in SALES. Since the AR(1) model is for the change in SALES, the final model for SALES is an ARIMA(1,1,0) model. Using B, the backshift operator, the mathematical form of the estimated model shown in this output is as follows:

$$(1 - B)sales_t = 0.902799 + \frac{1}{(1 - 0.86847B)}a_t$$

For further explanation of this notation, see the section "General Notation for ARIMA Models" on page 199.

Estimating an ARMA(1,1) Model

The IDENTIFY statement plots suggest a mixed autoregressive and moving-average model, and the previous ESTIMATE statement check of residuals indicates that an AR(1) model is not sufficient. You now try estimating an ARMA(1,1) model for the change in SALES.

An ARMA(1,1) model predicts the change in SALES as an average change, plus some fraction of the previous change, plus a random error, plus some fraction of the random error in the preceding period. An ARMA(1,1) model for the change in SALES is the same as an ARIMA(1,1,1) model for the level of SALES.

To estimate a mixed autoregressive moving-average model, you specify the order of the moving-average part of the model with the Q= option in an ESTIMATE statement in addition to specifying the order of the

autoregressive part with the P= option. The following statements fit an ARMA(1,1) model to the differenced SALES series:

```
estimate p=1 q=1;
run;
```

The parameter estimates table and goodness-of-fit statistics for this model are shown in Figure 7.13.

Figure 7.13 Estimated ARMA(1, 1) Model for Change in SALES

The ARIMA Procedure

Conditional Least Squares Estimation

Parameter	Estimate	Standard Error	t Value	Approx Pr > |t|	Lag
MU	0.89288	0.49391	1.81	0.0738	0
MA1,1	-0.58935	0.08988	-6.56	<.0001	1
AR1,1	0.74755	0.07785	9.60	<.0001	1

Constant Estimate	0.225409
Variance Estimate	0.904034
Std Error Estimate	0.950807
AIC	273.9155
SBC	281.7009
Number of Residuals	99

The moving-average parameter estimate, labeled "MA1,1", is –0.58935. Both the moving-average and the autoregressive parameters have significant *t* values. Note that the variance estimate, AIC, and SBC are all smaller than they were for the AR(1) model, indicating that the ARMA(1,1) model fits the data better without over-parameterizing.

The graphical check of the residuals from this model is shown in Figure 7.14 and Figure 7.15. The residual correlation and white noise test plots show that you cannot reject the hypothesis that the residuals are uncorrelated. The normality plots also show no departure from normality. Thus, you conclude that the ARMA(1,1) model is adequate for the change in SALES series, and there is no point in trying more complex models.

Figure 7.14 White Noise Check of Residuals for the ARMA(1,1) Model

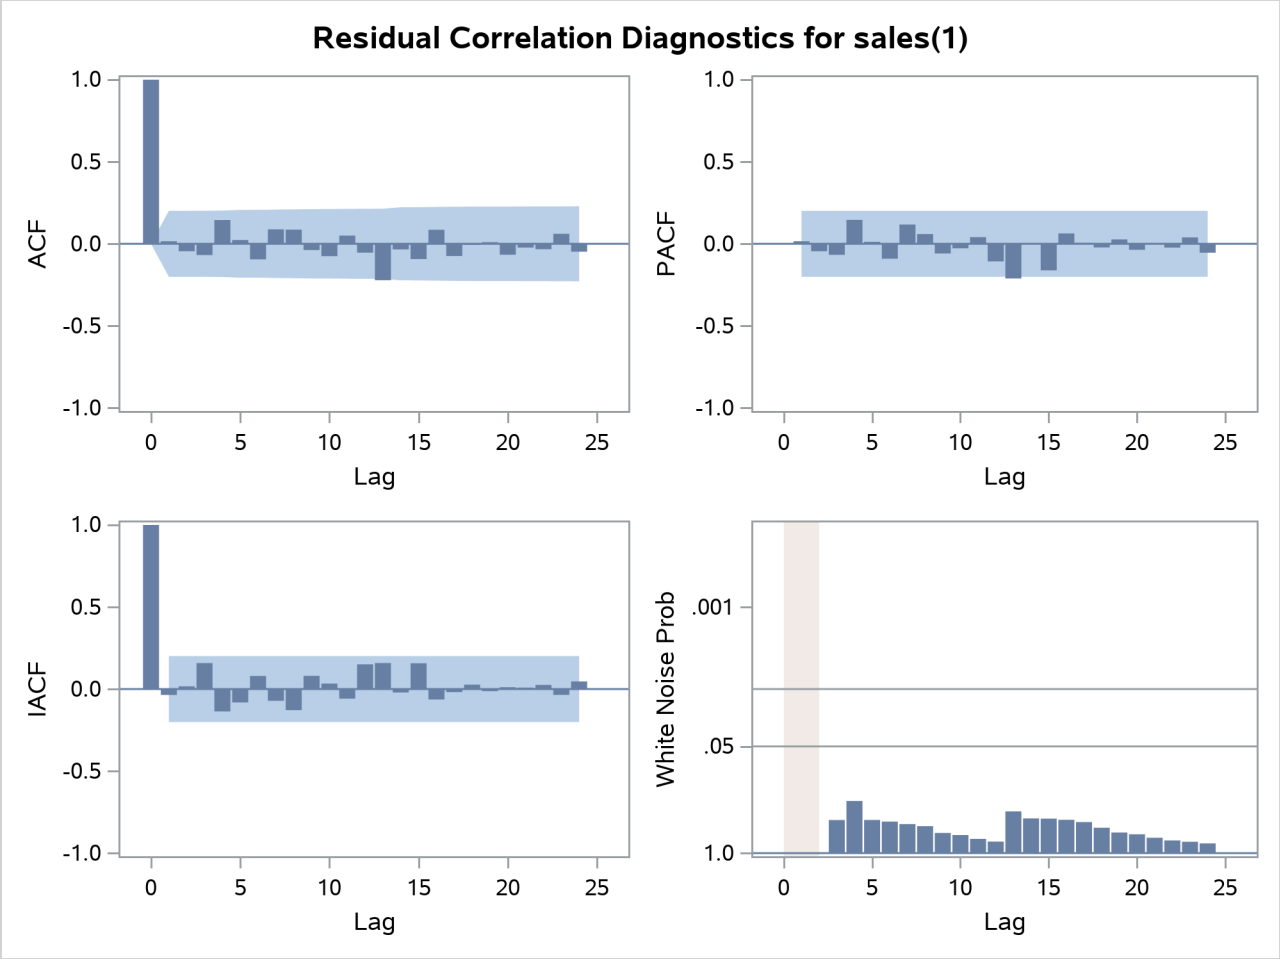


Figure 7.15 Normality Check of Residuals for the ARMA(1,1) Model

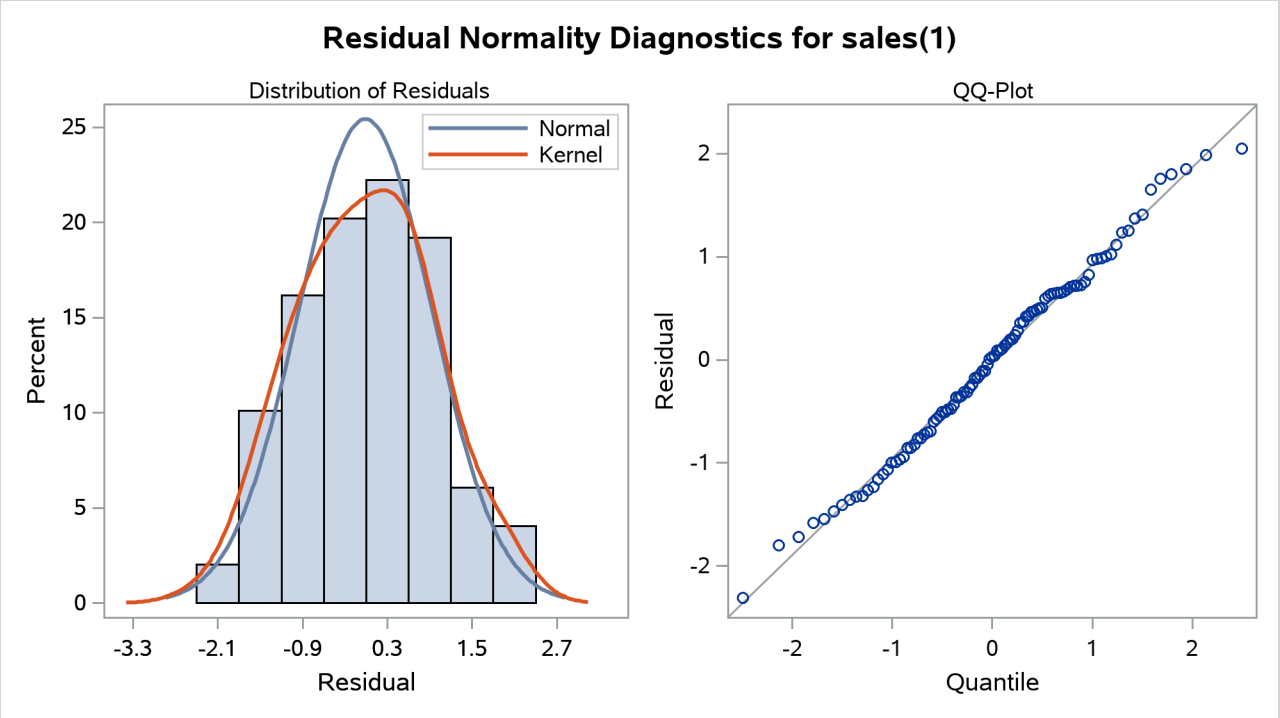

The form of the estimated ARIMA(1,1,1) model for SALES is shown in Figure 7.16.

Figure 7.16 Estimated ARIMA(1,1,1) Model for SALES

Model for variable sales	
Estimated Mean	0.892875
Period(s) of Differencing	1

Autoregressive Factors
Factor 1: 1 - 0.74755 B**(1)

Moving Average Factors
Factor 1: 1 + 0.58935 B**(1)

The estimated model shown in this output is

$$(1-B)sales_t = 0.892875 + \frac{(1+0.58935B)}{(1-0.74755B)}a_t$$

In addition to the residual analysis of a model, it is often useful to check whether there are any changes in the time series that are not accounted for by the currently estimated model. The OUTLIER statement enables you to detect such changes. For a long series, this task can be computationally burdensome. Therefore, in general, it is better done after a model that fits the data reasonably well has been found. Figure 7.17 shows the output of the simplest form of the OUTLIER statement:

```
outlier;
run;
```

Two possible outliers have been found for the model in question. For more information about modeling in the presence of outliers, see the section "Detecting Outliers" on page 249 and Example 7.6 and Example 7.7. In this illustration these outliers are not discussed any further.

Figure 7.17 Outliers for the ARIMA(1,1,1) Model for SALES

The ARIMA Procedure

Outlier Detection Summary	
Maximum number searched	2
Number found	2
Significance used	0.05

Outlier Details

Obs	Type	Estimate	Chi-Square	Approx Prob>ChiSq
10	Additive	0.56879	4.20	0.0403
67	Additive	0.55698	4.42	0.0355

Since the model diagnostic tests show that all the parameter estimates are significant and the residual series is white noise, the estimation and diagnostic checking stage is complete. You can now proceed to forecasting the SALES series with this ARIMA(1,1,1) model.

Forecasting Stage

To produce the forecast, use a FORECAST statement after the ESTIMATE statement for the model you decide is best. If the last model fit is not the best, then repeat the ESTIMATE statement for the best model before you use the FORECAST statement.

Suppose that the SALES series is monthly, that you want to forecast one year ahead from the most recently available SALES figure, and that the dates for the observations are given by a variable DATE in the input data set TEST. You use the following FORECAST statement:

```
forecast lead=12 interval=month id=date out=results;
run;
```

The LEAD= option specifies how many periods ahead to forecast (12 months, in this case). The ID= option specifies the ID variable, which is typically a SAS *date*, *time*, or *datetime* variable, used to date the observations of the SALES time series. The INTERVAL= option indicates that data are monthly and enables PROC ARIMA to extrapolate DATE values for forecast periods. The OUT= option writes the forecasts to the output data set RESULTS. For information about the contents of the output data set, see the section "OUT= Data Set" on page 251.

By default, the FORECAST statement also prints and plots the forecast values, as shown in Figure 7.18 and Figure 7.19. The forecast table shows for each forecast period the observation number, forecast value, standard error estimate for the forecast value, and lower and upper limits for a 95% confidence interval for the forecast.

Figure 7.18 Forecasts for ARIMA(1,1,1) Model for SALES

The ARIMA Procedure

Forecasts for variable sales

Obs	Forecast	Std Error	95% Confidence Limits	
101	171.0320	0.9508	169.1684	172.8955
102	174.7534	2.4168	170.0165	179.4903
103	177.7608	3.9879	169.9445	185.5770
104	180.2343	5.5658	169.3256	191.1430
105	182.3088	7.1033	168.3866	196.2310
106	184.0850	8.5789	167.2707	200.8993
107	185.6382	9.9841	166.0698	205.2066
108	187.0247	11.3173	164.8433	209.2061
109	188.2866	12.5807	163.6289	212.9443
110	189.4553	13.7784	162.4501	216.4605

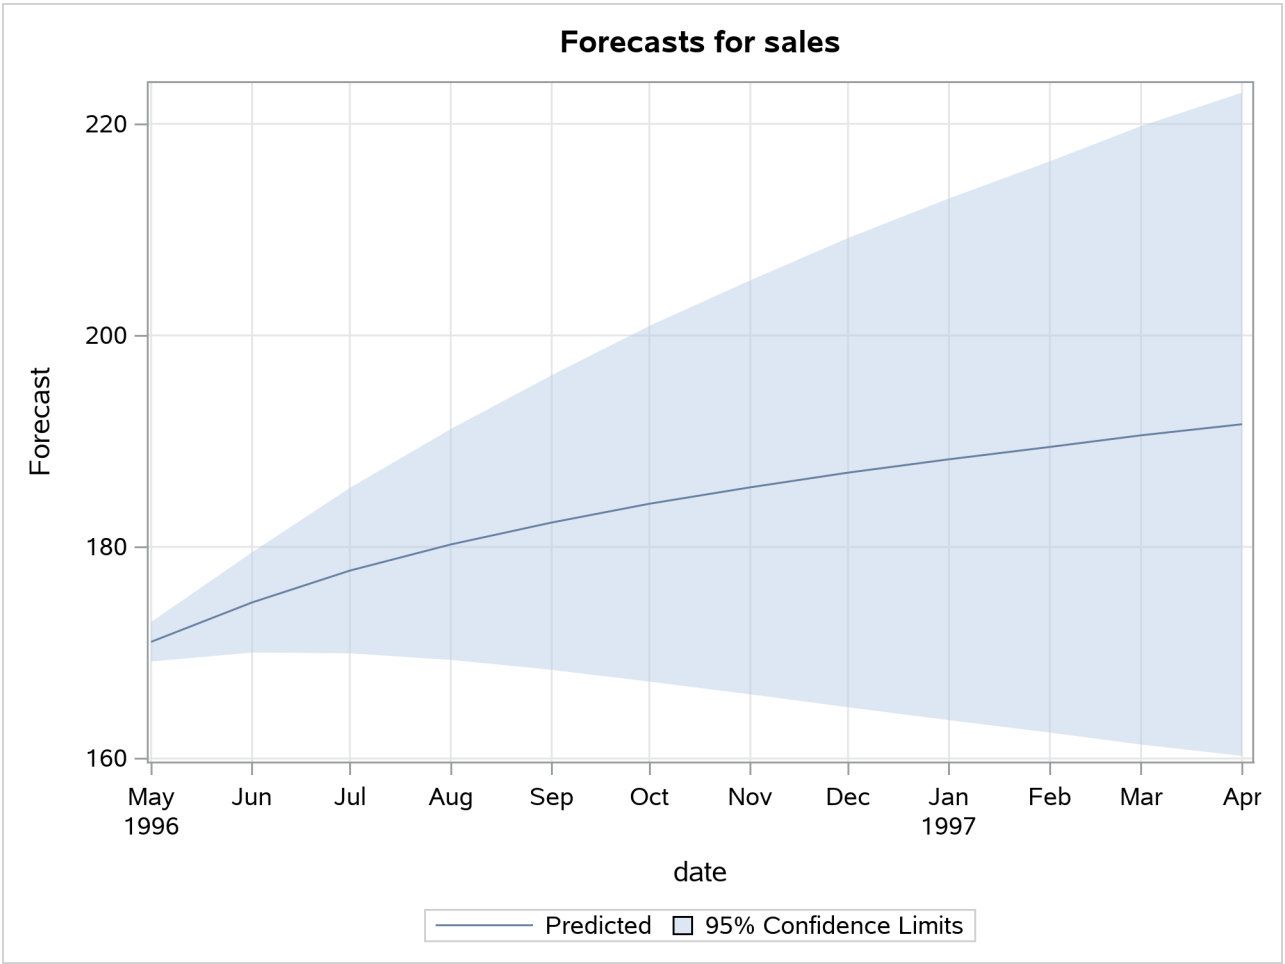
Figure 7.19 Forecasts for the ARMA(1,1,1) Model



Normally, you want the forecast values stored in an output data set, and you are not interested in seeing this printed list of the forecast. You can use the NOPRINT option in the FORECAST statement to suppress this output.

Using ARIMA Procedure Statements

The IDENTIFY, ESTIMATE, and FORECAST statements are related in a hierarchy. An IDENTIFY statement brings in a time series to be modeled; several ESTIMATE statements can follow to estimate different ARIMA models for the series; for each model estimated, several FORECAST statements can be used. Thus, a FORECAST statement must be preceded at some point by an ESTIMATE statement, and an ESTIMATE statement must be preceded at some point by an IDENTIFY statement. Additional IDENTIFY statements can be used to switch to modeling a different response series or to change the degree of differencing used.

The ARIMA procedure can be used interactively in the sense that all ARIMA procedure statements can be executed any number of times without reinvoking PROC ARIMA. You can execute ARIMA procedure statements singly or in groups by following the single statement or group of statements with a RUN statement. The output for each statement or group of statements is produced when the RUN statement is entered.

A RUN statement does not terminate the PROC ARIMA step but tells the procedure to execute the statements given so far. You can end PROC ARIMA by submitting a QUIT statement, a DATA step, another PROC step, or an ENDSAS statement.

The example in the preceding section illustrates the interactive use of ARIMA procedure statements. The complete PROC ARIMA program for that example is as follows:

```
proc arima data=test;
   identify var=sales nlag=24;
   run;
   identify var=sales(1);
   run;
   estimate p=1;
   run;
   estimate p=1 q=1;
   run;
   outlier;
   run;
   forecast lead=12 interval=month id=date out=results;
   run;
quit;
```

General Notation for ARIMA Models

The order of an ARIMA (autoregressive integrated moving-average) model is usually denoted by the notation ARIMA(p,d,q), where

p	is the order of the autoregressive part
d	is the order of the differencing
q	is the order of the moving-average process

If no differencing is done ($d = 0$), the models are usually referred to as ARMA(p, q) models. The final model in the preceding example is an ARIMA(1,1,1) model since the IDENTIFY statement specified $d = 1$, and the final ESTIMATE statement specified $p = 1$ and $q = 1$.

Notation for Pure ARIMA Models

Mathematically the pure ARIMA model is written as

$$W_t = \mu + \frac{\theta(B)}{\phi(B)} a_t$$

where

t	indexes time
W_t	is the response series Y_t or a difference of the response series
μ	is the mean term
B	is the backshift operator; that is, $BX_t = X_{t-1}$
$\phi(B)$	is the autoregressive operator, represented as a polynomial in the backshift operator: $\phi(B) = 1 - \phi_1 B - \cdots - \phi_p B^p$
$\theta(B)$	is the moving-average operator, represented as a polynomial in the backshift operator: $\theta(B) = 1 - \theta_1 B - \cdots - \theta_q B^q$
a_t	is the independent disturbance, also called the random error

The series W_t is computed by the IDENTIFY statement and is the series processed by the ESTIMATE statement. Thus, W_t is either the response series Y_t or a difference of Y_t specified by the differencing operators in the IDENTIFY statement.

For simple (nonseasonal) differencing, $W_t = (1 - B)^d Y_t$. For seasonal differencing $W_t = (1 - B)^d (1 - B^s)^D Y_t$, where d is the degree of nonseasonal differencing, D is the degree of seasonal differencing, and s is the length of the seasonal cycle.

For example, the mathematical form of the ARIMA(1,1,1) model estimated in the preceding example is

$$(1 - B)Y_t = \mu + \frac{(1 - \theta_1 B)}{(1 - \phi_1 B)} a_t$$

Model Constant Term

The ARIMA model can also be written as

$$\phi(B)(W_t - \mu) = \theta(B)a_t$$

or

$$\phi(B)W_t = const + \theta(B)a_t$$

where

$$const = \phi(B)\mu = \mu - \phi_1\mu - \phi_2\mu - \cdots - \phi_p\mu$$

Thus, when an autoregressive operator and a mean term are both included in the model, the constant term for the model can be represented as $\phi(B)\mu$. This value is printed with the label "Constant Estimate" in the ESTIMATE statement output.

Notation for Transfer Function Models

The general ARIMA model with input series, also called the ARIMAX model, is written as

$$W_t = \mu + \sum_i \frac{\omega_i(B)}{\delta_i(B)} B^{k_i} X_{i,t} + \frac{\theta(B)}{\phi(B)} a_t$$

where

$X_{i,t}$	is the ith input time series or a difference of the ith input series at time t
k_i	is the pure time delay for the effect of the ith input series
$\omega_i(B)$	is the numerator polynomial of the transfer function for the ith input series
$\delta_i(B)$	is the denominator polynomial of the transfer function for the ith input series

The model can also be written more compactly as

$$W_t = \mu + \sum_i \Psi_i(B)X_{i,t} + n_t$$

where

$\Psi_i(B)$	is the transfer function for the ith input series modeled as a ratio of the ω and δ polynomials: $\Psi_i(B) = (\omega_i(B)/\delta_i(B))B^{k_i}$
n_t	is the noise series: $n_t = (\theta(B)/\phi(B))a_t$

This model expresses the response series as a combination of past values of the random shocks and past values of other input series. The response series is also called the *dependent series* or *output series*. An input time series is also referred to as an *independent series* or a *predictor series*. Response variable, dependent variable, independent variable, or predictor variable are other terms often used.

Notation for Factored Models

ARIMA models are sometimes expressed in a factored form. This means that the ϕ, θ, ω, or δ polynomials are expressed as products of simpler polynomials. For example, you could express the pure ARIMA model as

$$W_t = \mu + \frac{\theta_1(B)\theta_2(B)}{\phi_1(B)\phi_2(B)}a_t$$

where $\phi_1(B)\phi_2(B) = \phi(B)$ and $\theta_1(B)\theta_2(B) = \theta(B)$.

When an ARIMA model is expressed in factored form, the order of the model is usually expressed by using a factored notation also. The order of an ARIMA model expressed as the product of two factors is denoted as ARIMA(p,d,q)×(P,D,Q).

Notation for Seasonal Models

ARIMA models for time series with regular seasonal fluctuations often use differencing operators and autoregressive and moving-average parameters at lags that are multiples of the length of the seasonal cycle. When all the terms in an ARIMA model factor refer to lags that are a multiple of a constant s, the constant is factored out and suffixed to the ARIMA(p,d,q) notation.

Thus, the general notation for the order of a seasonal ARIMA model with both seasonal and nonseasonal factors is ARIMA(p,d,q)×(P,D,Q)$_s$. The term (p,d,q) gives the order of the nonseasonal part of the ARIMA model; the term (P,D,Q)$_s$ gives the order of the seasonal part. The value of s is the number of observations in a seasonal cycle: 12 for monthly series, 4 for quarterly series, 7 for daily series with day-of-week effects, and so forth.

For example, the notation ARIMA(0,1,2)×(0,1,1)$_{12}$ describes a seasonal ARIMA model for monthly data with the following mathematical form:

$$(1-B)(1-B^{12})Y_t = \mu + (1-\theta_{1,1}B-\theta_{1,2}B^2)(1-\theta_{2,1}B^{12})a_t$$

Stationarity

The noise (or residual) series for an ARMA model must be *stationary*, which means that both the expected values of the series and its autocovariance function are independent of time.

The standard way to check for nonstationarity is to plot the series and its autocorrelation function. You can visually examine a graph of the series over time to see if it has a visible trend or if its variability changes noticeably over time. If the series is nonstationary, its autocorrelation function will usually decay slowly.

Another way of checking for stationarity is to use the stationarity tests described in the section "Stationarity Tests" on page 234.

Most time series are nonstationary and must be transformed to a stationary series before the ARIMA modeling process can proceed. If the series has a nonstationary variance, taking the log of the series can help. You can compute the log values in a DATA step and then analyze the log values with PROC ARIMA.

If the series has a trend over time, seasonality, or some other nonstationary pattern, the usual solution is to take the difference of the series from one period to the next and then analyze this differenced series. Sometimes a series might need to be differenced more than once or differenced at lags greater than one period. (If the trend or seasonal effects are very regular, the introduction of explanatory variables can be an appropriate alternative to differencing.)

Differencing

Differencing of the response series is specified with the VAR= option of the IDENTIFY statement by placing a list of differencing periods in parentheses after the variable name. For example, to take a simple first difference of the series SALES, use the statement

```
identify var=sales(1);
```

In this example, the change in SALES from one period to the next is analyzed.

A deterministic seasonal pattern also causes the series to be nonstationary, since the expected value of the series is not the same for all time periods but is higher or lower depending on the season. When the series has a seasonal pattern, you might want to difference the series at a lag that corresponds to the length of the seasonal cycle. For example, if SALES is a monthly series, the statement

```
identify var=sales(12);
```

takes a seasonal difference of SALES, so that the series analyzed is the change in SALES from its value in the same month one year ago.

To take a second difference, add another differencing period to the list. For example, the following statement takes the second difference of SALES:

```
identify var=sales(1,1);
```

That is, SALES is differenced once at lag 1 and then differenced again, also at lag 1. The statement

```
identify var=sales(2);
```

creates a 2-span difference—that is, current period SALES minus SALES from two periods ago. The statement

```
identify var=sales(1,12);
```

takes a second-order difference of SALES, so that the series analyzed is the difference between the current period-to-period change in SALES and the change 12 periods ago. You might want to do this if the series had both a trend over time and a seasonal pattern.

There is no limit to the order of differencing and the degree of lagging for each difference.

Differencing not only affects the series used for the IDENTIFY statement output but also applies to any following ESTIMATE and FORECAST statements. ESTIMATE statements fit ARMA models to the differenced series. FORECAST statements forecast the differences and automatically sum these differences back to undo the differencing operation specified by the IDENTIFY statement, thus producing the final forecast result.

Differencing of input series is specified by the CROSSCORR= option and works just like differencing of the response series. For example, the statement

```
identify var=y(1) crosscorr=(x1(1) x2(1));
```

takes the first difference of Y, the first difference of X1, and the first difference of X2. Whenever X1 and X2 are used in INPUT= options in following ESTIMATE statements, these names refer to the differenced series.

Subset, Seasonal, and Factored ARMA Models

The simplest way to specify an ARMA model is to give the order of the AR and MA parts with the P= and Q= options. When you do this, the model has parameters for the AR and MA parts for all lags through the order specified. However, you can control the form of the ARIMA model exactly as shown in the following section.

Subset Models

You can control which lags have parameters by specifying the P= or Q= option as a list of lags in parentheses. A model that includes parameters for only some lags is sometimes called a *subset* or *additive model*. For example, consider the following two ESTIMATE statements:

```
identify var=sales;
estimate p=4;
estimate p=(1 4);
```

Both specify AR(4) models, but the first has parameters for lags 1, 2, 3, and 4, while the second has parameters for lags 1 and 4, with the coefficients for lags 2 and 3 constrained to 0. The mathematical form of the autoregressive models produced by these two specifications is shown in Table 7.1.

Table 7.1 Saturated versus Subset Models

Option	Autoregressive Operator
P=4	$(1 - \phi_1 B - \phi_2 B^2 - \phi_3 B^3 - \phi_4 B^4)$
P=(1 4)	$(1 - \phi_1 B - \phi_4 B^4)$

Seasonal Models

One particularly useful kind of subset model is a *seasonal model*. When the response series has a seasonal pattern, the values of the series at the same time of year in previous years can be important for modeling the series. For example, if the series SALES is observed monthly, the statements

```
identify var=sales;
estimate p=(12);
```

model SALES as an average value plus some fraction of its deviation from this average value a year ago, plus a random error. Although this is an AR(12) model, it has only one autoregressive parameter.

Factored Models

A factored model (also referred to as a multiplicative model) represents the ARIMA model as a product of simpler ARIMA models. For example, you might model SALES as a combination of an AR(1) process that reflects short term dependencies and an AR(12) model that reflects the seasonal pattern.

It might seem that the way to do this is with the option P=(1 12), but the AR(1) process also operates in past years; you really need autoregressive parameters at lags 1, 12, and 13. You can specify a subset model with separate parameters at these lags, or you can specify a factored model that represents the model as the product of an AR(1) model and an AR(12) model. Consider the following two ESTIMATE statements:

```
identify var=sales;
estimate p=(1 12 13);
estimate p=(1)(12);
```

The mathematical form of the autoregressive models produced by these two specifications are shown in Table 7.2.

Table 7.2 Subset versus Factored Models

Option	Autoregressive Operator
P=(1 12 13)	$(1 - \phi_1 B - \phi_{12} B^{12} - \phi_{13} B^{13})$
P=(1)(12)	$(1 - \phi_1 B)(1 - \phi_{12} B^{12})$

Both models fit by these two ESTIMATE statements predict SALES from its values 1, 12, and 13 periods ago, but they use different parameterizations. The first model has three parameters, whose meanings may be hard to interpret.

The factored specification P=(1)(12) represents the model as the product of two different AR models. It has only two parameters: one that corresponds to recent effects and one that represents seasonal effects. Thus the factored model is more parsimonious, and its parameter estimates are more clearly interpretable.

Input Variables and Regression with ARMA Errors

In addition to past values of the response series and past errors, you can also model the response series using the current and past values of other series, called *input series*.

Several different names are used to describe ARIMA models with input series. *Transfer function model*, *intervention model*, *interrupted time series model*, *regression model with ARMA errors*, *Box-Tiao model*, and *ARIMAX model* are all different names for ARIMA models with input series. Pankratz (1991) refers to these models as *dynamic regression* models.

Using Input Series

To use input series, list the input series in a CROSSCORR= option on the IDENTIFY statement and specify how they enter the model with an INPUT= option on the ESTIMATE statement. For example, you might use a series called PRICE to help model SALES, as shown in the following statements:

```
proc arima data=a;
   identify var=sales crosscorr=price;
   estimate input=price;
run;
```

This example performs a simple linear regression of SALES on PRICE; it produces the same results as PROC REG or another SAS regression procedure. The mathematical form of the model estimated by these statements is

$$Y_t = \mu + \omega_0 X_t + a_t$$

The parameter estimates table for this example (using simulated data) is shown in Figure 7.20. The intercept parameter is labeled MU. The regression coefficient for PRICE is labeled NUM1. (For information about how parameters for input series are named, see the section "Naming of Model Parameters" on page 245.)

Figure 7.20 Parameter Estimates Table for Regression Model

The ARIMA Procedure

Conditional Least Squares Estimation

Parameter	Estimate	Standard Error	t Value	Approx Pr > |t|	Lag	Variable	Shift
MU	199.83602	2.99463	66.73	<.0001	0	sales	0
NUM1	-9.99299	0.02885	-346.38	<.0001	0	price	0

Any number of input variables can be used in a model. For example, the following statements fit a multiple regression of SALES on PRICE and INCOME:

```
proc arima data=a;
   identify var=sales crosscorr=(price income);
   estimate input=(price income);
run;
```

The mathematical form of the regression model estimated by these statements is

$$Y_t = \mu + \omega_1 X_{1,t} + \omega_2 X_{2,t} + a_t$$

Lagging and Differencing Input Series

You can also difference and lag the input series. For example, the following statements regress the change in SALES on the change in PRICE lagged by one period. The difference of PRICE is specified with the CROSSCORR= option and the lag of the change in PRICE is specified by the 1 $ in the INPUT= option.

```
proc arima data=a;
   identify var=sales(1) crosscorr=price(1);
   estimate input=( 1 $ price );
run;
```

These statements estimate the model

$$(1-B)Y_t = \mu + \omega_0(1-B)X_{t-1} + a_t$$

Regression with ARMA Errors

You can combine input series with ARMA models for the errors. For example, the following statements regress SALES on INCOME and PRICE but with the error term of the regression model (called the *noise series* in ARIMA modeling terminology) assumed to be an ARMA(1,1) process:

```
proc arima data=a;
   identify var=sales crosscorr=(price income);
   estimate p=1 q=1 input=(price income);
run;
```

These statements estimate the model

$$Y_t = \mu + \omega_1 X_{1,t} + \omega_2 X_{2,t} + \frac{(1-\theta_1 B)}{(1-\phi_1 B)} a_t$$

Stationarity and Input Series

Note that the requirement of stationarity applies to the noise series. If there are no input variables, the response series (after differencing and minus the mean term) and the noise series are the same. However, if there are inputs, the noise series is the residual after the effect of the inputs is removed.

There is no requirement that the input series be stationary. If the inputs are nonstationary, the response series will be nonstationary, even though the noise process might be stationary.

When nonstationary input series are used, you can fit the input variables first with no ARMA model for the errors and then consider the stationarity of the residuals before identifying an ARMA model for the noise part.

Identifying Regression Models with ARMA Errors

Previous sections described the ARIMA modeling identification process that uses the autocorrelation function plots produced by the IDENTIFY statement. This identification process does not apply when the response series depends on input variables. This is because it is the noise process for which you need to identify an ARIMA model, and when input series are involved the response series adjusted for the mean is no longer an estimate of the noise series.

However, if the input series are independent of the noise series, you can use the residuals from the regression model as an estimate of the noise series, then apply the ARIMA modeling identification process to this residual series. This assumes that the noise process is stationary.

The PLOT option in the ESTIMATE statement produces similar plots for the model residuals as the IDENTIFY statement produces for the response series. The PLOT option prints an autocorrelation function plot, an inverse autocorrelation function plot, and a partial autocorrelation function plot for the residual series. Note that these residual correlation plots are produced by default.

The following statements show how the PLOT option is used to identify the ARMA(1,1) model for the noise process used in the preceding example of regression with ARMA errors:

```
proc arima data=a;
   identify var=sales crosscorr=(price income) noprint;
   estimate input=(price income) plot;
   run;
   estimate p=1 q=1 input=(price income);
run;
```

In this example, the IDENTIFY statement includes the NOPRINT option since the autocorrelation plots for the response series are not useful when you know that the response series depends on input series.

The first ESTIMATE statement fits the regression model with no model for the noise process. The PLOT option produces plots of the autocorrelation function, inverse autocorrelation function, and partial autocorrelation function for the residual series of the regression on PRICE and INCOME.

By examining the PLOT option output for the residual series, you verify that the residual series is stationary and identify an ARMA(1,1) model for the noise process. The second ESTIMATE statement fits the final model.

Although this discussion addresses regression models, the same remarks apply to identifying an ARIMA model for the noise process in models that include input series with complex transfer functions.

Intervention Models and Interrupted Time Series

One special kind of ARIMA model with input series is called an *intervention model* or *interrupted time series* model. In an intervention model, the input series is an indicator variable that contains discrete values that flag the occurrence of an event affecting the response series. This event is an intervention in or an interruption of the normal evolution of the response time series, which, in the absence of the intervention, is usually assumed to be a pure ARIMA process.

Intervention models can be used both to model and forecast the response series and also to analyze the impact of the intervention. When the focus is on estimating the effect of the intervention, the process is often called *intervention analysis* or *interrupted time series analysis*.

Impulse Interventions

The intervention can be a one-time event. For example, you might want to study the effect of a short-term advertising campaign on the sales of a product. In this case, the input variable has the value of 1 for the period during which the advertising campaign took place and the value 0 for all other periods. Intervention variables of this kind are sometimes called *impulse functions* or *pulse functions*.

Suppose that SALES is a monthly series, and a special advertising effort was made during the month of March 1992. The following statements estimate the effect of this intervention by assuming an ARMA(1,1) model for SALES. The model is specified just like the regression model, but the intervention variable AD is constructed in the DATA step as a zero-one indicator for the month of the advertising effort.

```
data a;
   set a;
   ad = (date = '1mar1992'd);
run;

proc arima data=a;
   identify var=sales crosscorr=ad;
   estimate p=1 q=1 input=ad;
run;
```

Continuing Interventions

Other interventions can be continuing, in which case the input variable flags periods before and after the intervention. For example, you might want to study the effect of a change in tax rates on some economic measure. Another example is a study of the effect of a change in speed limits on the rate of traffic fatalities. In this case, the input variable has the value 1 after the new speed limit went into effect and the value 0 before. Intervention variables of this kind are called *step functions*.

Another example is the effect of news on product demand. Suppose it was reported in July 1996 that consumption of the product prevents heart disease (or causes cancer), and SALES is consistently higher (or lower) thereafter. The following statements model the effect of this news intervention:

```
data a;
   set a;
   news = (date >= '1jul1996'd);
run;

proc arima data=a;
   identify var=sales crosscorr=news;
   estimate p=1 q=1 input=news;
run;
```

Interaction Effects

You can include any number of intervention variables in the model. Intervention variables can have any pattern—impulse and continuing interventions are just two possible cases. You can mix discrete valued intervention variables and continuous regressor variables in the same model.

You can also form interaction effects by multiplying input variables and including the product variable as another input. Indeed, as long as the dependent measure is continuous and forms a regular time series, you can use PROC ARIMA to fit any general linear model in conjunction with an ARMA model for the error process by using input variables that correspond to the columns of the design matrix of the linear model.

Rational Transfer Functions and Distributed Lag Models

How an input series enters the model is called its *transfer function*. Thus, ARIMA models with input series are sometimes referred to as transfer function models.

In the preceding regression and intervention model examples, the transfer function is a single scale parameter. However, you can also specify complex transfer functions composed of numerator and denominator polynomials in the backshift operator. These transfer functions operate on the input series in the same way that the ARMA specification operates on the error term.

Numerator Factors

For example, suppose you want to model the effect of PRICE on SALES as taking place gradually with the impact distributed over several past lags of PRICE. This is illustrated by the following statements:

```
proc arima data=a;
   identify var=sales crosscorr=price;
   estimate input=( (1 2 3) price );
run;
```

These statements estimate the model

$$Y_t = \mu + (\omega_0 - \omega_1 B - \omega_2 B^2 - \omega_3 B^3) X_t + a_t$$

This example models the effect of PRICE on SALES as a linear function of the current and three most recent values of PRICE. It is equivalent to a multiple linear regression of SALES on PRICE, LAG(PRICE), LAG2(PRICE), and LAG3(PRICE).

This is an example of a transfer function with one *numerator factor*. The numerator factors for a transfer function for an input series are like the MA part of the ARMA model for the noise series.

Denominator Factors

You can also use transfer functions with *denominator factors*. The denominator factors for a transfer function for an input series are like the AR part of the ARMA model for the noise series. Denominator factors introduce exponentially weighted, infinite distributed lags into the transfer function.

To specify transfer functions with denominator factors, place the denominator factors after a slash (/) in the INPUT= option. For example, the following statements estimate the PRICE effect as an infinite distributed lag model with exponentially declining weights:

```
proc arima data=a;
   identify var=sales crosscorr=price;
   estimate input=( / (1) price );
run;
```

The transfer function specified by these statements is as follows:

$$\frac{\omega_0}{(1-\delta_1 B)} X_t$$

This transfer function also can be written in the following equivalent form:

$$\omega_0 \left(1 + \sum_{i=1}^{\infty} \delta_1^i B^i\right) X_t$$

This transfer function can be used with intervention inputs. When it is used with a pulse function input, the result is an intervention effect that dies out gradually over time. When it is used with a step function input, the result is an intervention effect that increases gradually to a limiting value.

Rational Transfer Functions

By combining various numerator and denominator factors in the INPUT= option, you can specify *rational transfer functions* of any complexity. To specify an input with a general rational transfer function of the form

$$\frac{\omega(B)}{\delta(B)} B^k X_t$$

use an INPUT= option in the ESTIMATE statement of the form

input=(*k* $ (*ω-lags*) / (*δ-lags*) x)

For more information, see the section "Specifying Inputs and Transfer Functions" on page 242.

Identifying Transfer Function Models

The CROSSCORR= option of the IDENTIFY statement prints sample cross-correlation functions that show the correlation between the response series and the input series at different lags. The sample cross-correlation function can be used to help identify the form of the transfer function appropriate for an input series. For information about using cross-correlation functions to identify transfer function models, see textbooks on time series analysis.

For the cross-correlation function to be meaningful, the input and response series must be filtered with a prewhitening model for the input series. For more information about this issue, see the section "Prewhitening" on page 236.

Forecasting with Input Variables

To forecast a response series by using an ARIMA model with inputs, you need values of the input series for the forecast periods. You can supply values for the input variables for the forecast periods in the DATA= data set, or you can have PROC ARIMA forecast the input variables.

If you do not have future values of the input variables in the input data set used by the FORECAST statement, the input series must be forecast before the ARIMA procedure can forecast the response series. If you fit an ARIMA model to each of the input series for which you need forecasts before fitting the model for the response series, the FORECAST statement automatically uses the ARIMA models for the input series to generate the needed forecasts of the inputs.

For example, suppose you want to forecast SALES for the next 12 months. In this example, the change in SALES is predicted as a function of the change in PRICE, plus an ARMA(1,1) noise process. To forecast SALES by using PRICE as an input, you also need to fit an ARIMA model for PRICE.

The following statements fit an AR(2) model to the change in PRICE before fitting and forecasting the model for SALES. The FORECAST statement automatically forecasts PRICE using this AR(2) model to get the future inputs needed to produce the forecast of SALES.

```
proc arima data=a;
   identify var=price(1);
   estimate p=2;
   identify var=sales(1) crosscorr=price(1);
   estimate p=1 q=1 input=price;
   forecast lead=12 interval=month id=date out=results;
run;
```

Fitting a model to the input series is also important for identifying transfer functions. (For more information, see the section "Prewhitening" on page 236.)

Input values from the DATA= data set and input values forecast by PROC ARIMA can be combined. For example, a model for SALES might have three input series: PRICE, INCOME, and TAXRATE. For the forecast, you assume that the tax rate will be unchanged. You have a forecast for INCOME from another source but only for the first few periods of the SALES forecast you want to make. You have no future values for PRICE, which needs to be forecast as in the preceding example.

In this situation, you include observations in the input data set for all forecast periods, with SALES and PRICE set to a missing value, with TAXRATE set to its last actual value, and with INCOME set to forecast values for the periods you have forecasts for and set to missing values for later periods. In the PROC ARIMA step, you estimate ARIMA models for PRICE and INCOME before you estimate the model for SALES, as shown in the following statements:

```
proc arima data=a;
   identify var=price(1);
   estimate p=2;
   identify var=income(1);
   estimate p=2;
   identify var=sales(1) crosscorr=( price(1) income(1) taxrate );
   estimate p=1 q=1 input=( price income taxrate );
   forecast lead=12 interval=month id=date out=results;
run;
```

In forecasting SALES, the ARIMA procedure uses as inputs the value of PRICE forecast by its ARIMA model, the value of TAXRATE found in the DATA= data set, and the value of INCOME found in the DATA= data set, or, when the INCOME variable is missing, the value of INCOME forecast by its ARIMA model. (Because SALES is missing for future time periods, the estimation of model parameters is not affected by the forecast values for PRICE, INCOME, or TAXRATE.)

Data Requirements

PROC ARIMA can handle time series of moderate size; there should be at least 30 observations. With fewer than 30 observations, the parameter estimates might be poor. With thousands of observations, the method requires considerable computer time and memory.

Syntax: ARIMA Procedure

The ARIMA procedure uses the following statements:

```
PROC ARIMA options ;
    BY variables ;
    IDENTIFY VAR=variable < options > ;
    ESTIMATE options ;
    OUTLIER options ;
    FORECAST options ;
```

The PROC ARIMA and IDENTIFY statements are required.

Functional Summary

The statements and options that control the ARIMA procedure are summarized in Table 7.3.

Table 7.3 Functional Summary

Description	Statement	Option
Data Set Options		
Specify the input data set	PROC ARIMA	DATA=
	IDENTIFY	DATA=
Specify the output data set	PROC ARIMA	OUT=
	FORECAST	OUT=
Include only forecasts in the output data set	FORECAST	NOOUTALL
Write autocovariances to output data set	IDENTIFY	OUTCOV=
Write parameter estimates to an output data set	ESTIMATE	OUTEST=
Write correlation of parameter estimates	ESTIMATE	OUTCORR
Write covariance of parameter estimates	ESTIMATE	OUTCOV
Write estimated model to an output data set	ESTIMATE	OUTMODEL=
Write statistics of fit to an output data set	ESTIMATE	OUTSTAT=

Table 7.3 *continued*

Description	Statement	Option
Options for Identifying the Series		
Difference time series and plot autocorrelations	IDENTIFY	
Specify response series and differencing	IDENTIFY	VAR=
Specify and cross-correlate input series	IDENTIFY	CROSSCORR=
Center data by subtracting the mean	IDENTIFY	CENTER
Exclude missing values	IDENTIFY	NOMISS
Delete previous models and start	IDENTIFY	CLEAR
Specify the significance level for tests	IDENTIFY	ALPHA=
Perform tentative ARMA order identification by using the ESACF method	IDENTIFY	ESACF
Perform tentative ARMA order identification by using the MINIC method	IDENTIFY	MINIC
Perform tentative ARMA order identification by using the SCAN method	IDENTIFY	SCAN
Specify the range of autoregressive model orders for estimating the error series for the MINIC method	IDENTIFY	PERROR=
Determine the AR dimension of the SCAN, ESACF, and MINIC tables	IDENTIFY	P=
Determine the MA dimension of the SCAN, ESACF, and MINIC tables	IDENTIFY	Q=
Perform stationarity tests	IDENTIFY	STATIONARITY=
Selection of white noise test statistic in the presence of missing values	IDENTIFY	WHITENOISE=
Options for Defining and Estimating the Model		
Specify and estimate ARIMA models	ESTIMATE	
Specify autoregressive part of model	ESTIMATE	P=
Specify moving-average part of model	ESTIMATE	Q=
Specify input variables and transfer functions	ESTIMATE	INPUT=
Drop mean term from the model	ESTIMATE	NOINT
Specify the estimation method	ESTIMATE	METHOD=
Use alternative form for transfer functions	ESTIMATE	ALTPARM
Suppress degrees-of-freedom correction in variance estimates	ESTIMATE	NODF
Selection of white noise test statistic in the presence of missing values	ESTIMATE	WHITENOISE=
Options for Outlier Detection		
Specify the significance level for tests	OUTLIER	ALPHA=
Identify detected outliers with variable	OUTLIER	ID=
Limit the number of outliers	OUTLIER	MAXNUM=

Table 7.3 *continued*

Description	Statement	Option
Limit the number of outliers to a percentage of the series	OUTLIER	MAXPCT=
Specify the variance estimator used for testing	OUTLIER	SIGMA=
Specify the type of level shifts	OUTLIER	TYPE=
Printing Control Options		
Limit number of lags shown in correlation plots	IDENTIFY	NLAG=
Suppress printed output for identification	IDENTIFY	NOPRINT
Plot autocorrelation functions of the residuals	ESTIMATE	PLOT
Print log likelihood around the estimates	ESTIMATE	GRID
Control spacing for GRID option	ESTIMATE	GRIDVAL=
Print details of the iterative estimation process	ESTIMATE	PRINTALL
Suppress printed output for estimation	ESTIMATE	NOPRINT
Suppress printing of the forecast values	FORECAST	NOPRINT
Print the one-step forecasts and residuals	FORECAST	PRINTALL
Plotting Control Options		
Request plots associated with model identification, residual analysis, and forecasting	PROC ARIMA	PLOTS=
Options to Specify Parameter Values		
Specify autoregressive starting values	ESTIMATE	AR=
Specify moving-average starting values	ESTIMATE	MA=
Specify a starting value for the mean parameter	ESTIMATE	MU=
Specify starting values for transfer functions	ESTIMATE	INITVAL=
Options to Control the Iterative Estimation Process		
Specify convergence criterion	ESTIMATE	CONVERGE=
Specify the maximum number of iterations	ESTIMATE	MAXITER=
Specify criterion for checking for singularity	ESTIMATE	SINGULAR=
Suppress the iterative estimation process	ESTIMATE	NOEST
Omit initial observations from objective	ESTIMATE	BACKLIM=
Specify perturbation for numerical derivatives	ESTIMATE	DELTA=
Omit stationarity and invertibility checks	ESTIMATE	NOSTABLE
Use preliminary estimates as starting values for ML and ULS	ESTIMATE	NOLS
Options for Forecasting		
Forecast the response series	FORECAST	
Specify how many periods to forecast	FORECAST	LEAD=
Specify the ID variable	FORECAST	ID=
Specify the periodicity of the series	FORECAST	INTERVAL=

Table 7.3 *continued*

Description	Statement	Option
Specify size of forecast confidence limits	FORECAST	ALPHA=
Start forecasting before end of the input data	FORECAST	BACK=
Specify the variance term used to compute forecast standard errors and confidence limits	FORECAST	SIGSQ=
Control the alignment of SAS date values	FORECAST	ALIGN=
BY Groups		
Specify BY-group processing	BY	

PROC ARIMA Statement

PROC ARIMA *options* **;**

The following *options* can be used in the PROC ARIMA statement.

DATA=*SAS-data-set*
specifies the name of the SAS data set that contains the time series. If different DATA= specifications appear in the PROC ARIMA and IDENTIFY statements, the one in the IDENTIFY statement is used. If the DATA= option is not specified in either the PROC ARIMA or IDENTIFY statement, the most recently created SAS data set is used.

PLOTS<(*global-plot-options***)><=** *plot-request* **<(***options***)>>**
PLOTS<(*global-plot-options***)><=(***plot-request* **<(***options***)>...** *plot-request* **<(***options***)>>)>**
controls the plots produced through ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses around it.

Here are some examples:

```
plots=none
plots=all
plots(unpack)=series(corr crosscorr)
plots(only)=(series(corr crosscorr) residual(normal smooth))
```

Global Plot Options

The *global-plot-options* apply to all relevant plots generated by the ARIMA procedure. The following *global-plot-options* are supported:

ONLY suppresses the default plots. Only the plots specifically requested are produced.

UNPACK displays each graph separately. (By default, some graphs can appear together in a single panel.)

Specific Plot Options

The following list describes the specific plots and their options.

ALL produces all plots appropriate for the particular analysis.

NONE suppresses all plots.

SERIES(< *series-plot-options* **>)**
produces plots associated with the identification stage of the modeling. The panel plots corresponding to the CORR and CROSSCORR options are produced by default. The following *series-plot-options* are available:

ACF produces the plot of autocorrelations.

ALL produces all the plots associated with the identification stage.

CORR produces a panel of plots that are useful in the trend and correlation analysis of the series. The panel consists of the following:

- the time series plot
- the series-autocorrelation plot
- the series-partial-autocorrelation plot
- the series-inverse-autocorrelation plot

CROSSCORR produces panels of cross-correlation plots.

IACF produces the plot of inverse-autocorrelations.

PACF produces the plot of partial-autocorrelations.

RESIDUAL(< *residual-plot-options* **>)**
produces the residuals plots. The residual correlation and normality diagnostic panels are produced by default. The following *residual-plot-options* are available:

ACF produces the plot of residual autocorrelations.

ALL produces all the residual diagnostics plots appropriate for the particular analysis.

CORR produces a summary panel of the residual correlation diagnostics that consists of the following:

- the residual-autocorrelation plot
- the residual-partial-autocorrelation plot
- the residual-inverse-autocorrelation plot
- a plot of Ljung-Box white-noise test p-values at different lags

HIST produces the histogram of the residuals.

IACF produces the plot of residual inverse-autocorrelations.

NORMAL produces a summary panel of the residual normality diagnostics that consists of the following:

- histogram of the residuals
- normal quantile plot of the residuals

PACF produces the plot of residual partial-autocorrelations.

QQ produces the normal quantile plot of the residuals.

SMOOTH produces a scatter plot of the residuals against time, which has an overlaid smooth fit.

WN produces the plot of Ljung-Box white-noise test *p*-values at different lags.

FORECAST(< *forecast-plot-options* **>)**
produces the forecast plots in the forecasting stage. The forecast-only plot that shows the multistep forecasts in the forecast region is produced by default.

The following *forecast-plot-options* are available:

ALL produces the forecast-only plot as well as the forecast plot.

FORECAST produces a plot that shows the one-step-ahead forecasts as well as the multistep-ahead forecasts.

FORECASTONLY produces a plot that shows only the multistep-ahead forecasts in the forecast region.

OUT=*SAS-data-set*
specifies a SAS data set to which the forecasts are output. If different OUT= specifications appear in the PROC ARIMA and FORECAST statements, the one in the FORECAST statement is used.

BY Statement

BY *variables* **;**

A BY statement can be used in the ARIMA procedure to process a data set in groups of observations defined by the BY variables. Note that all IDENTIFY, ESTIMATE, and FORECAST statements specified are applied to all BY groups.

Because of the need to make data-based model selections, BY-group processing is not usually done with PROC ARIMA. You usually want to use different models for the different series contained in different BY groups, and the PROC ARIMA BY statement does not let you do this.

Using a BY statement imposes certain restrictions. The BY statement must appear before the first RUN statement. If a BY statement is used, the input data must come from the data set specified in the PROC statement; that is, no input data sets can be specified in IDENTIFY statements.

When a BY statement is used with PROC ARIMA, interactive processing applies only to the first BY group. Once the end of the PROC ARIMA step is reached, all ARIMA statements specified are executed again for each of the remaining BY groups in the input data set.

IDENTIFY Statement

IDENTIFY VAR=*variable* < *options* > **;**

The IDENTIFY statement specifies the time series to be modeled, differences the series if desired, and computes statistics to help identify models to fit. Use an IDENTIFY statement for each time series that you want to model.

If other time series are to be used as inputs in a subsequent ESTIMATE statement, they must be listed in a CROSSCORR= list in the IDENTIFY statement.

You must specify the following argument:

VAR=*variable*

VAR= *variable* **(** *d1, d2, . . . , dk* **)**
names the variable that contains the time series to analyze. The VAR= option is required.

A list of differencing lags can be placed in parentheses after the variable name to request that the series be differenced at these lags. For example, VAR=X(1) takes the first differences of X. VAR=X(1,1) requests that X be differenced twice, both times with lag 1, producing a second difference series, which is $(X_t - X_{t-1}) - (X_{t-1} - X_{t-2}) = X_t - 2X_{t-1} + X_{t-2}$.

VAR=X(2) differences X once at lag two $(X_t - X_{t-2})$.

If differencing is specified, it is the differenced series that is processed by any subsequent ESTIMATE statement.

You can also specify the following *options*.

ALPHA=*significance-level*
specifies the significance level for tests in the IDENTIFY statement. The default is 0.05.

CENTER
centers each time series by subtracting its sample mean. The analysis is done on the centered data. Later, when forecasts are generated, the mean is added back. Note that centering is done after differencing. The CENTER option is normally used in conjunction with the NOCONSTANT option of the ESTIMATE statement.

CLEAR
deletes all old models. This option is useful when you want to delete old models so that the input variables are not prewhitened. (For more information, see the section "Prewhitening" on page 236.)

CROSSCORR=*variable* **(***d11, d12, . . . , d1k* **)**

CROSSCORR= (*variable* **(***d11, d12, . . . , d1k* **)...** *variable* **(***d21, d22, . . . , d2k* **))**
names the variables cross-correlated with the response variable given by the VAR= specification.

Each variable name can be followed by a list of differencing lags in parentheses, the same as for the VAR= specification. If differencing is specified for a variable in the CROSSCORR= list, the differenced series is cross-correlated with the VAR= option series, and the differenced series is used when the ESTIMATE statement INPUT= option refers to the variable.

DATA=*SAS-data-set*

specifies the input SAS data set that contains the time series. If the DATA= option is omitted, the DATA= data set specified in the PROC ARIMA statement is used; if the DATA= option is omitted from the PROC ARIMA statement as well, the most recently created data set is used.

ESACF

computes the extended sample autocorrelation function and uses these estimates to tentatively identify the autoregressive and moving-average orders of mixed models.

The ESACF option generates two tables. The first table displays extended sample autocorrelation estimates, and the second table displays probability values that can be used to test the significance of these estimates. The P=($p_{min} : p_{max}$) and Q=($q_{min} : q_{max}$) options determine the size of the table.

The autoregressive and moving-average orders are tentatively identified by finding a triangular pattern in which all values are insignificant. The ARIMA procedure finds these patterns based on the IDENTIFY statement ALPHA= option and displays possible recommendations for the orders.

The following code generates an ESACF table with dimensions of p = (0:7) and q = (0:8).

```
proc arima data=test;
   identify var=x esacf p=(0:7) q=(0:8);
run;
```

For more information, see the section "The ESACF Method" on page 230.

MINIC

uses information criteria or penalty functions to provide tentative ARMA order identification. The MINIC option generates a table that contains the computed information criterion associated with various ARMA model orders. The PERROR=($p_{\epsilon,min} : p_{\epsilon,max}$) option determines the range of the autoregressive model orders used to estimate the error series. The P=($p_{min} : p_{max}$) and Q=($q_{min} : q_{max}$) options determine the size of the table. The ARMA orders are tentatively identified by those orders that minimize the information criterion.

The following statements generate a MINIC table with default dimensions of p = (0:5) and q = (0:5) and with the error series estimated by an autoregressive model with an order, p_ϵ, that minimizes the AIC in the range from 8 to 11:

```
proc arima data=test;
   identify var=x minic perror=(8:11);
run;
```

For more information, see the section "The MINIC Method" on page 231.

NLAG=*number*

indicates the number of lags to consider in computing the autocorrelations and cross-correlations. To obtain preliminary estimates of an ARIMA(p, d, q) model, the NLAG= value must be at least $p + q + d$. The number of observations must be greater than or equal to the NLAG= value. The default value for NLAG= is 24 or one-fourth the number of observations, whichever is less. Even though the NLAG= value is specified, the NLAG= value can be changed according to the data set.

NOMISS
uses only the first continuous sequence of data with no missing values. By default, all observations are used.

NOPRINT
suppresses the normal printout (including the correlation plots) generated by the IDENTIFY statement.

OUTCOV=*SAS-data-set*
writes the autocovariances, autocorrelations, inverse autocorrelations, partial autocorrelations, and cross covariances to an output SAS data set. If the OUTCOV= option is not specified, no covariance output data set is created. For more information, see the section "OUTCOV= Data Set" on page 252.

P=($p_{min} : p_{max}$**)**
see the ESACF, MINIC, and SCAN options for more information.

PERROR=($p_{\epsilon,min} : p_{\epsilon,max}$**)**
determines the range of the autoregressive model orders used to estimate the error series in MINIC, a tentative ARMA order identification method. For more information, see the section "The MINIC Method" on page 231. By default $p_{\epsilon,min}$ is set to p_{max} and $p_{\epsilon,max}$ is set to $p_{max} + q_{max}$, where p_{max} and q_{max} are the maximum settings of the P= and Q= options in the IDENTIFY statement.

Q=($q_{min} : q_{max}$**)**
see the ESACF, MINIC, and SCAN options for more information.

SCAN
computes estimates of the squared canonical correlations and uses these estimates to tentatively identify the autoregressive and moving-average orders of mixed models.

The SCAN option generates two tables. The first table displays squared canonical correlation estimates, and the second table displays probability values that can be used to test the significance of these estimates. The P=($p_{min} : p_{max}$) and Q=($q_{min} : q_{max}$) options determine the size of each table.

The autoregressive and moving-average orders are tentatively identified by finding a rectangular pattern in which all values are insignificant. The ARIMA procedure finds these patterns based on the IDENTIFY statement ALPHA= option and displays possible recommendations for the orders.

The following code generates a SCAN table with default dimensions of p = (0:5) and q = (0:5). The recommended orders are based on a significance level of 0.1.

```
proc arima data=test;
   identify var=x scan alpha=0.1;
run;
```

For more information, see the section "The SCAN Method" on page 233.

STATIONARITY=
performs stationarity tests. Stationarity tests can be used to determine whether differencing terms should be included in the model specification. In each stationarity test, the autoregressive orders can be specified by a range, *test*= ar_{max}, or as a list of values, *test*= $(ar_1, .., ar_n)$, where *test* is ADF, PP, or RW. The default is (0,1,2).

For more information, see the section "Stationarity Tests" on page 234.

STATIONARITY=(ADF=*AR-orders* **DLAG=***s* **)**

STATIONARITY=(DICKEY=*AR-orders* **DLAG=***s* **)**

performs augmented Dickey-Fuller tests. If the DLAG=*s* option is specified with *s* greater than one, seasonal Dickey-Fuller tests are performed. The maximum allowable value of *s* is 12. The default value of *s* is 1. The following code performs augmented Dickey-Fuller tests with autoregressive orders 2 and 5:

```
proc arima data=test;
   identify var=x stationarity=(adf=(2,5));
run;
```

STATIONARITY=(PP=*AR-orders* **)**

STATIONARITY=(PHILLIPS=*AR-orders* **)**

performs Phillips-Perron tests. The following statements perform augmented Phillips-Perron tests with autoregressive orders ranging from 0 to 6:

```
proc arima data=test;
   identify var=x stationarity=(pp=6);
run;
```

STATIONARITY=(RW=*AR-orders* **)**

STATIONARITY=(RANDOMWALK=*AR-orders* **)**

performs random-walk-with-drift tests. The following statements perform random-walk-with-drift tests with autoregressive orders ranging from 0 to 2:

```
proc arima data=test;
   identify var=x stationarity=(rw);
run;
```

WHITENOISE=ST | IGNOREMISS

specifies the type of test statistic that is used in the white noise test of the series when the series contains missing values. You can specify the following values:

IGNOREMISS uses the standard Ljung-Box test statistic.

ST uses a modification of this statistic suggested by Stoffer and Toloi (1992).

By default, WHITENOISE=ST.

ESTIMATE Statement

< *label:* **>ESTIMATE** *options* **;**

The ESTIMATE statement specifies an ARMA model or transfer function model for the response variable that is specified in the previous IDENTIFY statement, and produces estimates of its parameters. The ESTIMATE statement also prints diagnostic information by which to check the model. The label in the ESTIMATE statement is optional. Include an ESTIMATE statement for each model that you want to estimate.

Options used in the ESTIMATE statement are described in the following sections.

Options for Defining the Model and Controlling Diagnostic Statistics

The following options are used to define the model to be estimated and to control the output that is printed.

ALTPARM
specifies the alternative parameterization of the overall scale of transfer functions in the model. For more information, see the section "Alternative Model Parameterization" on page 243.

INPUT=*variable*

INPUT=(*transfer-function variable* **...)**
specifies input variables and their transfer functions.

The variables in the INPUT= option must be included in the CROSSCORR= list in the previous IDENTIFY statement. If any differencing is specified in the CROSSCORR= list, then the differenced series is used as the input to the transfer function.

The transfer function specification for an input variable is optional. If no transfer function is specified, the input variable enters the model as a simple regressor. If specified, the transfer function specification has the following syntax:

$$S\$(L_{1,1}, L_{1,2}, \ldots)(L_{2,1}, \ldots)\ldots/(L_{j,1}, \ldots)\ldots$$

Here, S is a shift or lag of the input variable, the terms before the slash (/) are numerator factors, and the terms after the slash (/) are denominator factors of the transfer function. All three parts are optional. For more information, see the section "Specifying Inputs and Transfer Functions" on page 242.

METHOD=CLS | ML | ULS
specifies the estimation method to use. You can specify the following values:

CLS	specifies the conditional least squares method.
ML	specifies the maximum likelihood method.
ULS	specifies the unconditional least squares method.

For more information, see the section "Estimation Details" on page 238. By default, METHOD=CLS.

NOCONSTANT

NOINT

suppresses the fitting of a constant (or intercept) parameter in the model. (That is, the parameter μ is omitted.)

NODF

estimates the variance by dividing the error sum of squares (SSE) by the number of residuals. The default is to divide the SSE by the number of residuals minus the number of free parameters in the model.

NOPRINT

suppresses the normal printout generated by the ESTIMATE statement. If the NOPRINT option is specified for the ESTIMATE statement, then any error and warning messages are printed to the SAS log.

P=*order*

P=*(lag, . . . , lag) . . . (lag, . . . , lag)*

specifies the autoregressive part of the model. By default, no autoregressive parameters are fit.

P=($l_1, l_2, \ldots, l_k$) defines a model with autoregressive parameters at the specified lags. P=*order* is equivalent to P=(1, 2, . . . , *order*).

A concatenation of parenthesized lists specifies a factored model. For example, P=(1,2,5)(6,12) specifies the autoregressive model

$$(1 - \phi_{1,1}B - \phi_{1,2}B^2 - \phi_{1,3}B^5)(1 - \phi_{2,1}B^6 - \phi_{2,2}B^{12})$$

PLOT

plots the residual autocorrelation functions. The sample autocorrelation, the sample inverse autocorrelation, and the sample partial autocorrelation functions of the model residuals are plotted.

Q=*order*

Q=*(lag, . . . , lag) . . . (lag, . . . , lag)*

specifies the moving-average part of the model. By default, no moving-average part is included in the model.

Q=($l_1, l_2, \ldots, l_k$) defines a model with moving-average parameters at the specified lags. Q=*order* is equivalent to Q=(1, 2, . . . , *order*). A concatenation of parenthesized lists specifies a factored model. The interpretation of factors and lags is the same as for the P= option.

WHITENOISE=ST | IGNOREMISS

specifies the type of test statistic that is used in the white noise test of the series when the series contains missing values. You can specify the following values:

IGNOREMISS	uses the standard Ljung-Box test statistic.
ST	uses a modification of this statistic suggested by Stoffer and Toloi (1992).

By default, WHITENOISE=ST.

Options for Output Data Sets

The following options are used to store results in SAS data sets:

OUTEST=*SAS-data-set*
writes the parameter estimates to an output data set. If the OUTCORR or OUTCOV option is used, the correlations or covariances of the estimates are also written to the OUTEST= data set. For a description of the OUTEST= output data set, see the section "OUTEST= Data Set" on page 253.

OUTCORR
writes the correlations of the parameter estimates to the OUTEST= data set.

OUTCOV
writes the covariances of the parameter estimates to the OUTEST= data set.

OUTMODEL=*SAS-data-set*
writes the model and parameter estimates to an output data set. If OUTMODEL= is not specified, no model output data set is created. For a description of the OUTMODEL= output data set, see the section "OUTMODEL= SAS Data Set" on page 256.

OUTSTAT=*SAS-data-set*
writes the model diagnostic statistics to an output data set. If OUTSTAT= is not specified, no statistics output data set is created. For a description of the OUTSTAT= output data set, see the section "OUTSTAT= Data Set" on page 257.

Options to Specify Parameter Values

The following options enable you to specify values for the model parameters. These options can provide starting values for the estimation process, or you can specify fixed parameters for use in the FORECAST stage and suppress the estimation process with the NOEST option. By default, the ARIMA procedure finds initial parameter estimates and uses these estimates as starting values in the iterative estimation process.

If values for any parameters are specified, values for all parameters should be given. The number of values given must agree with the model specifications.

AR=*value* **. . .**
lists starting values for the autoregressive parameters. For more information, see the section "Initial Values" on page 244.

INITVAL=(*initializer-spec variable* **. . .)**
specifies starting values for the parameters in the transfer function parts of the model. For more information, see the section "Initial Values" on page 244.

MA=*value* **. . .**
lists starting values for the moving-average parameters. For more information, see the section "Initial Values" on page 244.

MU=*value*
specifies the MU parameter.

NOEST
uses the values specified with the AR=, MA=, INITVAL=, and MU= options as final parameter values. The estimation process is suppressed except for estimation of the residual variance. The specified parameter values are used directly by the next FORECAST statement. When NOEST is specified, standard errors, *t* values, and the correlations between estimates are displayed as 0 or missing. (The NOEST option is useful, for example, when you want to generate forecasts that correspond to a published model.)

Options to Control the Iterative Estimation Process

The following options can be used to control the iterative process of minimizing the error sum of squares or maximizing the log-likelihood function. These tuning options are not usually needed but can be useful if convergence problems arise.

BACKLIM=–*n*
omits the specified number of initial residuals from the sum of squares or likelihood function. Omitting values can be useful for suppressing transients in transfer function models that are sensitive to start-up values.

CONVERGE=*value*
specifies the convergence criterion. Convergence is assumed when the largest change in the estimate for any parameter is less that the CONVERGE= option value. If the absolute value of the parameter estimate is greater than 0.01, the relative change is used; otherwise, the absolute change in the estimate is used. The default is CONVERGE=0.001.

DELTA=*value*
specifies the perturbation value for computing numerical derivatives. The default is DELTA=0.001.

GRID
prints the error sum of squares (SSE) or concentrated log-likelihood surface in a small grid of the parameter space around the final estimates. For each pair of parameters, the SSE is printed for the nine parameter-value combinations formed by the grid, with a center at the final estimates and with spacing given by the GRIDVAL= specification. The GRID option can help you judge whether the estimates are truly at the optimum, since the estimation process does not always converge. For models with a large number of parameters, the GRID option produces voluminous output.

GRIDVAL=*number*
controls the spacing in the grid printed by the GRID option. The default is GRIDVAL=0.005.

MAXITER=*n*

MAXIT=*n*
specifies the maximum number of iterations allowed. The default is MAXITER=50.

NOLS
begins the maximum likelihood or unconditional least squares iterations from the preliminary estimates rather than from the conditional least squares estimates that are produced after four iterations. For more information, see the section "Estimation Details" on page 238.

NOSTABLE
specifies that the autoregressive and moving-average parameter estimates for the noise part of the model not be restricted to the stationary and invertible regions, respectively. For more information, see the section "Stationarity and Invertibility" on page 245.

PRINTALL
prints preliminary estimation results and the iterations in the final estimation process.

NOTFSTABLE
specifies that the parameter estimates for the denominator polynomial of the transfer function part of the model not be restricted to the stability region. For more information, see the section "Stationarity and Invertibility" on page 245.

SINGULAR=*value*
specifies the criterion for checking singularity. If a pivot of a sweep operation is less than the SINGULAR= value, the matrix is deemed singular. Sweep operations are performed on the Jacobian matrix during final estimation and on the covariance matrix when preliminary estimates are obtained. The default is SINGULAR=1E–7.

OUTLIER Statement

OUTLIER *options* **;**

The OUTLIER statement can be used to detect shifts in the level of the response series that are not accounted for by the previously estimated model. An ESTIMATE statement must precede the OUTLIER statement. The following options are used in the OUTLIER statement:

TYPE=ADDITIVE

TYPE=SHIFT

TYPE=TEMP ($d_1, \ldots, d_k$ **)**

TYPE=(< ADDITIVE > < SHIFT >) < TEMP ($d_1, \ldots, d_k$ **) >**
specifies the types of level shifts to search for. The default is TYPE=(ADDITIVE SHIFT), which requests searching for additive outliers and permanent level shifts. The option TEMP($d_1, \ldots, d_k$) requests searching for temporary changes in the level of durations $d_1, \ldots, d_k$. These options can also be abbreviated as AO, LS, and TC.

ALPHA=*significance-level*
specifies the significance level for tests in the OUTLIER statement. The default is 0.05.

SIGMA=ROBUST | MSE
specifies the type of error variance estimate to use in the statistical tests performed during the outlier detection. SIGMA=MSE corresponds to the usual mean squared error (MSE) estimate, and SIGMA=ROBUST corresponds to a robust estimate of the error variance. The default is SIGMA=ROBUST.

MAXNUM=*number*
limits the number of outliers to search. The default is MAXNUM=5.

MAXPCT=*number*
limits the number of outliers to search for according to a percentage of the series length. The default is MAXPCT=2. When both the MAXNUM= and MAXPCT= options are specified, the minimum of the two search numbers is used.

ID=*date-time-ID-variable*
specifies a SAS date, time, or datetime identification variable to label the detected outliers. This variable must be present in the input data set.

The following examples illustrate a few possibilities for the OUTLIER statement.

The most basic usage, shown as follows, sets all the options to their default values:

```
outlier;
```

That is, it is equivalent to

```
outlier type=(ao ls) alpha=0.05 sigma=robust maxnum=5 maxpct=2;
```

The following statement requests a search for permanent level shifts and for temporary level changes of durations 6 and 12. The search is limited to at most three changes and the significance level of the underlying tests is 0.001. MSE is used as the estimate of error variance. It also requests labeling of the detected shifts using an ID variable *date*.

```
outlier type=(ls tc(6 12)) alpha=0.001 sigma=mse maxnum=3 ID=date;
```

FORECAST Statement

FORECAST *options* **;**

The FORECAST statement generates forecast values for a time series by using the parameter estimates produced by the previous ESTIMATE statement. For more information about calculating forecasts, see the section "Forecasting Details" on page 246.

The following options can be used in the FORECAST statement:

ALIGN=*option*
controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. BEGINNING is the default.

ALPHA=*n*

sets the size of the forecast confidence limits. The ALPHA= value must be between 0 and 1. When you specify ALPHA=α, the upper and lower confidence limits have a $1-\alpha$ confidence level. The default is ALPHA=0.05, which produces 95% confidence intervals. ALPHA values are rounded to the nearest hundredth.

BACK=*n*

specifies the number of observations before the end of the data where the multistep forecasts are to begin. The BACK= option value must be less than or equal to the number of observations minus the number of parameters.

The default is BACK=0, which means that the forecast starts at the end of the available data. The end of the data is the last observation for which a noise value can be calculated. If there are no input series, the end of the data is the last nonmissing value of the response time series. If there are input series, this observation can precede the last nonmissing value of the response variable, since there may be missing values for some of the input series.

ID=*variable*

names a variable in the input data set that identifies the time periods associated with the observations. The ID= variable is used in conjunction with the INTERVAL= option to extrapolate ID values from the end of the input data to identify forecast periods in the OUT= data set.

If the INTERVAL= option specifies an interval type, the ID variable must be a SAS date or datetime variable with the spacing between observations indicated by the INTERVAL= value. If the INTERVAL= option is not used, the last input value of the ID= variable is incremented by one for each forecast period to extrapolate the ID values for forecast observations.

INTERVAL=*interval*

INTERVAL=*n*

specifies the time interval between observations. For information about valid INTERVAL= values, see Chapter 4, "Date Intervals, Formats, and Functions."

The value of the INTERVAL= option is used by PROC ARIMA to extrapolate the ID values for forecast observations and to check that the input data are in order with no missing periods. For more information, see the section "Specifying Series Periodicity" on page 248.

LEAD=*n*

specifies the number of multistep forecast values to compute. For example, if LEAD=10, PROC ARIMA forecasts for ten periods beginning with the end of the input series (or earlier if BACK= is specified). It is possible to obtain fewer than the requested number of forecasts if a transfer function model is specified and insufficient data are available to compute the forecast. The default is LEAD=24.

NOOUTALL

includes only the final forecast observations in the OUT= output data set, not the one-step forecasts for the data before the forecast period.

NOPRINT
suppresses the normal printout of the forecast and associated values.

OUT=*SAS-data-set*
writes the forecast (and other values) to an output data set. If OUT= is not specified, the OUT= data set specified in the PROC ARIMA statement is used. If OUT= is also not specified in the PROC ARIMA statement, no output data set is created. For more information, see the section "OUT= Data Set" on page 251.

PRINTALL
prints the FORECAST computation throughout the whole data set. The forecast values for the data before the forecast period (specified by the BACK= option) are one-step forecasts.

SIGSQ=*value*
specifies the variance term used in the formula for computing forecast standard errors and confidence limits. The default value is the variance estimate computed by the preceding ESTIMATE statement. This option is useful when you wish to generate forecast standard errors and confidence limits based on a published model. It would often be used in conjunction with the NOEST option in the preceding ESTIMATE statement.

Details: ARIMA Procedure

The Inverse Autocorrelation Function

The sample inverse autocorrelation function (SIACF) plays much the same role in ARIMA modeling as the sample partial autocorrelation function (SPACF), but it generally indicates subset and seasonal autoregressive models better than the SPACF.

Additionally, the SIACF can be useful for detecting over-differencing. If the data come from a nonstationary or nearly nonstationary model, the SIACF has the characteristics of a noninvertible moving-average. Likewise, if the data come from a model with a noninvertible moving average, then the SIACF has nonstationary characteristics and therefore decays slowly. In particular, if the data have been over-differenced, the SIACF looks like a SACF from a nonstationary process.

The inverse autocorrelation function is not often discussed in textbooks, so a brief description is given here. For more complete discussions, see Cleveland (1972); Chatfield (1980); Priestley (1981).

Let W_t be generated by the ARMA(p, q) process

$$\phi(B)W_t = \theta(B)a_t$$

where a_t is a white noise sequence. If $\theta(B)$ is invertible (that is, if θ considered as a polynomial in B has no roots less than or equal to 1 in magnitude), then the model

$$\theta(B)Z_t = \phi(B)a_t$$

is also a valid ARMA(q,p) model. This model is sometimes referred to as the dual model. The autocorrelation function (ACF) of this dual model is called the inverse autocorrelation function (IACF) of the original model.

Notice that if the original model is a pure autoregressive model, then the IACF is an ACF that corresponds to a pure moving-average model. Thus, it cuts off sharply when the lag is greater than p; this behavior is similar to the behavior of the partial autocorrelation function (PACF).

The sample inverse autocorrelation function (SIACF) is estimated in the ARIMA procedure by the following steps. A high-order autoregressive model is fit to the data by means of the Yule-Walker equations. The order of the autoregressive model used to calculate the SIACF is the minimum of the NLAG= value and one-half the number of observations after differencing. The SIACF is then calculated as the autocorrelation function that corresponds to this autoregressive operator when treated as a moving-average operator. That is, the autoregressive coefficients are convolved with themselves and treated as autocovariances.

Under certain conditions, the sampling distribution of the SIACF can be approximated by the sampling distribution of the SACF of the dual model (Bhansali 1980). In the plots generated by ARIMA, the confidence limit marks (.) are located at $\pm 2/\sqrt{n}$. These limits bound an approximate 95% confidence interval for the hypothesis that the data are from a white noise process.

The Partial Autocorrelation Function

The approximation for a standard error for the estimated partial autocorrelation function at lag k is based on a null hypothesis that a pure autoregressive Gaussian process of order $k-1$ generated the time series. This standard error is $1/\sqrt{n}$ and is used to produce the approximate 95% confidence intervals depicted by the dots in the plot.

The Cross-Correlation Function

The autocorrelation and partial and inverse autocorrelation functions described in the preceding sections help when you want to model a series as a function of its past values and past random errors. When you want to include the effects of past and current values of other series in the model, the correlations of the response series and the other series must be considered.

The CROSSCORR= option in the IDENTIFY statement computes cross-correlations of the VAR= series with other series and makes these series available for use as inputs in models specified by later ESTIMATE statements.

When the CROSSCORR= option is used, PROC ARIMA prints a plot of the cross-correlation function for each variable in the CROSSCORR= list. This plot is similar in format to the other correlation plots, but it shows the correlation between the two series at both lags and leads. For example,

```
identify var=y crosscorr=x ...;
```

plots the cross-correlation function of Y and X, $\mathrm{Cor}(y_t, x_{t-s})$, for $s = -L$ to L, where L is the value of the NLAG= option. Study of the cross-correlation functions can indicate the transfer functions through which the input series should enter the model for the response series.

The cross-correlation function is computed after any specified differencing has been done. If differencing is specified for the VAR= variable or for a variable in the CROSSCORR= list, it is the differenced series that is cross-correlated (and the differenced series is processed by any following ESTIMATE statement).

For example,

```
identify var=y(1) crosscorr=x(1);
```

computes the cross-correlations of the changes in Y with the changes in X. When differencing is specified, the subsequent ESTIMATE statement models changes in the variables rather than the variables themselves.

The ESACF Method

The extended sample autocorrelation function (ESACF) method can tentatively identify the orders of a *stationary or nonstationary* ARMA process based on iterated least squares estimates of the autoregressive parameters. Tsay and Tiao (1984) proposed the technique, and Choi (1992) provides useful descriptions of the algorithm.

Given a stationary or nonstationary time series $\{z_t : 1 \leq t \leq n\}$ with mean corrected form $\tilde{z}_t = z_t - \mu_z$ with a true autoregressive order of $p + d$ and with a true moving-average order of q, you can use the ESACF method to estimate the unknown orders $p + d$ and q by analyzing the autocorrelation functions associated with filtered series of the form

$$w_t^{(m,j)} = \hat{\Phi}_{(m,j)}(B)\tilde{z}_t = \tilde{z}_t - \sum_{i=1}^{m} \hat{\phi}_i^{(m,j)} \tilde{z}_{t-i}$$

where B represents the backshift operator, where $m = p_{min}, \ldots, p_{max}$ are the autoregressive *test* orders, where $j = q_{min} + 1, \ldots, q_{max} + 1$ are the moving-average *test* orders, and where $\hat{\phi}_i^{(m,j)}$ are the autoregressive parameter estimates under the assumption that the series is an ARMA(m, j) process.

For purely autoregressive models ($j = 0$), ordinary least squares (OLS) is used to consistently estimate $\hat{\phi}_i^{(m,0)}$. For ARMA models, consistent estimates are obtained by the iterated least squares recursion formula, which is initiated by the pure autoregressive estimates:

$$\hat{\phi}_i^{(m,j)} = \hat{\phi}_i^{(m+1,j-1)} - \hat{\phi}_{i-1}^{(m,j-1)} \frac{\hat{\phi}_{m+1}^{(m+1,j-1)}}{\hat{\phi}_m^{(m,j-1)}}$$

The jth lag of the sample autocorrelation function of the filtered series $w_t^{(m,j)}$ is the *extended sample autocorrelation function*, and it is denoted as $r_{j(m)} = r_j(w^{(m,j)})$.

The standard errors of $r_{j(m)}$ are computed in the usual way by using Bartlett's approximation of the variance of the sample autocorrelation function, $var(r_{j(m)}) \approx (1 + \sum_{t=1}^{j-1} r_j^2(w^{(m,j)}))$.

If the true model is an ARMA $(p + d, q)$ process, the filtered series $w_t^{(m,j)}$ follows an MA(q) model for $j \geq q$ so that

$$r_{j(p+d)} \approx 0 \quad j > q$$

$$r_{j(p+d)} \neq 0 \quad j = q$$

Additionally, Tsay and Tiao (1984) show that the extended sample autocorrelation satisfies

$$r_{j(m)} \approx 0 \quad j - q > m - p - d \leq 0$$

$$r_{j(m)} \neq c(m - p - d, j - q) \quad 0 \leq j - q \leq m - p - d$$

where $c(m-p-d, j-q)$ is a nonzero constant or a continuous random variable bounded by –1 and 1.

An ESACF table is then constructed by using the $r_{j(m)}$ for $m = p_{min}, \ldots, p_{max}$ and $j = q_{min}+1, \ldots, q_{max}+1$ to identify the ARMA orders (see Table 7.4). The orders are tentatively identified by finding a right (maximal) triangular pattern with vertices located at $(p+d, q)$ and $(p+d, q_{max})$ and in which all elements are insignificant (based on asymptotic normality of the autocorrelation function). The vertex $(p+d, q)$ identifies the order. Table 7.5 depicts the theoretical pattern associated with an ARMA(1,2) series.

The MINIC Method

The minimum information criterion (MINIC) method can tentatively identify the order of a *stationary and invertible* ARMA process. Note that Hannan and Rissanen (1982) proposed this method; for useful descriptions of the algorithm, see Box, Jenkins, and Reinsel (1994); Choi (1992).

Given a stationary and invertible time series $\{z_t : 1 \le t \le n\}$ with mean corrected form $\tilde{z}_t = z_t - \mu_z$ with a true autoregressive order of p and with a true moving-average order of q, you can use the MINIC method to compute information criteria (or penalty functions) for various autoregressive and moving average orders. The following paragraphs provide a brief description of the algorithm.

If the series is a stationary and invertible ARMA(p, q) process of the form

$$\Phi_{(p,q)}(B)\tilde{z}_t = \Theta_{(p,q)}(B)\epsilon_t$$

the error series can be approximated by a high-order AR process

$$\hat{\epsilon}_t = \hat{\Phi}_{(p_\epsilon,q)}(B)\tilde{z}_t \approx \epsilon_t$$

where the parameter estimates $\hat{\Phi}_{(p_\epsilon,q)}$ are obtained from the Yule-Walker estimates. The choice of the autoregressive order p_ϵ is determined by the order that minimizes Akaike's information criterion (AIC) in the range $p_{\epsilon,min} \le p_\epsilon \le p_{\epsilon,max}$,

$$\mathrm{AIC}(p_\epsilon, 0) = \ln(\tilde{\sigma}^2_{(p_\epsilon,0)}) + 2(p_\epsilon + 0)/n$$

where

$$\tilde{\sigma}^2_{(p_\epsilon,0)} = \frac{1}{n}\sum_{t=p_\epsilon+1}^{n} \hat{\epsilon}_t^2$$

Note that Hannan and Rissanen (1982) use the Bayesian information criterion (BIC) to determine the autoregressive order used to estimate the error series while others recommend the AIC (Box, Jenkins, and Reinsel 1994; Choi 1992).

Once the error series has been estimated for autoregressive test order $m = p_{min}, \ldots, p_{max}$ and for moving-average test order $j = q_{min}, \ldots, q_{max}$, the OLS estimates $\hat{\Phi}_{(m,j)}$ and $\hat{\Theta}_{(m,j)}$ are computed from the regression model

$$\tilde{z}_t = \sum_{i=1}^{m} \phi_i^{(m,j)} \tilde{z}_{t-i} + \sum_{k=1}^{j} \theta_k^{(m,j)} \hat{\epsilon}_{t-k} + error$$

From the preceding parameter estimates, the BIC is then computed

$$\mathrm{BIC}(m, j) = \ln(\tilde{\sigma}^2_{(m,j)}) + 2(m + j)\ln(n)/n$$

where

$$\tilde{\sigma}^2_{(m,j)} = \frac{1}{n}\sum_{t=t_0}^{n} \left(\tilde{z}_t - \sum_{i=1}^{m} \phi_i^{(m,j)} \tilde{z}_{t-i} + \sum_{k=1}^{j} \theta_k^{(m,j)} \hat{\epsilon}_{t-k} \right)$$

where $t_0 = p_\epsilon + \max(m, j)$.

A MINIC table is then constructed using $\mathrm{BIC}(m, j)$; see Table 7.6. If $p_{max} > p_{\epsilon,min}$, the preceding regression might fail due to linear dependence on the estimated error series and the mean-corrected series. Values of $\mathrm{BIC}(m, j)$ that cannot be computed are set to missing. For large autoregressive and moving-average test orders with relatively few observations, a nearly perfect fit can result. This condition can be identified by a large negative $\mathrm{BIC}(m, j)$ value.

The SCAN Method

The smallest canonical (SCAN) correlation method can tentatively identify the orders of a *stationary or nonstationary* ARMA process. Tsay and Tiao (1985) proposed the technique, and for useful descriptions of the algorithm, see Box, Jenkins, and Reinsel (1994); Choi (1992).

Given a stationary or nonstationary time series $\{z_t : 1 \leq t \leq n\}$ with mean corrected form $\tilde{z}_t = z_t - \mu_z$ with a true autoregressive order of $p + d$ and with a true moving-average order of q, you can use the SCAN method to analyze eigenvalues of the correlation matrix of the ARMA process. The following paragraphs provide a brief description of the algorithm.

For autoregressive test order $m = p_{min}, \ldots, p_{max}$ and for moving-average test order $j = q_{min}, \ldots, q_{max}$, perform the following steps:

1. Let $Y_{m,t} = (\tilde{z}_t, \tilde{z}_{t-1}, \ldots, \tilde{z}_{t-m})'$. Compute the following $(m+1) \times (m+1)$ matrix,

$$\begin{aligned}
\hat{\beta}(m, j+1) &= \left(\sum_t Y_{m,t-j-1} Y'_{m,t-j-1} \right)^{-1} \left(\sum_t Y_{m,t-j-1} Y'_{m,t} \right) \\
\hat{\beta}^*(m, j+1) &= \left(\sum_t Y_{m,t} Y'_{m,t} \right)^{-1} \left(\sum_t Y_{m,t} Y'_{m,t-j-1} \right) \\
\hat{A}^*(m, j) &= \hat{\beta}^*(m, j+1) \hat{\beta}(m, j+1)
\end{aligned}$$

   where t ranges from $j + m + 2$ to n.

2. Find the *smallest* eigenvalue, $\hat{\lambda}^*(m, j)$, of $\hat{A}^*(m, j)$ and its corresponding *normalized* eigenvector, $\Phi_{m,j} = (1, -\phi_1^{(m,j)}, -\phi_2^{(m,j)}, \ldots, -\phi_m^{(m,j)})$. The squared canonical correlation estimate is $\hat{\lambda}^*(m, j)$.

3. Using the $\Phi_{m,j}$ as AR(m) coefficients, obtain the residuals for $t = j + m + 1$ to n, by following the formula: $w_t^{(m,j)} = \tilde{z}_t - \phi_1^{(m,j)} \tilde{z}_{t-1} - \phi_2^{(m,j)} \tilde{z}_{t-2} - \cdots - \phi_m^{(m,j)} \tilde{z}_{t-m}$.

4. From the sample autocorrelations of the residuals, $r_k(w)$, approximate the standard error of the squared canonical correlation estimate by

$$var(\hat{\lambda}^*(m, j)^{1/2}) \approx d(m, j)/(n - m - j)$$

   where $d(m, j) = (1 + 2 \sum_{i=1}^{j-1} r_k(w^{(m,j)}))$.

The test statistic to be used as an identification criterion is

$$c(m, j) = -(n - m - j) \ln(1 - \hat{\lambda}^*(m, j)/d(m, j))$$

which is asymptotically χ_1^2 if $m = p + d$ and $j \geq q$ or if $m \geq p + d$ and $j = q$. For $m > p$ and $j < q$, there is more than one theoretical zero canonical correlation between $Y_{m,t}$ and $Y_{m,t-j-1}$. Since the $\hat{\lambda}^*(m, j)$ are the smallest canonical correlations for each (m, j), the percentiles of $c(m, j)$ are less than those of a χ_1^2; therefore, Tsay and Tiao (1985) state that it is safe to assume a χ_1^2. For $m < p$ and $j < q$, no conclusions about the distribution of $c(m, j)$ are made.

A SCAN table is then constructed using $c(m, j)$ to determine which of the $\hat{\lambda}^*(m, j)$ are significantly different from zero (see Table 7.7). The ARMA orders are tentatively identified by finding a (maximal) rectangular pattern in which the $\hat{\lambda}^*(m, j)$ are insignificant for all test orders $m \geq p + d$ and $j \geq q$. There might be more than one pair of values $(p + d, q)$ that permit such a rectangular pattern. In this case, parsimony and the number of insignificant items in the rectangular pattern should help determine the model order. Table 7.8 depicts the theoretical pattern associated with an ARMA(2,2) series.

Stationarity Tests

When a time series has a unit root, the series is nonstationary and the ordinary least squares (OLS) estimator is not normally distributed. Dickey and Fuller studied the limiting distribution of the OLS estimator of autoregressive models for time series that have a simple unit root (Dickey 1976; Dickey and Fuller 1979). Dickey, Hasza, and Fuller (1984) obtained the limiting distribution for time series that have seasonal unit roots. Hamilton (1994) discusses the various types of unit root testing.

The augmented Dickey-Fuller (ADF) test (Dickey and Fuller 1979) and the Phillips-Perron (PP) test (Phillips and Perron 1988) are usually used to test stationarity. Both tests can be used to test three types of data generation models: when the series is zero-mean stationary (zero mean), nonzero-mean stationary (single mean), and linear time trend stationary (trend). The following sections discuss these three models of order $p + 1$.

Zero Mean

A zero-mean, stationary autoregressive process of order $p+1$, AR($p+1$), can be described as follows:

$$y_t = \alpha_1 y_{t-1} + \alpha_2 y_{t-2} + \cdots + \alpha_{p+1} y_{t-p-1} + e_t$$

It could also be written as

$$\nabla y_t = \delta y_{t-1} + \theta_1 \nabla y_{t-1} + \cdots + \theta_p \nabla y_{t-p} + e_t$$

where $\nabla y_t = y_t - y_{t-1}$, $\delta = \alpha_1 + \cdots + \alpha_{p+1} - 1$, and $\theta_k = -\alpha_{k+1} - \cdots - \alpha_{p+1}$.

In this alternate form, y_t is difference stationary if $\delta = 0$. The zero-mean form of the ADF and PP tests is useful for testing whether y_t is difference stationary (null) or zero-mean stationary (alternative).

Single Mean

A stationary autoregressive process of order $p+1$, AR($p+1$), with mean μ can be described as follows:

$$y_t - \mu = \alpha_1(y_{t-1} - \mu) + \alpha_2(y_{t-2} - \mu) + \cdots + \alpha_{p+1}(y_{t-p-1} - \mu) + e_t$$

It could also be written as

$$\nabla y_t = -\delta\mu + \delta y_{t-1} + \theta_1 \nabla y_{t-1} + \cdots + \theta_p \nabla y_{t-p} + e_t$$

In this alternate form, y_t is difference stationary if $\delta = 0$. The single-mean form of the ADF and PP tests is useful for testing whether y_t is difference stationary (null) or nonzero-mean stationary (alternative).

Trend

A stationary autoregressive process of order $p+1$, AR($p+1$), with linear time trend $\mu + \beta t$ can be described as follows:

$$y_t - \mu - \beta t = \alpha_1(y_{t-1} - \mu - \beta(t-1)) + \alpha_2(y_{t-2} - \mu - \beta(t-2)) + \cdots + \alpha_{p+1}(y_{t-p-1} - \mu - \beta(t-p-1)) + e_t$$

It could also be written as

$$\nabla y_t = -\delta\mu - \delta\beta t + \nu\beta + \delta y_{t-1} + \theta_1 \nabla y_{t-1} + \cdots + \theta_p \nabla y_{t-p} + e_t$$

where $\nu = \alpha_1 + 2\alpha_2 + \cdots + (p+1)\alpha_{p+1}$.

In this alternate form, y_t is difference stationary (with nonzero mean) if $\delta = 0$. The trend form of the ADF and PP tests is useful for testing whether y_t is difference stationary with nonzero mean (null) or trend stationary (alternative).

When there is a unit root (that is, the series is nonstationary), the sum of the autoregressive parameters is 1 and hence $\delta = 0$. The ADF tests and the PP tests both build on δ. There are three kinds of tests under the ADF tests: rho (ρ) test, tau (τ) test, and F test. The rho test is the regression coefficient test, which is also called the normalized bias test. The tau test is the studentized test. The F test is a joint test for unit root. For more information about test statistics under the ADF tests, see Dickey (2005), the section "Stationarity Tests" on page 234, and Hamilton (1994). There are two kinds of test statistics under the PP tests: rho test and tau test statistics. For more information about test statistics under the PP tests, see Chapter 8, "The AUTOREG Procedure." The following table presents null hypotheses and decision rules for the three test statistics under the three different model types:

	Rho Test		Tau Test		F Test	
Types	H_0	p-value	H_0	p-value	H_0	p-value
Zero mean	$\delta = 0$	Stationary if low	$\delta = 0$	Stationary if low	N/A	N/A
Single mean	$\delta = 0$	Stationary if low	$\delta = 0$	Stationary if low	$\delta = \alpha_0 = 0$	Stationary if low
Trend	$\delta = 0$	Stationary if low	$\delta = 0$	Stationary if low	$\delta = \gamma = 0$	Stationary if low

In this table, α_0 is the intercept in the test regression for the single-mean model,

$$\nabla y_t = \alpha_0 + \delta y_{t-1} + \theta_1 \nabla y_{t-1} + \cdots + \theta_p \nabla y_{t-p} + e_t$$

and γ is the parameter of t in the test regression for the trend model,

$$\nabla y_t = \alpha_0 + \gamma t + \delta y_{t-1} + \theta_1 \nabla y_{t-1} + \cdots + \theta_p \nabla y_{t-p} + e_t$$

As shown in the regression for single-mean model, when $\delta = 0$ (that is, there is a unit root), the intercept $\alpha_0 = -\delta\mu = 0$. The F test with a joint hypothesis of zero intercept and zero slope can therefore be used as a unit root test for the single-mean model. The F test for the trend model follows a similar logic. When $\delta = 0$, $\gamma = -\delta\beta = 0$. The F statistic for the trend model therefore tests the joint null hypothesis: $\delta = \gamma = 0$. When you are testing for unit root, the tau (τ) test is more powerful than the F test.

For a more detailed description of the Dickey-Fuller tests, see the section "PROBDF Function for Dickey-Fuller Tests" on page 154 in Chapter 5. For a description of Phillips-Perron tests, see Chapter 8, "The AUTOREG Procedure." The random-walk-with-drift test suggests whether or not an integrated times series has a drift term. Hamilton (1994) discusses this test.

Prewhitening

If, as is usually the case, an input series is autocorrelated, the direct cross-correlation function between the input and response series gives a misleading indication of the relation between the input and response series.

One solution to this problem is called *prewhitening*. You first fit an ARIMA model for the input series sufficient to reduce the residuals to white noise; then, filter the input series with this model to get the white noise residual series. You then filter the response series with the same model and cross-correlate the filtered response with the filtered input series.

The ARIMA procedure performs this prewhitening process automatically when you precede the IDENTIFY statement for the response series with IDENTIFY and ESTIMATE statements to fit a model for the input series. If a model with no inputs was previously fit to a variable specified by the CROSSCORR= option, then that model is used to prewhiten both the input series and the response series before the cross-correlations are computed for the input series.

For example:

```
proc arima data=in;
   identify var=x;
   estimate p=1 q=1;
   identify var=y crosscorr=x;
run;
```

Both X and Y are filtered by the ARMA(1,1) model fit to X before the cross-correlations are computed.

Note that prewhitening is done to estimate the cross-correlation function; the unfiltered series are used in any subsequent ESTIMATE or FORECAST statements, and the correlation functions of Y with its own lags are computed from the unfiltered Y series. But initial values in the ESTIMATE statement are obtained with prewhitened data; therefore, the result with prewhitening can be different from the result without prewhitening.

To suppress prewhitening for all input variables, use the CLEAR option in the IDENTIFY statement to make PROC ARIMA disregard all previous models.

Prewhitening and Differencing

If the VAR= and CROSSCORR= options specify differencing, the series are differenced before the prewhitening filter is applied. When the differencing lists specified in the VAR= option for an input and in the CROSSCORR= option for that input are not the same, PROC ARIMA combines the two lists so that the differencing operators used for prewhitening include all differences in either list (in the least common multiple sense).

Identifying Transfer Function Models

When identifying a transfer function model with multiple input variables, the cross-correlation functions can be misleading if the input series are correlated with each other. Any dependencies among two or more input series will confound their cross-correlations with the response series.

The prewhitening technique assumes that the input variables do not depend on past values of the response variable. If there is feedback from the response variable to an input variable, as evidenced by significant cross-correlation at negative lags, both the input and the response variables need to be prewhitened before meaningful cross-correlations can be computed.

PROC ARIMA cannot handle feedback models. The STATESPACE and VARMAX procedures are more appropriate for models with feedback.

Missing Values and Autocorrelations

To compute the sample autocorrelation function when missing values are present, PROC ARIMA uses only crossproducts that do not involve missing values and employs divisors that reflect the number of crossproducts used rather than the total length of the series. Sample partial autocorrelations and inverse autocorrelations are then computed by using the sample autocorrelation function. If necessary, a taper is employed to transform the sample autocorrelations into a positive definite sequence before calculating the partial autocorrelation and inverse correlation functions. The confidence intervals produced for these functions might not be valid when there are missing values. The distributional properties for sample correlation functions are not clear for finite samples. For some asymptotic properties of the sample correlation functions, see Dunsmuir (1984).

Estimation Details

The ARIMA procedure primarily uses the computational methods outlined by Box and Jenkins. Marquardt's method is used for the nonlinear least squares iterations. Numerical approximations of the derivatives of the sum-of-squares function are taken by using a fixed delta (controlled by the DELTA= option).

The methods do not always converge successfully for a given set of data, particularly if the starting values for the parameters are not close to the least squares estimates.

Back-Forecasting

The unconditional sum of squares is computed exactly; thus, back-forecasting is not performed. Early versions of SAS/ETS software used the back-forecasting approximation and allowed a positive value of the BACKLIM= option to control the extent of the back-forecasting. In the current version, requesting a positive number of back-forecasting steps with the BACKLIM= option has no effect.

Preliminary Estimation

If an autoregressive or moving-average operator is specified with no missing lags, preliminary estimates of the parameters are computed by using the autocorrelations computed in the IDENTIFY stage. Otherwise, the preliminary estimates are arbitrarily set to values that produce stable polynomials.

When preliminary estimation is not performed by PROC ARIMA, then initial values of the coefficients for any given autoregressive or moving-average factor are set to 0.1 if the degree of the polynomial associated with the factor is 9 or less. Otherwise, the coefficients are determined by expanding the polynomial $(1-0.1B)$ to an appropriate power by using a recursive algorithm.

These preliminary estimates are the starting values in an iterative algorithm to compute estimates of the parameters.

Estimation Methods

Maximum Likelihood

The METHOD= ML option produces maximum likelihood estimates. The likelihood function is maximized via nonlinear least squares using Marquardt's method. Maximum likelihood estimates are more expensive to compute than the conditional least squares estimates; however, they may be preferable in some cases (Ansley and Newbold 1980; Davidson 1981).

The maximum likelihood estimates are computed as follows. Let the univariate ARMA model be

$$\phi(B)(W_t - \mu_t) = \theta(B)a_t$$

where a_t is an independent sequence of normally distributed innovations with mean 0 and variance σ^2. Here μ_t is the mean parameter μ plus the transfer function inputs. The log-likelihood function can be written as follows:

$$-\frac{1}{2\sigma^2}\mathbf{x}'\mathbf{\Omega}^{-1}\mathbf{x} - \frac{1}{2}\ln(|\mathbf{\Omega}|) - \frac{n}{2}\ln(\sigma^2)$$

In this equation, n is the number of observations, $\sigma^2\mathbf{\Omega}$ is the variance of $\mathbf{x}$ as a function of the ϕ and θ parameters, and $|\mathbf{\Omega}|$ denotes the determinant. The vector $\mathbf{x}$ is the time series W_t minus the structural part of

the model μ_t, written as a column vector, as follows:

$$\mathbf{x} = \begin{bmatrix} W_1 \\ W_2 \\ \vdots \\ W_n \end{bmatrix} - \begin{bmatrix} \mu_1 \\ \mu_2 \\ \vdots \\ \mu_n \end{bmatrix}$$

The maximum likelihood estimate (MLE) of σ^2 is

$$s^2 = \frac{1}{n}\mathbf{x}'\mathbf{\Omega}^{-1}\mathbf{x}$$

Note that the default estimator of the variance divides by $n - r$, where r is the number of parameters in the model, instead of by n. Specifying the NODF option causes a divisor of n to be used.

The log likelihood concentrated with respect to σ^2 can be taken up to additive constants as

$$-\frac{n}{2}\ln(\mathbf{x}'\mathbf{\Omega}^{-1}\mathbf{x}) - \frac{1}{2}\ln(|\mathbf{\Omega}|)$$

Let $\mathbf{H}$ be the lower triangular matrix with positive elements on the diagonal such that $\mathbf{H}\mathbf{H}' = \mathbf{\Omega}$. Let $\mathbf{e}$ be the vector $\mathbf{H}^{-1}\mathbf{x}$. The concentrated log likelihood with respect to σ^2 can now be written as

$$-\frac{n}{2}\ln(\mathbf{e}'\mathbf{e}) - \ln(|\mathbf{H}|)$$

or

$$-\frac{n}{2}\ln(|\mathbf{H}|^{1/n}\mathbf{e}'\mathbf{e}|\mathbf{H}|^{1/n})$$

The MLE is produced by using a Marquardt algorithm to minimize the following sum of squares:

$$|\mathbf{H}|^{1/n}\mathbf{e}'\mathbf{e}|\mathbf{H}|^{1/n}$$

The subsequent analysis of the residuals is done by using $\mathbf{e}$ as the vector of residuals.

Unconditional Least Squares

The METHOD=ULS option produces unconditional least squares estimates. The ULS method is also referred to as the *exact least squares* (ELS) method. For METHOD=ULS, the estimates minimize

$$\sum_{t=1}^{n} \tilde{a}_t^2 = \sum_{t=1}^{n} (x_t - \mathbf{C}_t\mathbf{V}_t^{-1}(x_1, \ldots, x_{t-1})')^2$$

where $\mathbf{C}_t$ is the covariance matrix of x_t and $(x_1, \ldots, x_{t-1})$, and $\mathbf{V}_t$ is the variance matrix of $(x_1, \ldots, x_{t-1})$. In fact, $\sum_{t=1}^{n} \tilde{a}_t^2$ is the same as $\mathbf{x}'\mathbf{\Omega}^{-1}\mathbf{x}$, and hence $\mathbf{e}'\mathbf{e}$. Therefore, the unconditional least squares estimates are obtained by minimizing the sum of squared residuals rather than using the log likelihood as the criterion function.

Conditional Least Squares

The METHOD=CLS option produces conditional least squares estimates. The CLS estimates are conditional on the assumption that the past unobserved errors are equal to 0. The series x_t can be represented in terms of the previous observations, as follows:

$$x_t = a_t + \sum_{i=1}^{\infty} \pi_i x_{t-i}$$

The π weights are computed from the ratio of the ϕ and θ polynomials, as follows:

$$\frac{\phi(B)}{\theta(B)} = 1 - \sum_{i=1}^{\infty} \pi_i B^i$$

The CLS method produces estimates minimizing

$$\sum_{t=1}^{n} \hat{a}_t^2 = \sum_{t=1}^{n} (x_t - \sum_{i=1}^{\infty} \hat{\pi}_i x_{t-i})^2$$

where the unobserved past values of x_t are set to 0 and $\hat{\pi}_i$ are computed from the estimates of ϕ and θ at each iteration.

For METHOD=ULS and METHOD=ML, initial estimates are computed using the METHOD=CLS algorithm.

Start-Up for Transfer Functions

When computing the noise series for transfer function and intervention models, the start-up for the transferred variable is done by assuming that past values of the input series are equal to the first value of the series. The estimates are then obtained by applying least squares or maximum likelihood to the noise series. Thus, for transfer function models, the ML option does not generate the full (multivariate ARMA) maximum likelihood estimates, but it uses only the univariate likelihood function applied to the noise series.

Because PROC ARIMA uses all of the available data for the input series to generate the noise series, other start-up options for the transferred series can be implemented by prefixing an observation to the beginning of the real data. For example, if you fit a transfer function model to the variable Y with the single input X, then you can employ a start-up using 0 for the past values by prefixing to the actual data an observation with a missing value for Y and a value of 0 for X.

Information Criteria

PROC ARIMA computes and prints two information criteria, Akaike's information criterion (AIC) (Akaike 1974; Harvey 1981) and Schwarz's Bayesian criterion (SBC) (Schwarz 1978). The AIC and SBC are used to compare competing models fit to the same series. The model with the smaller information criteria is said to fit the data better. The AIC is computed as

$$-2\ln(L) + 2k$$

where L is the likelihood function and k is the number of free parameters. The SBC is computed as

$$-2\ln(L) + \ln(n)k$$

where n is the number of residuals that can be computed for the time series. Sometimes Schwarz's Bayesian criterion is called the Bayesian information criterion (BIC).

If METHOD=CLS is used to do the estimation, an approximation value of L is used, where L is based on the conditional sum of squares instead of the exact sum of squares, and a Jacobian factor is left out.

Tests of Residuals

A table of test statistics for the hypothesis that the model residuals are white noise is printed as part of the ESTIMATE statement output. The chi-square statistics used in the test for lack of fit are computed using the Ljung-Box formula

$$\chi^2_m = n(n+2)\sum_{k=1}^{m}\frac{r_k^2}{(n-k)}$$

where

$$r_k = \frac{\sum_{t=1}^{n-k} a_t a_{t+k}}{\sum_{t=1}^{n} a_t^2}$$

and a_t is the residual series.

This formula has been suggested by Ljung and Box (1978) as yielding a better fit to the asymptotic chi-square distribution than the Box-Pierce Q statistic. Some simulation studies of the finite sample properties of this statistic are given by Davies, Triggs, and Newbold (1977); Ljung and Box (1978). When the time series has missing values, Stoffer and Toloi (1992) suggest a modification of this test statistic that has improved distributional properties over the standard Ljung-Box formula given above. When the series contains missing values, this modified test statistic is used by default.

Each chi-square statistic is computed for all lags up to the indicated lag value and is not independent of the preceding chi-square values. The null hypothesis tested is that the current set of autocorrelations is white noise.

t-Values

The t values reported in the table of parameter estimates are approximations whose accuracy depends on the validity of the model, the nature of the model, and the length of the observed series. When the length of the observed series is short and the number of estimated parameters is large with respect to the series length, the t approximation is usually poor. Probability values that correspond to a t distribution should be interpreted carefully because they may be misleading.

Cautions during Estimation

The ARIMA procedure uses a general nonlinear least squares estimation method that can yield problematic results if your data do not fit the model. Output should be examined carefully. The GRID option can be used to ensure the validity and quality of the results. Problems you might encounter include the following:

- Preliminary moving-average estimates might not converge. If this occurs, preliminary estimates are derived as described previously in the section "Preliminary Estimation" on page 238. You can supply your own preliminary estimates with the ESTIMATE statement options.

- The estimates can lead to an unstable time series process, which can cause extreme forecast values or overflows in the forecast.
- The Jacobian matrix of partial derivatives might be singular; usually, this happens because not all the parameters are identifiable. Removing some of the parameters or using a longer time series might help.
- The iterative process might not converge. PROC ARIMA's estimation method stops after *n* iterations, where *n* is the value of the MAXITER= option. If an iteration does not improve the SSE, the Marquardt parameter is increased by a factor of ten until parameters that have a smaller SSE are obtained or until the limit value of the Marquardt parameter is exceeded.
- For METHOD=CLS, the estimates might converge but not to least squares estimates. The estimates might converge to a local minimum, the numerical calculations might be distorted by data whose sum-of-squares surface is not smooth, or the minimum might lie outside the region of invertibility or stationarity.
- If the data are differenced and a moving-average model is fit, the parameter estimates might try to converge exactly on the invertibility boundary. In this case, the standard error estimates that are based on derivatives might be inaccurate.

Specifying Inputs and Transfer Functions

Input variables and transfer functions for them can be specified using the INPUT= option in the ESTIMATE statement. The variables used in the INPUT= option must be included in the CROSSCORR= list in the previous IDENTIFY statement. If any differencing is specified in the CROSSCORR= list, then the differenced variable is used as the input to the transfer function.

General Syntax of the INPUT= Option

The general syntax of the INPUT= option is

ESTIMATE . . . INPUT=*(transfer-function variable . . .)*

The transfer function for an input variable is optional. The name of a variable by itself can be used to specify a pure regression term for the variable.

If specified, the syntax of the transfer function is

$$S \ \$ \ (L_{1,1}, L_{1,2}, \ldots)(L_{2,1}, \ldots) \ldots / (L_{i,1}, L_{i,2}, \ldots)(L_{i+1,1}, \ldots) \ldots$$

S is the number of periods of time delay (lag) for this input series. Each term in parentheses specifies a polynomial factor with parameters at the lags specified by the $L_{i,j}$ values. The terms before the slash (/) are numerator factors. The terms after the slash (/) are denominator factors. All three parts are optional.

Commas can optionally be used between input specifications to make the INPUT= option more readable. The $ sign after the shift is also optional.

Except for the first numerator factor, each of the terms $L_{i,1}, L_{i,2}, \ldots, L_{i,k}$ indicates a factor of the form

$$(1 - \omega_{i,1} B^{L_{i,1}} - \omega_{i,2} B^{L_{i,2}} - \cdots - \omega_{i,k} B^{L_{i,k}})$$

The form of the first numerator factor depends on the ALTPARM option. By default, the constant 1 in the first numerator factor is replaced with a free parameter ω_0.

Alternative Model Parameterization

When the ALTPARM option is specified, the ω_0 parameter is factored out so that it multiplies the entire transfer function, and the first numerator factor has the same form as the other factors.

The ALTPARM option does not materially affect the results; it just presents the results differently. Some people prefer to see the model written one way, while others prefer the alternative representation. Table 7.9 illustrates the effect of the ALTPARM option.

Table 7.9 The ALTPARM Option

INPUT= Option	ALTPARM	Model
INPUT=((1 2)(12)/(1)X);	No	$(\omega_0 - \omega_1 B - \omega_2 B^2)(1 - \omega_3 B^{12})/(1 - \delta_1 B) X_t$
	Yes	$\omega_0(1 - \omega_1 B - \omega_2 B^2)(1 - \omega_3 B^{12})/(1 - \delta_1 B) X_t$

Differencing and Input Variables

If you difference the response series and use input variables, take care that the differencing operations do not change the meaning of the model. For example, if you want to fit the model

$$Y_t = \frac{\omega_0}{(1 - \delta_1 B)} X_t + \frac{(1 - \theta_1 B)}{(1 - B)(1 - B^{12})} a_t$$

then the IDENTIFY statement must read

```
identify var=y(1,12) crosscorr=x(1,12);
estimate q=1 input=(/(1)x) noconstant;
```

If instead you specify the differencing as

```
identify var=y(1,12) crosscorr=x;
estimate q=1 input=(/(1)x) noconstant;
```

then the model being requested is

$$Y_t = \frac{\omega_0}{(1 - \delta_1 B)(1 - B)(1 - B^{12})} X_t + \frac{(1 - \theta_1 B)}{(1 - B)(1 - B^{12})} a_t$$

which is a very different model.

The point to remember is that a differencing operation requested for the response variable specified by the VAR= option is applied only to that variable and not to the noise term of the model.

Initial Values

The syntax for giving initial values to transfer function parameters in the INITVAL= option parallels the syntax of the INPUT= option. For each transfer function in the INPUT= option, the INITVAL= option should give an initialization specification followed by the input series name. The initialization specification for each transfer function has the form

$$C \ \$ \ (V_{1,1}, V_{1,2}, \ldots)(V_{2,1}, \ldots) \ldots /(V_{i,1}, \ldots) \ldots$$

where C is the lag 0 term in the first numerator factor of the transfer function (or the overall scale factor if the ALTPARM option is specified) and $V_{i,j}$ is the coefficient of the $L_{i,j}$ element in the transfer function.

To illustrate, suppose you want to fit the model

$$Y_t = \mu + \frac{(\omega_0 - \omega_1 B - \omega_2 B^2)}{(1 - \delta_1 B - \delta_2 B^2 - \delta_3 B^3)} X_{t-3} + \frac{1}{(1 - \phi_1 B - \phi_2 B^3)} a_t$$

and start the estimation process with the initial values μ=10, ω_0=1, ω_1=0.5, ω_2=0.03, δ_1=0.8, δ_2=–0.1, δ_3=0.002, ϕ_1=0.1, ϕ_2=0.01. (These are arbitrary values for illustration only.) You would use the following statements:

```
identify var=y crosscorr=x;
estimate p=(1,3) input=(3$(1,2)/(1,2,3)x)
         mu=10 ar=.1 .01
         initval=(1$(.5,.03)/(.8,-.1,.002)x);
```

Note that the lags specified for a particular factor are sorted, so initial values should be given in sorted order. For example, if the P= option had been entered as P=(3,1) instead of P=(1,3), the model would be the same and so would the AR= option. Sorting is done within all factors, including transfer function factors, so initial values should always be given in order of increasing lags.

Here is another illustration, showing initialization for a factored model with multiple inputs. The model is

$$\begin{aligned} Y_t = \mu \ &+ \ \frac{\omega_{1,0}}{(1 - \delta_{1,1} B)} W_t + (\omega_{2,0} - \omega_{2,1} B) X_{t-3} \\ &+ \ \frac{1}{(1 - \phi_1 B)(1 - \phi_2 B^6 - \phi_3 B^{12})} a_t \end{aligned}$$

and the initial values are μ=10, $\omega_{1,0}$=5, $\delta_{1,1}$=0.8, $\omega_{2,0}$=1, $\omega_{2,1}$=0.5, ϕ_1=0.1, ϕ_2=0.05, and ϕ_3=0.01. You would use the following statements:

```
identify var=y crosscorr=(w x);
estimate p=(1)(6,12) input=(/(1)w, 3$(1)x)
         mu=10 ar=.1 .05 .01
         initval=(5$/(.8)w 1$(.5)x);
```

Stationarity and Invertibility

By default, PROC ARIMA requires that the parameter estimates for the AR and MA parts of the model always remain in the stationary and invertible regions, respectively. The NOSTABLE option removes this restriction and for high-order models can save some computer time. Note that using the NOSTABLE option does not necessarily result in an unstable model being fit, since the estimates can leave the stable region for some iterations but still ultimately converge to stable values. Similarly, by default, the parameter estimates for the denominator polynomial of the transfer function part of the model are also restricted to be stable. The NOTFSTABLE option can be used to remove this restriction.

Naming of Model Parameters

In the table of parameter estimates produced by the ESTIMATE statement, model parameters are referred to by using the naming convention described in this section.

The parameters in the noise part of the model are named as AR*i,j* or MA*i,j*, where AR refers to autoregressive parameters and MA to moving-average parameters. The subscript *i* refers to the particular polynomial factor, and the subscript *j* refers to the *j*th term within the *i*th factor. These terms are sorted in order of increasing lag within factors, so the subscript *j* refers to the *j*th term after sorting.

When inputs are used in the model, the parameters of each transfer function are named NUM*i,j* and DEN*i,j*. The *j*th term in the *i*th factor of a numerator polynomial is named NUM*i,j*. The *j*th term in the *i*th factor of a denominator polynomial is named DEN*i,j*.

This naming process is repeated for each input variable, so if there are multiple inputs, parameters in transfer functions for different input series have the same name. The table of parameter estimates shows in the "Variable" column the input with which each parameter is associated. The parameter name shown in the "Parameter" column and the input variable name shown in the "Variable" column must be combined to fully identify transfer function parameters.

The lag 0 parameter in the first numerator factor for the first input variable is named NUM1. For subsequent input variables, the lag 0 parameter in the first numerator factor is named NUM*k*, where *k* is the position of the input variable in the INPUT= option list. If the ALTPARM option is specified, the NUM*k* parameter is replaced by an overall scale parameter named SCALE*k*.

For the mean and noise process parameters, the response series name is shown in the "Variable" column. The lag and shift for each parameter are also shown in the table of parameter estimates when inputs are used.

Missing Values and Estimation and Forecasting

Estimation and forecasting are carried out in the presence of missing values by forecasting the missing values with the current set of parameter estimates. The maximum likelihood algorithm employed was suggested by Jones (1980) and is used for both unconditional least squares (ULS) and maximum likelihood (ML) estimation.

The CLS algorithm simply fills in missing values with infinite memory forecast values, computed by forecasting ahead from the nonmissing past values as far as required by the structure of the missing values. These artificial values are then employed in the nonmissing value CLS algorithm. Artificial values are updated at each iteration along with parameter estimates.

For models with input variables, embedded missing values (that is, missing values other than at the beginning or end of the series) are not generally supported. Embedded missing values in input variables are supported for the special case of a multiple regression model that has ARIMA errors. A multiple regression model is specified by an INPUT= option that simply lists the input variables (possibly with lag shifts) without any numerator or denominator transfer function factors. One-step-ahead forecasts are not available for the response variable when one or more of the input variables have missing values.

When embedded missing values are present for a model with complex transfer functions, PROC ARIMA uses the first continuous nonmissing piece of each series to do the analysis. That is, PROC ARIMA skips observations at the beginning of each series until it encounters a nonmissing value and then uses the data from there until it encounters another missing value or until the end of the data is reached. This makes the current version of PROC ARIMA compatible with earlier releases that did not allow embedded missing values.

Forecasting Details

If the model has input variables, a forecast beyond the end of the data for the input variables is possible only if univariate ARIMA models have previously been fit to the input variables or future values for the input variables are included in the DATA= data set.

If input variables are used, the forecast standard errors and confidence limits of the response depend on the estimated forecast error variance of the predicted inputs. If several input series are used, the forecast errors for the inputs should be independent; otherwise, the standard errors and confidence limits for the response series will not be accurate. If future values for the input variables are included in the DATA= data set, the standard errors of the forecasts will be underestimated since these values are assumed to be known with certainty.

The forecasts are generated using forecasting equations consistent with the method used to estimate the model parameters. Thus, the estimation method specified in the ESTIMATE statement also controls the way forecasts are produced by the FORECAST statement. If METHOD=CLS is used, the forecasts are *infinite memory forecasts*, also called *conditional forecasts*. If METHOD=ULS or METHOD=ML, the forecasts are *finite memory forecasts*, also called *unconditional forecasts*. A complete description of the steps to produce the series forecasts and their standard errors by using either of these methods is quite involved, and only a brief explanation of the algorithm is given in the next two sections. Additional information about the finite and infinite memory forecasts can be found in Brockwell and Davis (1991). The prediction of stationary ARMA processes is explained in Chapter 5, and the prediction of nonstationary ARMA processes is given in Chapter 9 of Brockwell and Davis (1991).

Infinite Memory Forecasts

If METHOD=CLS is used, the forecasts are *infinite memory forecasts*, also called *conditional forecasts*. The term *conditional* is used because the forecasts are computed by assuming that the unknown values of the response series before the start of the data are equal to the mean of the series. Thus, the forecasts are conditional on this assumption.

The series x_t can be represented as

$$x_t = a_t + \sum_{i=1}^{\infty} \pi_i x_{t-i}$$

where $\phi(B)/\theta(B) = 1 - \sum_{i=1}^{\infty} \pi_i B^i$.

The k-step forecast of x_{t+k} is computed as

$$\hat{x}_{t+k} = \sum_{i=1}^{k-1} \hat{\pi}_i \hat{x}_{t+k-i} + \sum_{i=k}^{\infty} \hat{\pi}_i x_{t+k-i}$$

where unobserved past values of x_t are set to zero and $\hat{\pi}_i$ is obtained from the estimated parameters $\hat{\phi}$ and $\hat{\theta}$.

Finite Memory Forecasts

For METHOD=ULS or METHOD=ML, the forecasts are *finite memory forecasts*, also called *unconditional forecasts*. For finite memory forecasts, the covariance function of the ARMA model is used to derive the best linear prediction equation.

That is, the k-step forecast of x_{t+k}, given $(x_1, \ldots, x_{t-1})$, is

$$\tilde{x}_{t+k} = \mathbf{C}_{k,t} \mathbf{V}_t^{-1} (x_1, \ldots, x_{t-1})'$$

where $\mathbf{C}_{k,t}$ is the covariance of x_{t+k} and $(x_1, \ldots, x_{t-1})$ and $\mathbf{V}_t$ is the covariance matrix of the vector $(x_1, \ldots, x_{t-1})$. $\mathbf{C}_{k,t}$ and $\mathbf{V}_t$ are derived from the estimated parameters.

Finite memory forecasts minimize the mean squared error of prediction if the parameters of the ARMA model are known exactly. (In most cases, the parameters of the ARMA model are estimated, so the predictors are not true best linear forecasts.)

If the response series is differenced, the final forecast is produced by summing the forecast of the differenced series. This summation and the forecast are conditional on the initial values of the series. Thus, when the response series is differenced, the final forecasts are not true finite memory forecasts because they are derived by assuming that the differenced series begins in a steady-state condition. Thus, they fall somewhere between finite memory and infinite memory forecasts. In practice, there is seldom any practical difference between these forecasts and true finite memory forecasts.

Forecasting Log Transformed Data

The log transformation is often used to convert time series that are nonstationary with respect to the innovation variance into stationary time series. The usual approach is to take the log of the series in a DATA step and then apply PROC ARIMA to the transformed data. A DATA step is then used to transform the forecasts of the logs back to the original units of measurement. The confidence limits are also transformed by using the exponential function.

As one alternative, you can simply exponentiate the forecast series. This procedure gives a forecast for the median of the series, but the antilog of the forecast log series underpredicts the mean of the original series. If you want to predict the expected value of the series, you need to take into account the standard error of the forecast, as shown in the following example, which uses an AR(2) model to forecast the log of a series Y:

```
data in;
   set in;
   ylog = log( y );
run;

proc arima data=in;
   identify var=ylog;
   estimate p=2;
   forecast lead=10 out=out;
run;

data out;
   set out;
   y   = exp( ylog );
   l95 = exp( l95 );
   u95 = exp( u95 );
   forecast = exp( forecast + std*std/2 );
run;
```

Specifying Series Periodicity

The INTERVAL= option is used together with the ID= variable to describe the observations that make up the time series. For example, INTERVAL=MONTH specifies a monthly time series in which each observation represents one month. For more information about the interval values supported, see Chapter 4, "Date Intervals, Formats, and Functions."

The variable specified by the ID= option in the PROC ARIMA statement identifies the time periods associated with the observations. Usually, SAS date, time, or datetime values are used for this variable. PROC ARIMA uses the ID= variable in the following ways:

- to validate the data periodicity. When the INTERVAL= option is specified, PROC ARIMA uses the ID variable to check the data and verify that successive observations have valid ID values that correspond to successive time intervals. When the INTERVAL= option is not used, PROC ARIMA verifies that the ID values are nonmissing and in ascending order.

- to check for gaps in the input observations. For example, if INTERVAL=MONTH and an input observation for April 1970 follows an observation for January 1970, there is a gap in the input data with two omitted observations (namely February and March 1970). A warning message is printed when a gap in the input data is found.

- to label the forecast observations in the output data set. PROC ARIMA extrapolates the values of the ID variable for the forecast observations from the ID value at the end of the input data according to the frequency specifications of the INTERVAL= option. If the INTERVAL= option is not specified, PROC ARIMA extrapolates the ID variable by incrementing the ID variable value for the last observation in the input data by 1 for each forecast period. Values of the ID variable over the range of the input data are copied to the output data set.

The ALIGN= option is used to align the ID variable to the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

Detecting Outliers

You can use the OUTLIER statement to detect changes in the level of the response series that are not accounted for by the estimated model. The types of changes considered are additive outliers (AO), level shifts (LS), and temporary changes (TC).

Let η_t be a regression variable that describes some type of change in the mean response. In time series literature η_t is called a shock signature. An additive outlier at some time point s corresponds to a shock signature η_t such that $\eta_s = 1.0$ and η_t is 0.0 at all other points. Similarly a permanent level shift that originates at time s has a shock signature such that η_t is 0.0 for $t < s$ and 1.0 for $t \geq s$. A temporary level shift of duration d that originates at time s has η_t equal to 1.0 between s and $s + d$ and 0.0 otherwise.

Suppose that you are estimating the ARIMA model

$$D(B)Y_t = \mu_t + \frac{\theta(B)}{\phi(B)}a_t$$

where Y_t is the response series, $D(B)$ is the differencing polynomial in the backward shift operator B (possibly identity), μ_t is the transfer function input, $\phi(B)$ and $\theta(B)$ are the AR and MA polynomials, respectively, and a_t is the Gaussian white noise series.

The problem of detection of level shifts in the OUTLIER statement is formulated as a problem of sequential selection of shock signatures that improve the model in the ESTIMATE statement. This is similar to the forward selection process in the stepwise regression procedure. The selection process starts with considering shock signatures of the type specified in the TYPE= option, originating at each nonmissing measurement. This involves testing $H_0: \beta = 0$ versus $H_a: \beta \neq 0$ in the model

$$D(B)(Y_t - \beta\eta_t) = \mu_t + \frac{\theta(B)}{\phi(B)}a_t$$

for each of these shock signatures. The most significant shock signature, if it also satisfies the significance criterion in ALPHA= option, is included in the model. If no significant shock signature is found, then the outlier detection process stops; otherwise this augmented model, which incorporates the selected shock signature in its transfer function input, becomes the null model for the subsequent selection process. This

iterative process stops if at any stage no more significant shock signatures are found or if the number of iterations exceeds the maximum search number that results due to the MAXNUM= and MAXPCT= settings. In all these iterations, the parameters of the ARIMA model in the ESTIMATE statement are held fixed.

The precise details of the testing procedure for a given shock signature η_t are as follows:

The preceding testing problem is equivalent to testing $H_0: \beta = 0$ versus $H_a: \beta \neq 0$ in the following "regression with ARMA errors" model,

$$N_t = \beta\zeta_t + \frac{\theta(B)}{\phi(B)}a_t$$

where $N_t = (D(B)Y_t - \mu_t)$ is the "noise" process and $\zeta_t = D(B)\eta_t$ is the "effective" shock signature.

In this setting, under H_0, $N = (N_1, N_2, \ldots, N_n)^T$ is a mean zero Gaussian vector with variance covariance matrix $\sigma^2\mathbf{\Omega}$. Here σ^2 is the variance of the white noise process a_t and $\mathbf{\Omega}$ is the variance-covariance matrix associated with the ARMA model. Moreover, under H_a, N has $\beta\zeta$ as the mean vector where $\zeta = (\zeta_1, \zeta_2, \ldots, \zeta_n)^T$. Additionally, the generalized least squares estimate of β and its variance is given by

$$\begin{aligned} \hat{\beta} &= \delta/\kappa \\ \mathrm{Var}(\hat{\beta}) &= \sigma^2/\kappa \end{aligned}$$

where $\delta = \zeta^T\mathbf{\Omega}^{-1}N$ and $\kappa = \zeta^T\mathbf{\Omega}^{-1}\zeta$. The test statistic $\tau^2 = \delta^2/(\sigma^2\kappa)$ is used to test the significance of β, which has an approximate chi-squared distribution with 1 degree of freedom under H_0. The type of estimate of σ^2 used in the calculation of τ^2 can be specified by the SIGMA= option. The default setting is SIGMA=ROBUST, which corresponds to a robust estimate suggested in an outlier detection procedure in X-12-ARIMA, the Census Bureau's time series analysis program; see Findley et al. (1998) for additional information. The robust estimate of σ^2 is computed by the formula

$$\hat{\sigma}^2 = (1.49 \times \mathrm{Median}(|\hat{a}_t|))^2$$

where $\hat{a}_t$ are the standardized residuals of the null ARIMA model. The setting SIGMA=MSE corresponds to the usual mean squared error estimate (MSE) computed the same way as in the ESTIMATE statement with the NODF option.

The quantities δ and κ are efficiently computed by a method described in De Jong and Penzer (1998); see also Kohn and Ansley (1985).

Modeling in the Presence of Outliers

In practice, modeling and forecasting time series data in the presence of outliers is a difficult problem for several reasons. The presence of outliers can adversely affect the model identification and estimation steps. Their presence close to the end of the observation period can have a serious impact on the forecasting performance of the model. In some cases, level shifts are associated with changes in the mechanism that drives the observation process, and separate models might be appropriate to different sections of the data. In view of all these difficulties, diagnostic tools such as outlier detection and residual analysis are essential in any modeling process.

The following modeling strategy, which incorporates level shift detection in the familiar Box-Jenkins modeling methodology, seems to work in many cases:

1. Proceed with model identification and estimation as usual. Suppose this results in a tentative ARIMA model, say M.
2. Check for additive and permanent level shifts unaccounted for by the model M by using the OUTLIER statement. In this step, unless there is evidence to justify it, the number of level shifts searched should be kept small.
3. Augment the original data set with the regression variables that correspond to the detected outliers.
4. Include the first few of these regression variables in M, and call this model M1. Reestimate all the parameters of M1. It is important not to include too many of these outlier variables in the model in order to avoid the danger of over-fitting.
5. Check the adequacy of M1 by examining the parameter estimates, residual analysis, and outlier detection. Refine it more if necessary.

OUT= Data Set

The output data set produced by the OUT= option of the PROC ARIMA or FORECAST statements contains the following:

- the BY variables
- the ID variable
- the variable specified by the VAR= option in the IDENTIFY statement, which contains the actual values of the response series
- FORECAST, a numeric variable that contains the one-step-ahead predicted values and the multistep forecasts
- STD, a numeric variable that contains the standard errors of the forecasts
- a numeric variable that contains the lower confidence limits of the forecast. This variable is named L95 by default but has a different name if the ALPHA= option specifies a different size for the confidence limits.
- RESIDUAL, a numeric variable that contains the differences between actual and forecast values
- a numeric variable that contains the upper confidence limits of the forecast. This variable is named U95 by default but has a different name if the ALPHA= option specifies a different size for the confidence limits.

The ID variable, the BY variables, and the response variable are the only ones copied from the input to the output data set. In particular, the input variables are not copied to the OUT= data set.

Unless the NOOUTALL option is specified, the data set contains the whole time series. The FORECAST variable has the one-step forecasts (predicted values) for the input periods, followed by n forecast values, where n is the LEAD= value. The actual and RESIDUAL values are missing beyond the end of the series.

If you specify the same OUT= data set in different FORECAST statements, the latter FORECAST statements overwrite the output from the previous FORECAST statements. If you want to combine the forecasts from different FORECAST statements in the same output data set, specify the OUT= option once in the PROC ARIMA statement and omit the OUT= option in the FORECAST statements.

When a global output data set is created by the OUT= option in the PROC ARIMA statement, the variables in the OUT= data set are defined by the first FORECAST statement that is executed. The results of subsequent FORECAST statements are vertically concatenated onto the OUT= data set. Thus, if no ID variable is specified in the first FORECAST statement that is executed, no ID variable appears in the output data set, even if one is specified in a later FORECAST statement. If an ID variable is specified in the first FORECAST statement that is executed but not in a later FORECAST statement, the value of the ID variable is the same as the last value processed for the ID variable for all observations created by the later FORECAST statement. Furthermore, even if the response variable changes in subsequent FORECAST statements, the response variable name in the output data set is that of the first response variable analyzed.

OUTCOV= Data Set

The output data set produced by the OUTCOV= option of the IDENTIFY statement contains the following variables:

- LAG, a numeric variable that contains the lags that correspond to the values of the covariance variables. The values of LAG range from 0 to N for covariance functions and from –N to N for cross-covariance functions, where N is the value of the NLAG= option.
- VAR, a character variable that contains the name of the variable specified by the VAR= option.
- CROSSVAR, a character variable that contains the name of the variable specified in the CROSSCORR= option, which labels the different cross-covariance functions. The CROSSVAR variable is blank for the autocovariance observations. When there is no CROSSCORR= option, this variable is not created.
- N, a numeric variable that contains the number of observations used to calculate the current value of the covariance or cross-covariance function.
- COV, a numeric variable that contains the autocovariance or cross-covariance function values. COV contains the autocovariances of the VAR= variable when the value of the CROSSVAR variable is blank. Otherwise COV contains the cross covariances between the VAR= variable and the variable named by the CROSSVAR variable.
- CORR, a numeric variable that contains the autocorrelation or cross-correlation function values. CORR contains the autocorrelations of the VAR= variable when the value of the CROSSVAR variable is blank. Otherwise CORR contains the cross-correlations between the VAR= variable and the variable named by the CROSSVAR variable.
- STDERR, a numeric variable that contains the standard errors of the autocorrelations. The standard error estimate is based on the hypothesis that the process that generates the time series is a pure moving-average process of order LAG–1. For the cross-correlations, STDERR contains the value $1/\sqrt{n}$, which approximates the standard error under the hypothesis that the two series are uncorrelated.

- INVCORR, a numeric variable that contains the inverse autocorrelation function values of the VAR= variable. For cross-correlation observations (that is, when the value of the CROSSVAR variable is not blank), INVCORR contains missing values.
- PARTCORR, a numeric variable that contains the partial autocorrelation function values of the VAR= variable. For cross-correlation observations (that is, when the value of the CROSSVAR variable is not blank), PARTCORR contains missing values.

OUTEST= Data Set

PROC ARIMA writes the parameter estimates for a model to an output data set when the OUTEST= option is specified in the ESTIMATE statement. The OUTEST= data set contains the following:

- the BY variables
- _MODLABEL_, a character variable that contains the model label, if it is provided by using the label option in the ESTIMATE statement (otherwise this variable is not created).
- _NAME_, a character variable that contains the name of the parameter for the covariance or correlation observations or is blank for the observations that contain the parameter estimates. (This variable is not created if neither OUTCOV nor OUTCORR is specified.)
- _TYPE_, a character variable that identifies the type of observation. A description of the _TYPE_ variable values is given below.
- variables for model parameters

The variables for the model parameters are named as follows:

ERRORVAR — This numeric variable contains the variance estimate. The _TYPE_=EST observation for this variable contains the estimated error variance, and the remaining observations are missing.

MU — This numeric variable contains values for the mean parameter for the model. (This variable is not created if NOCONSTANT is specified.)

MA*j* _*k* — These numeric variables contain values for the moving-average parameters. The variables for moving-average parameters are named MA*j* _*k*, where *j* is the factor-number and *k* is the index of the parameter within a factor.

AR*j* _*k* — These numeric variables contain values for the autoregressive parameters. The variables for autoregressive parameters are named AR*j* _*k*, where *j* is the factor number and *k* is the index of the parameter within a factor.

I*j* _*k* — These variables contain values for the transfer function parameters. Variables for transfer function parameters are named I*j* _*k*, where *j* is the number of the INPUT variable associated with the transfer function component and *k* is the number of the parameter for the particular INPUT variable. INPUT variables are numbered according to the order in which they appear in the INPUT= list.

STATUS	This variable describes the convergence status of the model. A value of 0_CONVERGED indicates that the model converged.

The value of the _TYPE_ variable for each observation indicates the kind of value contained in the variables for model parameters for the observation. The OUTEST= data set contains observations with the following _TYPE_ values:

EST	The observation contains parameter estimates.
STD	The observation contains approximate standard errors of the estimates.
CORR	The observation contains correlations of the estimates. OUTCORR must be specified to get these observations.
COV	The observation contains covariances of the estimates. OUTCOV must be specified to get these observations.
FACTOR	The observation contains values that identify for each parameter the factor that contains it. Negative values indicate denominator factors in transfer function models.
LAG	The observation contains values that identify the lag associated with each parameter.
SHIFT	The observation contains values that identify the shift associated with the input series for the parameter.

The values given for _TYPE_=FACTOR, _TYPE_=LAG, or _TYPE_=SHIFT observations enable you to reconstruct the model employed when provided with only the OUTEST= data set.

OUTEST= Examples

This section clarifies how model parameters are stored in the OUTEST= data set with two examples.

Consider the following example:

```
proc arima data=input;
   identify var=y cross=(x1 x2);
   estimate p=(1)(6) q=(1,3)(12) input=(x1 x2) outest=est;
run;

proc print data=est;
run;
```

The model specified by these statements is

$$Y_t = \mu + \omega_{1,0}X_{1,t} + \omega_{2,0}X_{2,t} + \frac{(1-\theta_{11}B-\theta_{12}B^3)(1-\theta_{21}B^{12})}{(1-\phi_{11}B)(1-\phi_{21}B^6)}a_t$$

The OUTEST= data set contains the values shown in Table 7.10.

Table 7.10 OUTEST= Data Set for First Example

Obs	_TYPE_	Y	MU	MA1_1	MA1_2	MA2_1	AR1_1	AR2_1	I1_1	I2_1
1	EST	σ^2	μ	θ_{11}	θ_{12}	θ_{21}	ϕ_{11}	ϕ_{21}	$\omega_{1,0}$	$\omega_{2,0}$
2	STD	.	se μ	se θ_{11}	se θ_{12}	se θ_{21}	se ϕ_{11}	se ϕ_{21}	se $\omega_{1,0}$	se $\omega_{2,0}$
3	FACTOR	.	0	1	1	2	1	2	1	1
4	LAG	.	0	1	3	12	1	6	0	0
5	SHIFT	.	0	0	0	0	0	0	0	0

Note that the symbols in the rows for _TYPE_=EST and _TYPE_=STD in Table 7.10 would be numeric values in a real data set.

Next, consider the following example:

```
proc arima data=input;
   identify var=y cross=(x1 x2);
   estimate p=1 q=1 input=(2 $ (1)/(1,2)x1 1 $ /(1)x2) outest=est;
run;

proc print data=est;
run;
```

The model specified by these statements is

$$Y_t = \mu + \frac{\omega_{10} - \omega_{11}B}{1 - \delta_{11}B - \delta_{12}B^2}X_{1,t-2} + \frac{\omega_{20}}{1 - \delta_{21}B}X_{2,t-1} + \frac{(1 - \theta_1 B)}{(1 - \phi_1 B)}a_t$$

The OUTEST= data set contains the values shown in Table 7.11.

Table 7.11 OUTEST= Data Set for Second Example

Obs	_TYPE_	Y	MU	MA1_1	AR1_1	I1_1	I1_2	I1_3	I1_4	I2_1	I2_2
1	EST	σ^2	μ	θ_1	ϕ_1	ω_{10}	ω_{11}	δ_{11}	δ_{12}	ω_{20}	δ_{21}
2	STD	.	se μ	se θ_1	se ϕ_1	se ω_{10}	se ω_{11}	se δ_{11}	se δ_{12}	se ω_{20}	se δ_{21}
3	FACTOR	.	0	1	1	1	1	–1	–1	1	–1
4	LAG	.	0	1	1	0	1	1	2	0	1
5	SHIFT	.	0	0	0	2	2	2	2	1	1

OUTMODEL= SAS Data Set

The OUTMODEL= option in the ESTIMATE statement writes an output data set that enables you to reconstruct the model. The OUTMODEL= data set contains much the same information as the OUTEST= data set but in a transposed form that might be more useful for some purposes. In addition, the OUTMODEL= data set includes the differencing operators.

The OUTMODEL data set contains the following:

- the BY variables
- _MODLABEL_, a character variable that contains the model label, if it is provided by using the label option in the ESTIMATE statement (otherwise this variable is not created).
- _NAME_, a character variable that contains the name of the response or input variable for the observation.
- _TYPE_, a character variable that contains the estimation method that was employed. The value of _TYPE_ can be CLS, ULS, or ML.
- _STATUS_, a character variable that describes the convergence status of the model. A value of 0_CONVERGED indicates that the model converged.
- _PARM_, a character variable that contains the name of the parameter given by the observation. _PARM_ takes on the values ERRORVAR, MU, AR, MA, NUM, DEN, and DIF.
- _VALUE_, a numeric variable that contains the value of the estimate defined by the _PARM_ variable.
- _STD_, a numeric variable that contains the standard error of the estimate.
- _FACTOR_, a numeric variable that indicates the number of the factor to which the parameter belongs.
- _LAG_, a numeric variable that contains the number of the term within the factor that contains the parameter.
- _SHIFT_, a numeric variable that contains the shift value for the input variable associated with the current parameter.

The values of _FACTOR_ and _LAG_ identify which particular MA, AR, NUM, or DEN parameter estimate is given by the _VALUE_ variable. The _NAME_ variable contains the response variable name for the MU, AR, or MA parameters. Otherwise, _NAME_ contains the input variable name associated with NUM or DEN parameter estimates. The _NAME_ variable contains the appropriate variable name associated with the current DIF observation as well. The _VALUE_ variable is 1 for all DIF observations, and the _LAG_ variable indicates the degree of differencing employed.

The observations contained in the OUTMODEL= data set are identified by the _PARM_ variable. A description of the values of the _PARM_ variable follows:

NUMRESID _VALUE_ contains the number of residuals.

NPARMS _VALUE_ contains the number of parameters in the model.

NDIFS	_VALUE_ contains the sum of the differencing lags employed for the response variable.
ERRORVAR	_VALUE_ contains the estimate of the innovation variance.
MU	_VALUE_ contains the estimate of the mean term.
AR	_VALUE_ contains the estimate of the autoregressive parameter indexed by the _FACTOR_ and _LAG_ variable values.
MA	_VALUE_ contains the estimate of a moving-average parameter indexed by the _FACTOR_ and _LAG_ variable values.
NUM	_VALUE_ contains the estimate of the parameter in the numerator factor of the transfer function of the input variable indexed by the _FACTOR_, _LAG_, and _SHIFT_ variable values.
DEN	_VALUE_ contains the estimate of the parameter in the denominator factor of the transfer function of the input variable indexed by the _FACTOR_, _LAG_, and _SHIFT_ variable values.
DIF	_VALUE_ contains the difference operator defined by the difference lag given by the value in the _LAG_ variable.

OUTSTAT= Data Set

PROC ARIMA writes the diagnostic statistics for a model to an output data set when the OUTSTAT= option is specified in the ESTIMATE statement. The OUTSTAT data set contains the following:

- the BY variables.
- _MODLABEL_, a character variable that contains the model label, if it is provided by using the label option in the ESTIMATE statement (otherwise this variable is not created).
- _TYPE_, a character variable that contains the estimation method used. _TYPE_ can have the value CLS, ULS, or ML.
- _STAT_, a character variable that contains the name of the statistic given by the _VALUE_ variable in this observation. _STAT_ takes on the values AIC, SBC, LOGLIK, SSE, NUMRESID, NPARMS, NDIFS, ERRORVAR, MU, CONV, and NITER.
- _VALUE_, a numeric variable that contains the value of the statistic named by the _STAT_ variable.

The observations contained in the OUTSTAT= data set are identified by the _STAT_ variable. A description of the values of the _STAT_ variable follows:

AIC	Akaike's information criterion
SBC	Schwarz's Bayesian criterion
LOGLIK	the log likelihood, if METHOD=ML or METHOD=ULS is specified
SSE	the sum of the squared residuals
NUMRESID	the number of residuals

NPARMS	the number of parameters in the model
NDIFS	the sum of the differencing lags employed for the response variable
ERRORVAR	the estimate of the innovation variance
MU	the estimate of the mean term
CONV	tells if the estimation converged. The value of 0 signifies that estimation converged. Nonzero values reflect convergence problems.
NITER	the number of iterations

Remark. CONV takes an integer value that corresponds to the error condition of the parameter estimation process. The value of 0 signifies that estimation process has converged. The higher values signify convergence problems of increasing severity. Specifically:

- CONV= 0 indicates that the estimation process has converged.
- CONV= 1 or 2 indicates that the estimation process has run into numerical problems (such as encountering an unstable model or a ridge) during the iterations.
- CONV= 3 or greater indicates that the estimation process has failed to converge.

Printed Output

The ARIMA procedure produces printed output for each of the IDENTIFY, ESTIMATE, and FORECAST statements. The output produced by each ARIMA statement is described in the following sections.

IDENTIFY Statement Printed Output

The printed output of the IDENTIFY statement consists of the following:

- a table of summary statistics, including the name of the response variable, any specified periods of differencing, the mean and standard deviation of the response series after differencing, and the number of observations after differencing
- a plot of the sample autocorrelation function for lags up to and including the NLAG= option value. Standard errors of the autocorrelations also appear to the right of the autocorrelation plot if the value of LINESIZE= option is sufficiently large. The standard errors are derived using Bartlett's approximation (Box and Jenkins 1976, p. 177). The approximation for a standard error for the estimated autocorrelation function at lag k is based on a null hypothesis that a pure moving-average Gaussian process of order $k-1$ generated the time series. The relative position of an approximate 95% confidence interval under this null hypothesis is indicated by the dots in the plot, while the asterisks represent the relative magnitude of the autocorrelation value.
- a plot of the sample inverse autocorrelation function. For more information about the inverse autocorrelation function, see the section "The Inverse Autocorrelation Function" on page 228.
- a plot of the sample partial autocorrelation function

- a table of test statistics for the hypothesis that the series is white noise. These test statistics are the same as the tests for white noise residuals produced by the ESTIMATE statement and are described in the section "Estimation Details" on page 238.
- a plot of the sample cross-correlation function for each series specified in the CROSSCORR= option. If a model was previously estimated for a variable in the CROSSCORR= list, the cross-correlations for that series are computed for the prewhitened input and response series. For each input variable with a prewhitening filter, the cross-correlation report for the input series includes the following:
  - a table of test statistics for the hypothesis of no cross-correlation between the input and response series
  - the prewhitening filter used for the prewhitening transformation of the predictor and response variables
- ESACF tables if the ESACF option is used
- MINIC table if the MINIC option is used
- SCAN table if the SCAN option is used
- STATIONARITY test results if the STATIONARITY option is used

ESTIMATE Statement Printed Output

The printed output of the ESTIMATE statement consists of the following:

- if the PRINTALL option is specified, the preliminary parameter estimates and an iteration history that shows the sequence of parameter estimates tried during the fitting process
- a table of parameter estimates that show the following for each parameter: the parameter name, the parameter estimate, the approximate standard error, t value, approximate probability ($Pr > |t|$), the lag for the parameter, the input variable name for the parameter, and the lag or "Shift" for the input variable
- the estimates of the constant term, the innovation variance (variance estimate), the innovation standard deviation (Std Error Estimate), Akaike's information criterion (AIC), Schwarz's Bayesian criterion (SBC), and the number of residuals
- the correlation matrix of the parameter estimates
- a table of test statistics for hypothesis that the residuals of the model are white noise. The table is titled "Autocorrelation Check of Residuals."
- if the PLOT option is specified, autocorrelation, inverse autocorrelation, and partial autocorrelation function plots of the residuals
- if an INPUT variable has been modeled in such a way that prewhitening is performed in the IDENTIFY step, a table of test statistics titled "Cross-correlation Check of Residuals." The test statistic is based on the chi-square approximation suggested by Box and Jenkins (1976, pp. 395–396). The cross-correlation function is computed by using the residuals from the model as one series and the prewhitened input variable as the other series.

- if the GRID option is specified, the sum-of-squares or likelihood surface over a grid of parameter values near the final estimates
- a summary of the estimated model that shows the autoregressive factors, moving-average factors, and transfer function factors in backshift notation with the estimated parameter values.

OUTLIER Statement Printed Output

The printed output of the OUTLIER statement consists of the following:

- a summary that contains the information about the maximum number of outliers searched, the number of outliers actually detected, and the significance level used in the outlier detection.
- a table that contains the results of the outlier detection process. The outliers are listed in the order in which they are found. This table contains the following columns:
  - The Obs column contains the observation number of the start of the level shift.
  - If an ID= option is specified, then the Time ID column contains the time identification labels of the start of the outlier.
  - The Type column lists the type of the outlier.
  - The Estimate column contains $\hat{\beta}$, the estimate of the regression coefficient of the shock signature.
  - The Chi-Square column lists the value of the test statistic τ^2.
  - The Approx Prob > ChiSq column lists the approximate p-value of the test statistic.

FORECAST Statement Printed Output

The printed output of the FORECAST statement consists of the following:

- a summary of the estimated model
- a table of forecasts with following columns:
  - The Obs column contains the observation number.
  - The Forecast column contains the forecast values.
  - The Std Error column contains the forecast standard errors.
  - The Lower and Uppers columns contain the approximate 95% confidence limits. The ALPHA= option can be used to change the confidence interval for forecasts.
  - If the PRINTALL option is specified, the forecast table also includes columns for the actual values of the response series (Actual) and the residual values (Residual).

ODS Table Names

PROC ARIMA assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 7.12.

Table 7.12 ODS Tables Produced by PROC ARIMA

ODS Table Name	Description	Statement	Option
ChiSqAuto	Chi-square statistics table for autocorrelation	IDENTIFY	
ChiSqCross	Chi-square statistics table for cross-correlations	IDENTIFY	CROSSCORR
AutoCorrGraph	Correlations graph	IDENTIFY	
CrossCorrGraph	Cross-correlations graph	IDENTIFY	
DescStats	Descriptive statistics	IDENTIFY

Statistical Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

This section provides information about the graphics produced by the ARIMA procedure. (For more information about ODS statistical graphics, see Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).) The main types of plots available are as follows:

- plots useful in the trend and correlation analysis of the dependent and input series
- plots useful for the residual analysis of an estimated model
- forecast plots

You can obtain most plots relevant to the specified model by default. For finer control of the graphics, you can use the PLOTS= option in the PROC ARIMA statement. The following example is a simple illustration of how to use the PLOTS= option.

Airline Series: Illustration of ODS Graphics

The series in this example, the monthly airline passenger series, is also discussed later, in Example 7.2.

The following statements specify an ARIMA$(0,1,1)\times(0,1,1)_{12}$ model without a mean term to the logarithms of the airline passengers series, xlog. Notice the use of the global plot option **ONLY** in the PLOTS= option of the PROC ARIMA statement. It suppresses the production of default graphics and produces only the plots specified by the subsequent RESIDUAL and FORECAST plot options. The **RESIDUAL(SMOOTH)** plot specification produces a time series plot of residuals that has an overlaid loess fit; see Figure 7.21. The **FORECAST(FORECAST)** option produces a plot that shows the one-step-ahead forecasts, as well as the multistep-ahead forecasts; see Figure 7.22.

```
proc arima data=seriesg
   plots(only)=(residual(smooth) forecast(forecasts));
   identify var=xlog(1,12);
   estimate q=(1)(12) noint method=ml;
   forecast id=date interval=month;
run;
```

Figure 7.21 Residual Plot of the Airline Model

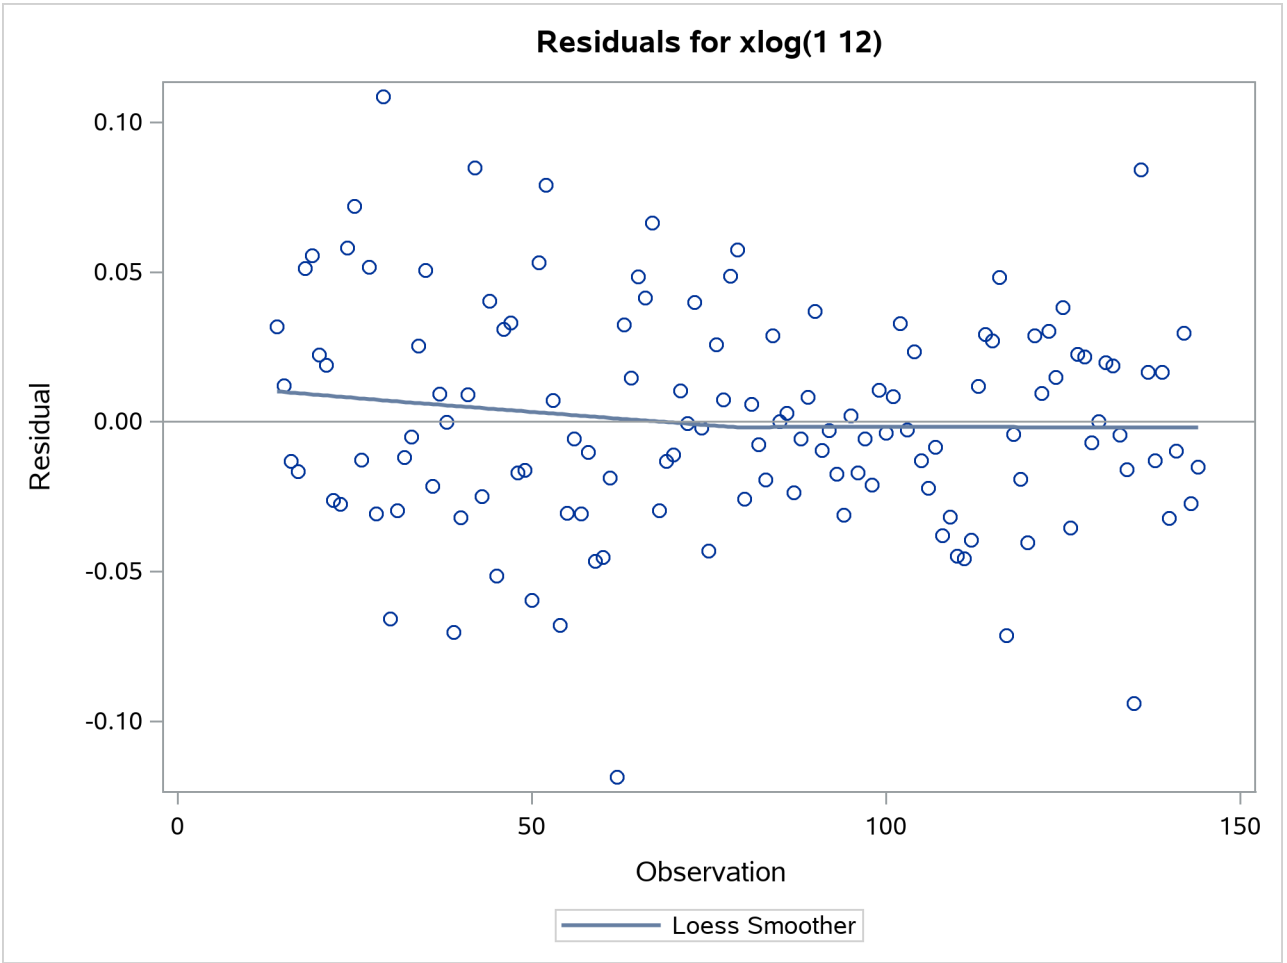

Figure 7.22 Forecast Plot of the Airline Model

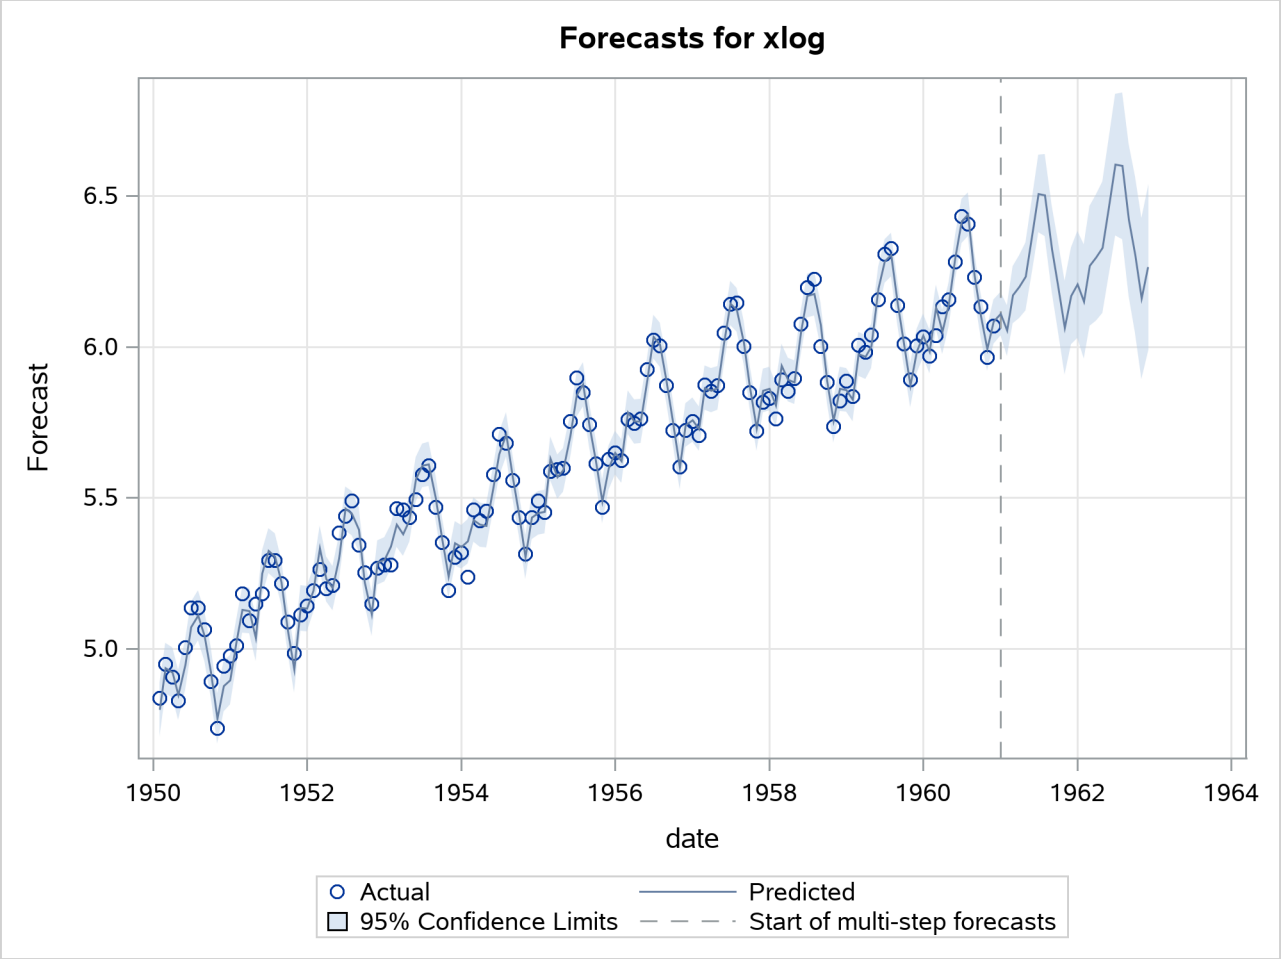


ODS Graph Names

PROC ARIMA assigns a name to each graph it creates by using ODS. You can use these names to reference the graphs when you use ODS. The names are listed in Table 7.13.

Table 7.13 ODS Graphics Produced by PROC ARIMA

ODS Graph Name	Plot Description	Option
SeriesPlot	Time series plot of the dependent series	PLOTS(UNPACK)
SeriesACFPlot	Autocorrelation plot of the dependent series	PLOTS(UNPACK)
SeriesPACFPlot	Partial-autocorrelation plot of the dependent series	PLOTS(UNPACK)
SeriesIACFPlot	Inverse-autocorrelation plot of the dependent series	PLOTS(UNPACK)
SeriesCorrPanel	Series trend and correlation analysis panel	Default

Table 7.13 *continued*

ODS Graph Name	Plot Description	Option
CrossCorrPanel	Cross-correlation plots, either individual or paneled. They are numbered 1, 2, and so on as needed.	Default
ResidualACFPlot	Residual-autocorrelation plot	PLOTS(UNPACK)
ResidualPACFPlot	Residual-partial-autocorrelation plot	PLOTS(UNPACK)
ResidualIACFPlot	Residual-inverse-autocorrelation plot	PLOTS(UNPACK)
ResidualWNPlot	Residual-white-noise-probability plot	PLOTS(UNPACK)
ResidualHistogram	Residual histogram	PLOTS(UNPACK)
ResidualQQPlot	Residual normal Q-Q plot	PLOTS(UNPACK)
ResidualPlot	Time series plot of residuals with a superimposed smoother	PLOTS=RESIDUAL(SMOOTH)
ForecastsOnlyPlot	Time series plot of multistep forecasts	Default
ForecastsPlot	Time series plot of one-step-ahead as well as multistep forecasts	PLOTS=FORECAST(FORECAST)

Examples: ARIMA Procedure

Example 7.1: Simulated IMA Model

This example illustrates the ARIMA procedure results for a case where the true model is known. An integrated moving-average model is used for this illustration.

The following DATA step generates a pseudo-random sample of 100 periods from the ARIMA(0,1,1) process $u_t = u_{t-1} + a_t - 0.8a_{t-1}$, a_t iid $\mathrm{N}(0, 1)$:

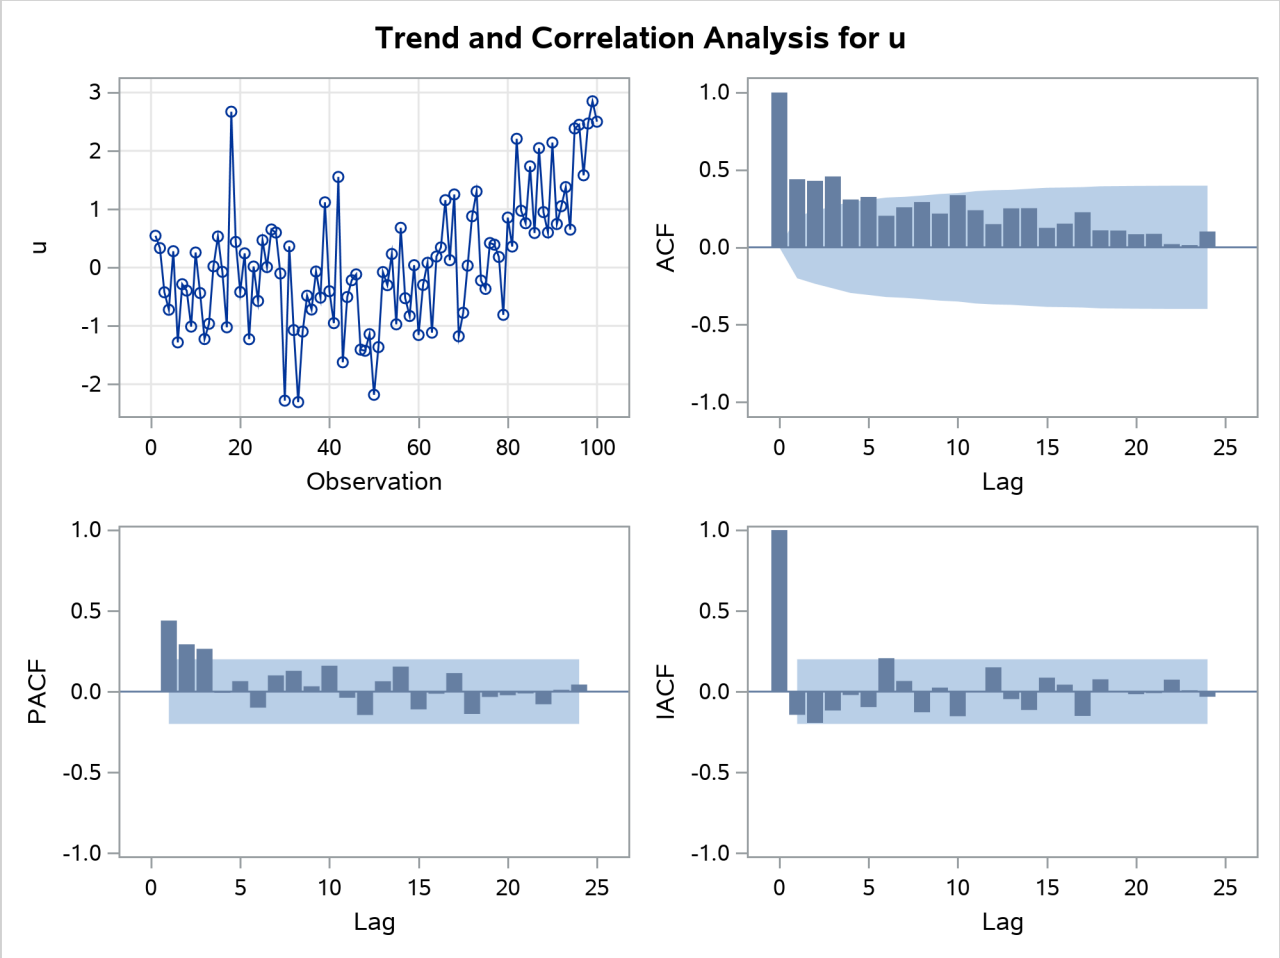
```
title1 'Simulated IMA(1,1) Series';
data a;
  u1 = 0.9; a1 = 0;
  do i = -50 to 100;
     a = rannor( 32565 );
     u = u1 + a - .8 * a1;
     if i > 0 then output;
     a1 = a;
     u1 = u;
  end;
run;
```

The following ARIMA procedure statements identify and estimate the model:

```
/*-- Simulated IMA Model --*/
proc arima data=a;
  identify var=u;
  run;
  identify var=u(1);
  run;
  estimate q=1 ;
  run;
quit;
```

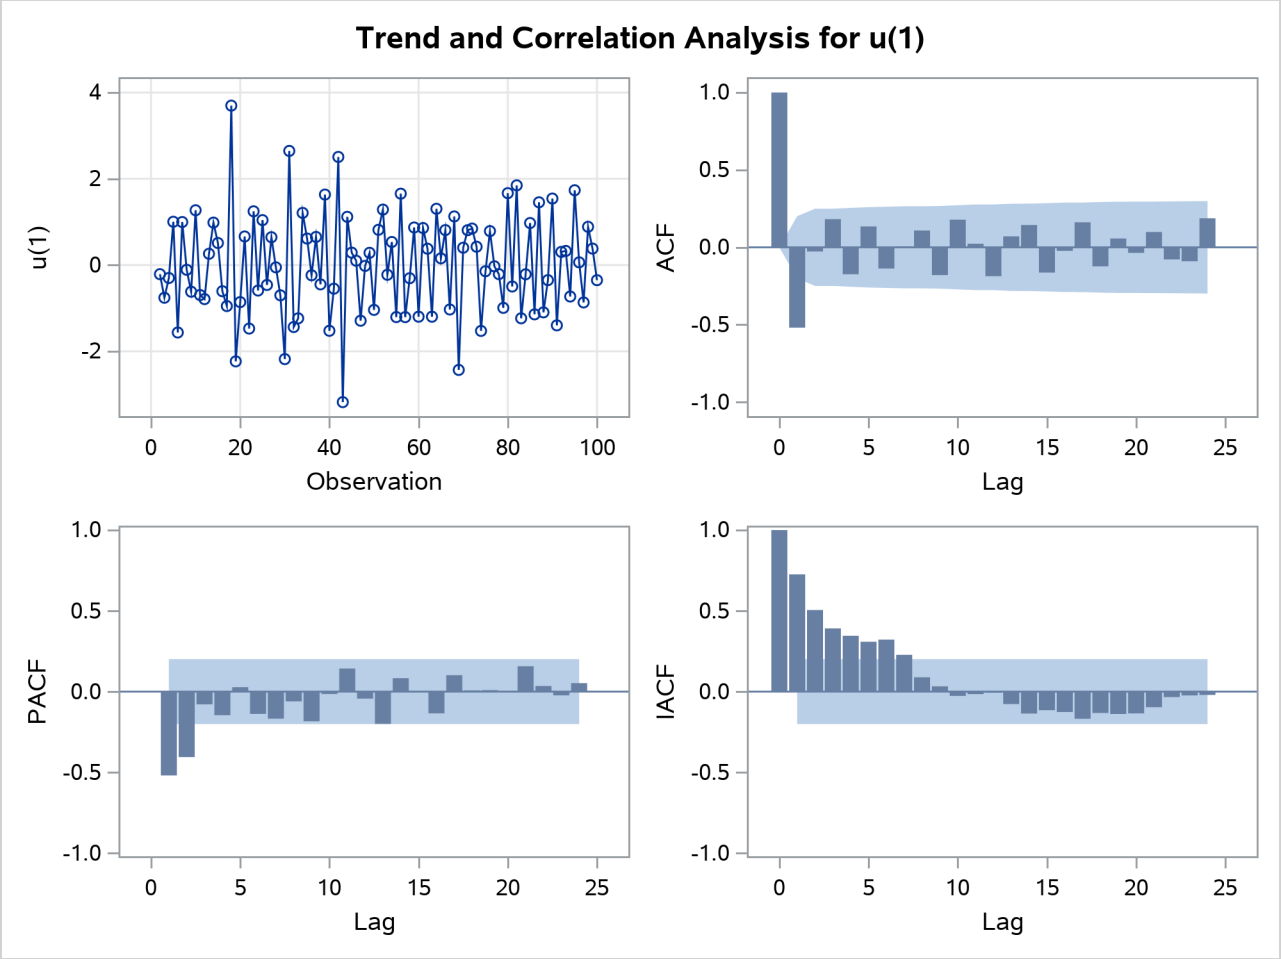
The graphical series correlation analysis output of the first IDENTIFY statement is shown in Output 7.1.1. The output shows the behavior of the sample autocorrelation function when the process is nonstationary. Note that in this case the estimated autocorrelations are not very high, even at small lags. Nonstationarity is reflected in a pattern of significant autocorrelations that do not decline quickly with increasing lag, not in the size of the autocorrelations.

Output 7.1.1 Correlation Analysis from the First IDENTIFY Statement



The second IDENTIFY statement differences the series. The results of the second IDENTIFY statement are shown in Output 7.1.2. This output shows autocorrelation, inverse autocorrelation, and partial autocorrelation functions typical of MA(1) processes.

Output 7.1.2 Correlation Analysis from the Second IDENTIFY Statement



The ESTIMATE statement fits an ARIMA(0,1,1) model to the simulated data. Note that in this case the parameter estimates are reasonably close to the values used to generate the simulated data. ($\mu = 0$, $\hat{\mu} = 0.02$; $\theta_1 = 0.8$, $\hat{\theta}_1 = 0.79$; $\sigma^2 = 1$, $\hat{\sigma}^2 = 0.82$.) Moreover, the graphical analysis of the residuals shows no model inadequacies (see Output 7.1.4 and Output 7.1.5).

The ESTIMATE statement results are shown in Output 7.1.3.

Output 7.1.3 Output from Fitting ARIMA(0,1,1) Model

Conditional Least Squares Estimation

Parameter	Estimate	Standard Error	t Value	Approx Pr > |t|	Lag
MU	0.02056	0.01972	1.04	0.2997	0

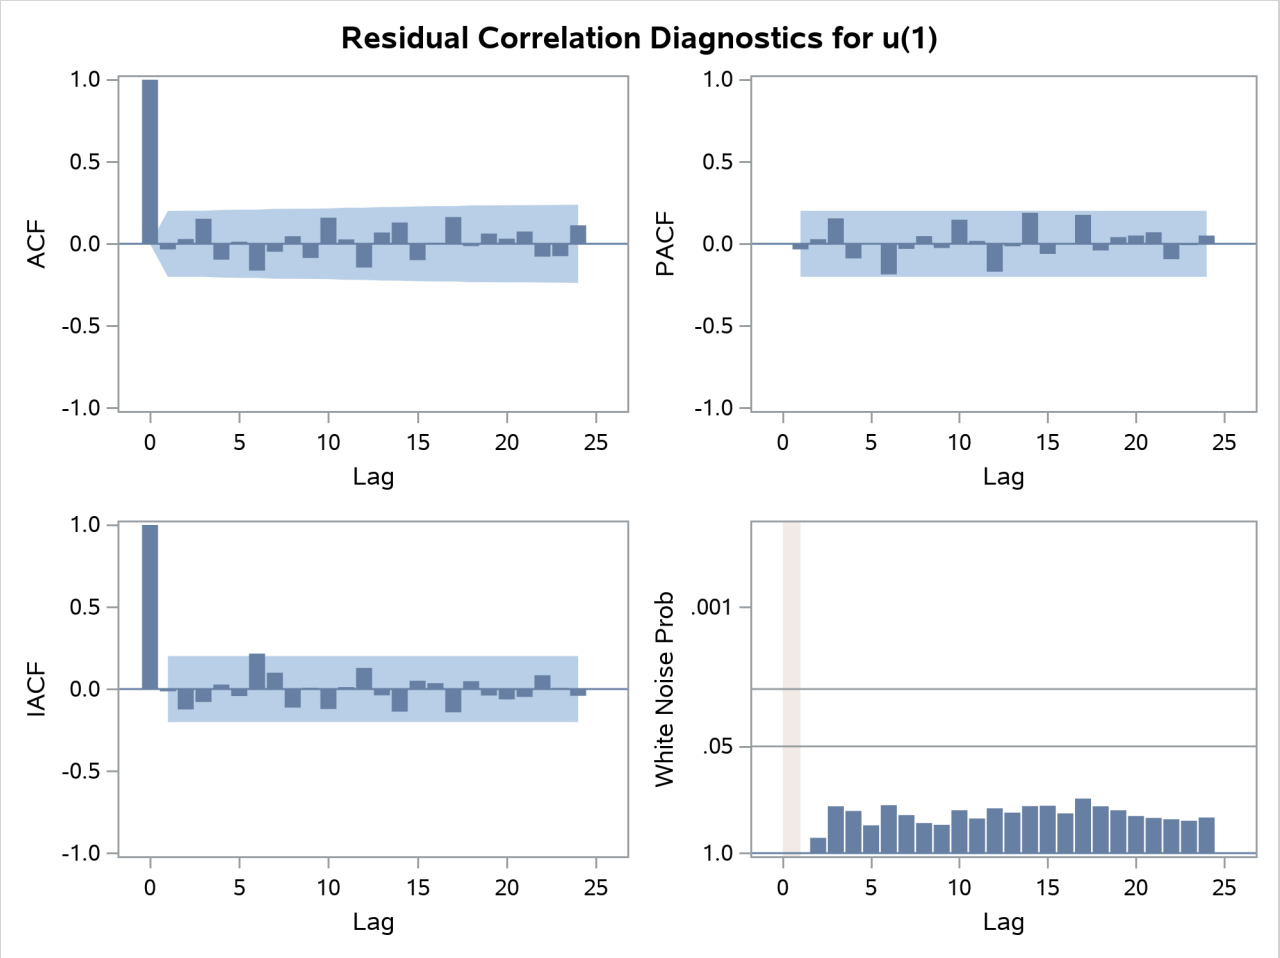
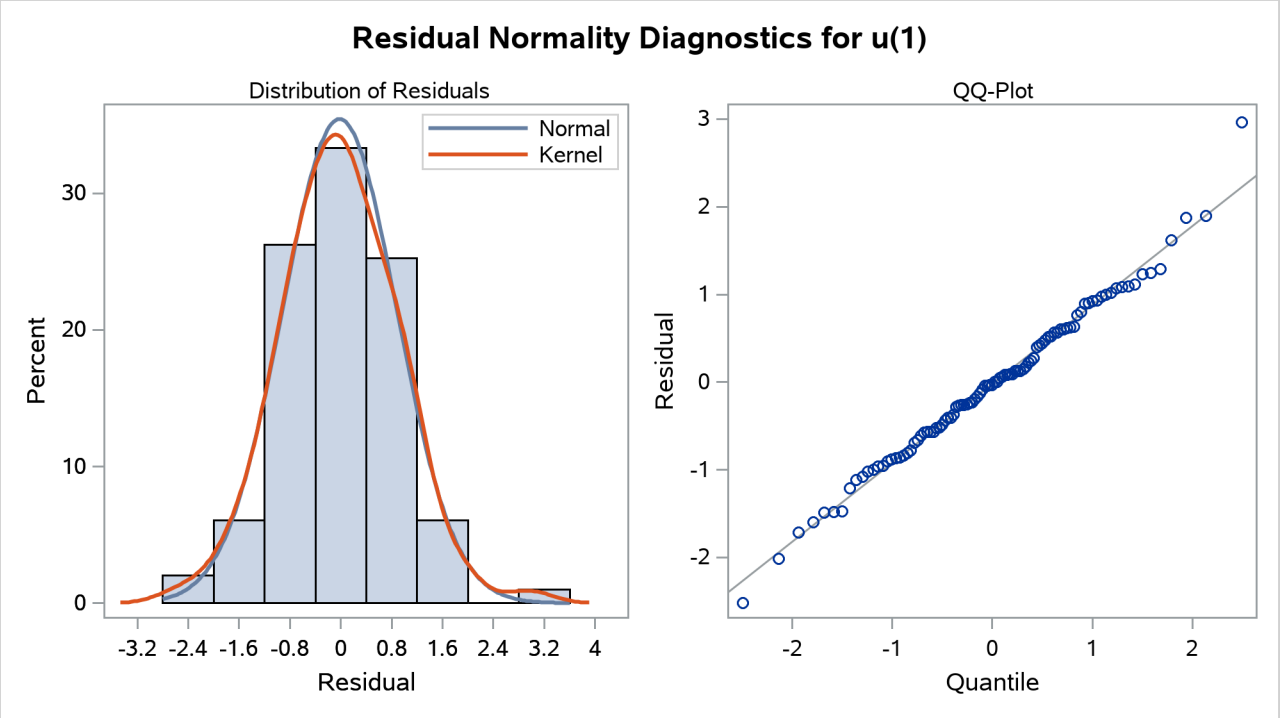
Output 7.1.4 Residual Correlation Analysis of the ARIMA(0,1,1) Model



Output 7.1.5 Residual Normality Analysis of the ARIMA(0,1,1) Model



Example 7.2: Seasonal Model for the Airline Series

The airline passenger data, given as Series G in Box and Jenkins (1976), have been used in time series analysis literature as an example of a nonstationary seasonal time series. This example uses PROC ARIMA to fit the airline model, ARIMA$(0,1,1)\times(0,1,1)_{12}$, to Box and Jenkins' Series G. The following statements read the data and log-transform the series:

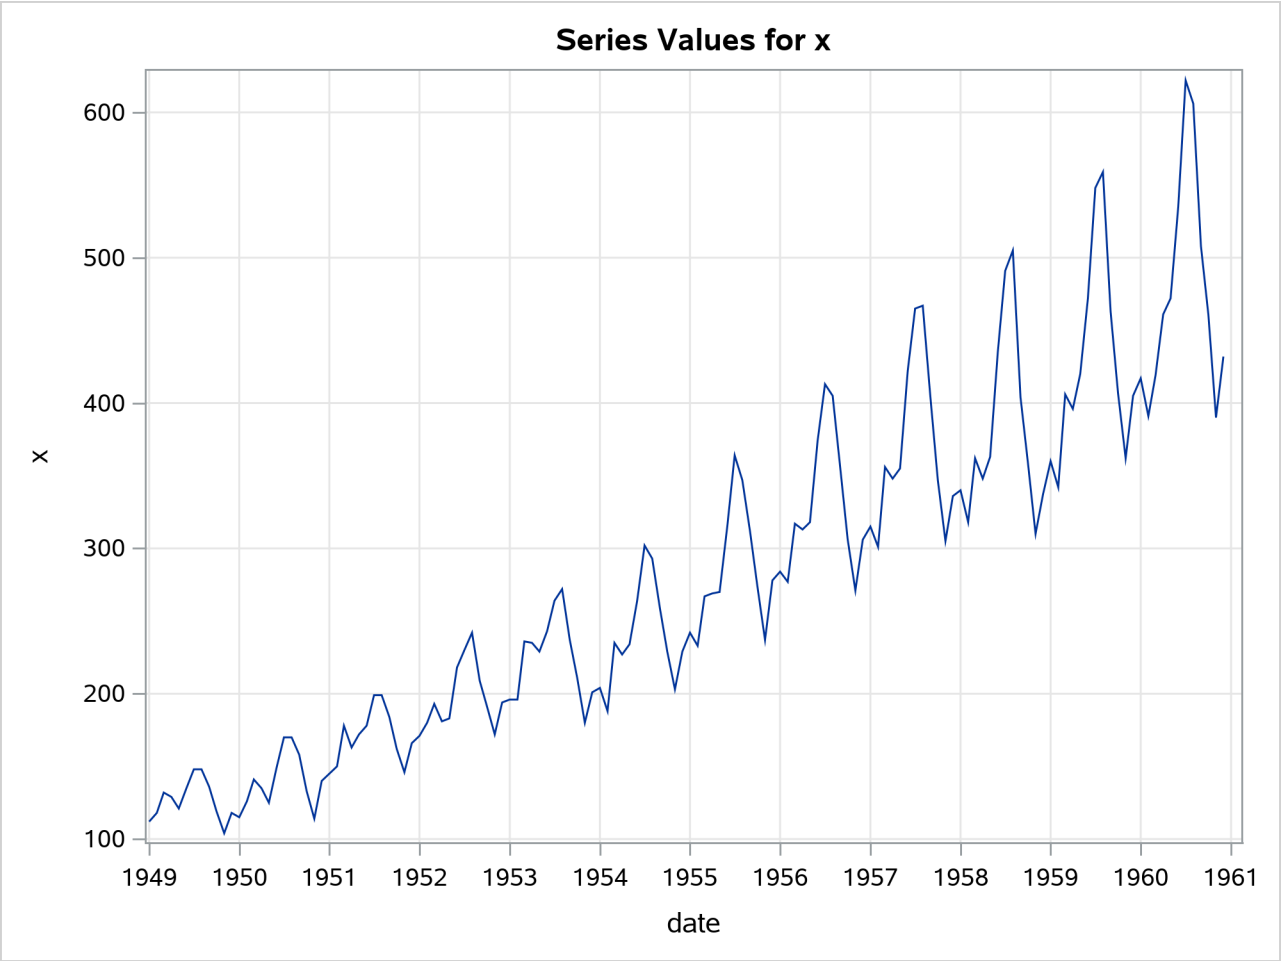
```
title1 'International Airline Passengers';
title2 '(Box and Jenkins Series-G)';
data seriesg;
   input x @@;
   xlog = log( x );
   date = intnx( 'month', '31dec1948'd, _n_ );
   format date monyy.;
datalines;
112 118 132 129 121 135 148 148 136 119 104 118

   ... more lines ...
```

The following PROC TIMESERIES step plots the series, as shown in Output 7.2.1:

```
proc timeseries data=seriesg plot=series;
   id date interval=month;
   var x;
run;
```

Output 7.2.1 Time Series Plot of the Airline Passenger Series



The following statements specify an ARIMA$(0,1,1)\times(0,1,1)_{12}$ model without a mean term to the logarithms of the airline passengers series, xlog. The model is forecast, and the results are stored in the data set B.

```
/*-- Seasonal Model for the Airline Series --*/
proc arima data=seriesg;
   identify var=xlog(1,12);
   estimate q=(1)(12) noint method=ml;
   forecast id=date interval=month printall out=b;
run;
```

The output from the IDENTIFY statement is shown in Output 7.2.2. The autocorrelation plots shown are for the twice differenced series $(1-B)(1-B^{12})XLOG$. Note that the autocorrelation functions have the pattern characteristic of a first-order moving-average process combined with a seasonal moving-average process with lag 12.

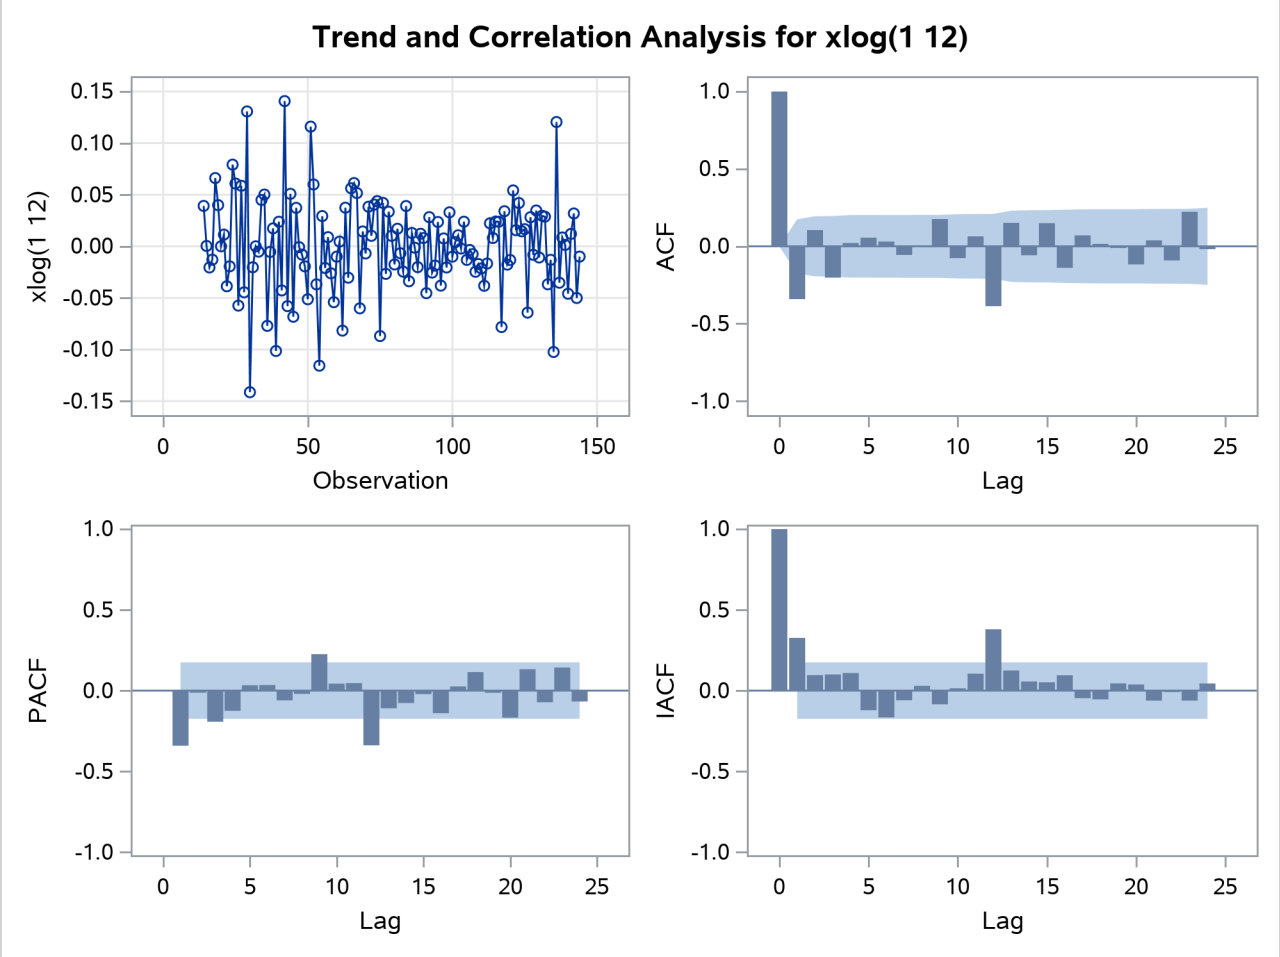
Output 7.2.2 IDENTIFY Statement Output

International Airline Passengers
(Box and Jenkins Series-G)

The ARIMA Procedure

Name of Variable = xlog	
Period(s) of Differencing	1,12
Mean of Working Series	0.000291
Standard Deviation	0.045673
Number of Observations	131
Observation(s) eliminated by differencing	13

Output 7.2.3 Trend and Correlation Analysis for the Twice Differenced Series



The results of the ESTIMATE statement are shown in Output 7.2.4, Output 7.2.5, and Output 7.2.6. The model appears to fit the data quite well.

Output 7.2.4 ESTIMATE Statement Output

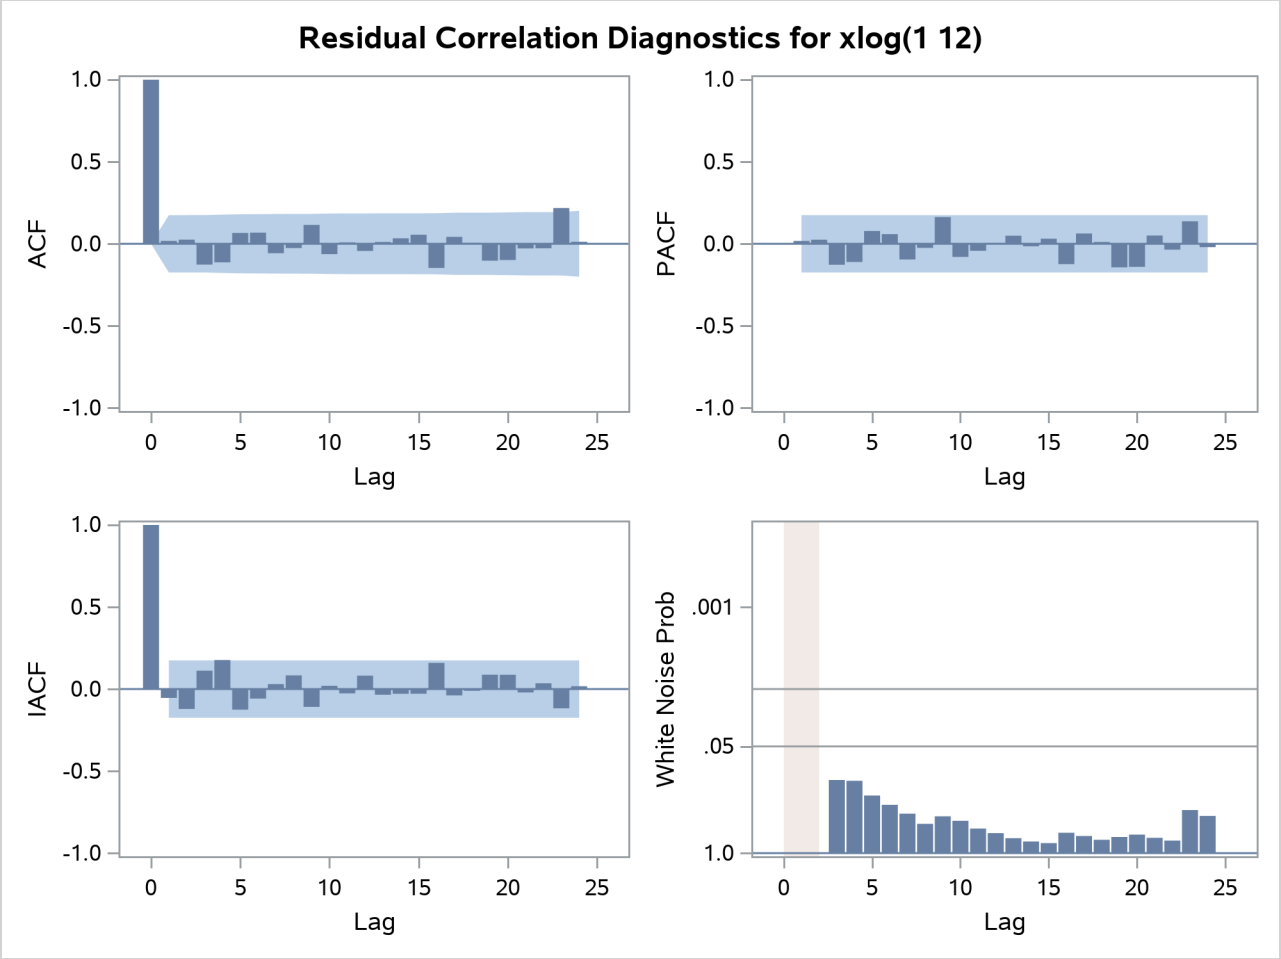
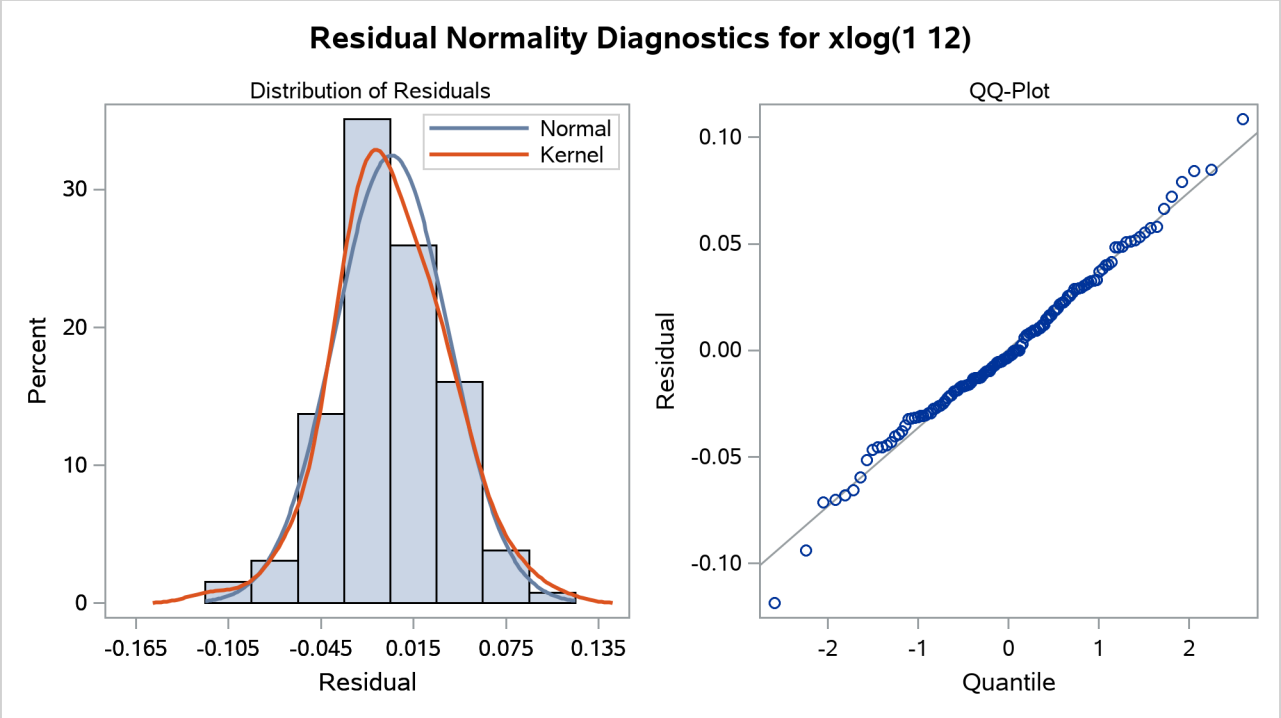
Output 7.2.5 Residual Analysis of the Airline Model: Correlation

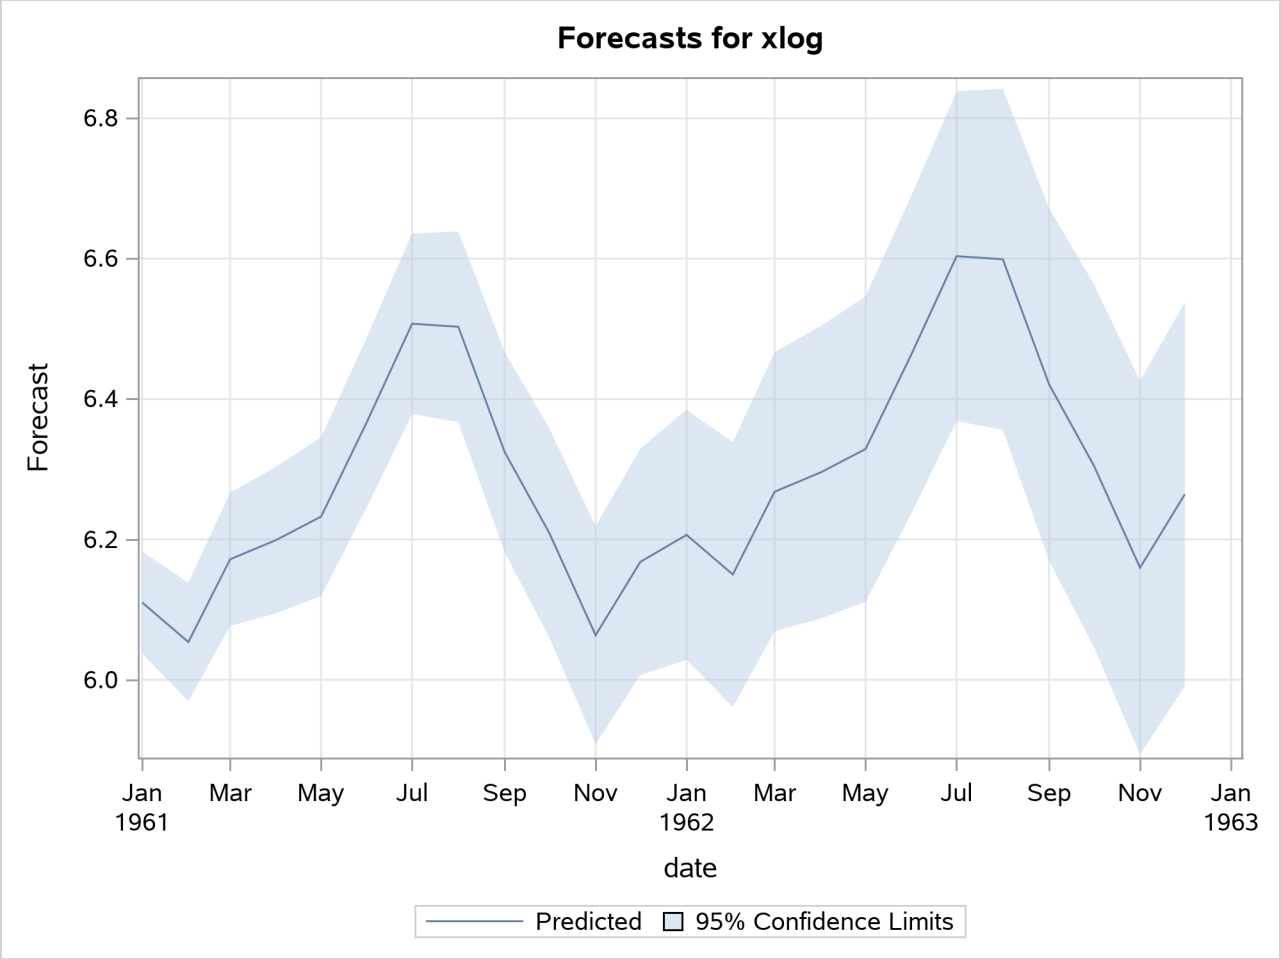


Output 7.2.6 Residual Analysis of the Airline Model: Normality



The forecasts and their confidence limits for the transformed series are shown in Output 7.2.7.

Output 7.2.7 Forecast Plot for the Transformed Series



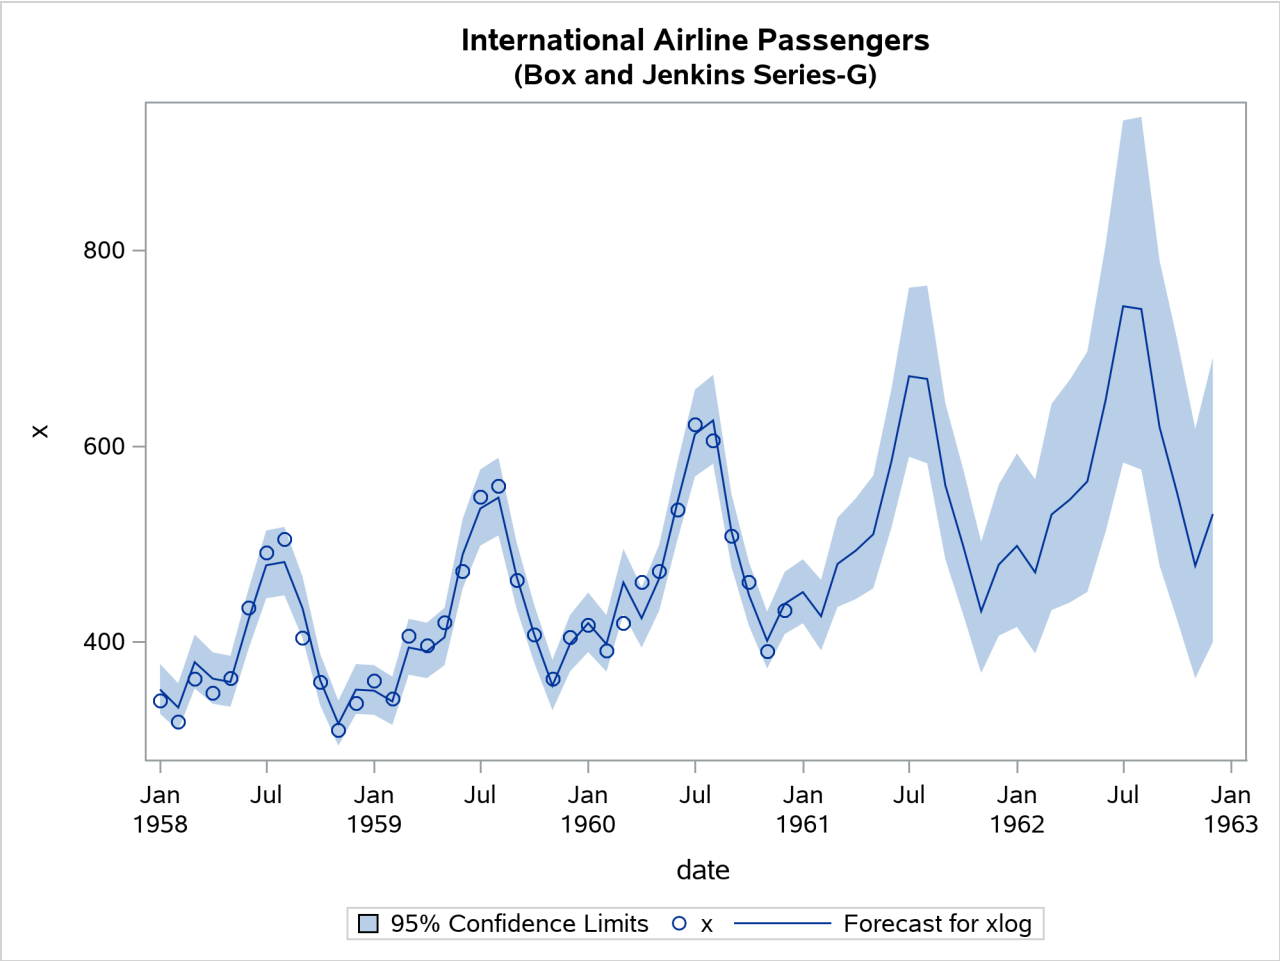
The following statements retransform the forecast values to get forecasts in the original scales. For more information, see the section "Forecasting Log Transformed Data" on page 248.

```
data c;
   set b;
   x        = exp( xlog );
   forecast = exp( forecast + std*std/2 );
   l95      = exp( l95 );
   u95      = exp( u95 );
run;
```

The forecasts and their confidence limits are plotted by using the following PROC SGPLOT step. The plot is shown in Output 7.2.8.

```
proc sgplot data=c;
   where date >= '1jan58'd;
   band Upper=u95 Lower=l95 x=date
      / LegendLabel="95% Confidence Limits";
   scatter x=date y=x;
   series x=date y=forecast;
run;
```

Output 7.2.8 Plot of the Forecast for the Original Series



Example 7.3: Model for Series J Data from Box and Jenkins

This example uses the Series J data from Box and Jenkins (1976). First, the input series X is modeled with a univariate ARMA model. Next, the dependent series Y is cross-correlated with the input series. Since a model has been fit to X, both Y and X are prewhitened by this model before the sample cross-correlations are computed. Next, a transfer function model is fit with no structure on the noise term. The residuals from this model are analyzed; then, the full model, transfer function and noise, is fit to the data.

The following statements read `'Input Gas Rate'` and `'Output CO'`$_2$ from a gas furnace. (Data values are not shown. The full example including data is in the SAS/ETS sample library.)

```
title1 'Gas Furnace Data';
title2 '(Box and Jenkins, Series J)';
data seriesj;
   input x y @@;
   label x = 'Input Gas Rate'
         y = 'Output CO2';
datalines;
```

```
-0.109  53.8  0.000  53.6  0.178  53.5  0.339  53.5

   ... more lines ...
```

The following statements produce Output 7.3.1 through Output 7.3.11:

```
proc arima data=seriesj;

   /*--- Look at the input process ----------------------------*/
   identify var=x;
   run;

   /*--- Fit a model for the input ----------------------------*/
   estimate p=3 plot;
   run;

   /*--- Cross-correlation of prewhitened series ---------------*/
   identify var=y crosscorr=(x) nlag=12;
   run;

   /*--- Fit a simple transfer function - look at residuals ---*/
   estimate input=( 3 $ (1,2)/(1) x );
   run;

   /*--- Final Model - look at residuals ----------------------*/
   estimate p=2 input=( 3 $ (1,2)/(1) x );
   run;

quit;
```

The results of the first IDENTIFY statement for the input series X are shown in Output 7.3.1. The correlation analysis suggests an AR(3) model.

Example 7.4: An Intervention Model for Ozone Data

This example fits an intervention model to ozone data as suggested by Box and Tiao (1975). Notice that the response variable, OZONE, and the innovation, X1, are seasonally differenced. The final model for the differenced data is a multiple regression model with a moving-average structure assumed for the residuals.

The model is fit by maximum likelihood. The seasonal moving-average parameter and its standard error are fairly sensitive to which method is chosen to fit the model (Ansley and Newbold 1980; Davidson 1981); thus, fitting the model by the unconditional or conditional least squares method produces somewhat different estimates for these parameters.

Some missing values are appended to the end of the input data to generate additional values for the independent variables. Since the independent variables are not modeled, values for them must be available for any times at which predicted values are desired. In this case, predicted values are requested for 12 periods beyond the end of the data. Thus, values for X1, WINTER, and SUMMER must be given for 12 periods ahead.

The following statements read in the data and compute dummy variables for use as intervention inputs:

```
title1 'Intervention Data for Ozone Concentration';
title2 '(Box and Tiao, JASA 1975 P.70)';
data air;
   input ozone @@;
   label ozone  = 'Ozone Concentration'
         x1     = 'Intervention for post 1960 period'
         summer = 'Summer Months Intervention'
         winter = 'Winter Months Intervention';
   date = intnx( 'month', '31dec1954'd, _n_ );
   format date monyy.;
   month = month( date );
   year = year( date );
   x1 = year >= 1960;
   summer = ( 5 < month < 11 ) * ( year > 1965 );
   winter = ( year > 1965 ) - summer;
```

```
datalines;
2.7  2.0  3.6  5.0  6.5  6.1  5.9  5.0  6.4  7.4  8.2  3.9
4.1  4.5  5.5  3.8  4.8  5.6  6.3  5.9  8.7  5.3  5.7  5.7

Example 7.5: Using Diagnostics to Identify ARIMA Models

Fitting ARIMA models is as much an art as it is a science. The ARIMA procedure has diagnostic options to help tentatively identify the orders of both stationary and nonstationary ARIMA processes.

Consider the Series A in Box, Jenkins, and Reinsel (1994), which consists of 197 concentration readings taken every two hours from a chemical process. Let Series A be a data set that contains these readings in a variable named X. The following SAS statements use the SCAN option of the IDENTIFY statement to generate Output 7.5.1 and Output 7.5.2. For more information about the SCAN method, see the section "The SCAN Method" on page 233.

```
/*-- Order Identification Diagnostic with SCAN Method --*/
proc arima data=SeriesA;
   identify var=x scan;
run;
```

Output 7.5.1 Example of SCAN Tables

SERIES A: Chemical Process Concentration Readings

The ARIMA Procedure

ESACF Probability Values

Lags	MA 0	MA 1	MA 2	MA 3	MA 4	MA 5
AR 0	<.0001	<.0001	0.0001	0.0014	0.0053	0.0041
AR 1	<.0001	0.5974	0.4622	0.9198	0.4292	0.8768
AR 2	<.0001	0.0002	0.6106	0.9182	0.5683	0.8592
AR 3	<.0001	0.9022	0.2400	0.8713	0.8930	0.7372
AR 4	<.0001	0.8380	0.3180	0.7737	0.8913	0.6213
AR 5	<.0001	<.0001	0.0765	0.9142	0.1038	0.8103

In Output 7.5.3, there are three right-triangular regions in which all elements are insignificant at the 5% level. The triangles have vertices (1,1), (3,1), and (4,1). Since the triangle at (1,1) covers more insignificant terms, it is recommended first. Similarly, the remaining recommendations are ordered by the number of insignificant terms contained in the triangle. Output 7.5.4 gives recommendations based on the significance level specified by the ALPHA=*siglevel* option.

Output 7.5.4 Example of ESACF Option Tentative Order Selection

ARMA(p+d,q) Tentative Order Selection Tests

ESACF

p+d	q
1	1
3	1
4	1

(5% Significance Level)

If you also specify the SCAN option in the same IDENTIFY statement, the two recommendations are printed side by side:

```
/*-- Combination of SCAN and ESACF Methods --*/
proc arima data=SeriesA;
   identify var=x scan esacf;
run;
```

Output 7.5.5 shows the results.

Output 7.5.5 Example of SCAN and ESACF Option Combined

SERIES A: Chemical Process Concentration Readings

The ARIMA Procedure

ARMA(p+d,q) Tentative Order Selection Tests

SCAN		ESACF	
p+d	q	p+d	q
1	1	1	1
		3	1
		4	1

(5% Significance Level)

From Output 7.5.5, the autoregressive and moving-average orders are tentatively identified by both SCAN and ESACF tables to be $(p+d, q) = (1,1)$. Because both the SCAN and ESACF indicate a $p+d$ term of 1, a unit root test should be used to determine whether this autoregressive term is a unit root. Since a moving-average term appears to be present, a large autoregressive term is appropriate for the augmented Dickey-Fuller test for a unit root.

Submitting the following statements generates Output 7.5.6:

```
/*-- Augmented Dickey-Fuller Unit Root Tests --*/
proc arima data=SeriesA;
   identify var=x stationarity=(adf=(5,6,7,8));
run;
```

Output 7.5.6 Example of STATIONARITY Option Output

SERIES A: Chemical Process Concentration Readings

	6	-10.8436	0.3710	-2.01	0.5939	2.04	0.7694
	7	-10.7427	0.3773	-1.90	0.6519	1.91	0.7956
	8	-10.0370	0.4236	-1.79	0.7081	1.74	0.8293

The preceding test results show that a unit root is very likely given that none of the *p*-values are small enough to cause you to reject the null hypothesis that the series has a unit root. Based on this test and the previous results, the series should be differenced, and an ARIMA(0,1,1) would be a good choice for a tentative model for Series A.

Using the recommendation that the series be differenced, the following statements generate Output 7.5.7:

```
/*-- Minimum Information Criterion --*/
proc arima data=SeriesA;
   identify var=x(1) minic;
run;
```

Output 7.5.7 Example of MINIC Table

SERIES A: Chemical Process Concentration Readings

The error series is estimated by using an AR(7) model, and the minimum of this MINIC table is $BIC(0,1)$. This diagnostic confirms the previous result which indicates that an ARIMA(0,1,1) is a tentative model for Series A.

If you also specify the SCAN or MINIC option in the same IDENTIFY statement as follows, the BIC associated with the SCAN table and ESACF table recommendations is listed. Output 7.5.8 shows the results.

```
/*-- Combination of MINIC, SCAN and ESACF Options --*/
proc arima data=SeriesA;
   identify var=x(1) minic scan esacf;
run;
```

Example 7.6: Detection of Level Changes in the Nile River Data

This example shows how to use the OUTLIER statement to detect changes in the dynamics of the time series being modeled. The time series used here is discussed in De Jong and Penzer (1998). The data consist of readings of the annual flow volume of the Nile River at Aswan from 1871 to 1970. These data have also been studied by Cobb (1978). These studies indicate that river flow levels in the years 1877 and 1913 are strong candidates for additive outliers and that there was a shift in the flow levels starting from the year 1899. This shift in 1899 is attributed partly to the weather changes and partly to the start of construction work for a new dam at Aswan. The following DATA step statements create the input data set:

```
data nile;
   input level @@;
   year = intnx( 'year', '1jan1871'd, _n_-1 );
   format year year4.;
datalines;
1120  1160  963  1210  1160  1160  813  1230   1370  1140
995   935   1110 994   1020  960   1180 799    958   1140
1100  1210  1150 1250  1260  1220  1030 1100   774   840

   ... more lines ...
```

The following program fits an ARIMA model, ARIMA(0,1,1), similar to the structural model suggested in De Jong and Penzer (1998). This model is also suggested by the usual correlation analysis of the series. By default, the OUTLIER statement requests detection of additive outliers and level shifts, assuming that the series follows the estimated model.

```
/*-- ARIMA(0, 1, 1) Model --*/
proc arima data=nile;
   identify var=level(1);
   estimate q=1 noint method=ml;
   outlier maxnum= 5 id=year;
run;
```

The outlier detection output is shown in Output 7.6.1.

Output 7.6.1 ARIMA(0, 1, 1) Model

The ARIMA Procedure

Outlier Detection Summary	
Maximum number searched	5
Number found	5
Significance used	0.05

Outlier Details

Obs	Time ID	Type	Estimate	Chi-Square	Approx Prob>ChiSq
29	1899	Shift	-315.75346	13.13	0.0003
43	1913	Additive	-403.97105	11.83	0.0006
7	1877	Additive	-335.49351	7.69	0.0055
94	1964	Additive	305.03568	6.16	0.0131
18	1888	Additive	-287.81484	6.00	0.0143

Note that the first three outliers detected are indeed the ones discussed earlier. You can include the shock signatures that correspond to these three outliers in the Nile data set as follows:

```
data nile;
   set nile;
   AO1877 = ( year = '1jan1877'd );
   AO1913 = ( year = '1jan1913'd );
   LS1899 = ( year >= '1jan1899'd );
run;
```

Now you can refine the earlier model by including these outliers. After examining the parameter estimates and residuals (not shown) of the ARIMA(0,1,1) model with these regressors, the following stationary MA1 model (with regressors) appears to fit the data well:

```
/*-- MA1 Model with Outliers --*/
proc arima data=nile;
   identify var=level
            crosscorr=( AO1877 AO1913 LS1899 );
   estimate q=1
            input=( AO1877 AO1913 LS1899 )
            method=ml;
   outlier maxnum=5 alpha=0.01 id=year;
run;
```

The relevant outlier detection process output is shown in Output 7.6.2. No outliers, at significance level 0.01, were detected.

Output 7.6.2 MA1 Model with Outliers

The ARIMA Procedure

Outlier Detection Summary	
Maximum number searched	5
Number found	0
Significance used	0.01

Example 7.7: Iterative Outlier Detection

This example illustrates the iterative nature of the outlier detection process. This is done by using a simple test example where an additive outlier at observation number 50 and a level shift at observation number 100 are artificially introduced in the international airline passenger data used in Example 7.2. The following DATA step shows the modifications introduced in the data set:

```
data airline;
   set sashelp.air;
   logair = log(air);
   if _n_ = 50 then logair = logair - 0.25;
   if _n_ >= 100 then logair = logair + 0.5;
run;
```

In Example 7.2 the airline model, ARIMA$(0,1,1)\times(0,1,1)_{12}$, was seen to be a good fit to the unmodified log-transformed airline passenger series. The preliminary identification steps (not shown) again suggest the airline model as a suitable initial model for the modified data. The following statements specify the airline model and request an outlier search:

```
/*-- Outlier Detection --*/
proc arima data=airline;
   identify var=logair( 1, 12 )  noprint;
   estimate q= (1)(12) noint method= ml;
   outlier maxnum=3 alpha=0.01;
run;
```

The outlier detection output is shown in Output 7.7.1.

Output 7.7.1 Initial Model

The ARIMA Procedure

Outlier Detection Summary	
Maximum number searched	3
Number found	3
Significance used	0.01

Outlier Details

Obs	Type	Estimate	Chi-Square	Approx Prob>ChiSq
100	Shift	0.49325	199.36	<.0001
50	Additive	-0.27508	104.78	<.0001
135	Additive	-0.10488	13.08	0.0003

Clearly the level shift at observation number 100 and the additive outlier at observation number 50 are the dominant outliers. Moreover, the corresponding regression coefficients seem to correctly estimate the size and sign of the change. You can augment the airline data with these two regressors, as follows:

```
data airline;
   set airline;
   if _n_ = 50 then AO = 1;
   else AO = 0.0;
   if _n_ >= 100 then LS  = 1;
   else LS = 0.0;
run;
```

You can now refine the previous model by including these regressors, as follows. Note that the differencing order of the dependent series is matched to the differencing orders of the outlier regressors to get the correct "effective" outlier signatures.

```
/*-- Airline Model with Outliers --*/
proc arima data=airline;
   identify var=logair(1, 12)
            crosscorr=( AO(1, 12) LS(1, 12) )
            noprint;
   estimate q= (1)(12) noint
            input=( AO LS )
            method=ml plot;
   outlier maxnum=3 alpha=0.01;
run;
```

The outlier detection results are shown in Output 7.7.2.

Output 7.7.2 Airline Model with Outliers

The ARIMA Procedure

Outlier Detection Summary	
Maximum number searched	3
Number found	3
Significance used	0.01

Outlier Details

Obs	Type	Estimate	Chi-Square	Approx Prob>ChiSq
135	Additive	-0.10310	12.63	0.0004
62	Additive	-0.08872	12.33	0.0004
29	Additive	0.08686	11.66	0.0006

The output shows that a few outliers still remain to be accounted for and that the model could be refined further.

Example 7.8: Test for Stationarity

As mentioned in the section "The Three Stages of ARIMA Modeling" on page 183, identification is the first stage of time series modeling. Stationarity tests can help you decide whether to difference; this decision is an important part of identification. If a series is nonstationary, it requires differencing. Dickey (2005) demonstrates how to conduct stationarity tests and how to difference series by using PROC ARIMA. This example follows a similar fashion with two different data generation models.

The following DATA step generates a sample of 100 periods from the ARIMA(1,1,0) process: $\nabla u_t = 0.6\nabla u_{t-1} + a_t$, $\nabla u_t = u_t - u_{t-1}$, and a_t iid $\mathrm{N}(0,1)$.

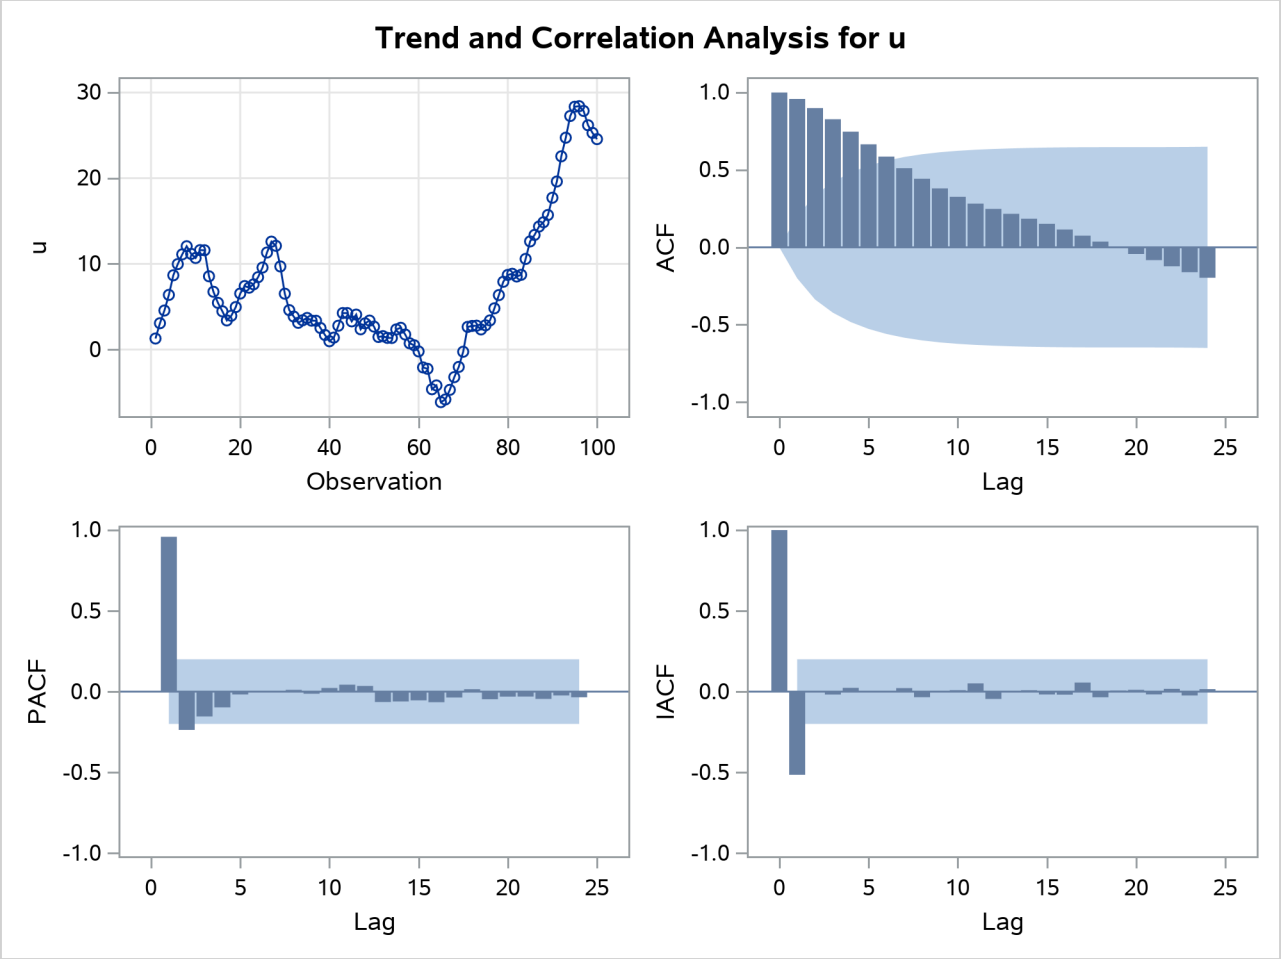
```
title1 'Simulated ARIMA(1,1,0)';
data a;
  u1 = 0;
  u2=0;
  do i = -50 to 100;
     a = rannor( 1234 );
     du1 = u1 - u2;
     du = 0.6 * du1 + a;
     u = du + u1;
     if i > 0 then output;
     u2 = u1;
     u1 = u;
  end;
run;
```

First, you should check the observation and correlation analysis graphs. This not only helps you better understand the data, but it is also needed in order to conduct the augmented Dickey-Fuller (ADF) tests. When conducting the ADF tests, you need to specify how many lagged differences to include in the test regression and which model (zero mean, single mean, or trend) to use. An inappropriate choice can lead to incorrect results. The following statements identify the model and generate observation and correlation graphs:

```
proc arima data=a;
  identify var=u;
run;
```

The results of the graphical series correlation analysis are shown in Output 7.8.1.

Output 7.8.1 Correlation Analysis for the Nonstationary Series



As shown in Output 7.8.1, there is no obvious time trend in the data, and the mean is not close to zero. An AR(1) model would suffice for the test, because the partial autocorrelation functions (PACFs) decline quickly after the first lag, as shown in the PACF plot. The ADF= option in ADF tests should be set to 0 here, because zero lagged differences are used in the test regression for the AR(1) model. However, to better illustrate how the ADF= and PP= options work, they are set to 1 in this example. The following PROC ARIMA statements conduct stationarity tests:

```
proc arima data=a;
  identify var=u stationarity=(adf=1);
  run;
  identify var=u stationarity=(pp=1);
  run;
quit;
```

The first IDENTIFY statement performs the ADF unit root tests for the original series, u. The descriptive statistics and stationarity test results are shown in Output 7.8.2.

Output 7.8.2 Descriptive Statistics and ADF Tests for the Nonstationary Series

Simulated ARIMA(1,1,0)

The ARIMA Procedure

Name of Variable = u	
Mean of Working Series	7.033652
Standard Deviation	7.81187
Number of Observations	100

Augmented Dickey-Fuller Unit Root Tests

Type	Lags	Rho	Pr < Rho	Tau	Pr < Tau	F	Pr > F
Zero Mean	0	2.0617	0.9892	1.66	0.9758		
	1	-1.0989	0.4543	-0.39	0.5405		
Single Mean	0	0.9908	0.9879	0.59	0.9889	1.83	0.6090
	1	-4.0438	0.5273	-1.08	0.7209	0.80	0.8684
Trend	0	0.1327	0.9964	0.08	0.9967	1.32	0.9121
	1	-5.3582	0.7871	-1.43	0.8471	1.50	0.8767

The three types of models are listed in the Type column in the "Augmented Dickey-Fuller Unit Root Tests" table in Output 7.8.2. The single-mean model fits best in this case, because the mean is not zero, as shown in Output 7.8.2, and there is no obvious time trend, as demonstrated in the observation plot in Output 7.8.1.

For each type of model, two rows of test statistics are reported: 0 lags and 1 lag. This is set by the ADF=1 option in the STATIONARITY= option. The row of 0 lags shows test statistics for an AR(1) model, where zero lagged differences are used in the test regression. The row of 1 lag shows test statistics for the AR(2) model, where one lagged differenced term is used in the test regression. As mentioned earlier, an AR(1) model would suffice in this case.

All three kinds of test statistics are reported under the ADF tests, as presented in Output 7.8.2. Tau test statistics are mostly used to decide whether to reject the null hypothesis. The p-values of the tau test statistics in both the AR(1) and AR(2) models are greater than 0.1, and the null hypothesis (the series is nonstationary; that is, there is a unit root) cannot be rejected at the 10% level.

The second IDENTIFY statement performs the Phillips-Perron (PP) tests for the original series, u. The stationarity test results are shown in Output 7.8.3.

Output 7.8.3 PP Tests for the Nonstationary Series

Phillips-Perron Unit Root Tests

Type	Lags	Rho	Pr < Rho	Tau	Pr < Tau
Zero Mean	0	2.0617	0.9892	1.66	0.9758
	1	1.5957	0.9715	1.01	0.9169
Single Mean	0	0.9908	0.9879	0.59	0.9889
	1	0.1542	0.9632	0.07	0.9618
Trend	0	0.1327	0.9964	0.08	0.9967
	1	-0.7639	0.9901	-0.35	0.9881

The output structure of the PP tests is similar to that of the ADF tests, except that there is no F test. The PP tests also report the rho test statistic (shown in the Rho column) and the tau test statistic (shown in the Tau

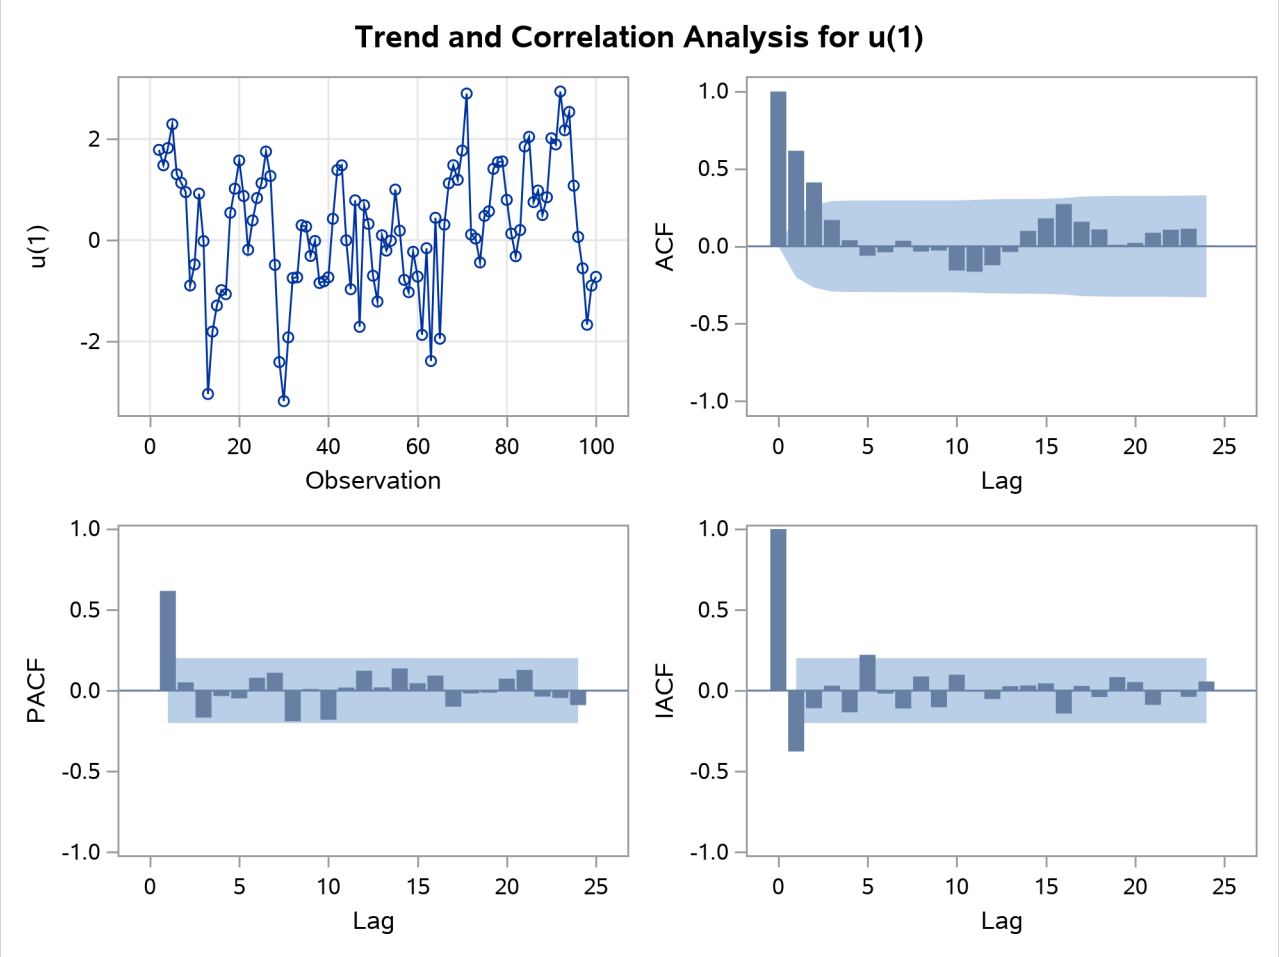
column), but they are calculated differently from the ADF tests. As shown in Output 7.8.3, the p-values of the tau test statistics are greater than 0.1, and therefore the PP tests also fail to reject the null hypothesis that the series is nonstationary.

The preceding results of the stationarity tests are consistent with the correlation analysis output. As shown in Output 7.8.1, the ACFs are significant and decay very slowly with increasing lag. This also suggests nonstationarity. Note that the estimated partial autocorrelation for the first lag is close to 1 and the PACFs decline quickly after the first lag. This suggests that you should consider differencing the series. The following statements identify the differenced series, ∇u:

```
proc arima data=a;
  identify var=u(1);
run;
```

The results of the graphical series correlation analysis are shown in Output 7.8.4.

Output 7.8.4 Correlation Analysis for the Differenced Series



The series also presents no trend and moves around 0, as shown in Output 7.8.4. As in the original series, the PACFs decline quickly after the first lag, suggesting an AR(1) model. Therefore, the stationarity tests are conducted with zero lagged differences, as in the following statements:

```
proc arima data=a;
  identify var=u(1) stationarity=(adf=0);
  run;
  identify var=u(1) stationarity=(pp=0);
  run;
quit;
```

The descriptive statistics and ADF test results are shown in Output 7.8.5. The PP test results are shown in Output 7.8.6.

Output 7.8.5 Descriptive Statistics and ADF Tests for the Differenced Series

Simulated ARIMA(1,1,0)

The ARIMA Procedure

Name of Variable = u	
Period(s) of Differencing	1
Mean of Working Series	0.235092
Standard Deviation	1.275033
Number of Observations	99
Observation(s) eliminated by differencing	1

Dickey-Fuller Unit Root Tests							
Type	Lags	Rho	Pr < Rho	Tau	Pr < Tau	F	Pr > F
Zero Mean	0	-36.1794	<.0001	-4.75	<.0001		
Single Mean	0	-37.1317	0.0009	-4.77	0.0002	11.42	0.0010
Trend	0	-38.5203	0.0005	-4.87	0.0007	11.87	0.0010

Output 7.8.6 PP Tests for the Differenced Series

Phillips-Perron Unit Root Tests					
Type	Lags	Rho	Pr < Rho	Tau	Pr < Tau
Zero Mean	0	-36.1794	<.0001	-4.75	<.0001
Single Mean	0	-37.1317	0.0009	-4.77	0.0002
Trend	0	-38.5203	0.0005	-4.87	0.0007

As indicated in Output 7.8.5, the mean of the differenced series is very close to 0, as is also suggested by Output 7.8.4. Therefore, you should look at the test statistics for the zero-mean model. You can also look at the single-mean model if you are not sure about the mean. The first IDENTIFY statement performs the ADF tests, and the second IDENTIFY statement performs the PP tests for the differenced series. Based on the p-values of both tests, the null hypothesis is rejected at the 1% level, indicating that the differenced series is stationary.

The preceding example demonstrates a nonstationary process that is stationary after first differencing. The next example demonstrates the unit root tests of a trend series that is composed of a time trend and a stationary part. The following DATA step generates a sample of 100 periods from the process: $u_t = 2t + 0.5u_t + a_t$, a_t iid $\mathrm{N}(0, 1)$.

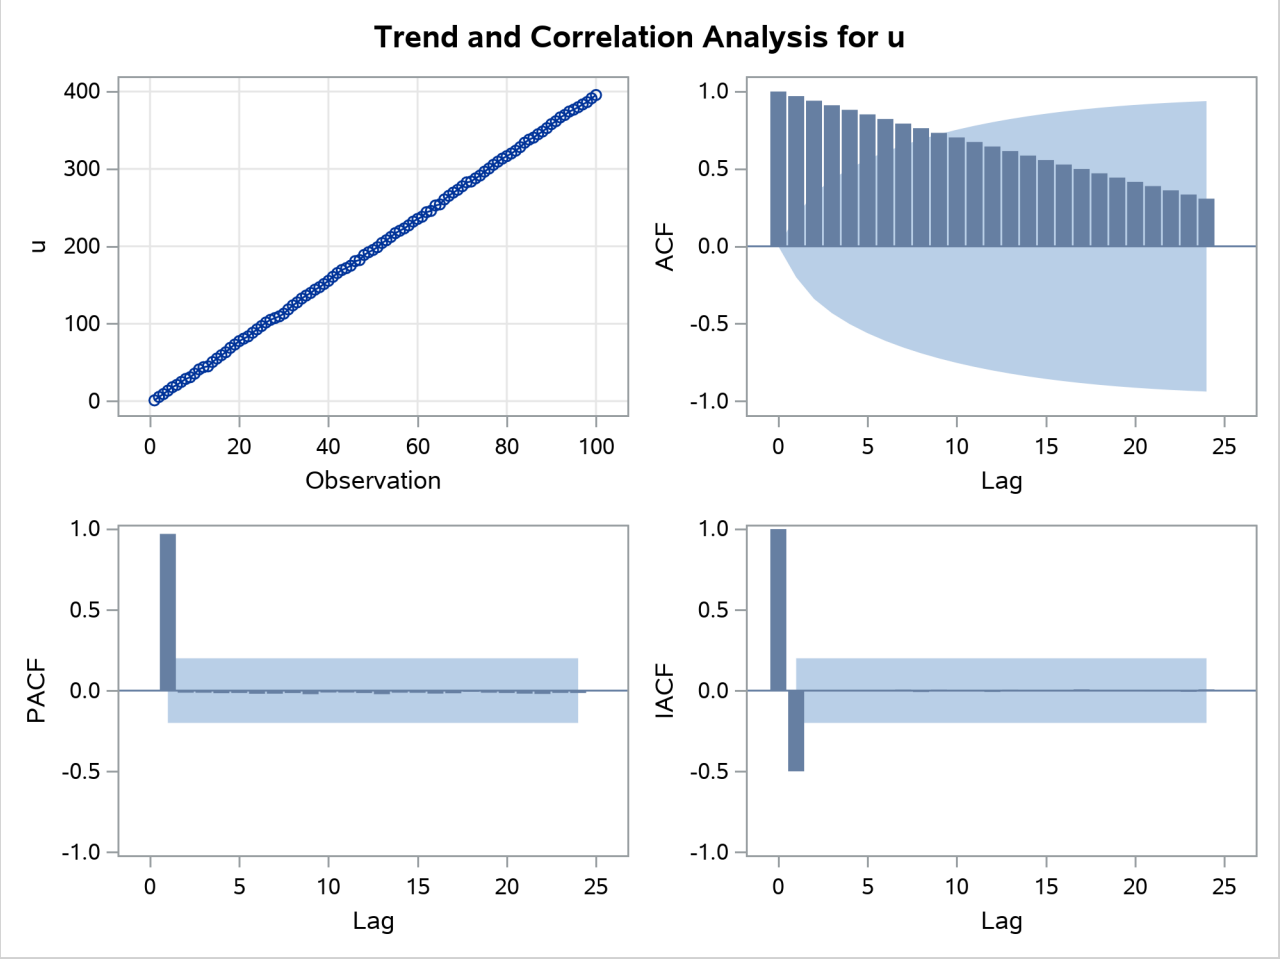
```
title 'Simulated Trend Series with a Stationary AR(1) Process';
data b;
  u1 = -20;
  do i = -50 to 100;
     a = rannor( 1234 );
     u = 2*i + 0.5*u1 + a;
     if i > 0 then output;
     u1 = u;
  end;
run;
```

As in the previous example, you first identify the model and check the observation and correlation graphs by using the following statements:

```
proc arima data=b;
  identify var=u;
run;
```

The results of the graphical series correlation analysis are shown in Output 7.8.7.

Output 7.8.7 Correlation Analysis for a Trend Series with a Stationary Part



As shown in the observation plot in Output 7.8.7, the series has an obvious time trend. From the ACF and PACF plots in Output 7.8.7, you could conclude that it should be an AR(1) process, because the ACF does not decline as much as the lag increases and the PACF shows only one significant lag. The ADF=0 and PP=0 options should be specified in the stationarity tests, as in the following statements:

```
proc arima data=b;
  identify var=u stationarity=(adf=0);
  run;
  identify var=u stationarity=(pp=0);
  run;
quit;
```

The first IDENTIFY statement performs the ADF unit root tests for u. The stationarity test results are shown in Output 7.8.8.

Output 7.8.8 ADF Tests for a Trend Series with a Stationary Part

Simulated Trend Series with a Stationary AR(1) Process

The ARIMA Procedure

Dickey-Fuller Unit Root Tests

Type	Lags	Rho	Pr < Rho	Tau	Pr < Tau	F	Pr > F
Zero Mean	0	1.4988	0.9653	14.74	0.9999		
Single Mean	0	-0.0036	0.9557	-0.04	0.9523	597.85	0.0010
Trend	0	-47.5985	0.0003	-5.52	<.0001	15.22	0.0010

As mentioned earlier, there is a trend in the data, and the "Trend" type in Output 7.8.8 should be the focus here. As shown in Output 7.8.8, the p-value of the tau test statistic for AR(1) (that is, the LAG=0 case) is less than 0.0001, indicating that the null hypothesis (nonstationarity) is rejected and the series is trend stationary. The p-value of the F test statistic is 0.001. This means that the joint test of time trend and nonstationarity is rejected at the 1% level. Note that a random walk process with a positive drift would have plots very similar to those in this case, but both the tau test and the F test would fail to reject the null hypothesis (nonstationarity) for a random-walk-with-drift process. The number of lagged differences in the test regression is important. In this particular case, when the model includes more than 12 lags of differenced terms, the p-values of the tau test statistics are greater than 0.15 and the null hypothesis cannot be rejected at the 10% level. To conduct valid ADF tests, you need to select the autocorrelations first. The PP tests correct the statistics for autocorrelations and do not require you to select the autocorrelations. The second IDENTIFY statement in the preceding code performs the PP tests for u. The stationarity test results are shown in Output 7.8.9.

Output 7.8.9 PP Tests for a Trend Series with a Stationary Part

Phillips-Perron Unit Root Tests

Type	Lags	Rho	Pr < Rho	Tau	Pr < Tau
Zero Mean	0	1.4988	0.9653	14.74	0.9999
Single Mean	0	-0.0036	0.9557	-0.04	0.9523
Trend	0	-47.5985	0.0003	-5.52	<.0001

As shown in Output 7.8.9, the p-value of the tau test statistic under the trend type is less than 0.001. If you include many lagged differences here, you will find that the p-values of the tau test statistic under the trend

type are still less than 0.001. The PP tests reject the null hypothesis of nonstationarity with all the different levels of autocorrelation. As a trade-off, the PP tests work well only in large samples.

Overview: AUTOREG Procedure

The AUTOREG procedure estimates and forecasts linear regression models for time series data when the errors are autocorrelated or heteroscedastic. The autoregressive error model is used to correct for autocorrelation, and the generalized autoregressive conditional heteroscedasticity (GARCH) model and its variants are used to model and correct for heteroscedasticity.

When time series data are used in regression analysis, often the error term is not independent through time. Instead, the errors are *serially correlated* (*autocorrelated*). If the error term is autocorrelated, the efficiency of ordinary least squares (OLS) parameter estimates is adversely affected and standard error estimates are biased.

The autoregressive error model corrects for serial correlation. The AUTOREG procedure can fit autoregressive error models of any order and can fit subset autoregressive models. You can also specify stepwise autoregression to select the autoregressive error model automatically.

To diagnose autocorrelation, the AUTOREG procedure produces generalized Durbin-Watson (DW) statistics and their marginal probabilities. Exact p-values are reported for generalized DW tests to any specified order. For models with lagged dependent regressors, PROC AUTOREG performs the Durbin t test and the Durbin h test for first-order autocorrelation and reports their marginal significance levels.

Ordinary regression analysis assumes that the error variance is the same for all observations. When the error variance is not constant, the data are said to be *heteroscedastic*, and ordinary least squares estimates are inefficient. Heteroscedasticity also affects the accuracy of forecast confidence limits. More efficient use of the data and more accurate prediction error estimates can be made by models that take the heteroscedasticity into account.

To test for heteroscedasticity, the AUTOREG procedure uses the portmanteau Q test statistics (McLeod and Li 1983), Engle's Lagrange multiplier tests (Engle 1982), tests from Lee and King (1993), and tests from Wong and Li (1995). Test statistics and significance p-values are reported for conditional heteroscedasticity at lags 1 through 12. The Jarque-Bera normality test statistic and its significance level are also reported to test for conditional nonnormality of residuals. The following tests for independence are also supported by the AUTOREG procedure for residual analysis and diagnostic checking: Brock-Dechert-Scheinkman (BDS) test, runs test, turning point test, and the rank version of the von Neumann ratio test.

The family of GARCH models provides a means of estimating and correcting for the changing variability of the data. The GARCH process assumes that the errors, although uncorrelated, are not independent, and it models the conditional error variance as a function of the past realizations of the series.

The AUTOREG procedure supports the following variations of the GARCH models:

- generalized ARCH (GARCH)
- integrated GARCH (IGARCH)
- exponential GARCH (EGARCH)
- quadratic GARCH (QGARCH)
- threshold GARCH (TGARCH)
- power GARCH (PGARCH)
- GARCH-in-mean (GARCH-M)

For GARCH-type models, the AUTOREG procedure produces the conditional prediction error variances in addition to parameter and covariance estimates.

The AUTOREG procedure can also analyze models that combine autoregressive errors and GARCH-type heteroscedasticity. PROC AUTOREG can output predictions of the conditional mean and variance for models with autocorrelated disturbances and changing conditional error variances over time.

Four estimation methods are supported for the autoregressive error model:

- Yule-Walker
- iterated Yule-Walker
- unconditional least squares
- exact maximum likelihood

The maximum likelihood method is used for GARCH models and for mixed AR-GARCH models.

The AUTOREG procedure produces forecasts and forecast confidence limits when future values of the independent variables are included in the input data set. PROC AUTOREG is a useful tool for forecasting because it uses the time series part of the model in addition to the systematic part in generating predicted values. The autoregressive error model takes into account recent departures from the trend in producing forecasts.

The AUTOREG procedure permits embedded missing values for the independent or dependent variables. The procedure should be used only for ordered and equally spaced time series data.

Getting Started: AUTOREG Procedure

Regression with Autocorrelated Errors

Ordinary regression analysis is based on several statistical assumptions. One key assumption is that the errors are independent of each other. However, with time series data, the ordinary regression residuals usually are correlated over time. It is not desirable to use ordinary regression analysis for time series data since the assumptions on which the classical linear regression model is based will usually be violated.

Violation of the independent errors assumption has three important consequences for ordinary regression. First, statistical tests of the significance of the parameters and the confidence limits for the predicted values are not correct. Second, the estimates of the regression coefficients are not as efficient as they would be if the autocorrelation were taken into account. Third, since the ordinary regression residuals are not independent, they contain information that can be used to improve the prediction of future values.

The AUTOREG procedure solves this problem by augmenting the regression model with an autoregressive model for the random error, thereby accounting for the autocorrelation of the errors. Instead of the usual regression model, the following autoregressive error model is used:

$$
\begin{aligned}
y_t &= \mathbf{x}_t'\beta + \nu_t \\
\nu_t &= -\varphi_1 \nu_{t-1} - \varphi_2 \nu_{t-2} - \cdots - \varphi_m \nu_{t-m} + \epsilon_t \\
\epsilon_t &\sim \mathrm{IN}(0, \sigma^2)
\end{aligned}
$$

The notation $\epsilon_t \sim \mathrm{IN}(0, \sigma^2)$ indicates that each ϵ_t is normally and independently distributed with mean 0 and variance σ^2.

By simultaneously estimating the regression coefficients β and the autoregressive error model parameters φ_i, the AUTOREG procedure corrects the regression estimates for autocorrelation. Thus, this kind of regression analysis is often called *autoregressive error correction* or *serial correlation correction*.

Example of Autocorrelated Data

A simulated time series is used to introduce the AUTOREG procedure. The following statements generate a simulated time series Y with second-order autocorrelation:

```
/* Regression with Autocorrelated Errors */
data a;
   ul = 0; ull = 0;
   do time = -10 to 36;
      u = + 1.3 * ul - .5 * ull + 2*rannor(12346);
      y = 10 + .5 * time + u;
      if time > 0 then output;
      ull = ul; ul = u;
   end;
run;
```

The series Y is a time trend plus a second-order autoregressive error. The model simulated is

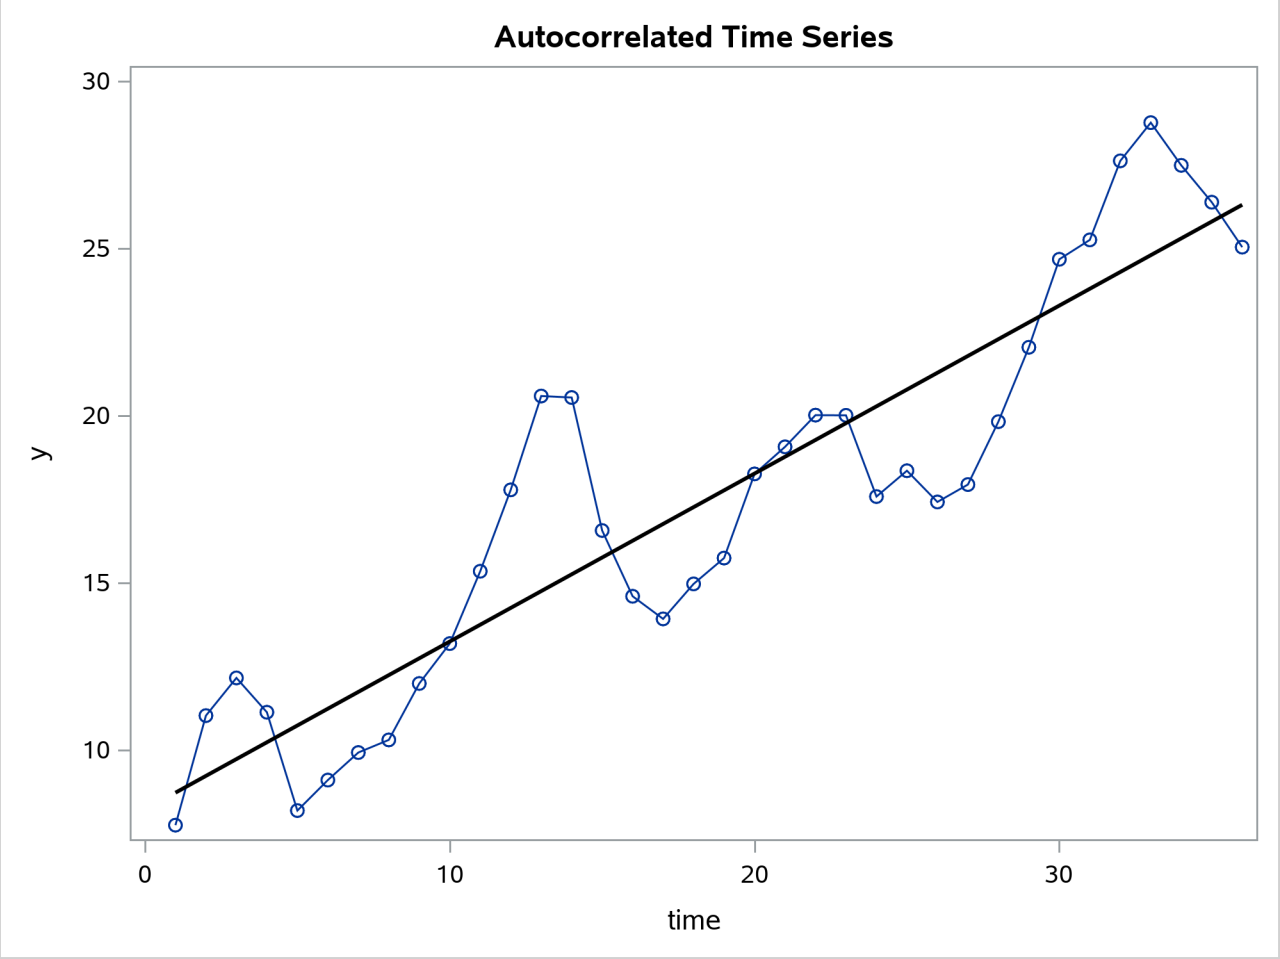
$$y_t = 10 + 0.5t + v_t$$
$$v_t = 1.3v_{t-1} - 0.5v_{t-2} + \epsilon_t$$
$$\epsilon_t \sim \text{IN}(0, 4)$$

The following statements plot the simulated time series Y. A linear regression trend line is shown for reference.

```
title 'Autocorrelated Time Series';
proc sgplot data=a noautolegend;
   series x=time y=y / markers;
   reg x=time y=y/  lineattrs=(color=black);
run;
```

The plot of series Y and the regression line are shown in Figure 8.1.

Figure 8.1 Autocorrelated Time Series



Note that when the series is above (or below) the OLS regression trend line, it tends to remain above (below) the trend for several periods. This pattern is an example of *positive autocorrelation*.

Time series regression usually involves independent variables other than a time trend. However, the simple time trend model is convenient for illustrating regression with autocorrelated errors, and the series Y shown in Figure 8.1 is used in the following introductory examples.

Ordinary Least Squares Regression

To use the AUTOREG procedure, specify the input data set in the PROC AUTOREG statement and specify the regression model in a MODEL statement. Specify the model by first naming the dependent variable and then listing the regressors after an equal sign, as is done in other SAS regression procedures. The following statements regress Y on TIME by using ordinary least squares:

```
proc autoreg data=a;
   model y = time;
run;
```

The AUTOREG procedure output is shown in Figure 8.2.

Figure 8.2 PROC AUTOREG Results for OLS Estimation

Autocorrelated Time Series

The AUTOREG Procedure

Dependent Variable	y

Ordinary Least Squares Estimates			
SSE	214.953429	DFE	34
MSE	6.32216	Root MSE	2.51439
SBC	173.659101	AIC	170.492063
MAE	2.01903356	AICC	170.855699
MAPE	12.5270666	HQC	171.597444
Durbin-Watson	0.4752	Total R-Square	0.8200

Parameter Estimates

Variable	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	8.2308	0.8559	9.62	<.0001
time	1	0.5021	0.0403	12.45	<.0001

The output first shows statistics for the model residuals. The model root mean square error (Root MSE) is 2.51, and the model R^2 (Total R-Square) is 0.82.

Other statistics shown are the sum of square errors (SSE); mean square error (MSE); mean absolute error (MAE); mean absolute percentage error (MAPE); error degrees of freedom (DFE, the number of observations minus the number of parameters); the information criteria SBC, HQC, AIC, and AICC; and the Durbin-Watson statistic. (Durbin-Watson statistics, MAE, MAPE, SBC, HQC, AIC, and AICC are discussed in the section "Goodness-of-Fit Measures and Information Criteria" on page 377.)

The output then shows a table of regression coefficients, with standard errors and *t* tests. The estimated model

is

$$y_t = 8.23 + 0.502t + \epsilon_t$$
$$\text{Est. Var}(\epsilon_t) = 6.32$$

The OLS parameter estimates are reasonably close to the true values, but the estimated error variance, 6.32, is much larger than the true value, 4.

Autoregressive Error Model

The following statements regress Y on TIME with the errors assumed to follow a second-order autoregressive process. The order of the autoregressive model is specified by the NLAG=2 option. The Yule-Walker estimation method is used by default. The example uses the METHOD=ML option to specify the exact maximum likelihood method instead.

```
ods graphics on;
proc autoreg data=a;
   model y = time / nlag=2 method=ml;
run;
```

The first part of the results is shown in Figure 8.3. The initial OLS results are produced first, followed by estimates of the autocorrelations computed from the OLS residuals. The autocorrelations are also displayed graphically.

Autoregressive parameters assumed given

Variable	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	7.8833	1.1678	6.75	<.0001
time	1	0.5096	0.0551	9.26	<.0001

The diagnostic statistics and parameter estimates tables in Figure 8.5 have the same form as in the OLS output, but the values shown are for the autoregressive error model. The MSE for the autoregressive model is 1.71, which is much smaller than the true value of 4. In small samples, the autoregressive error model tends to underestimate σ^2, while the OLS MSE overestimates σ^2.

Notice that the total R^2 statistic computed from the autoregressive model residuals is 0.954, reflecting the improved fit from the use of past residuals to help predict the next Y value. The transformed regression R^2 0.728 is the R^2 statistic for a regression of transformed variables adjusted for the estimated autocorrelation. (This is not the R^2 for the estimated trend line. For more information, see the section "Goodness-of-Fit Measures and Information Criteria" on page 377, later in this chapter.)

The parameter estimates table shows the ML estimates of the regression coefficients and includes two additional rows for the estimates of the autoregressive parameters, labeled AR(1) and AR(2).

The estimated model is

$$y_t = 7.88 + 0.5096t + v_t$$
$$v_t = 1.25v_{t-1} - 0.628v_{t-2} + \epsilon_t$$
$$\text{Est. Var}(\epsilon_t) = 1.71$$

Note that the signs of the autoregressive parameters shown in this equation for v_t are the reverse of the estimates shown in the AUTOREG procedure output. Figure 8.5 also shows the estimates of the regression coefficients with the standard errors recomputed on the assumption that the autoregressive parameter estimates equal the true values.

Predicted Values and Residuals

The AUTOREG procedure can produce two kinds of predicted values and corresponding residuals and confidence limits. The first kind of predicted value is obtained from only the structural part of the model, $\mathbf{x}_t'\mathbf{b}$. This is an estimate of the unconditional mean of the response variable at time t. For the time trend model, these predicted values trace the estimated trend. The second kind of predicted value includes both the structural part of the model and the predicted values of the autoregressive error process. The full model (conditional) predictions are used to forecast future values.

Use the OUTPUT statement to store predicted values and residuals in a SAS data set and to output other values such as confidence limits and variance estimates. The P= option specifies an output variable to contain the full model predicted values. The PM= option names an output variable for the predicted mean. The R= and RM= options specify output variables for the corresponding residuals, computed as the actual value minus the predicted value.

The following statements store both kinds of predicted values in the output data set. (The printed output is the same as previously shown in Figure 8.3 and Figure 8.5.)

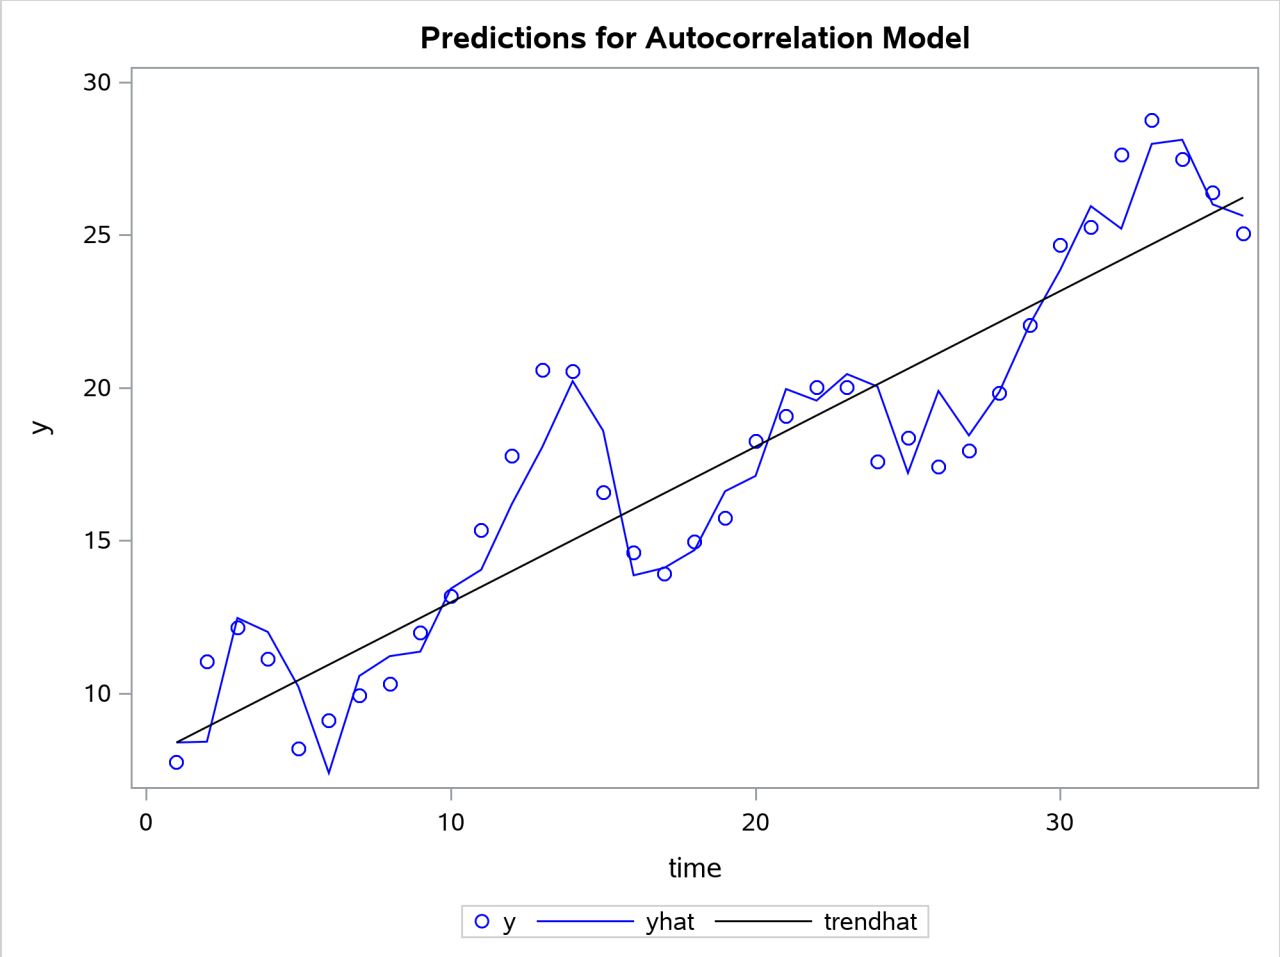
```
proc autoreg data=a;
   model y = time / nlag=2 method=ml;
   output out=p p=yhat pm=trendhat;
run;
```

The following statements plot the predicted values from the regression trend line and from the full model together with the actual values:

```
title 'Predictions for Autocorrelation Model';
proc sgplot data=p;
   scatter x=time y=y / markerattrs=(color=blue);
   series x=time y=yhat / lineattrs=(color=blue);
   series x=time y=trendhat / lineattrs=(color=black);
run;
```

The plot of predicted values is shown in Figure 8.6.

Figure 8.6 PROC AUTOREG Predictions



In Figure 8.6 the straight line is the autocorrelation corrected regression line, traced out by the structural predicted values TRENDHAT. The jagged line traces the full model prediction values. The actual values are marked by asterisks. This plot graphically illustrates the improvement in fit provided by the autoregressive error process for highly autocorrelated data.

Forecasting Autoregressive Error Models

To produce forecasts for future periods, include observations for the forecast periods in the input data set. The forecast observations must provide values for the independent variables and have missing values for the response variable.

For the time trend model, the only regressor is time. The following statements add observations for time periods 37 through 46 to the data set A to produce an augmented data set B:

```
data b;
   y = .;
   do time = 37 to 46; output; end;
run;

data b;
   merge a b;
   by time;
run;
```

To produce the forecast, use the augmented data set as input to PROC AUTOREG, and specify the appropriate options in the OUTPUT statement. The following statements produce forecasts for the time trend with autoregressive error model. The output data set includes all the variables in the input data set, the forecast values (YHAT), the predicted trend (YTREND), and the upper (UCL) and lower (LCL) 95% confidence limits.

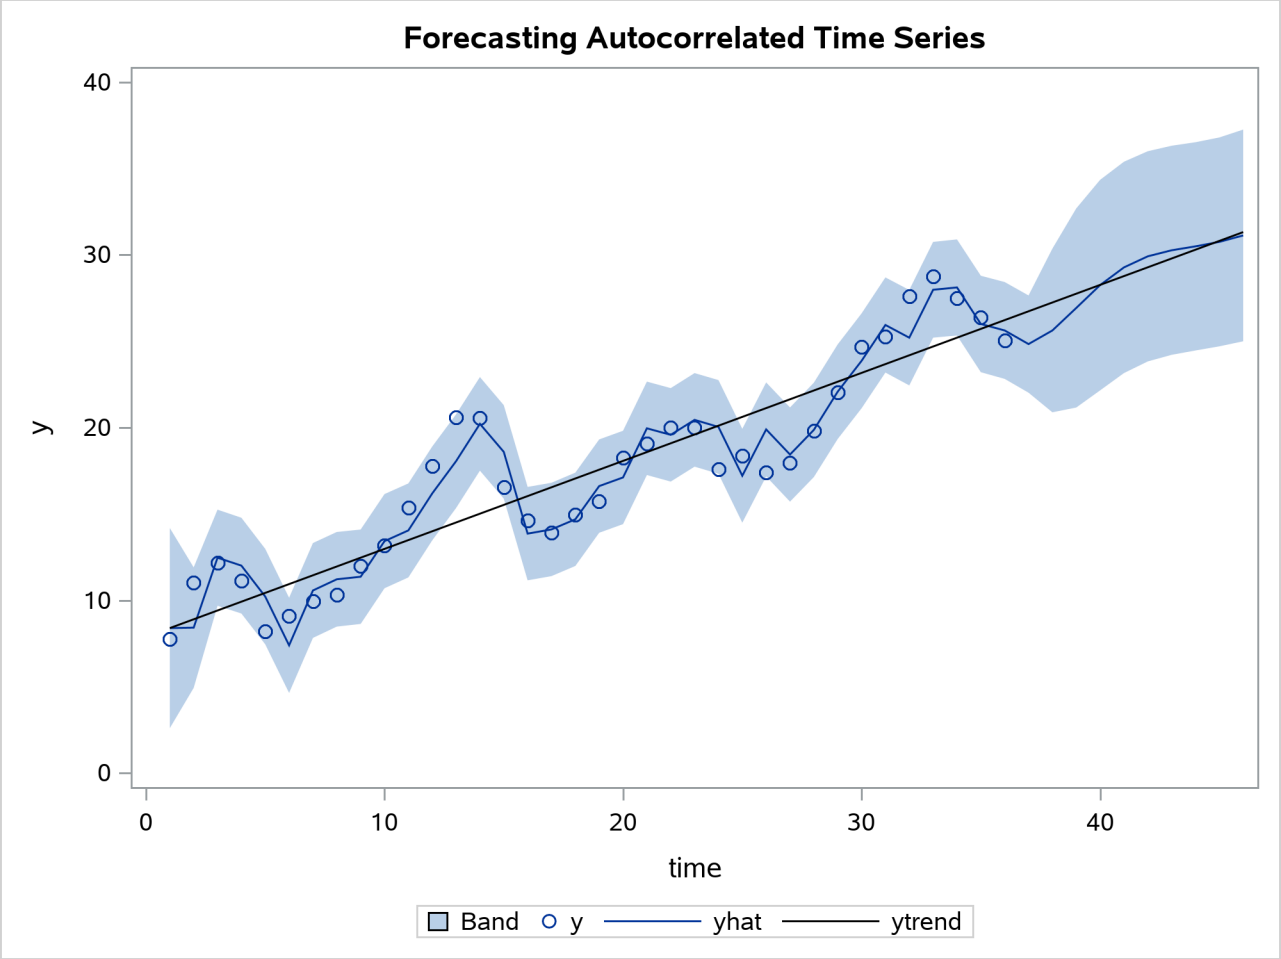
```
proc autoreg data=b;
   model y = time / nlag=2 method=ml;
   output out=p p=yhat pm=ytrend
                lcl=lcl ucl=ucl;
run;
```

The following statements plot the predicted values and confidence limits, and they also plot the trend line for reference. The actual observations are shown for periods 16 through 36, and a reference line is drawn at the start of the out-of-sample forecasts.

```
title 'Forecasting Autocorrelated Time Series';
proc sgplot data=p;
   band x=time upper=ucl lower=lcl;
   scatter x=time y=y;
   series x=time y=yhat;
   series x=time y=ytrend / lineattrs=(color=black);
run;
```

The plot is shown in Figure 8.7. Notice that the forecasts take into account the recent departures from the trend but converge back to the trend line for longer forecast horizons.

Figure 8.7 PROC AUTOREG Forecasts



Testing for Autocorrelation

In the preceding section, it is assumed that the order of the autoregressive process is known. In practice, you need to test for the presence of autocorrelation.

The Durbin-Watson test is a widely used method of testing for autocorrelation. The first-order Durbin-Watson statistic is printed by default. This statistic can be used to test for first-order autocorrelation. Use the DWPROB option to print the significance level (p-values) for the Durbin-Watson tests. (Since the Durbin-Watson p-values are computationally expensive, they are not reported by default.)

You can use the DW= option to request higher-order Durbin-Watson statistics. Since the ordinary Durbin-Watson statistic tests only for first-order autocorrelation, the Durbin-Watson statistics for higher-order autocorrelation are called *generalized Durbin-Watson statistics*.

The following statements perform the Durbin-Watson test for autocorrelation in the OLS residuals for orders 1 through 4. The DWPROB option prints the marginal significance levels (p-values) for the Durbin-Watson statistics.

```
/*-- Durbin-Watson test for autocorrelation --*/
proc autoreg data=a;
   model y = time / dw=4 dwprob;
run;
```

The AUTOREG procedure output is shown in Figure 8.8. In this case, the first-order Durbin-Watson test is highly significant, with $p < .0001$ for the hypothesis of no first-order autocorrelation. Thus, autocorrelation correction is needed.

Figure 8.8 Durbin-Watson Test Results for OLS Residuals

Forecasting Autocorrelated Time Series

The AUTOREG Procedure

Dependent Variable	y

Ordinary Least Squares Estimates			
SSE	214.953429	DFE	34
MSE	6.32216	Root MSE	2.51439
SBC	173.659101	AIC	170.492063
MAE	2.01903356	AICC	170.855699
MAPE	12.5270666	HQC	171.597444
		Total R-Square	0.8200

Durbin-Watson Statistics			
Order	DW	Pr < DW	Pr > DW
1	0.4752	<.0001	1.0000
2	1.2935	0.0137	0.9863
3	2.0694	0.6545	0.3455
4	2.5544	0.9818	0.0182

NOTE: Pr<DW is the p-value for testing positive autocorrelation, and Pr>DW is the p-value for testing negative autocorrelation.

Parameter Estimates					
Variable	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	8.2308	0.8559	9.62	<.0001
time	1	0.5021	0.0403	12.45	<.0001

Using the Durbin-Watson test, you can decide if autocorrelation correction is needed. However, generalized Durbin-Watson tests should not be used to decide on the autoregressive order. The higher-order tests assume the absence of lower-order autocorrelation. If the ordinary Durbin-Watson test indicates no first-order autocorrelation, you can use the second-order test to check for second-order autocorrelation. Once autocorrelation is detected, further tests at higher orders are not appropriate. In Figure 8.8, since the first-order Durbin-Watson test is significant, the order 2, 3, and 4 tests can be ignored.

When using Durbin-Watson tests to check for autocorrelation, you should specify an order at least as large as the order of any potential seasonality, since seasonality produces autocorrelation at the seasonal lag. For example, for quarterly data use DW=4, and for monthly data use DW=12.

Lagged Dependent Variables

The Durbin-Watson tests are not valid when the lagged dependent variable is used in the regression model. In this case, the Durbin *h* test or Durbin *t* test can be used to test for first-order autocorrelation.

For the Durbin *h* test, specify the name of the lagged dependent variable in the LAGDEP= option. For the Durbin *t* test, specify the LAGDEP option without giving the name of the lagged dependent variable.

For example, the following statements add the variable YLAG to the data set A and regress Y on YLAG instead of TIME:

```
data b;
   set a;
   ylag = lag1( y );
run;

proc autoreg data=b;
   model y = ylag / lagdep=ylag;
run;
```

The results are shown in Figure 8.9. The Durbin *h* statistic 2.78 is significant with a *p*-value of 0.0027, indicating autocorrelation.

Stepwise Autoregression

Once you determine that autocorrelation correction is needed, you must select the order of the autoregressive error model to use. One way to select the order of the autoregressive error model is *stepwise autoregression*. The stepwise autoregression method initially fits a high-order model with many autoregressive lags and then sequentially removes autoregressive parameters until all remaining autoregressive parameters have significant *t* tests.

To use stepwise autoregression, specify the BACKSTEP option, and specify a large order with the NLAG= option. The following statements show the stepwise feature, using an initial order of 5:

```
/*-- stepwise autoregression --*/
proc autoreg data=a;
   model y = time / method=ml nlag=5 backstep;
run;
```

The results are shown in Figure 8.10.

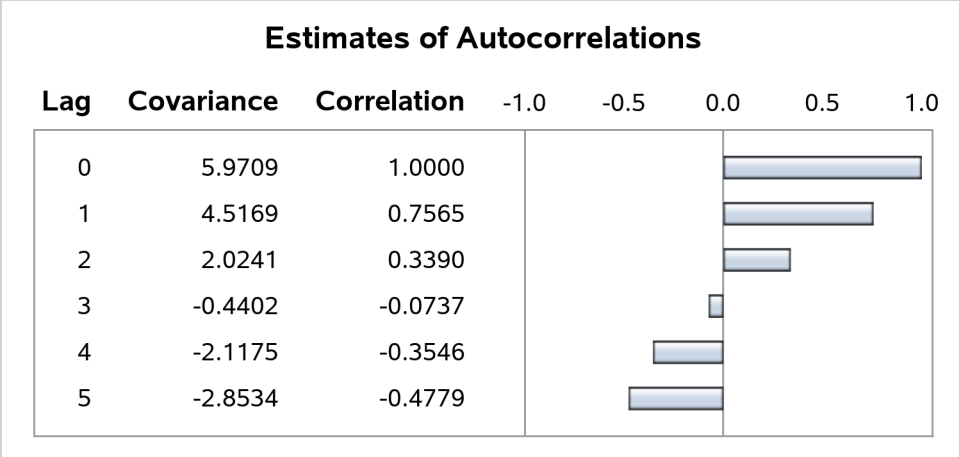
5	0.131734	1.21	0.2340

Figure 8.11 Estimates of Autocorrelations



The estimates of the autocorrelations are shown for five lags. The backward elimination of autoregressive terms report shows that the autoregressive parameters at lags 3, 4, and 5 were insignificant and eliminated, resulting in the second-order model shown previously in Figure 8.5. By default, retained autoregressive parameters must be significant at the 0.05 level, but you can control this with the SLSTAY= option. The remainder of the output from this example is the same as that in Figure 8.3 and Figure 8.5. It is not repeated here.

The stepwise autoregressive process is performed using the Yule-Walker method. The maximum likelihood estimates are produced after the order of the model is determined from the significance tests of the preliminary Yule-Walker estimates.

When you use stepwise autoregression, it is a good idea to specify an NLAG= option value larger than the order of any potential seasonality, because seasonality produces autocorrelation at the seasonal lag. For example, for monthly data use NLAG=13, and for quarterly data use NLAG=5.

Subset and Factored Models

In the previous example, the BACKSTEP option dropped lags 3, 4, and 5, leaving a second-order model. However, in other cases a parameter at a longer lag may be kept while some smaller lags are dropped. For example, the stepwise autoregression method might drop lags 2, 3, and 5 but keep lags 1 and 4. This is called a *subset model*, because the number of estimated autoregressive parameters is lower than the order of the model.

Subset models are common for seasonal data and often correspond to *factored* autoregressive models. A factored model is the product of simpler autoregressive models. For example, the best model for seasonal monthly data might be the combination of a first-order model for recent effects with a 12th-order subset model for the seasonality, with a single parameter at lag 12. This results in a 13th-order subset model with nonzero parameters at lags 1, 12, and 13. For further discussion of subset and factored autoregressive models, see Chapter 7, "The ARIMA Procedure."

You can specify subset models by using the NLAG= option. List the lags to include in the autoregressive model within parentheses. The following statements show an example of specifying the subset model that results from the combination of a first-order process for recent effects with a fourth-order seasonal process:

```
/*-- specifying the lags --*/
proc autoreg data=a;
   model y = time / nlag=(1 4 5);
run;
```

The MODEL statement specifies the following fifth-order autoregressive error model:

$$y_t = a + bt + v_t$$

$$v_t = -\varphi_1 v_{t-1} - \varphi_4 v_{t-4} - \varphi_5 v_{t-5} + \epsilon_t$$

Testing for Heteroscedasticity

One of the key assumptions of the ordinary regression model is that the errors have the same variance throughout the sample. This is also called the *homoscedasticity* model. If the error variance is not constant, the data are said to be *heteroscedastic*.

Since ordinary least squares regression assumes constant error variance, heteroscedasticity causes the OLS estimates to be inefficient. Models that take into account the changing variance can make more efficient use of the data. Also, heteroscedasticity can make the OLS forecast error variance inaccurate because the predicted forecast variance is based on the average variance instead of on the variability at the end of the series.

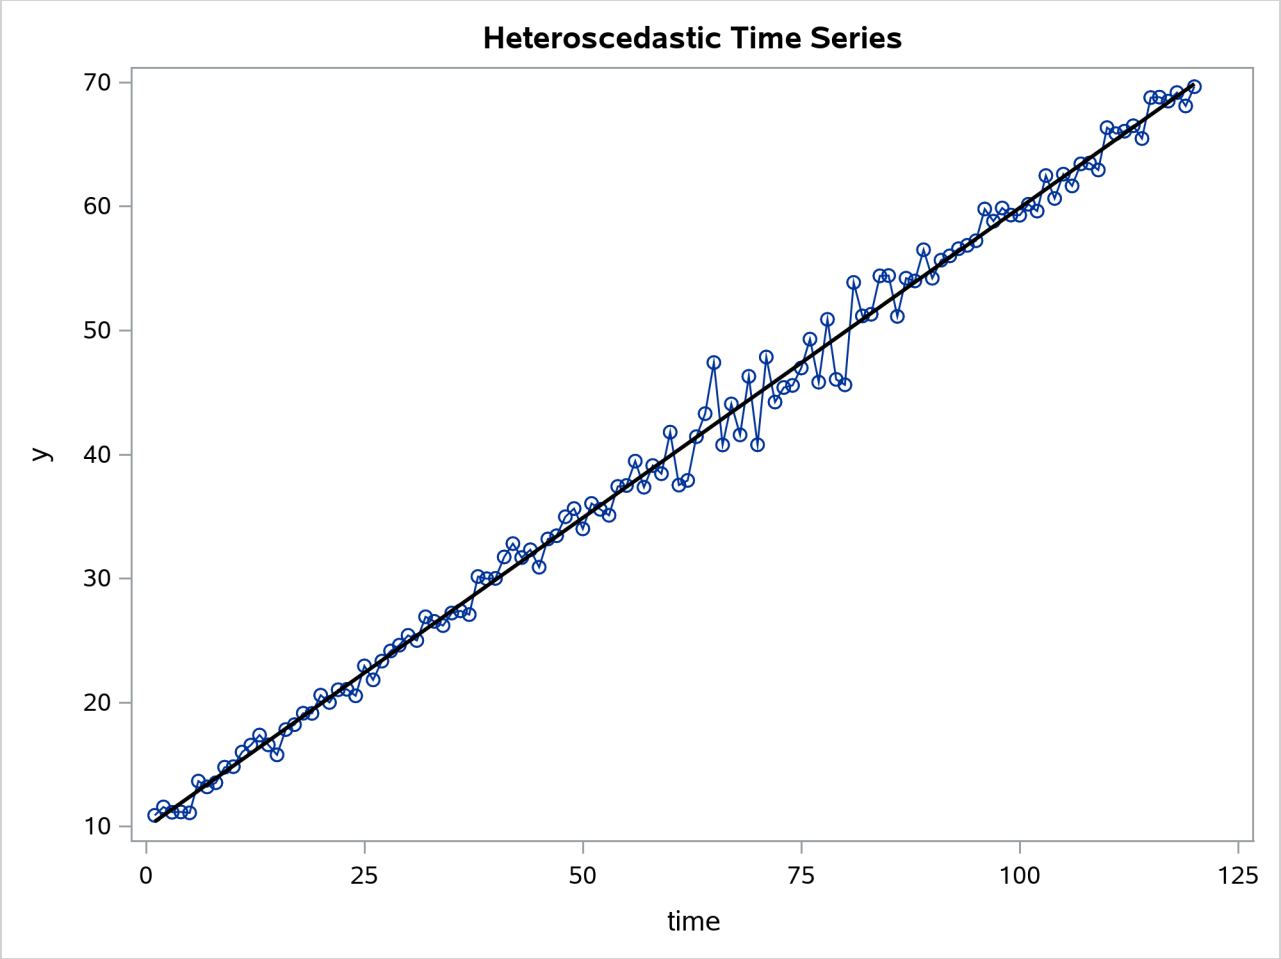
To illustrate heteroscedastic time series, the following statements create the simulated series Y. The variable Y has an error variance that changes from 1 to 4 in the middle part of the series.

```
data a;
   do time = -10 to 120;
      s = 1 + (time >= 60 & time < 90);
      u = s*rannor(12346);
      y = 10 + .5 * time + u;
      if time > 0 then output;
      end;
run;

title 'Heteroscedastic Time Series';
proc sgplot data=a noautolegend;
   series x=time y=y / markers;
   reg x=time y=y / lineattrs=(color=black);
run;
```

The simulated series is plotted in Figure 8.12.

Figure 8.12 Heteroscedastic and Autocorrelated Series



To test for heteroscedasticity with PROC AUTOREG, specify the ARCHTEST option. The following statements regress Y on TIME and use the ARCHTEST= option to test for heteroscedastic OLS residuals:

```
/*-- test for heteroscedastic OLS residuals --*/
proc autoreg data=a;
   model y = time / archtest;
   output out=r r=yresid;
run;
```

The PROC AUTOREG output is shown in Figure 8.13. The Q statistics test for changes in variance across time by using lag windows that range from 1 through 12. (For more information, see the section "Testing for Nonlinear Dependence: Heteroscedasticity Tests" on page 399.) The p-values for the test statistics strongly indicate heteroscedasticity, with $p < 0.0001$ for all lag windows.

The Lagrange multiplier (LM) tests also indicate heteroscedasticity. These tests can also help determine the order of the ARCH model that is appropriate for modeling the heteroscedasticity, assuming that the changing variance follows an autoregressive conditional heteroscedasticity model.

10	73.2949	<.0001	38.9814	<.0001
11	74.9273	<.0001	39.9395	<.0001
12	76.0254	<.0001	40.8144	<.0001

Parameter Estimates					
Variable	**DF**	**Estimate**	**Standard Error**	**t Value**	**Approx Pr > |t|**
Intercept	1	9.8684	0.2529	39.02	<.0001
time	1	0.5000	0.003628	137.82	<.0001

The tests of Lee and King (1993) and Wong and Li (1995) can also be applied to check the absence of ARCH effects. The following example shows that Wong and Li's test is robust to detect the presence of ARCH effects with the existence of outliers:

```
/*-- data with outliers at observation 10 --*/
data b;
   do time = -10 to 120;
      s = 1 + (time >= 60 & time < 90);
      u = s*rannor(12346);
      y = 10 + .5 * time + u;
      if time = 10 then
         do; y = 200; end;
      if time > 0 then output;
   end;
```

```
run;
/*-- test for heteroscedastic OLS residuals --*/
proc autoreg data=b;
   model y = time / archtest=(qlm) ;
   model y = time / archtest=(lk,wl) ;
run;
```

As shown in Figure 8.14, the *p*-values of Q or LM statistics for all lag windows are above 90%, which fails to reject the null hypothesis of the absence of ARCH effects. Lee and King's test, which rejects the null hypothesis for lags more than 8 at 10% significance level, works better. Wong and Li's test works best, rejecting the null hypothesis and detecting the presence of ARCH effects for all lag windows.

Heteroscedasticity and GARCH Models

There are several approaches to dealing with heteroscedasticity. If the error variance at different times is known, weighted regression is a good method. If, as is usually the case, the error variance is unknown and must be estimated from the data, you can model the changing error variance.

The *generalized autoregressive conditional heteroscedasticity* (GARCH) model is one approach to modeling time series with heteroscedastic errors. The GARCH regression model with autoregressive errors is

$$y_t = \mathbf{x}_t'\beta + v_t$$

$$v_t = \epsilon_t - \varphi_1 v_{t-1} - \cdots - \varphi_m v_{t-m}$$

$$\epsilon_t = \sqrt{h_t}e_t$$

$$h_t = \omega + \sum_{i=1}^{q} \alpha_i \epsilon_{t-i}^2 + \sum_{j=1}^{p} \gamma_j h_{t-j}$$

$$e_t \sim \mathrm{IN}(0,1)$$

This model combines the mth-order autoregressive error model with the GARCH(p,q) variance model. It is denoted as the AR(m)-GARCH(p,q) regression model.

The tests for the presence of ARCH effects (namely, Q and LM tests, tests from Lee and King (1993) and tests from Wong and Li (1995)) can help determine the order of the ARCH model appropriate for the data. For example, the Lagrange multiplier (LM) tests shown in Figure 8.13 are significant ($p < 0.0001$) through order 12, which indicates that a very high-order ARCH model is needed to model the heteroscedasticity.

The basic ARCH(q) model ($p = 0$) is a *short memory* process in that only the most recent q squared residuals are used to estimate the changing variance. The GARCH model ($p > 0$) allows *long memory* processes, which use all the past squared residuals to estimate the current variance. The LM tests in Figure 8.13 suggest the use of the GARCH model ($p > 0$) instead of the ARCH model.

The GARCH(p,q) model is specified with the GARCH=(P=p, Q=q) option in the MODEL statement. The basic ARCH(q) model is the same as the GARCH$(0,q)$ model and is specified with the GARCH=(Q=q) option.

The following statements fit an AR(2)-GARCH(1, 1) model for the Y series that is regressed on TIME. The GARCH=(P=1,Q=1) option specifies the GARCH(1, 1) conditional variance model. The NLAG=2 option specifies the AR(2) error process. Only the maximum likelihood method is supported for GARCH models; therefore, the METHOD= option is not needed. The CEV= option in the OUTPUT statement stores the estimated conditional error variance at each time period in the variable VHAT in an output data set named OUT. The data set is the same as in the section "Testing for Heteroscedasticity" on page 321.

```
data c;
   ul=0; ull=0;
   do time = -10 to 120;
      s = 1 + (time >= 60 & time < 90);
      u = + 1.3 * ul - .5 * ull + s*rannor(12346);
      y = 10 + .5 * time + u;
      if time > 0 then output;
      ull = ul; ul = u;
```

```
      end;
run;
title 'AR(2)-GARCH(1,1) model for the Y series regressed on TIME';
proc autoreg data=c;
   model y = time / nlag=2 garch=(q=1,p=1) maxit=50;
   output out=out cev=vhat;
run;
```

The results for the GARCH model are shown in Figure 8.15. (The preliminary estimates are not shown.)

MAPE	2.75945337	**HQC**	396.804343
		Normality Test	0.0838
		Pr > ChiSq	0.9590

Parameter Estimates

Variable	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	8.9301	0.7456	11.98	<.0001
time	1	0.5075	0.0111	45.90	<.0001
AR1	1	-1.2301	0.1111	-11.07	<.0001
AR2	1	0.5023	0.1090	4.61	<.0001
ARCH0	1	0.0850	0.0780	1.09	0.2758
ARCH1	1	0.2103	0.0873	2.41	0.0159
GARCH1	1	0.7375	0.0989	7.46	<.0001

The normality test is not significant ($p = 0.959$), which is consistent with the hypothesis that the residuals from the GARCH model, $\epsilon_t / \sqrt{h_t}$, are normally distributed. The parameter estimates table includes rows for the GARCH parameters. ARCH0 represents the estimate for the parameter ω, ARCH1 represents α_1, and GARCH1 represents γ_1.

The following statements transform the estimated conditional error variance series VHAT to the estimated standard deviation series SHAT. Then, they plot SHAT together with the true standard deviation S used to generate the simulated data.

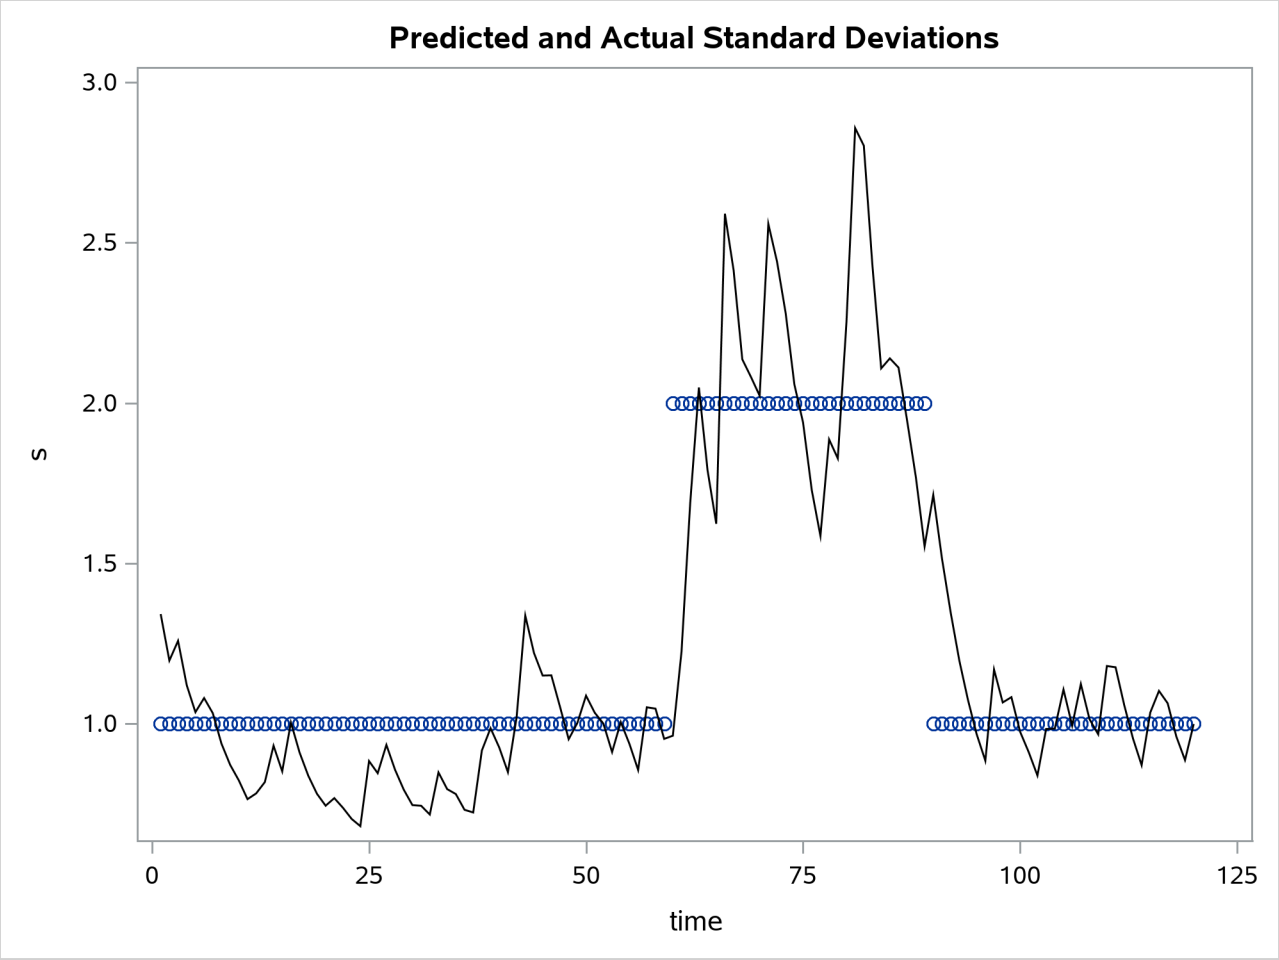
```
data out;
   set out;
   shat = sqrt( vhat );
run;

title 'Predicted and Actual Standard Deviations';
proc sgplot data=out noautolegend;
```

```
    scatter x=time y=s;
    series x=time y=shat/ lineattrs=(color=black);
run;
```

The plot is shown in Figure 8.16.

Figure 8.16 Estimated and Actual Error Standard Deviation Series



In this example note that the form of heteroscedasticity used in generating the simulated series Y does not fit the GARCH model. The GARCH model assumes *conditional* heteroscedasticity, with homoscedastic unconditional error variance. That is, the GARCH model assumes that the changes in variance are a function of the realizations of preceding errors and that these changes represent temporary and random departures from a constant unconditional variance. The data-generating process used to simulate series Y, contrary to the GARCH model, has exogenous unconditional heteroscedasticity that is independent of past errors.

Nonetheless, as shown in Figure 8.16, the GARCH model does a reasonably good job of approximating the error variance in this example, and some improvement in the efficiency of the estimator of the regression parameters can be expected.

The GARCH model might perform better in cases where theory suggests that the data-generating process produces true autoregressive conditional heteroscedasticity. This is the case in some economic theories of asset returns, and GARCH-type models are often used for analysis of financial market data.

GARCH Models

The AUTOREG procedure supports several variations of GARCH models.

Using the TYPE= option along with the GARCH= option enables you to control the constraints placed on the estimated GARCH parameters. You can specify unconstrained, nonnegativity-constrained (default), stationarity-constrained, or integration-constrained models. The integration constraint produces the integrated GARCH (IGARCH) model.

You can also use the TYPE= option to specify the exponential form of the GARCH model, called the EGARCH model, or other types of GARCH models, namely the quadratic GARCH (QGARCH), threshold GARCH (TGARCH), and power GARCH (PGARCH) models. The MEAN= option along with the GARCH= option specifies the GARCH-in-mean (GARCH-M) model.

The following statements illustrate the use of the TYPE= option to fit an AR(2)-EGARCH(1, 1) model to the series Y. (Output is not shown.)

```
/*-- AR(2)-EGARCH(1,1) model --*/
proc autoreg data=a;
   model y = time / nlag=2 garch=(p=1,q=1,type=exp);
run;
```

For more information, see the section "GARCH Models" on page 368.

Syntax: AUTOREG Procedure

The following statements are available in the AUTOREG procedure:

PROC AUTOREG *options* ;
BY *variables* ;
CLASS *variables* ;
MODEL *dependent* = *regressors* / *options* ;
HETERO *variables* / *options* ;
NLOPTIONS *options* ;
OUTPUT < **OUT=***SAS-data-set* > < *options* > < *keyword=name* > ;
RESTRICT *equation , . . . , equation* ;
TEST *equation , . . . , equation* / *option* ;

You must specify at least one MODEL statement. One OUTPUT statement can follow each MODEL statement. One HETERO statement can follow each MODEL statement.

Functional Summary

The statements and options available in the AUTOREG procedure are summarized in Table 8.1.

Table 8.1 AUTOREG Functional Summary

Description	Statement	Option
Data Set Options

Output transformed variables	OUTPUT	TRANSFORM=
Output upper confidence limit	OUTPUT	UCL=
Output upper confidence limit for structural predicted values	OUTPUT	UCLM=

PROC AUTOREG Statement

PROC AUTOREG *options* **;**

You can specify the following *options*:

COVOUT
writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if you specify the OUTEST= option.

DATA=*SAS-data-set*
specifies the input SAS data set. If you do not specify this option, PROC AUTOREG uses the most recently created SAS data set.

JACOBOUT
writes the errors ϵ_t and their derivatives with respect to regression parameters to the data set that is specified in the OUTEST= option. The JACOBOUT option is valid only if you specify the OUTEST= option. The errors are written in a column labeled Parameter Estimate for y, and the derivatives with respect to the coefficient of a regression variable x are written in a column labeled Parameter Estimate

for x. Note that both the errors and their derivatives appear in the gradient vector of the unconditional least squares objective function S, and hence you can use them to compute the Jacobian matrix.

OUTEST=*SAS-data-set*
writes the parameter estimates to an output data set. For information about the contents of this data set, see the section "OUTEST= Data Set" on page 409.

PLOTS<(*global-plot-options***)> < = (***specific-plot-options***)>**
requests that the AUTOREG procedure produce statistical graphics via the Output Delivery System, provided that the ODS GRAPHICS statement has been specified. For general information about ODS Graphics, see Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*). The *global-plot-options* apply to all relevant plots generated by the AUTOREG procedure. You can specify the following *global-plot-options*.

Global Plot Options

ONLY suppresses the default plots. Only the plots that you specifically request are produced.

UNPACKPANEL | UNPACK displays each graph separately. (By default, some graphs can appear together in a single panel.)

Specific Plot Options

ACF produces the autocorrelation function plot.

IACF produces the inverse autocorrelation function plot of residuals.

PACF produces the partial autocorrelation function plot of residuals.

ALL produces all plots appropriate for the particular analysis.

COOKSD produces the Cook's D plot.

FITPLOT plots the predicted and actual values.

NONE suppresses all plots.

QQ produces the Q-Q plot of residuals.

RESIDUAL | RES plots the residuals.

RESIDUALHISTOGRAM | RESIDHISTOGRAM plots the histogram of residuals.

STANDARDRESIDUAL plots the standardized residuals, which are the residuals divided by the standard errors of individual predicted values. The formula of the standardized residuals for the observation $i = 1, 2, \ldots, n$ is $r_i / \sqrt{(1 + h_i)\hat{\sigma}^2}$, where $r_i = Y - \hat{Y}$ and $h_i = x_i (X'X)^{-1} x_i'$. For the models that use the NLAG= or GARCH= option in the MODEL statement or use the HETERO statement, this option replaces the STUDENTRESIDUAL option.

STUDENTRESIDUAL plots the studentized residuals, which are the residuals divided by their standard errors. The formula of the studentized residuals for the observation $i = 1, 2, \ldots, n$ is $r_i / \sqrt{(1 - h_i)\hat{\sigma}^2}$, where $r_i = Y - \hat{Y}$ and $h_i = x_i (X'X)^{-1} x_i'$. For the models that use the NLAG= or GARCH= option in the MODEL statement or use the HETERO statement, this option is replaced by the STANDARDRESIDUAL option.

WHITENOISE plots the white noise probabilities.

In addition, any of the following MODEL statement options can be specified in the PROC AUTOREG statement, which is equivalent to specifying the option for every MODEL statement: ALL, ARCHTEST, BACKSTEP, CENTER, COEF, CONVERGE=, CORRB, COVB, DW=, DWPROB, GINV, ITER, ITPRINT, MAXITER=, METHOD=, NOINT, NOMISS, NOPRINT, and PARTIAL.

BY Statement

BY *variables* **;**

A BY statement can be used in PROC AUTOREG to obtain separate analyses on observations in groups defined by the BY variables.

CLASS Statement

CLASS *variables* **;**

The CLASS statement names the classification variables to be used in the analysis. Classification variables can be either character or numeric.

In PROC AUTOREG, the CLASS statement enables you to output classification variables to a data set that contains a copy of the original data.

Class levels are determined from the formatted values of the CLASS variables. Thus, you can use formats to group values into levels. For more information, see the discussion of the FORMAT procedure in *Base SAS Procedures Guide*.

HETERO Statement

HETERO *variables / options* **;**

The HETERO statement specifies variables that are related to the heteroscedasticity of the residuals and the way these variables are used to model the error variance of the regression.

The heteroscedastic regression model supported by the HETERO statement is

$$y_t = \mathbf{x}_t \beta + \epsilon_t$$

$$\epsilon_t \sim \mathrm{N}(0, \sigma_t^2)$$

$$\sigma_t^2 = \sigma^2 h_t$$

$$h_t = l(\mathbf{z}'_t \eta)$$

The HETERO statement specifies a model for the conditional variance h_t. The vector $\mathbf{z}_t$ is composed of the variables listed in the HETERO statement, η is a parameter vector, and $l(\cdot)$ is a link function that depends on the value of the LINK= option. In the printed output, $HET0$ represents the estimate of sigma, while $HET1$ - $HETn$ are the estimates of parameters in the η vector.

The keyword XBETA can be used in the *variables* list to refer to the model predicted value $\mathbf{x}'_t\beta$. If XBETA is specified in the *variables* list, other variables in the HETERO statement will be ignored. In addition, XBETA cannot be specified in the GARCH process.

For heteroscedastic regression models without GARCH effects, the errors ϵ_t are assumed to be uncorrelated—the heteroscedasticity models specified by the HETERO statement cannot be combined with an autoregressive model for the errors. Thus, when a HETERO statement is used, the NLAG= option cannot be specified unless the GARCH= option is also specified.

You can specify the following options in the HETERO statement.

COEF=*value*

imposes constraints on the estimated parameters η of the heteroscedasticity model. You can specify the following *values*:

NONNEG specifies that the estimated heteroscedasticity parameters η must be nonnegative.

UNIT constrains all heteroscedasticity parameters η to equal 1.

UNREST specifies unrestricted estimation of η.

ZERO constrains all heteroscedasticity parameters η to equal 0.

If you specify the GARCH= option in the MODEL statement, then by default COEF=NONNEG. If you do not specify the GARCH= option in the MODEL statement, then by default COEF=UNREST.

LINK=*value*

specifies the functional form of the heteroscedasticity model. By default, LINK=EXP. If you specify a GARCH model in the HETERO statement, the model is estimated using LINK=LINEAR only. For more information, see the section "Using the HETERO Statement with GARCH Models" on page 371. You can specify the following values:

EXP specifies the exponential link function. The following model is estimated when you specify LINK=EXP:

$$h_t = \exp(\mathbf{z}'_t\eta)$$

LINEAR specifies the linear function; that is, the HETERO statement variables predict the error variance linearly. The following model is estimated when you specify LINK=LINEAR:

$$h_t = (1 + \mathbf{z}'_t\eta)$$

SQUARE specifies the square link function. The following model is estimated when you specify LINK=SQUARE:

$$h_t = (1 + \mathbf{z}'_t\eta)^2$$

NOCONST
specifies that the heteroscedasticity model does not include the unit term for the LINK=SQUARE and LINK=LINEAR options. For example, the following model is estimated when you specify the options LINK=SQUARE NOCONST:

$$h_t = (\mathbf{z}'_t \eta)^2$$

STD=*value*
imposes constraints on the estimated standard deviation σ of the heteroscedasticity model. You can specify the following *values*:

NONNEG	specifies that the estimated standard deviation parameter σ must be nonnegative.
UNIT	constrains the standard deviation parameter σ to equal 1.
UNREST	specifies unrestricted estimation of σ.

By default, STD=UNREST.

TEST=LM
produces a Lagrange multiplier test for heteroscedasticity. The null hypothesis is homoscedasticity; the alternative hypothesis is heteroscedasticity of the form specified by the HETERO statement. The power of the test depends on the variables specified in the HETERO statement.

The test may give different results depending on the functional form specified by the LINK= option. However, in many cases the test does not depend on the LINK= option. The test is invariant to the form of h_t when $h_t(0) = 1$ and $h'_t(0) \neq 0$. (The condition $h_t(0) = 1$ is satisfied except when the NOCONST option is specified with LINK=SQUARE or LINK=LINEAR.)

MODEL Statement

MODEL *dependent = regressors / options* **;**

The MODEL statement specifies the dependent variable and independent regressor variables for the regression model. If no independent variables are specified in the MODEL statement, only the mean is fitted. (This is a way to obtain autocorrelations of a series.)

Models can be given labels of up to eight characters. Model labels are used in the printed output to identify the results for different models. The model label is specified as follows:

label **: MODEL . . . ;**

The following *options* can be used in the MODEL statement after a slash (/).

CENTER
centers the dependent variable by subtracting its mean and suppresses the intercept parameter from the model. This option is valid only when the model does not have regressors (explanatory variables).

NOINT
suppresses the intercept parameter.

Autoregressive Error Options

NLAG=*number*

NLAG=*(number-list)*
specifies the order of the autoregressive error process or the subset of autoregressive error lags to be fitted. Note that NLAG=3 is the same as NLAG=(1 2 3). If you omit the NLAG= option, PROC AUTOREG does not fit an autoregressive model.

GARCH Estimation Options

DIST=*value*
specifies the distribution assumed for the error term in GARCH-type estimation. If you omit the GARCH= option, the DIST= option is ignored. If you specify the EGARCH option, the distribution is always the normal distribution. You can specify the following *values*:

NORMAL	specifies the standard normal distribution.
T	specifies Student's *t* distribution.

By default, DIST=NORMAL.

GARCH=*(option-list)*
specifies a GARCH-type conditional heteroscedasticity model. The GARCH= option in the MODEL statement specifies the family of ARCH models to be estimated. The GARCH(1, 1) regression model is specified in the following statement:

```
model y = x1 x2 / garch=(q=1,p=1);
```

When you want to estimate the subset of ARCH terms, such as ARCH(1, 3), you can write the SAS statement as follows:

```
model y = x1 x2 / garch=(q=(1 3));
```

With the TYPE= option, you can specify various GARCH models. The IGARCH(2, 1) model without trend in variance is estimated as follows:

```
model y = / garch=(q=2,p=1,type=integ,noint);
```

You can specify the following options in the GARCH=( ) option. The options are listed within parentheses and separated by commas.

MEAN=*value*

specifies the functional form of the GARCH-M model. You can specify the following *values*:

LINEAR specifies the linear function:

$$y_t = \mathbf{x}_t'\beta + \delta h_t + \epsilon_t$$

LOG specifies the log function:

$$y_t = \mathbf{x}_t'\beta + \delta \ln(h_t) + \epsilon_t$$

SQRT specifies the square root function:

$$y_t = \mathbf{x}_t'\beta + \delta \sqrt{h_t} + \epsilon_t$$

NOINT

suppresses the intercept parameter in the conditional variance model. This option is valid only when you also specify the TYPE=INTEG option.

P=*number*

P=*(number-list)*

specifies the order of the process or the subset of GARCH terms to be fitted. If only the P= option is specified, the P= option is ignored and Q=1 is assumed.

Q=*number*

Q=*(number-list)*

specifies the order of the process or the subset of ARCH terms to be fitted.

TYPE=*value*

specifies the type of GARCH model. The *values* of the TYPE= option are as follows:

EXP | EGARCH specifies the exponential GARCH, or EGARCH, model.

INTEGRATED | IGARCH specifies the integrated GARCH, or IGARCH, model.

NELSON | NELSONCAO specifies the Nelson-Cao inequality constraints.

NOCONSTRAINT specifies the GARCH model with no constraints.

NONNEG specifies the GARCH model with nonnegativity constraints.

POWER | PGARCH specifies the power GARCH, or PGARCH, model.

QUADR | QUADRATIC | QGARCH specifies the quadratic GARCH, or QGARCH, model.

STATIONARY constrains the sum of GARCH coefficients to be less than 1.

THRES | THRESHOLD | TGARCH | GJR | GJRGARCH specifies the threshold GARCH, or TGARCH, model.

By default, TYPE=NELSON.

STARTUP=MSE | ESTIMATE
requests that the positive constant c for the start-up values of the GARCH conditional error variance process be estimated. By default, or if you specify STARTUP=MSE, the value of the mean square error is used as the default constant.

TR
uses the trust region method for GARCH estimation. This algorithm is numerically stable, although computation is expensive. The double quasi-Newton method is the default.

Printing Options

ALL
requests all printing options.

ARCHTEST

ARCHTEST=*(option-list)*
specifies tests for the absence of ARCH effects. The following options can be used in the ARCHTEST=( ) option. The options are listed within parentheses and separated by commas.

ALL	requests all ARCH tests, namely Q and Engle's LM tests, Lee and King's tests, and Wong and Li's tests.
LK | LKARCH	requests Lee and King's ARCH tests.
QLM | QLMARCH	requests the Q and Engle's LM tests.
WL | WLARCH	requests Wong and Li's ARCH tests.

If ARCHTEST is defined without additional suboptions, it requests the Q and Engle's LM tests. That is, the statement

```
model return = x1 x2 / archtest;
```

is equivalent to the statement

```
model return = x1 x2 / archtest=(qlm);
```

The following statement requests Lee and King's tests and Wong and Li's tests:

```
model return = / archtest=(lk,wl);
```

BDS

BDS=*(option-list)*
specifies Brock-Dechert-Scheinkman (BDS) tests for independence. The following options can be used in the BDS=( ) option. The options are listed within parentheses and separated by commas.

D=*number*
specifies the parameter to determine the radius for BDS test. The BDS test sets up the radius as $r = D * \sigma$, where σ is the standard deviation of the time series to be tested. By default, D=1.5.

M=*number*
specifies the maximum number of the embedding dimension. The BDS tests with embedding dimension from 2 to M are calculated. M must be an integer between 2 and 20. The default value of the M= suboption is 20.

PVALUE=DIST | SIM
specifies the way to calculate the *p*-values. By default, or if PVALUE=DIST is specified, the *p*-values are calculated according to the asymptotic distribution of BDS statistics (that is, the standard normal distribution). Otherwise, for samples of size less than 500, the *p*-values are obtained though Monte Carlo simulation.

Z=*value*
specifies the type of the time series (residuals) to be tested. You can specify the following *values*:

R specifies the residuals of the final model.

RM specifies the structural residuals of the final model.

RO specifies the OLS residuals.

SR specifies the standardized residuals of the final model, defined by residuals over the square root of the conditional variance.

Y specifies the regressand.

By default, Z=Y.

If BDS is defined without additional suboptions, all suboptions are set as default values. That is, the following two statements are equivalent:

```
model return = x1 x2 / nlag=1 BDS;
```

```
model return = x1 x2 / nlag=1 BDS=(M=20, D=1.5, PVALUE=DIST, Z=Y);
```

To do the specification check of a GARCH(1,1) model, you can write the SAS statement as follows:

```
model return = / garch=(p=1,q=1) BDS=(Z=SR);
```

BP

BP=(*option-list***)**
specifies Bai-Perron (BP) tests for multiple structural changes, introduced in Bai and Perron (1998). You can specify the following *options* in parentheses and separated by commas.

EPS=*number*

specifies the minimum length of regime; that is, if EPS=ε, then for any $i, i = 1, \ldots, M$, $T_i - T_{i-1} \geq T\varepsilon$, where T is the sample size; M is the number of breaks specified in the M= option; $(T_1 \ldots T_M)$ are the break dates; and $T_0 = 0$ and $T_{M+1} = T$. The restriction that $(M + 1)\varepsilon \leq 1$ is required. By default, EPS=0.05.

ETA=*number*

specifies that the second method is to be used in the calculation of the $supF(l + 1|l)$ test, and the minimum length of regime for the new additional break date is $(T_i - T_{i-1})\eta$ if ETA=η and the new break date is in regime i for the given break dates $(T_1 \ldots T_l)$. The default value of the ETA= suboption is the missing value; that is, the first method is to be used in the calculation of the $supF(l + 1|l)$ test and, no matter which regime the new break date is in, the minimum length of regime for the new additional break date is $T\varepsilon$ when EPS=ε.

HAC<(*option-list***)>**

specifies that the heteroscedasticity- and autocorrelation-consistent estimator be applied in the estimation of the variance covariance matrix and the confidence intervals of break dates. When you specify this option, you can specify the following *options* within parentheses and separated by commas:

ANDREWS91 | ANDREWS

specifies the Andrews (1991) bandwidth selection method.

BANDWIDTH=*value*

specifies the fixed bandwidth value or bandwidth selection method to use in the kernel function. You can specify the following *values*:

KERNELLB=*number*

specifies the lower bound of the kernel weight value. Any kernel weight less than this lower bound is regarded as zero, which accelerates the calculation for big samples, especially for the quadratic spectral kernel. By default, KERNELLB=0.

NEWEYWEST94 | NW94 <(C=*number***)>**

specifies the Newey and West (1994) bandwidth selection method. You can specify the C= option in parentheses to calculate the lag selection parameter; by default, C=12.

SAMPLESIZE | SS <(*option-list***)>**

specifies that the bandwidth be calculated according to the following equation, based on the sample size:

$$b = \gamma T^r + c$$

where b is the bandwidth parameter and T is the sample size, and γ, r, and c are values specified by the following options within parentheses and separated by commas.

CONSTANT=*number*

specifies the constant c in the equation. By default, $c = 0.5$.

GAMMA=*number*
specifies the coefficient γ in the equation. By default, $\gamma = 0.75$.

INT
specifies that the bandwidth parameter must be integer; that is, $b = \lfloor \gamma T^r + c \rfloor$, where $\lfloor x \rfloor$ denotes the largest integer less than or equal to x.

RATE=*number*
specifies the growth rate r in the equation. By default, $r = 0.3333$.

number
specifies the fixed value of the bandwidth parameter.

By default, BANDWIDTH=ANDREWS91.

KERNEL=*value*
specifies the type of kernel function. You can specify the following *values*:

BARTLETT specifies the Bartlett kernel function.

PARZEN specifies the Parzen kernel function.

QUADRATICSPECTRAL | QS specifies the quadratic spectral kernel function.

TRUNCATED specifies the truncated kernel function.

TUKEYHANNING | TUKEY | TH specifies the Tukey-Hanning kernel function.

By default, KERNEL=QUADRATICSPECTRAL.

PREWHITENING
specifies that prewhitening is required in the calculation.

In the calculation of the HAC estimator, the adjustment for degrees of freedom is always applied. For more information about the HAC estimator, see the section "Heteroscedasticity- and Autocorrelation-Consistent Covariance Matrix Estimator" on page 374. For more information about the HAC estimator, see the section "Heteroscedasticity- and Autocorrelation-Consistent Covariance Matrix Estimator" on page 374.

HE
specifies that the errors are assumed to have heterogeneous distribution across regimes in the estimation of covariance matrix.

HO
specifies that Ω_is in the calculation of confidence intervals of break dates are different across regimes.

HQ
specifies that Q_is in the calculation of confidence intervals of break dates are different across regimes.

HR

specifies that the regressors are assumed to have heterogeneous distribution across regimes in the estimation of covariance matrix.

M=*number*

specifies the number of breaks. For a given M, the following tests are to be performed: (1) the $supF$ tests of no break versus the alternative hypothesis that there are i breaks, $i = 1, \ldots, M$; (2) the $UDmaxF$ and $WDmaxF$ double maximum tests of no break versus the alternative hypothesis that there are unknown number of breaks up to M; and (3) the $supF(l+1|l)$ tests of l versus $l+1$ breaks, $l = 0, \ldots, M$. The restriction that $(M+1)\varepsilon \leq 1$ is required, where ε is specified in the EPS= option. By default, M=5.

NTHREADS=*number*

specifies the number of threads to be used for parallel computing. The default is the number of CPUs available.

P=*number*

specifies the number of covariates whose coefficients are unchanged over time in the partial structural change model. The first P=p independent variables that are specified in the MODEL statement have unchanged coefficients; the rest of the independent variables have coefficients that change across regimes. By default, P=0; that is, the pure structural change model is estimated.

PRINTEST=ALL | **BIC** | **LWZ** | **NONE** | **SEQ***<(number)>* | *number*

specifies in which structural change models the parameter estimates are to be printed. You can specify the following values:

ALL specifies that the parameter estimates in all structural change models with m breaks, $m = 0, \ldots, M$, be printed.

BIC specifies that the parameter estimates in the structural change model that minimizes the BIC information criterion be printed.

LWZ specifies that the parameter estimates in the structural change model that minimizes the LWZ information criterion be printed.

NONE specifies that none of the parameter estimates be printed.

SEQ specifies that the parameter estimates in the structural change model that is chosen by sequentially applying $supF(l+1|l)$ tests, l from 0 to M, be printed. If you specify the SEQ option, you can also specify the significance level in the parentheses, for example, SEQ(0.10). The first l such that the p-value of $supF(l+1|l)$ test is greater than the significance level is selected as the number of breaks in the structural change model. By default, the significance level 5% is used for the SEQ option; that is, specifying SEQ is equivalent to specifying SEQ(0.05).

number specifies that the parameter estimates in the structural change model with the specified number of breaks be printed. If the specified number is greater than the number specified in the M= option, none of the parameter estimates are printed; that is, it is equivalent to specifying the NONE option.

By default, PRINTEST=ALL.

If you define the BP option without additional suboptions, all suboptions are set as default values. That is, the following two statements are equivalent:

```
model y = z1 z2 / BP;
```

```
model y = z1 z2 / BP=(M=5, P=0, EPS=0.05, PRINTEST=ALL);
```

To apply the HAC estimator with the Bartlett kernel function and print only the parameter estimates in the structural change model selected by the LWZ information criterion, you can write the SAS statement as follows:

```
model y = z1 z2 / BP=(HAC(KERNEL=BARTLETT), PRINTEST=LWZ);
```

To specify a partial structural change model, you can write the SAS statement as follows:

```
model y = x1 x2 x3 z1 z2 / NOINT BP=(P=3);
```

CHOW=($obs_1 \ldots obs_n$)
computes Chow tests to evaluate the stability of the regression coefficient. The Chow test is also called the analysis-of-variance test.

Each value obs_i listed on the CHOW= option specifies a break point of the sample. The sample is divided into parts at the specified break point, with observations before obs_i in the first part and obs_i and later observations in the second part, and the fits of the model in the two parts are compared to whether both parts of the sample are consistent with the same model.

The break points obs_i refer to observations within the time range of the dependent variable, ignoring missing values before the start of the dependent series. Thus, CHOW=20 specifies the 20th observation after the first nonmissing observation for the dependent variable. For example, if the dependent variable Y contains 10 missing values before the first observation with a nonmissing Y value, then CHOW=20 actually refers to the 30th observation in the data set.

When you specify the break point, you should note the number of presample missing values.

COEF
prints the transformation coefficients for the first p observations. These coefficients are formed from a scalar multiplied by the inverse of the Cholesky root of the Toeplitz matrix of autocovariances.

CORRB
prints the estimated correlations of the parameter estimates.

COVB
prints the estimated covariances of the parameter estimates.

COVEST=OP | HESSIAN | QML | HC0 | HC1 | HC2 | HC3 | HC4 | HAC <(...)> | NEWEYWEST <(...)>
specifies the type of covariance matrix. You can specify the following values (by default, COVEST=OP):

OP

uses the outer product matrix to compute the covariance matrix of the parameter estimates. When the final model is an OLS or AR error model, this option is ignored; the method to calculate the estimate of covariance matrix is illustrated in the section "Variance Estimates and Standard Errors" on page 366.

HESSIAN

produces the covariance matrix by using the Hessian matrix. When the final model is an OLS or AR error model, this option is ignored; the method to calculate the estimate of covariance matrix is illustrated in the section "Variance Estimates and Standard Errors" on page 366.

QML

computes the quasi–maximum likelihood estimates. This option is equivalent to COVEST=HC0. When the final model is an OLS or AR error model, this option is ignored; the method to calculate the estimate of covariance matrix is illustrated in the section "Variance Estimates and Standard Errors" on page 366.

HC*n*

calculates the heteroscedasticity-consistent covariance matrix estimator (HCCME) that corresponds to *n*, where $n = 0, 1, 2, 3, 4$.

HAC<(*options***)>**

specifies the heteroscedasticity- and autocorrelation-consistent (HAC) covariance matrix estimator. When you specify this option, you can specify the following *options* in parentheses and separate them with commas:

ADJUSTDF

specifies that the adjustment for degrees of freedom be required in the calculation.

BANDWIDTH=*value*

specifies the fixed bandwidth value or bandwidth selection method to use in the kernel function. You can specify the following *values*:

ANDREWS91 | ANDREWS specifies the Andrews (1991) bandwidth selection method.

NEWEYWEST94 | NW94 <(C=*number***)>** specifies the Newey and West (1994) bandwidth selection method. You can specify the C= option in the parentheses to calculate the lag selection parameter. By default, C=12.

SAMPLESIZE | SS <(*option-list***)>** calculates the bandwidth according to the following equation, based on the sample size:

$$b = \gamma T^r + c$$

where b is the bandwidth parameter; T is the sample size; and γ, r, and c are values specified by the following options within parentheses and separated by commas.

CONSTANT=*number*
specifies the constant c in the equation. By default, $c = 0.5$.

GAMMA=*number*
specifies the coefficient γ in the equation. By default, $\gamma = 0.75$.

INT
specifies that the bandwidth parameter must be integer; that is, $b = \lfloor \gamma T^r + c \rfloor$, where $\lfloor x \rfloor$ denotes the largest integer less than or equal to x.

RATE=*number*
specifies the growth rate r in the equation. By default, $r = 0.3333$.

number specifies the fixed value of the bandwidth parameter.

By default, BANDWIDTH=ANDREWS91.

KERNEL=*value*
specifies the type of kernel function. You can specify the following *values*:

BARTLETT specifies the Bartlett kernel function.

PARZEN specifies the Parzen kernel function.

QUADRATICSPECTRAL | QS specifies the quadratic spectral kernel function.

TRUNCATED specifies the truncated kernel function.

TUKEYHANNING | TUKEY | TH specifies the Tukey-Hanning kernel function.

By default, KERNEL=QUADRATICSPECTRAL.

KERNELLB=*number*
specifies the lower bound of the kernel weight value. Any kernel weight less than *number* is regarded as zero, which accelerates the calculation for big samples, especially for the quadratic spectral kernel. By default, KERNELLB=0.

PREWHITENING
specifies that prewhitening is required in the calculation.

NEWEYWEST<(*options***)>**
specifies the well-known Newey-West estimator, which is a special HAC estimator with (1) the Bartlett kernel; (2) the bandwidth parameter determined by the equation based on the sample size, $b = \lfloor \gamma T^r + c \rfloor$; and (3) no adjustment for degrees of freedom and no prewhitening. By default, the bandwidth parameter for the Newey-West estimator is $\lfloor 0.75T^{0.3333} + 0.5 \rfloor$, as shown in equation (15.17) in Stock and Watson (2002). You can specify the following *options* in parentheses and separate them with commas:

CONSTANT=*number*
specifies the constant c in the equation. By default, $c = 0.5$.

GAMMA=*number*
specifies the coefficient γ in the equation. By default, $\gamma = 0.75$.

RATE=*number*
specifies the growth rate r in the equation. By default, $r = 0.3333$.

The following two statements are equivalent:

```
model y = x / COVEST=NEWEYWEST;

model y = x / COVEST=HAC(KERNEL=BARTLETT,
                         BANDWIDTH=SAMPLESIZE(GAMMA=0.75,
                                              RATE=0.3333,
                                              CONSTANT=0.5,
                                              INT));
```

Another popular sample-size-dependent bandwidth, $\left\lfloor T^{1/4} + 1.5 \right\rfloor$, as mentioned in Newey and West (1987), can be specified by the following statement:

```
model y = x / COVEST=NEWEYWEST(GAMMA=1,RATE=0.25,CONSTANT=1.5);
```

For more information about the HC0 to HC4, HAC, and Newey-West estimators, see the section "Heteroscedasticity- and Autocorrelation-Consistent Covariance Matrix Estimator" on page 374. By default, COVEST=OP.

DW=*n*
prints Durbin-Watson statistics up to the order *n*. When the LAGDEP option is specified, the Durbin-Watson statistic is not printed unless the DW= option is explicitly specified. By default, DW=1.

DWPROB
now produces *p*-values for the generalized Durbin-Watson test statistics for large sample sizes. Previously, the Durbin-Watson probabilities were calculated only for small sample sizes. The new method of calculating Durbin-Watson probabilities is based on the algorithm of Ansley, Kohn, and Shively (1992).

GINV
prints the inverse of the Toeplitz matrix of autocovariances for the Yule-Walker solution. For more information, see the section "Computational Methods" on page 365.

GODFREY

GODFREY=*r*
produces Godfrey's general Lagrange multiplier test against ARMA errors.

ITPRINT
prints the objective function and parameter estimates at each iteration. The objective function is the full log-likelihood function for the maximum likelihood method, while the error sum of squares is produced as the objective function of unconditional least squares. For the ML method, the ITPRINT option prints the value of the full log-likelihood function, not the concentrated likelihood.

LAGDEP
LAGDV
prints the Durbin t statistic, which is used to detect residual autocorrelation in the presence of lagged dependent variables. For more information, see the section "Generalized Durbin-Watson Tests" on page 394.

LAGDEP=*name*
LAGDV=*name*
prints the Durbin h statistic for testing the presence of first-order autocorrelation when regressors contain the lagged dependent variable whose name is specified as LAGDEP=*name*. If the Durbin h statistic cannot be computed, the asymptotically equivalent t statistic is printed instead. For more information, see the section "Generalized Durbin-Watson Tests" on page 394.

When the regression model contains several lags of the dependent variable, specify the lagged dependent variable for the smallest lag in the LAGDEP= option. For example:

```
model y = x1 x2 ylag2 ylag3 / lagdep=ylag2;
```

LOGLIKL
prints the log-likelihood value of the regression model, assuming normally distributed errors.

NOPRINT
suppresses all printed output.

NORMAL
specifies the Jarque-Bera's normality test statistic for regression residuals.

PARTIAL
prints partial autocorrelations.

PCHOW=*(obs$_1$ ... obs$_n$)*
computes the predictive Chow test. The form of the PCHOW= option is the same as the form of the CHOW= option; see the discussion of the CHOW= option.

RESET
produces Ramsey's RESET test statistics. The RESET option tests the null model

$$y_t = \mathbf{x}_t \beta + u_t$$

against the alternative

$$y_t = \mathbf{x}_t \beta + \sum_{j=2}^{p} \phi_j \hat{y}_t^j + u_t$$

where $\hat{y}_t$ is the predicted value from the OLS estimation of the null model. The RESET option produces three RESET test statistics for $p = 2$, 3, and 4.

RUNS

RUNS=*(Z=value)*

specifies the runs test for independence. The Z= suboption specifies the type of the time series or residuals to be tested. The values of the Z= suboption are as follows:

R specifies the residuals of the final model.

RM specifies the structural residuals of the final model.

RO specifies the OLS residuals.

SR specifies the standardized residuals of the final model, defined by residuals over the square root of the conditional variance.

Y specifies the regressand.

By default, Z=Y.

STATIONARITY=(*test***<=(***test-options***)><, *test*<=(***test-options***)>>...<, *test*<=(***test-options***)>>)**

specifies tests of stationarity or unit roots. You can specify one of more of the following *tests* along with their *test-options*. For example, the following statement tests the stationarity of a variable by using the augmented Dickey-Fuller unit root test and the KPSS test in which the quadratic spectral kernel is applied:

```
model y=  / stationarity = (adf, kpss=(kernel=qs));
```

STATIONARITY=(ADF)

STATIONARITY=(ADF=(*value . . . value***))**

produces the augmented Dickey-Fuller unit root test (Dickey and Fuller 1979). As in the Phillips-Perron test, three regression models can be specified for the null hypothesis for the augmented Dickey-Fuller test (zero mean, single mean, and trend). These models assume that the disturbances are distributed as white noise. The augmented Dickey-Fuller test can account for the serial correlation between the disturbances in some way. The model, with the time trend specification for example, is

$$y_t = \mu + \rho y_{t-1} + \delta t + \gamma_1 \Delta y_{t-1} + \cdots + \gamma_p \Delta y_{t-p} + u_t$$

This formulation has the advantage that it can accommodate higher-order autoregressive processes in u_t. The test statistic follows the same distribution as the Dickey-Fuller test statistic. For more information, see the section "PROBDF Function for Dickey-Fuller Tests" on page 154.

In the presence of regressors, the ADF option tests the cointegration relation between the dependent variable and the regressors. Following Engle and Granger (1987), a two-step estimation and testing procedure is carried out, in a fashion similar to the Phillips-Ouliaris test. The OLS residuals of the regression in the MODEL statement are used to compute the t statistic of the augmented Dickey-Fuller regression in a second step. Three cases arise based on which type of deterministic terms are included in the first step of regression. Only the constant term and linear trend cases are practically useful (Davidson and MacKinnon 1993, page 721), and therefore are computed and reported. The test statistic, as shown in Phillips and Ouliaris (1990), follows the same distribution as the $\hat{Z}_t$ statistic in the Phillips-Ouliaris cointegration test. The asymptotic distribution is tabulated in tables IIa–IIc of Phillips and Ouliaris (1990), and the finite sample distribution is obtained in Table 2 and Table 3 in Engle and Yoo (1987) by Monte Carlo simulation.

STATIONARITY=(ERS)

STATIONARITY=(ERS=(*value*))

STATIONARITY=(NP)

STATIONARITY=(NP=(*value*))

provides a class of *efficient unit root tests*, because they reduce the size distortion and improve the power compared with traditional unit root tests such as the augmented Dickey-Fuller and Phillips-Perron tests. Two test statistics are reported with the ERS= suboption: the point optimal test and the DF-GLS test, which are originally proposed in Elliott, Rothenberg, and Stock (1996). Elliott, Rothenberg, and Stock suggest using the Schwarz Bayesian information criterion to select the optimal lag length in the augmented Dickey-Fuller regression. The maximum lag length can be specified by ERS=*value*. The minimum lag length is 3, and the default maximum lag length is 8.

Six tests, namely MZ_α, MSB, MZ_t, the modified point optimal test, the point optimal test, and the DF-GLS test, which are discussed in Ng and Perron (2001), are reported with the NP= suboption. Ng and Perron suggest using the modified AIC to select the optimal lag length in the augmented Dickey-Fuller regression by using GLS detrended data. The maximum lag length can be specified by NP=*value*. The default maximum lag length is 8. The maximum lag length in the ERS tests and Ng-Perron tests cannot exceed $T/2 - 2$, where T is the sample size.

STATIONARITY=(KPSS)

STATIONARITY=(KPSS=(KERNEL=(*type*)))

STATIONARITY=(KPSS=(KERNEL=(*type* TRUNCPOINTMETHOD)))

produce the Kwiatkowski, Phillips, Schmidt, and Shin (1992) (KPSS) unit root test or Shin (1994) cointegration test.

Unlike the null hypothesis of the Dickey-Fuller and Phillips-Perron tests, the null hypothesis of the KPSS states that the time series is stationary. As a result, it tends to reject a random walk more often. If the model does not have an intercept, the KPSS option performs the KPSS test for three null hypothesis cases: zero mean, single mean, and deterministic trend. Otherwise, it reports the single mean and deterministic trend only. It computes a test statistic and provides p-value (Hobijn, Franses, and Ooms 2004) for the hypothesis that the random walk component of the time series is equal to zero in the following cases (for more information, see the section "Kwiatkowski, Phillips, Schmidt, and Shin (KPSS) Unit Root Test and Shin Cointegration Test" on page 389):

Zero mean — computes the KPSS test statistic based on the zero mean autoregressive model.

$$y_t = u_t$$

Single mean — computes the KPSS test statistic based on the autoregressive model with a constant term.

$$y_t = \mu + u_t$$

Trend — computes the KPSS test statistic based on the autoregressive model with constant and time trend terms.

$$y_t = \mu + \delta t + u_t$$

This test depends on the long-run variance of the series being defined as

$$\sigma_{Tl}^2 = \frac{1}{T}\sum_{i=1}^{T}\hat{u}_i^2 + \frac{2}{T}\sum_{s=1}^{l} w_{sl} \sum_{t=s+1}^{T} \hat{u}_t \hat{u}_{t-s}$$

where w_{sl} is a kernel, s is a maximum lag (truncation point), and $\hat{u}_t$ are OLS residuals or original data series. You can specify two types of the kernel:

KERNEL=NW | BART Newey-West (or Bartlett) kernel

$$w(s,l) = 1 - \frac{s}{l+1}$$

KERNEL=QS Quadratic spectral kernel

$$w(s/l) = w(x) = \frac{25}{12\pi^2 x^2}\left(\frac{\sin(6\pi x/5)}{6\pi x/5} - \cos(6\pi x/5)\right)$$

You can set the truncation point l by using three different methods:

AUTO Automatic bandwidth selection (Hobijn, Franses, and Ooms 2004) (for more information, see the section "Kwiatkowski, Phillips, Schmidt, and Shin (KPSS) Unit Root Test and Shin Cointegration Test" on page 389).

LAG=*l* LAG=*l* manually defined number of lags.

SCHW=c Schwert maximum lag formula

$$l = \max\left\{1, \text{floor}\left[c\left(\frac{T}{100}\right)^{1/4}\right]\right\}$$

If STATIONARITY=KPSS is defined without additional parameters, the Newey-West kernel is used. For the Newey-West kernel, the default is the Schwert truncation point method with $c = 12$. For the quadratic spectral kernel, the default is AUTO.

The KPSS test can be used in general time series models because its limiting distribution is derived in the context of a class of weakly dependent and heterogeneously distributed data. The limiting probability for the KPSS test is computed assuming that error disturbances are normally distributed. The *p*-values that are reported are based on the simulation of the limiting probability for the KPSS test.

To test for stationarity of a variable, y, by using default KERNEL=NW and SCHW=12, you can use the following statements:

```
/*-- test for stationarity of regression residuals --*/
proc autoreg data=a;
   model y=  / stationarity = (KPSS);
run;
```

To test for stationarity of a variable, y, by using quadratic spectral kernel and automatic bandwidth selection, you can use the following statements:

```
/*-- test for stationarity using quadratic
     spectral kernel and automatic bandwidth selection --*/
proc autoreg data=a;
   model y= /
   stationarity = (KPSS=(KERNEL=QS AUTO));
run;
```

If there are regressors in the MODEL statement except for the intercept, the Shin (1994) cointegration test, an extension of the KPSS test, is carried out. The limiting distribution of the tests, and then the reported p-values, are different from those in the KPSS tests. For more information, see the section "Kwiatkowski, Phillips, Schmidt, and Shin (KPSS) Unit Root Test and Shin Cointegration Test" on page 389.

STATIONARITY=(PHILLIPS)

STATIONARITY=(PHILLIPS=(*value . . . value*))

produces the Phillips-Perron unit root test when there are no regressors in the MODEL statement. When the model includes regressors, the PHILLIPS option produces the Phillips-Ouliaris cointegration test. The PHILLIPS option can be abbreviated as PP.

The PHILLIPS option performs the Phillips-Perron test for three null hypothesis cases: zero mean, single mean, and deterministic trend. For each case, the PHILLIPS option computes two test statistics, $\hat{Z}_\rho$ and $\hat{Z}_t$—in the original paper, Phillips and Perron (1988), they are referred to as $\hat{Z}_\alpha$ and $\hat{Z}_t$)—and reports their p-values. These test statistics have the same limiting distributions as the corresponding Dickey-Fuller tests.

The three types of the Phillips-Perron unit root test reported by the PHILLIPS option are as follows:

Zero mean — computes the Phillips-Perron test statistic based on the zero mean autoregressive model:

$$y_t = \rho y_{t-1} + u_t$$

Single mean — computes the Phillips-Perron test statistic based on the autoregressive model with a constant term:

$$y_t = \mu + \rho y_{t-1} + u_t$$

Trend — computes the Phillips-Perron test statistic based on the autoregressive model with constant and time trend terms:

$$y_t = \mu + \rho y_{t-1} + \delta t + u_t$$

You can specify several truncation points l for weighted variance estimators by using the PHILLIPS=($l_1 \ldots l_n$) specification. The statistic for each truncation point l is computed as

$$\sigma^2_{Tl} = \frac{1}{T}\sum_{i=1}^{T}\hat{u}_i^2 + \frac{2}{T}\sum_{s=1}^{l} w_{sl} \sum_{t=s+1}^{T} \hat{u}_t \hat{u}_{t-s}$$

where $w_{sl} = 1 - s/(l+1)$ and $\hat{u}_t$ are OLS residuals. If you specify the PHILLIPS option without specifying truncation points, the default truncation point is $\max(1, \sqrt{T}/5)$, where T is the number of observations.

The Phillips-Perron test can be used in general time series models because its limiting distribution is derived in the context of a class of weakly dependent and heterogeneously distributed data. The marginal probability for the Phillips-Perron test is computed assuming that error disturbances are normally distributed.

When there are regressors in the MODEL statement, the PHILLIPS option computes the Phillips-Ouliaris cointegration test statistic by using the least squares residuals. The normalized cointegrating vector is estimated using OLS regression. Therefore, the cointegrating vector estimates might vary with the regressand (normalized element) unless the regression R-square is 1. You can define the truncation points in the calculation of weighted variance estimators, $\sigma^2_{Tl}, l = l_1 \ldots l_n$, in the same way as you define the truncation points for the Phillips-Perron test—by using the PHILLIPS=($l_1 \ldots l_n$) option.

The marginal probabilities for cointegration testing are not produced. You can refer to Phillips and Ouliaris (1990) tables Ia–Ic for the $\hat{Z}_\alpha$ test and tables IIa–IIc for the $\hat{Z}_t$ test. The standard residual-based cointegration test can be obtained using the NOINT option in the MODEL statement, and the de-meaned test is computed by including the intercept term. To obtain the de-meaned and detrended cointegration tests, you should include the time trend variable in the regressors. For information about the Phillips-Ouliaris cointegration test, see Phillips and Ouliaris (1990) or Hamilton (1994, Tbl. 19.1). Note that Hamilton (1994, Tbl. 19.1) uses Z_ρ and Z_t instead of the original Phillips and Ouliaris (1990) notation. This chapter adopts the notation introduced in Hamilton. To distinguish from Student's t distribution, these two statistics are named accordingly as ρ (rho) and τ (tau).

TP

TP=*(***Z=***value)*

specifies the turning point test for independence. The Z= suboption specifies the type of the time series or residuals to be tested. You can specify the following *values*:

R specifies the residuals of the final model.

RM specifies the structural residuals of the final model.

RO specifies the OLS residuals.

SR specifies the standardized residuals of the final model, defined by residuals over the square root of the conditional variance.

Y specifies the regressand.

By default, Z=Y.

URSQ

prints the uncentered regression R^2. The uncentered regression R^2 is useful to compute Lagrange multiplier test statistics, since most LM test statistics are computed as T *URSQ, where T is the number of observations used in estimation.

VNRRANK

VNRRANK=*(option-list)*

specifies the rank version of the von Neumann ratio test for independence. You can specify the following options in the VNRRANK=( ) option. The options are listed within parentheses and separated by commas.

PVALUE=DIST | SIM

specifies how to calculate the *p*-value. You can specify the following values:

DIST calculates the *p*-value according to the asymptotic distribution of the statistic (that is, the standard normal distribution).

SIM calculates the *p*-value as follows:

- If the sample size is less than or equal to 10, the *p*-value is calculated according to the exact CDF of the statistic.
- If the sample size is between 11 and 100, the *p*-value is calculated according to Monte Carlo simulation of the distribution of the statistic.
- If the sample size is more than 100, the *p*-value is calculated according to the standard normal distribution because the simulated distribution of the statistic in this case is almost the same as the standard normal distribution.

By default, PVALUE=DIST.

Z=*value*

specifies the type of the time series or residuals to be tested. You can specify the following *values*:

R specifies the residuals of the final model.

RM specifies the structural residuals of the final model.

RO specifies the OLS residuals.

SR specifies the standardized residuals of the final model, defined by residuals over the square root of the conditional variance.

Y specifies the regressand.

By default, Z=Y.

Stepwise Selection Options

BACKSTEP

removes insignificant autoregressive parameters. The parameters are removed in order of least significance. This backward elimination is done only once on the Yule-Walker estimates computed after the initial ordinary least squares estimation. You can use the BACKSTEP option with all estimation methods because the initial parameter values for other estimation methods are estimated by using the Yule-Walker method.

SLSTAY=*value*

specifies the significance level criterion to be used by the BACKSTEP option. By default, SLSTAY=.05.

Estimation Control Options

CONVERGE=*value*

specifies the convergence criterion. If the maximum absolute value of the change in the autoregressive parameter estimates between iterations is less than this criterion, then convergence is assumed. By default, CONVERGE=.001.

If you specify the GARCH= option or the HETERO statement, convergence is assumed when the absolute maximum gradient is smaller than the value specified by the CONVERGE= option or when the relative gradient is smaller than 1E–8. By default, CONVERGE=1E–5.

INITIAL=*(initial-values)*

START=*(initial-values)*

specifies initial values for some or all of the parameter estimates. This option is not applicable when the Yule-Walker method or iterative Yule-Walker method is used. The specified values are assigned to model parameters in the same order in which the parameter estimates are printed in the AUTOREG procedure output. The order of values in the INITIAL= or START= option is as follows: the intercept, the regressor coefficients, the autoregressive parameters, the ARCH parameters, the GARCH parameters, the inverted degrees of freedom for Student's t distribution, the start-up value for conditional variance, and the heteroscedasticity model parameters η specified by the HETERO statement.

The following is an example of specifying initial values for an AR(1)-GARCH(1, 1) model with regressors X1 and X2:

```
/*-- specifying initial values --*/
model y = w x / nlag=1 garch=(p=1,q=1)
                initial=(1 1 1 .5 .8 .1 .6);
```

The model that is specified by this MODEL statement is

$$y_t = \beta_0 + \beta_1 w_t + \beta_2 x_t + v_t$$

$$v_t = \epsilon_t - \phi_1 v_{t-1}$$

$$\epsilon_t = \sqrt{h_t} e_t$$

$$h_t = \omega + \alpha_1 \epsilon_{t-1}^2 + \gamma_1 h_{t-1}$$

$$\epsilon_t \ \mathrm{N}(0, \sigma_t^2)$$

The initial values for the regression parameters, INTERCEPT (β_0), X1 (β_1), and X2 (β_2), are specified as 1. The initial value of the AR(1) coefficient (ϕ_1) is specified as 0.5. The initial value of ARCH0 (ω) is 0.8, the initial value of ARCH1 (α_1) is 0.1, and the initial value of GARCH1 (γ_1) is 0.6.

When you use the RESTRICT statement, the initial values that you specify in the INITIAL= option should satisfy the restrictions specified for the parameter estimates. If they do not, these initial values are adjusted to satisfy the restrictions.

LDW
specifies that *p*-values for the Durbin-Watson test be computed by using a linearized approximation of the design matrix when the model is nonlinear because an autoregressive error process is present. (The Durbin-Watson tests of the OLS linear regression model residuals are not affected by the LDW option.) For information about Durbin-Watson testing of nonlinear models, see White (1992).

MAXITER=*number*
sets the maximum number of iterations allowed. By default, MAXITER=50. When you specify both the GARCH= option in the MODEL statement and the MAXITER= option in the NLOPTIONS statement, the MAXITER= option in the MODEL statement is ignored. This option is not applicable when the Yule-Walker method is used.

METHOD=*value*
requests the type of estimates to be computed. You can specify the following *values*:

ITYW specifies iterative Yule-Walker estimates.

ML specifies maximum likelihood estimates.

ULS specifies unconditional least squares estimates.

YW specifies Yule-Walker estimates.

The default is defined as follows:

- When the GARCH= option or the HETERO statement is specified, METHOD=ML by default.
- When the GARCH= option and the HETERO statement are not specified but the NLAG= option and the LAGDEP option are specified, METHOD=ML by default.
- When the GARCH= option, the LAGDEP option, and the HETERO statement are not specified, but the NLAG= option is specified, METHOD=YW by default.
- When none of the NLAG= option, the GARCH= option, and the HETERO statement is specified (that is, only the OLS model is to be estimated), then the estimates are calculated through the OLS method and the METHOD= option is ignored.

NOMISS
requests the estimation to the first contiguous sequence of data with no missing values. Otherwise, all complete observations are used.

OPTMETHOD=QN | TR
specifies the optimization technique when the GARCH or heteroscedasticity model is estimated. The OPTMETHOD=QN option specifies the quasi-Newton method. The OPTMETHOD=TR option specifies the trust region method. By default, OPTMETHOD=QN.

NLOPTIONS Statement

NLOPTIONS < *options* > **;**

PROC AUTOREG uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks when the GARCH= option is specified. If the GARCH= option is not specified, the NLOPTIONS statement is ignored. For a list of all the options of the NLOPTIONS statement, see Chapter 6, "Nonlinear Optimization Methods."

For the TECHNIQUE= option in the NLOPTIONS statement, only the QUANEW and TRUREG methods are supported, corresponding to the OPTMETHOD=QN and TR in the MODEL statement, respectively.

OUTPUT Statement

OUTPUT < **OUT=***SAS-data-set* > < *options* > < *keyword=name* > **;**

The OUTPUT statement creates an output SAS data set as specified by the following options.

OUT=*SAS-data-set*
names the output SAS data set to contain the predicted and transformed values. If the OUT= option is not specified, the new data set is named according to the DATA*n* convention.

You can specify any of the following *options*:

ALPHACLI=*number*
sets the confidence limit size for the estimates of future values of the response time series. The ALPHACLI= value must be between 0 and 1. The resulting confidence interval has 1–*number* confidence. By default, ALPHACLI=0.05, which corresponds to a 95% confidence interval.

ALPHACLM=*number*
sets the confidence limit size for the estimates of the structural or regression part of the model. The ALPHACLM= value must be between 0 and 1. The resulting confidence interval has 1–*number* confidence. By default, ALPHACLM=0.05, which corresponds to a 95% confidence interval.

ALPHACSM=0.01 | **0.05** | **0.10**
specifies the significance level for the upper and lower bounds of the CUSUM and CUSUMSQ statistics output by the CUSUMLB=, CUSUMUB=, CUSUMSQLB=, and CUSUMSQUB= options. The significance level specified by the ALPHACSM= option can be 0.01, 0.05, or 0.10. Other values are not supported.

You can specify the following values for *keyword=name*, where *keyword* specifies the statistic to include in the output data set and *name* gives the name of the variable in the OUT= data set to contain the statistic.

BLUS=*variable*
specifies the name of a variable to contain the values of the Theil's BLUS residuals. For more information about BLUS residuals, see Theil (1971).

CEV=*variable*

HT=*variable*

writes to the output data set the value of the error variance σ_t^2 from the heteroscedasticity model specified by the HETERO statement or the value of the conditional error variance h_t by the GARCH= option in the MODEL statement.

CONSTANT=*variable*

writes the transformed intercept to the output data set. For information about the transformation, see the section "Computational Methods" on page 365.

CPEV=*variable*

writes the conditional prediction error variance to the output data set. The value of conditional prediction error variance is equal to that of the conditional error variance when there are no autoregressive parameters. For more information, see the section "Predicted Values" on page 404.

CUSUM=*variable*

specifies the name of a variable to contain the CUSUM statistics.

CUSUMLB=*variable*

specifies the name of a variable to contain the lower confidence bound for the CUSUM statistic.

CUSUMSQ=*variable*

specifies the name of a variable to contain the CUSUMSQ statistics.

CUSUMSQLB=*variable*

specifies the name of a variable to contain the lower confidence bound for the CUSUMSQ statistic.

CUSUMSQUB=*variable*

specifies the name of a variable to contain the upper confidence bound for the CUSUMSQ statistic.

CUSUMUB=*variable*

specifies the name of a variable to contain the upper confidence bound for the CUSUM statistic.

LCL=*name*

writes the lower confidence limit for the predicted value (specified in the PREDICTED= option) to the output data set. The size of the confidence interval is set by the ALPHACLI= option. For more information, see the section "Predicted Values" on page 404.

LCLM=*name*

writes the lower confidence limit for the structural predicted value (specified in the PREDICTEDM= option) to the output data set under the name given. The size of the confidence interval is set by the ALPHACLM= option.

PREDICTED=*name*

P=*name*

writes the predicted values to the output data set. These values are formed from both the structural and autoregressive parts of the model. For more information, see the section "Predicted Values" on page 404.

PREDICTEDM=*name*

PM=*name*

writes the structural predicted values to the output data set. These values are formed from only the structural part of the model. For more information, see the section "Predicted Values" on page 404.

RECPEV=*variable*

specifies the name of a variable to contain the part of the predictive error variance (v_t) that is used to compute the recursive residuals.

RECRES=*variable*

specifies the name of a variable to contain recursive residuals. The recursive residuals are used to compute the CUSUM and CUSUMSQ statistics.

RESIDUAL=*name*

R=*name*

writes the residuals from the predicted values based on both the structural and time series parts of the model to the output data set.

RESIDUALM=*name*

RM=*name*

writes the residuals from the structural prediction to the output data set.

STDERR=*name*

SE=*name*

writes the standard errors of the predicted values to the data set that is specified in the OUT= option.

STDERRM=*name*

SEM=*name*

writes the standard errors of the structural predicted values to the data set that is specified in the OUT= option.

TRANSFORM=*variables*

transforms the specified variables from the input data set by the autoregressive model and writes the transformed variables to the output data set. For information about the transformation, see the section "Computational Methods" on page 365. If you need to reproduce the data suitable for re-estimation, you must also transform an intercept variable. To do this, transform a variable that is all 1s or use the CONSTANT= option.

UCL=*name*

writes the upper confidence limit for the predicted value (specified in the PREDICTED= option) to the output data set. The size of the confidence interval is set by the ALPHACLI= option. For more information, see the section "Predicted Values" on page 404.

UCLM=*name*

writes the upper confidence limit for the structural predicted value (specified in the PREDICTEDM= option) to the output data set. The size of the confidence interval is set by the ALPHACLM= option.

RESTRICT Statement

RESTRICT *equation , . . . , equation* **;**

The RESTRICT statement provides constrained estimation and places restrictions on the parameter estimates for covariates in the preceding MODEL statement. The AR, GARCH, and HETERO parameters are also supported in the RESTRICT statement when you specify the GARCH= option. Any number of RESTRICT statements can follow a MODEL statement. To specify more than one restriction in a single RESTRICT statement, separate them with commas.

Each restriction is written as a linear equation composed of constants and parameter names. Refer to model parameters by the name of the corresponding regressor variable. Each name that is used in the equation must be a regressor in the preceding MODEL statement. Use the keyword INTERCEPT to refer to the intercept parameter in the model. For the names of these parameters, see the section "OUTEST= Data Set" on page 409. Inequality constraints are supported only when you specify the GARCH= option. For non-GARCH models, if inequality signs are specified, they are treated as equality signs.

Lagrange multipliers are reported in the "Parameter Estimates" table for all the active linear constraints. They are identified by the names Restrict1, Restrict2, and so on. The probabilities of these Lagrange multipliers are computed using a beta distribution (LaMotte 1994). Nonactive (nonbinding) restrictions have no effect on the estimation results and are not noted in the output.

The following is an example of a RESTRICT statement:

```
model y = a b c d;
restrict a+b=0, 2*d-c=0;
```

When restricting a linear combination of parameters to be 0, you can omit the equal sign. For example, the following RESTRICT statement is equivalent to the preceding example:

```
restrict a+b, 2*d-c;
```

The following RESTRICT statement constrains the parameters estimates for three regressors (X1, X2, and X3) to be equal:

```
restrict x1 = x2, x2 = x3;
```

The preceding restriction can be abbreviated as follows:

```
restrict x1 = x2 = x3;
```

The following example shows how to specify AR, GARCH, and HETERO parameters in the RESTRICT statement:

```
model y = a b / nlag=2 garch=(p=2,q=3,mean=sqrt);
hetero c d;
restrict _A_1=0,_AH_2=0.2,_HET_2=1,_DELTA_=0.1;
```

You can specify only simple linear combinations of parameters in RESTRICT statement expressions. You cannot specify complex expressions that involve parentheses, division, functions, or complex products.

TEST Statement

The AUTOREG procedure supports a TEST statement for linear hypothesis tests. The syntax of the TEST statement is

TEST *equation , . . . , equation / option* **;**

The TEST statement tests hypotheses about the covariates in the model that are estimated by the preceding MODEL statement. The AR, GARCH, and HETERO parameters are also supported in the TEST statement when you specify the GARCH= option. Each equation specifies a linear hypothesis to be tested. If you specify more than one equation, separate them with commas.

Each test is written as a linear equation composed of constants and parameter names. Refer to parameters by the name of the corresponding regressor variable. Each name that is used in the equation must be a regressor in the preceding MODEL statement. Use the keyword INTERCEPT to refer to the intercept parameter in the model. For the names of these parameters, see the section "OUTEST= Data Set" on page 409.

You can specify the following options in the TEST statement:

TYPE=*value*

specifies the test statistics to use. By default, TYPE=F. You can specify the following values:

ALL produces all tests applicable for a particular model. For non-GARCH-type models, only *F* and Wald tests are output. For all other models, all four tests (LR, LM, *F*, and Wald) are computed.

F produces an *F* test. This option is supported for all models specified in the MODEL statement.

LM produces a Lagrange multiplier test. This option is supported only when the GARCH= option is specified (for example, when there is a statement like MODEL Y = C D I / GARCH=(Q=2)).

LR produces a likelihood ratio test. This option is supported only when the GARCH= option is specified (for example, when there is a statement like MODEL Y = C D I / GARCH=(Q=2)).

WALD produces a Wald test. This option is supported for all models specified in the MODEL statement.

The following example of a TEST statement tests the hypothesis that the coefficients of two regressors A and B are equal:

```
model y = a b c d;
test a = b;
```

To test separate null hypotheses, use separate TEST statements. To test a joint hypothesis, specify the component hypotheses on the same TEST statement, separated by commas.

For example, consider the following linear model:

$$y_t = \beta_0 + \beta_1 x1_t + \beta_2 x2_t + \epsilon_t$$

The following statements test the two hypotheses $H_0 : \beta_0 = 1$ and $H_0 : \beta_1 + \beta_2 = 0$:

```
model y = x1 x2;
test intercept = 1;
test x1 + x2 = 0;
```

The following statements test the joint hypothesis $H_0 : \beta_0 = 1$ and $\beta_1 + \beta_2 = 0$:

```
model y = x1 x2;
test intercept = 1, x1 + x2 = 0;
```

To illustrate the TYPE= option, consider the following examples:

```
model Y = C D I / garch=(q=2);
test C + D = 1;
```

The preceding statements produce only one default test, the F test.

```
model Y = C D I / garch=(q=2);
test C + D = 1 / type = LR;
```

The preceding statements produce one of four tests applicable for GARCH-type models, the likelihood ratio test.

```
model Y = C D I / nlag = 2;
test C + D = 1 / type = LM;
```

The preceding statements produce the warning and do not output any test because the Lagrange multiplier test is not applicable for non-GARCH models.

```
model Y = C D I / nlag=2;
test C + D = 1 / type = ALL;
```

The preceding statements produce all tests that are applicable for non-GARCH models (namely, the F and Wald tests). The TYPE= prefix is optional. Thus the test statement in the previous example could also have been written as

```
test C + D = 1 / ALL;
```

The following example shows how to test AR, GARCH, and HETERO parameters:

```
model y = a b / nlag=2 garch=(p=2,q=3,mean=sqrt);
hetero c d;
test _A_1=0,_AH_2=0.2,_HET_2=1,_DELTA_=0.1;
```

Details: AUTOREG Procedure

Missing Values

PROC AUTOREG skips any missing values at the beginning of the data set. If the NOMISS option is specified, the first contiguous set of data with no missing values is used; otherwise, all data with nonmissing values for the independent and dependent variables are used. Note, however, that the observations containing missing values are still needed to maintain the correct spacing in the time series. PROC AUTOREG can generate predicted values when the dependent variable is missing.

Autoregressive Error Model

The regression model with autocorrelated disturbances is as follows:

$$y_t = \mathbf{x}_t'\beta + \nu_t$$

$$\nu_t = \epsilon_t - \varphi_1\nu_{t-1} - \cdots - \varphi_m\nu_{t-m}$$

$$\epsilon_t \ \mathrm{N}(0, \sigma^2)$$

In these equations, y_t are the dependent values, $\mathbf{x}_t$ is a column vector of regressor variables, β is a column vector of structural parameters, and ϵ_t is normally and independently distributed with a mean of 0 and a variance of σ^2. Note that in this parameterization, the signs of the autoregressive parameters are reversed from the parameterization documented in most of the literature.

PROC AUTOREG offers four estimation methods for the autoregressive error model. The default method, Yule-Walker (YW) estimation, is the fastest computationally. The Yule-Walker method used by PROC AUTOREG is described in Gallant and Goebel (1976). Harvey (1981) calls this method the *two-step full transform method*. The other methods are iterated YW, unconditional least squares (ULS), and maximum likelihood (ML). The ULS method is also referred to as nonlinear least squares (NLS) or exact least squares (ELS).

You can use all of the methods with data containing missing values, but you should use ML estimation if the missing values are plentiful. For further discussion of the advantages of different methods, see the section "Alternative Autocorrelation Correction Methods" on page 367, later in this chapter.

The Yule-Walker Method

Let $\boldsymbol{\varphi}$ represent the vector of autoregressive parameters,

$$\boldsymbol{\varphi} = (\varphi_1, \varphi_2, \ldots, \varphi_m)'$$

and let the variance matrix of the error vector $\boldsymbol{\nu} = (\nu_1, \ldots, \nu_N)'$ be $\boldsymbol{\Sigma}$,

$$E(\nu\nu') = \boldsymbol{\Sigma} = \sigma^2\mathbf{V}$$

If the vector of autoregressive parameters $\boldsymbol{\varphi}$ is known, the matrix $\mathbf{V}$ can be computed from the autoregressive parameters. $\boldsymbol{\Sigma}$ is then $\sigma^2\mathbf{V}$. Given $\boldsymbol{\Sigma}$, the efficient estimates of regression parameters β can be computed

using generalized least squares (GLS). The GLS estimates then yield the unbiased estimate of the variance σ^2,

The Yule-Walker method alternates estimation of β using generalized least squares with estimation of $\boldsymbol{\varphi}$ using the Yule-Walker equations applied to the sample autocorrelation function. The YW method starts by forming the OLS estimate of β. Next, $\boldsymbol{\varphi}$ is estimated from the sample autocorrelation function of the OLS residuals by using the Yule-Walker equations. Then $\mathbf{V}$ is estimated from the estimate of $\boldsymbol{\varphi}$, and $\boldsymbol{\Sigma}$ is estimated from $\mathbf{V}$ and the OLS estimate of σ^2. The autocorrelation corrected estimates of the regression parameters β are then computed by GLS, using the estimated $\boldsymbol{\Sigma}$ matrix. These are the Yule-Walker estimates.

If the ITER option is specified, the Yule-Walker residuals are used to form a new sample autocorrelation function, the new autocorrelation function is used to form a new estimate of $\boldsymbol{\varphi}$ and $\mathbf{V}$, and the GLS estimates are recomputed using the new variance matrix. This alternation of estimates continues until either the maximum change in the $\widehat{\varphi}$ estimate between iterations is less than the value specified by the CONVERGE= option or the maximum number of allowed iterations is reached. This produces the iterated Yule-Walker estimates. Iteration of the estimates may not yield much improvement.

The Yule-Walker equations, solved to obtain $\widehat{\varphi}$ and a preliminary estimate of σ^2, are

$$\mathbf{R}\hat{\varphi} = -\mathbf{r}$$

Here $\mathbf{r} = (r_1, \ldots, r_m)'$, where r_i is the lag i sample autocorrelation. The matrix $\mathbf{R}$ is the Toeplitz matrix whose i,jth element is $r_{|i-j|}$. If you specify a subset model, then only the rows and columns of $\mathbf{R}$ and $\mathbf{r}$ corresponding to the subset of lags specified are used.

If the BACKSTEP option is specified, for purposes of significance testing, the matrix $[\mathbf{R}\ \mathbf{r}]$ is treated as a sum-of-squares-and-crossproducts matrix arising from a simple regression with $N - k$ observations, where k is the number of estimated parameters.

The Unconditional Least Squares and Maximum Likelihood Methods

Define the transformed error, $\mathbf{e} = (\epsilon_1, \ldots, \epsilon_T)$, as

$$\mathbf{e} = \mathbf{L}^{-1}\mathbf{n}$$

where $\mathbf{n} = \mathbf{y} - \mathbf{X}\beta$ and $\mathbf{L}$ is the Cholesky root of $\mathbf{V}$—that is, $\mathbf{V} = \mathbf{L}\mathbf{L}'$ with $\mathbf{L}$ lower triangular..

The unconditional sum of squares for the model, S, is

$$S = \mathbf{n}'\mathbf{V}^{-1}\mathbf{n} = \mathbf{e}'\mathbf{e}$$

The ULS estimates are computed by minimizing S with respect to the parameters β and φ_i.

The full log-likelihood function for the autoregressive error model is

$$l = -\frac{N}{2}\ln(2\pi) - \frac{N}{2}\ln(\sigma^2) - \frac{1}{2}\ln(|\mathbf{V}|) - \frac{S}{2\sigma^2}$$

where $|\mathbf{V}|$ denotes determinant of $\mathbf{V}$. For the ML method, the likelihood function is maximized by minimizing an equivalent sum-of-squares function.

Maximizing l with respect to σ^2 (and concentrating σ^2 out of the likelihood) and dropping the constant term $-\frac{N}{2}\ln(2\pi) + 1 - \ln(N)$ produces the concentrated log-likelihood function

$$l_c = -\frac{N}{2}\ln(S|\mathbf{V}|^{1/N})$$

Rewriting the variable term within the logarithm gives

$$S_{ml} = |\mathbf{L}|^{1/N}\mathbf{e}'\mathbf{e}|\mathbf{L}|^{1/N}$$

PROC AUTOREG computes the ML estimates by minimizing the objective function $S_{ml} = |\mathbf{L}|^{1/N}\mathbf{e}'\mathbf{e}|\mathbf{L}|^{1/N}$.

The maximum likelihood estimates may not exist for some data sets (Anderson and Mentz 1980). This is the case for very regular data sets, such as an exact linear trend.

Computational Methods

Sample Autocorrelation Function

The sample autocorrelation function is computed from the structural residuals or noise $\mathbf{n_t} = y_t - \mathbf{x}_t'\mathbf{b}$, where $\mathbf{b}$ is the current estimate of β. The sample autocorrelation function is the sum of all available lagged products of $\mathbf{n}_t$ of order j divided by $\ell + j$, where ℓ is the number of such products.

If there are no missing values, then $\ell + j = N$, the number of observations. In this case, the Toeplitz matrix of autocorrelations, $\mathbf{R}$, is at least positive semidefinite. If there are missing values, these autocorrelation estimates of r can yield an $\mathbf{R}$ matrix that is not positive semidefinite. If such estimates occur, a warning message is printed, and the estimates are tapered by exponentially declining weights until $\mathbf{R}$ is positive definite.

Data Transformation and the Kalman Filter

The calculation of $\mathbf{V}$ from $\boldsymbol{\varphi}$ for the general AR(m) model is complicated, and the size of $\mathbf{V}$ depends on the number of observations. Instead of actually calculating $\mathbf{V}$ and performing GLS in the usual way, in practice a Kalman filter algorithm is used to transform the data and compute the GLS results through a recursive process.

In all of the estimation methods, the original data are transformed by the inverse of the Cholesky root of $\mathbf{V}$. Let $\mathbf{L}$ denote the Cholesky root of $\mathbf{V}$—that is, $\mathbf{V} = \mathbf{L}\mathbf{L}'$ with $\mathbf{L}$ lower triangular. For an AR(m) model, $\mathbf{L}^{-1}$ is a band diagonal matrix with m anomalous rows at the beginning and the autoregressive parameters along the remaining rows. Thus, if there are no missing values, after the first $m - 1$ observations the data are transformed as

$$z_t = x_t + \hat{\varphi}_1 x_{t-1} + \cdots + \hat{\varphi}_m x_{t-m}$$

The transformation is carried out using a Kalman filter, and the lower triangular matrix $\mathbf{L}$ is never directly computed. The Kalman filter algorithm, as it applies here, is described in Harvey and Phillips (1979) and Jones (1980). Although $\mathbf{L}$ is not computed explicitly, for ease of presentation the remaining discussion is in terms of $\mathbf{L}$. If there are missing values, then the submatrix of $\mathbf{L}$ consisting of the rows and columns with nonmissing values is used to generate the transformations.

Gauss-Newton Algorithms

The ULS and ML estimates employ a Gauss-Newton algorithm to minimize the sum of squares and maximize the log likelihood, respectively. The relevant optimization is performed simultaneously for both the regression and AR parameters. The OLS estimates of β and the Yule-Walker estimates of $\boldsymbol{\varphi}$ are used as starting values for these methods.

The Gauss-Newton algorithm requires the derivatives of $\mathbf{e}$ or $|\mathbf{L}|^{1/N}\mathbf{e}$ with respect to the parameters. The derivatives with respect to the parameter vector β are

$$\frac{\partial \mathbf{e}}{\partial \beta'} = -\mathbf{L}^{-1}\mathbf{X}$$

$$\frac{\partial |\mathbf{L}|^{1/N}\mathbf{e}}{\partial \boldsymbol{\beta}'} = -|\mathbf{L}|^{1/N}\mathbf{L}^{-1}\mathbf{X}$$

These derivatives are computed by the transformation described previously. The derivatives with respect to $\boldsymbol{\varphi}$ are computed by differentiating the Kalman filter recurrences and the equations for the initial conditions.

Variance Estimates and Standard Errors

For the Yule-Walker method, the estimate of the error variance, s^2, is the error sum of squares from the last application of GLS, divided by the error degrees of freedom (number of observations N minus the number of free parameters).

The variance-covariance matrix for the components of $\mathbf{b}$ is taken as $s^2(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$ for the Yule-Walker method. For the ULS and ML methods, the variance-covariance matrix of the parameter estimates is computed as $s^2(\mathbf{J}'\mathbf{J})^{-1}$. For the ULS method, $\mathbf{J}$ is the matrix of derivatives of $\mathbf{e}$ with respect to the parameters. For the ML method, $\mathbf{J}$ is the matrix of derivatives of $|\mathbf{L}|^{1/N}\mathbf{e}$ divided by $|\mathbf{L}|^{1/N}$. The estimate of the variance-covariance matrix of $\mathbf{b}$ assuming that $\boldsymbol{\varphi}$ is known is $s^2(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$. For OLS model, the estimate of the variance-covariance matrix is $s^2(\mathbf{X}'\mathbf{X})^{-1}$.

Park and Mitchell (1980) investigated the small sample performance of the standard error estimates obtained from some of these methods. In particular, simulating an AR(1) model for the noise term, they found that the standard errors calculated using GLS with an estimated autoregressive parameter underestimated the true standard errors. These estimates of standard errors are the ones calculated by PROC AUTOREG with the Yule-Walker method.

The estimates of the standard errors calculated with the ULS or ML method take into account the joint estimation of the AR and the regression parameters and may give more accurate standard-error values than the YW method. At the same values of the autoregressive parameters, the ULS and ML standard errors will always be larger than those computed from Yule-Walker. However, simulations of the models used by Park and Mitchell (1980) suggest that the ULS and ML standard error estimates can also be underestimates. Caution is advised, especially when the estimated autocorrelation is high and the sample size is small.

High autocorrelation in the residuals is a symptom of lack of fit. An autoregressive error model should not be used as a nostrum for models that simply do not fit. It is often the case that time series variables tend to move as a random walk. This means that an AR(1) process with a parameter near one absorbs a great deal of the variation. See Example 8.3, which fits a linear trend to a sine wave.

For ULS or ML estimation, the joint variance-covariance matrix of all the regression and autoregression parameters is computed. For the Yule-Walker method, the variance-covariance matrix is computed only for the regression parameters.

Lagged Dependent Variables

The Yule-Walker estimation method is not directly appropriate for estimating models that include lagged dependent variables among the regressors. Therefore, the maximum likelihood method is the default when the LAGDEP or LAGDEP= option is specified in the MODEL statement. However, when lagged dependent variables are used, the maximum likelihood estimator is not exact maximum likelihood but is conditional on the first few values of the dependent variable.

Alternative Autocorrelation Correction Methods

Autocorrelation correction in regression analysis has a long history, and various approaches have been suggested. Moreover, the same method may be referred to by different names.

Pioneering work in the field was done by Cochrane and Orcutt (1949). The *Cochrane-Orcutt method* refers to a more primitive version of the Yule-Walker method that drops the first observation. The Cochrane-Orcutt method is like the Yule-Walker method for first-order autoregression, except that the Yule-Walker method retains information from the first observation. The iterative Cochrane-Orcutt method is also in use.

The Yule-Walker method used by PROC AUTOREG is also known by other names. Harvey (1981) refers to the Yule-Walker method as the *two-step full transform method*. The Yule-Walker method can be considered as generalized least squares using the OLS residuals to estimate the covariances across observations, and Judge et al. (1985) use the term *estimated generalized least squares* (EGLS) for this method. For a first-order AR process, the Yule-Walker estimates are often termed *Prais-Winsten estimates* (Prais and Winsten 1954). There are variations to these methods that use different estimators of the autocorrelations or the autoregressive parameters.

The unconditional least squares (ULS) method, which minimizes the error sum of squares for all observations, is referred to as the nonlinear least squares (NLS) method by Spitzer (1979).

The *Hildreth-Lu* method (Hildreth and Lu 1960) uses nonlinear least squares to jointly estimate the parameters with an AR(1) model, but it omits the first transformed residual from the sum of squares. Thus, the Hildreth-Lu method is a more primitive version of the ULS method supported by PROC AUTOREG in the same way Cochrane-Orcutt is a more primitive version of Yule-Walker.

The maximum likelihood method is also widely cited in the literature. Although the maximum likelihood method is well defined, some early literature refers to estimators that are called maximum likelihood but are not full unconditional maximum likelihood estimates. The AUTOREG procedure produces full unconditional maximum likelihood estimates.

Harvey (1981) and Judge et al. (1985) summarize the literature on various estimators for the autoregressive error model. Although asymptotically efficient, the various methods have different small sample properties. Several Monte Carlo experiments have been conducted, although usually for the AR(1) model.

Harvey and McAvinchey (1978) found that for a one-variable model, when the independent variable is trending, methods similar to Cochrane-Orcutt are inefficient in estimating the structural parameter. This is not surprising since a pure trend model is well modeled by an autoregressive process with a parameter close to 1.

Harvey and McAvinchey (1978) also made the following conclusions:

- The Yule-Walker method appears to be about as efficient as the maximum likelihood method. Although Spitzer (1979) recommended ML and NLS, the Yule-Walker method (labeled Prais-Winsten) did as

well or better in estimating the structural parameter in Spitzer's Monte Carlo study (table A2 in their article) when the autoregressive parameter was not too large. Maximum likelihood tends to do better when the autoregressive parameter is large.

- For small samples, it is important to use a full transformation (Yule-Walker) rather than the Cochrane-Orcutt method, which loses the first observation. This was also demonstrated by Maeshiro (1976), Chipman (1979), and Park and Mitchell (1980).
- For large samples (Harvey and McAvinchey used 100), losing the first few observations does not make much difference.

GARCH Models

Consider the series y_t, which follows the GARCH process. The conditional distribution of the series Y for time t is written

$$y_t|\Psi_{t-1} \sim \mathrm{N}(0, h_t)$$

where Ψ_{t-1} denotes all available information at time $t-1$. The conditional variance h_t is

$$h_t = \omega + \sum_{i=1}^{q} \alpha_i y_{t-i}^2 + \sum_{j=1}^{p} \gamma_j h_{t-j}$$

where

$$p \geq 0, q > 0$$

$$\omega > 0, \alpha_i \geq 0, \gamma_j \geq 0$$

The GARCH(p,q) model reduces to the ARCH(q) process when $p = 0$. At least one of the ARCH parameters must be nonzero ($q > 0$). The GARCH regression model can be written

$$y_t = \mathbf{x}_t'\beta + \epsilon_t$$

$$\epsilon_t = \sqrt{h_t} e_t$$

$$h_t = \omega + \sum_{i=1}^{q} \alpha_i \epsilon_{t-i}^2 + \sum_{j=1}^{p} \gamma_j h_{t-j}$$

where $\epsilon_t \sim \mathrm{IN}(0,1)$.

In addition, you can consider the model with disturbances following an autoregressive process and with the GARCH errors. The AR(m)-GARCH(p,q) regression model is denoted

$$y_t = \mathbf{x}_t'\beta + \nu_t$$

$$\nu_t = \epsilon_t - \varphi_1 \nu_{t-1} - \cdots - \varphi_m \nu_{t-m}$$

$$\epsilon_t = \sqrt{h_t} e_t$$

$$h_t = \omega + \sum_{i=1}^{q} \alpha_i \epsilon_{t-i}^2 + \sum_{j=1}^{p} \gamma_j h_{t-j}$$

GARCH Estimation with Nelson-Cao Inequality Constraints

The GARCH(p, q) model is written in ARCH(∞) form as

$$\begin{aligned} h_t &= \left(1 - \sum_{j=1}^{p} \gamma_j B^j\right)^{-1} \left[\omega + \sum_{i=1}^{q} \alpha_i \epsilon_{t-i}^2\right] \\ &= \omega^* + \sum_{i=1}^{\infty} \phi_i \epsilon_{t-i}^2 \end{aligned}$$

where B is a backshift operator. Therefore, $h_t \geq 0$ if $\omega^* \geq 0$ and $\phi_i \geq 0, \ \forall i$. Assume that the roots of the following polynomial equation are inside the unit circle,

$$\sum_{j=0}^{p} -\gamma_j Z^{p-j}$$

where $\gamma_0 = -1$ and Z is a complex scalar. $-\sum_{j=0}^{p} \gamma_j Z^{p-j}$ and $\sum_{i=1}^{q} \alpha_i Z^{q-i}$ do not share common factors. Under these conditions, $|\omega^*| < \infty$, $|\phi_i| < \infty$, and these coefficients of the ARCH(∞) process are well defined.

Define $n = \max(p, q)$. The coefficient ϕ_i is written

$$\begin{aligned} \phi_0 &= \alpha_1 \\ \phi_1 &= \gamma_1 \phi_0 + \alpha_2 \\ &\cdots \\ \phi_{n-1} &= \gamma_1 \phi_{n-2} + \gamma_2 \phi_{n-3} + \cdots + \gamma_{n-1} \phi_0 + \alpha_n \\ \phi_k &= \gamma_1 \phi_{k-1} + \gamma_2 \phi_{k-2} + \cdots + \gamma_n \phi_{k-n} \text{ for } k \geq n \end{aligned}$$

where $\alpha_i = 0$ for $i > q$ and $\gamma_j = 0$ for $j > p$.

Nelson and Cao (1992) proposed the finite inequality constraints for GARCH$(1, q)$ and GARCH$(2, q)$ cases. However, it is not straightforward to derive the finite inequality constraints for the general GARCH(p, q) model.

For the GARCH$(1, q)$ model, the nonlinear inequality constraints are

$$\begin{aligned} \omega &\geq 0 \\ \gamma_1 &\geq 0 \\ \phi_k &\geq 0 \text{ for } k = 0, 1, \ldots, q-1 \end{aligned}$$

For the GARCH$(2, q)$ model, the nonlinear inequality constraints are

$$\begin{aligned} \Delta_i &\in R \text{ for } i = 1, 2 \\ \omega^* &\geq 0 \\ \Delta_1 &> 0 \\ \sum_{j=0}^{q-1} \Delta_1^{-j} \alpha_{j+1} &> 0 \\ \phi_k &\geq 0 \text{ for } k = 0, 1, \ldots, q \end{aligned}$$

where Δ_1 and Δ_2 are the roots of $(Z^2 - \gamma_1 Z - \gamma_2)$.

For the GARCH(p, q) model with $p > 2$, only $\max(q-1, p) + 1$ nonlinear inequality constraints ($\phi_k \geq 0$ for $k = 0$ to $\max(q-1, p)$) are imposed, together with the in-sample positivity constraints of the conditional variance h_t.

IGARCH and Stationary GARCH Model

The condition $\sum_{i=1}^{q} \alpha_i + \sum_{j=1}^{p} \gamma_j < 1$ implies that the GARCH process is weakly stationary since the mean, variance, and autocovariance are finite and constant over time. When the GARCH process is stationary, the unconditional variance of ϵ_t is computed as

$$\mathbf{V}(\epsilon_t) = \frac{\omega}{(1 - \sum_{i=1}^{q} \alpha_i - \sum_{j=1}^{p} \gamma_j)}$$

where $\epsilon_t = \sqrt{h_t} e_t$ and h_t is the GARCH(p, q) conditional variance.

Sometimes the multistep forecasts of the variance do not approach the unconditional variance when the model is integrated in variance; that is, $\sum_{i=1}^{q} \alpha_i + \sum_{j=1}^{p} \gamma_j = 1$.

The unconditional variance does not exist for the IGARCH model. However, it is interesting that the IGARCH model can be strongly stationary even though it is not weakly stationary. For more information, see Nelson (1990).

EGARCH Model

The EGARCH model was proposed by Nelson (1991). Nelson and Cao (1992) argue that the nonnegativity constraints in the linear GARCH model are too restrictive. The GARCH model imposes the nonnegative constraints on the parameters, α_i and γ_j, while there are no restrictions on these parameters in the EGARCH model. In the EGARCH model, the conditional variance, h_t, is an asymmetric function of lagged disturbances ϵ_{t-i},

$$\ln(h_t) = \omega + \sum_{i=1}^{q} \alpha_i g(z_{t-i}) + \sum_{j=1}^{p} \gamma_j \ln(h_{t-j})$$

where

$$g(z_t) = \theta z_t + \gamma[|z_t| - E|z_t|]$$
$$z_t = \epsilon_t / \sqrt{h_t}$$

The coefficient of the second term in $g(z_t)$ is set to be 1 (γ=1) in our formulation. Note that $E|z_t| = (2/\pi)^{1/2}$ if $z_t \sim \mathrm{N}(0, 1)$. The properties of the EGARCH model are summarized as follows:

- The function $g(z_t)$ is linear in z_t with slope coefficient $\theta + 1$ if z_t is positive while $g(z_t)$ is linear in z_t with slope coefficient $\theta - 1$ if z_t is negative.
- Suppose that $\theta = 0$. Large innovations increase the conditional variance if $|z_t| - E|z_t| > 0$ and decrease the conditional variance if $|z_t| - E|z_t| < 0$.
- Suppose that $\theta < 1$. The innovation in variance, $g(z_t)$, is positive if the innovations z_t are less than $(2/\pi)^{1/2}/(\theta - 1)$. Therefore, the negative innovations in returns, ϵ_t, cause the innovation to the conditional variance to be positive if θ is much less than 1.

The unconditional variance does not exist for the EGARCH model.

QGARCH, TGARCH, and PGARCH Models

As shown in many empirical studies, positive and negative innovations have different impacts on future volatility. There is a long list of variations of GARCH models that consider the asymmetricity. Three typical variations are the quadratic GARCH (QGARCH) model (Engle and Ng 1993), the threshold GARCH (TGARCH) model (Glosten, Jaganathan, and Runkle 1993; Zakoian 1994), and the power GARCH (PGARCH) model (Ding, Granger, and Engle 1993). For more information about the asymmetric GARCH models, see Engle and Ng (1993).

In the QGARCH model, the lagged errors' centers are shifted from zero to some constant values:

$$h_t = \omega + \sum_{i=1}^{q} \alpha_i (\epsilon_{t-i} - \psi_i)^2 + \sum_{j=1}^{p} \gamma_j h_{t-j}$$

In the TGARCH model, there is an extra slope coefficient for each lagged squared error,

$$h_t = \omega + \sum_{i=1}^{q} (\alpha_i + 1_{\epsilon_{t-i}<0}\psi_i)\epsilon_{t-i}^2 + \sum_{j=1}^{p} \gamma_j h_{t-j}$$

where the indicator function $1_{\epsilon_t<0}$ is one if $\epsilon_t < 0$; otherwise, it is zero.

The PGARCH model not only considers the asymmetric effect but also provides another way to model the long memory property in the volatility,

$$h_t^{\lambda} = \omega + \sum_{i=1}^{q} \alpha_i (|\epsilon_{t-i}| - \psi_i \epsilon_{t-i})^{2\lambda} + \sum_{j=1}^{p} \gamma_j h_{t-j}^{\lambda}$$

where $\lambda > 0$ and $|\psi_i| \leq 1, i = 1, \ldots, q$.

Note that the implemented TGARCH model is also well known as GJR-GARCH (Glosten, Jaganathan, and Runkle 1993), which is similar to the threshold GARCH model proposed by Zakoian (1994) but not exactly the same. In Zakoian's model, the conditional standard deviation is a linear function of the past values of the white noise. Zakoian's version can be regarded as a special case of the PGARCH model when $\lambda = 1/2$. The unconditional variance does not exist for the QGARCH, TGARCH, and PGARCH models.

Using the HETERO Statement with GARCH Models

The HETERO statement can be combined with the GARCH= option in the MODEL statement to include input variables in the GARCH conditional variance model. For example, the GARCH(1, 1) variance model with two dummy input variables, D1 and D2, is

$$\begin{aligned} \epsilon_t &= \sqrt{h_t} e_t \\ h_t &= \omega + \alpha_1 \epsilon_{t-1}^2 + \gamma_1 h_{t-1} + \eta_1 D1_t + \eta_2 D2_t \end{aligned}$$

The following statements estimate this GARCH model:

```
proc autoreg data=one;
   model y = x z / garch=(p=1,q=1);
   hetero d1 d2;
run;
```

The parameters for the variables D1 and D2 can be constrained using the COEF= option. For example, the constraints $\eta_1 = \eta_2 = 1$ are imposed by the following statements:

```
proc autoreg data=one;
   model y = x z / garch=(p=1,q=1);
   hetero d1 d2 / coef=unit;
run;
```

For the EGARCH model, the input variables enter $\ln(h_t)$. For example, the EGARCH(1, 1) model with two dummy input variables, D1 and D2, is

$$\ln(h_t) = \omega + \alpha_1 g(z_{t-1}) + \gamma_1 \ln(h_{t-1}) + \eta_1 D1_t + \eta_2 D2_t$$

where

$$g(z_t) = \theta z_t + \gamma[|z_t| - E|z_t|]$$

$$z_t = \epsilon_t / \sqrt{h_t}$$

The following statements estimate the EGARCH model:

```
proc autoreg data=one;
   model y = x z / garch=(p=1,q=1,type=egarch);
   hetero d1 d2;
run;
```

For the PGARCH model, the input variables enter h_t^λ. For example, the PGARCH(1, 1) model with two dummy input variables, D1 and D2, is

$$h_t^\lambda = \omega + \alpha_1(|\epsilon_{t-1}| - \psi_1\epsilon_{t-1})^{2\lambda} + \gamma_j h_{t-j}^\lambda + \eta_1 D1_t + \eta_2 D2_t$$

The following statements estimate the PGARCH model:

```
proc autoreg data=one;
   model y = x z / garch=(p=1,q=1,type=pgarch);
   hetero d1 d2;
run;
```

GARCH-in-Mean

The GARCH-M model has the added regressor that is the conditional standard deviation,

$$y_t = \mathbf{x}_t'\beta + \delta\sqrt{h_t} + \epsilon_t$$

$$\epsilon_t = \sqrt{h_t} e_t$$

where h_t follows the ARCH or GARCH process.

Maximum Likelihood Estimation

The family of GARCH models are estimated using the maximum likelihood method. The log-likelihood function is computed from the product of all conditional densities of the prediction errors.

When e_t is assumed to have a standard normal distribution ($e_t \sim \mathrm{N}(0,1)$), the log-likelihood function is given by

$$l = \sum_{t=1}^{N} \frac{1}{2}\left[-\ln(2\pi) - \ln(h_t) - \frac{\epsilon_t^2}{h_t}\right]$$

where $\epsilon_t = y_t - \mathbf{x}_t'\beta$ and h_t is the conditional variance. When the GARCH(p,q)-M model is estimated, $\epsilon_t = y_t - \mathbf{x}_t'\beta - \delta\sqrt{h_t}$. When there are no regressors, the residuals ϵ_t are denoted as y_t or $y_t - \delta\sqrt{h_t}$.

If e_t has the standardized Student's t distribution, the log-likelihood function for the conditional t distribution is

$$\ell = \sum_{t=1}^{N}\left[\ln\left(\Gamma\left(\frac{\nu+1}{2}\right)\right) - \ln\left(\Gamma\left(\frac{\nu}{2}\right)\right) - \frac{1}{2}\ln((\nu-2)\pi h_t)\right.$$

$$\left. -\frac{1}{2}(\nu+1)\ln\left(1 + \frac{\epsilon_t^2}{h_t(\nu-2)}\right)\right]$$

where $\Gamma(\cdot)$ is the gamma function and ν is the degree of freedom ($\nu > 2$). Under the conditional t distribution, the additional parameter $1/\nu$ is estimated. The log-likelihood function for the conditional t distribution converges to the log-likelihood function of the conditional normal GARCH model as $1/\nu \rightarrow 0$.

The likelihood function is maximized via either the dual quasi-Newton or the trust region algorithm. The default is the dual quasi-Newton algorithm. The starting values for the regression parameters β are obtained from the OLS estimates. When there are autoregressive parameters in the model, the initial values are obtained from the Yule-Walker estimates. The starting value 1.0^{-6} is used for the GARCH process parameters. Computation of the conditional variance sequence h_t requires values for $h_{-p+1}, \ldots, h0$ and $\epsilon^2_{-q+1}, \ldots, \epsilon^2_0$. For the GARCH(p,q) model, $\epsilon^2_{-q+1}, \ldots, \epsilon^2_0$ are set to the mean square error from the OLS estimation if no autoregressive model is specified, and set to the mean square error from the Yule-Walker estimation if an autoregressive model is specified. Values for $h_{-p+1}, \ldots, h_0$ are then set equal to the expected conditional variance, $E(h_t)$, which you compute by setting $E(\epsilon_t^2)$ to the initializing MSE for $\epsilon^2_{-q+1}, \ldots, \epsilon^2_0$. For the GARCH(1,1) model, this gives $h_0 = (\omega + \alpha_1 * \mathrm{MSE})/(1-\gamma_1)$.

The variance-covariance matrix is computed using the Hessian matrix. The dual quasi-Newton method approximates the Hessian matrix while the quasi-Newton method gets an approximation of the inverse of Hessian. The trust region method uses the Hessian matrix obtained using numerical differentiation. When there are active constraints, that is, $\mathbf{q}(\theta) = \mathbf{0}$, the variance-covariance matrix is given by

$$\mathbf{V}(\hat{\theta}) = \mathbf{H}^{-1}[\mathbf{I} - \mathbf{Q}'(\mathbf{Q}\mathbf{H}^{-1}\mathbf{Q}')^{-1}\mathbf{Q}\mathbf{H}^{-1}]$$

where $\mathbf{H} = -\partial^2 l/\partial\theta\partial\theta'$ and $\mathbf{Q} = \partial\mathbf{q}(\theta)/\partial\theta'$. Therefore, the variance-covariance matrix without active constraints reduces to $\mathbf{V}(\hat{\theta}) = \mathbf{H}^{-1}$.

Heteroscedasticity- and Autocorrelation-Consistent Covariance Matrix Estimator

The heteroscedasticity-consistent covariance matrix estimator (HCCME), also known as the sandwich (or robust or empirical) covariance matrix estimator, has been popular in recent years because it gives the consistent estimation of the covariance matrix of the parameter estimates even when the heteroscedasticity structure might be unknown or misspecified. White (1980) proposes the concept of HCCME, known as HC0. However, the small-sample performance of HC0 is not good in some cases. Davidson and MacKinnon (1993) introduce more improvements to HC0, namely HC1, HC2 and HC3, with the degrees-of-freedom or leverage adjustment. Cribari-Neto (2004) proposes HC4 for cases that have points of high leverage.

HCCME can be expressed in the following general "sandwich" form,

$$\Sigma = B^{-1} M B^{-1}$$

where B, which stands for "bread," is the Hessian matrix and M, which stands for "meat," is the outer product of gradient (OPG) with or without adjustment. For HC0, M is the OPG without adjustment; that is,

$$M_{\mathrm{HC0}} = \sum_{t=1}^{T} g_t g_t'$$

where T is the sample size and g_t is the gradient vector of tth observation. For HC1, M is the OPG with the degrees-of-freedom correction; that is,

$$M_{\mathrm{HC1}} = \frac{T}{T-k} \sum_{t=1}^{T} g_t g_t'$$

where k is the number of parameters. For HC2, HC3, and HC4, the adjustment is related to leverage, namely,

$$M_{\mathrm{HC2}} = \sum_{t=1}^{T} \frac{g_t g_t'}{1-h_{tt}}$$

$$M_{\mathrm{HC3}} = \sum_{t=1}^{T} \frac{g_t g_t'}{(1-h_{tt})^2}$$

$$M_{\mathrm{HC4}} = \sum_{t=1}^{T} \frac{g_t g_t'}{(1-h_{tt})^{\min(4, T h_{tt}/k)}}$$

The leverage h_{tt} is defined as $h_{tt} \equiv j_t' (\sum_{t=1}^{T} j_t j_t')^{-1} j_t$, where j_t is defined as follows:

- For an OLS model, j_t is the tth observed regressors in column vector form.
- For an AR error model, j_t is the derivative vector of the tth residual with respect to the parameters.
- For a GARCH or heteroscedasticity model, j_t is the gradient of the tth observation (that is, g_t).

The heteroscedasticity- and autocorrelation-consistent (HAC) covariance matrix estimator can also be expressed in "sandwich" form,

$$\Sigma = B^{-1}MB^{-1}$$

where B is still the Hessian matrix, but M is the kernel estimator in the following form:

$$M_{\mathrm{HAC}} = a\left(\sum_{t=1}^{T} g_t g_t' + \sum_{j=1}^{T-1} k\left(\frac{j}{b}\right)\sum_{t=1}^{T-j}\left(g_t g_{t+j}' + g_{t+j} g_t'\right)\right)$$

where T is the sample size, g_t is the gradient vector of tth observation, $k(.)$ is the real-valued kernel function, b is the bandwidth parameter, and a is the adjustment factor of small-sample degrees of freedom (that is, $a = 1$ if ADJUSTDF option is not specified and otherwise $a = T/(T-k)$, where k is the number of parameters). The types of kernel functions are listed in Table 8.2.

Table 8.2 Kernel Functions

Kernel Name	Equation
Bartlett	$k(x) = \begin{cases} 1-\lvert x\rvert & \lvert x\rvert \le 1 \\ 0 & \text{otherwise} \end{cases}$
Parzen	$k(x) = \begin{cases} 1-6x^2+6\lvert x\rvert^3 & 0 \le \lvert x\rvert \le 1/2 \\ 2(1-\lvert x\rvert)^3 & 1/2 \le \lvert x\rvert \le 1 \\ 0 & \text{otherwise} \end{cases}$
Quadratic spectral	$k(x) = \frac{25}{12\pi^2x^2}\left(\frac{\sin(6\pi x/5)}{6\pi x/5} - \cos(6\pi x/5)\right)$
Truncated	$k(x) = \begin{cases} 1 & \lvert x\rvert \le 1 \\ 0 & \text{otherwise} \end{cases}$
Tukey-Hanning	$k(x) = \begin{cases} (1+\cos(\pi x))/2 & \lvert x\rvert \le 1 \\ 0 & \text{otherwise} \end{cases}$

When you specify BANDWIDTH=ANDREWS91, according to Andrews (1991) the bandwidth parameter is estimated as shown in Table 8.3.

Table 8.3 Bandwidth Parameter Estimation

Kernel Name	Bandwidth Parameter
Bartlett	$b = 1.1447(\alpha(1)T)^{1/3}$
Parzen	$b = 2.6614(\alpha(2)T)^{1/5}$
Quadratic spectral	$b = 1.3221(\alpha(2)T)^{1/5}$
Truncated	$b = 0.6611(\alpha(2)T)^{1/5}$
Tukey-Hanning	$b = 1.7462(\alpha(2)T)^{1/5}$

Let $\{g_{at}\}$ denote each series in $\{g_t\}$, and let (ρ_a, σ_a^2) denote the corresponding estimates of the autoregressive and innovation variance parameters of the AR(1) model on $\{g_{at}\}$, $a = 1, \ldots, k$, where the AR(1) model is parameterized as $g_{at} = \rho g_{at-1} + \epsilon_{at}$ with $Var(\epsilon_{at}) = \sigma_a^2$. The factors $\alpha(1)$ and $\alpha(2)$ are estimated with

the formulas

$$\alpha(1) = \frac{\sum_{a=1}^{k} \frac{4\rho_a^2\sigma_a^4}{(1-\rho_a)^6(1+\rho_a)^2}}{\sum_{a=1}^{k} \frac{\sigma_a^4}{(1-\rho_a)^4}}$$

$$\alpha(2) = \frac{\sum_{a=1}^{k} \frac{4\rho_a^2\sigma_a^4}{(1-\rho_a)^8}}{\sum_{a=1}^{k} \frac{\sigma_a^4}{(1-\rho_a)^4}}$$

When you specify BANDWIDTH=NEWEYWEST94, according to Newey and West (1994) the bandwidth parameter is estimated as shown in Table 8.4.

Table 8.4 Bandwidth Parameter Estimation

Kernel Name	Bandwidth Parameter
Bartlett	$b = 1.1447(\{s_1/s_0\}^2 T)^{1/3}$
Parzen	$b = 2.6614(\{s_1/s_0\}^2 T)^{1/5}$
Quadratic spectral	$b = 1.3221(\{s_1/s_0\}^2 T)^{1/5}$
Truncated	$b = 0.6611(\{s_1/s_0\}^2 T)^{1/5}$
Tukey-Hanning	$b = 1.7462(\{s_1/s_0\}^2 T)^{1/5}$

The factors s_1 and s_0 are estimated with the following formulas:

$$s_1 = 2\sum_{j=1}^{n} j\sigma_j$$

$$s_0 = \sigma_0 + 2\sum_{j=1}^{n} \sigma_j$$

where n is the lag selection parameter and is determined by kernels, as listed in Table 8.5.

Table 8.5 Lag Selection Parameter Estimation

Kernel Name	Lag Selection Parameter
Bartlett	$n = c(T/100)^{2/9}$
Parzen	$n = c(T/100)^{4/25}$
Quadratic spectral	$n = c(T/100)^{2/25}$
Truncated	$n = c(T/100)^{1/5}$
Tukey-Hanning	$n = c(T/100)^{1/5}$

The factor c in Table 8.5 is specified by the C= option. By default, it is 12.

The factor σ_j is estimated with the equation

$$\sigma_j = T^{-1} \sum_{t=j+1}^{T} \left(\sum_{a=i}^{k} g_{at} \sum_{a=i}^{k} g_{at-j} \right), j = 0, \ldots, n$$

where i is 1 if the NOINT option in the MODEL statement is specified (otherwise, it is 2), and g_{at} is the same as in the Andrews method.

If you specify BANDWIDTH=SAMPLESIZE, the bandwidth parameter is estimated with the equation

$$b = \begin{cases} \lfloor \gamma T^r + c \rfloor & \text{if BANDWIDTH=SAMPLESIZE(INT) option is specified} \\ \gamma T^r + c & \text{otherwise} \end{cases}$$

where T is the sample size; $\lfloor x \rfloor$ is the largest integer less than or equal to x; and γ, r, and c are values specified by the BANDWIDTH=SAMPLESIZE(GAMMA=, RATE=, CONSTANT=) options, respectively.

If you specify the PREWHITENING option, g_t is prewhitened by the VAR(1) model,

$$g_t = A g_{t-1} + w_t$$

Then M is calculated by

$$M_{\mathrm{HAC}} = a(I - A)^{-1} \left(\sum_{t=1}^{T} w_t w_t' + \sum_{j=1}^{T-1} k\left(\frac{j}{b}\right) \sum_{t=1}^{T-j} \left(w_t w_{t+j}' + w_{t+j} w_t' \right) \right) \left((I - A)^{-1} \right)'$$

The bandwidth calculation is also based on the prewhitened series w_t.

Goodness-of-Fit Measures and Information Criteria

This section discusses various goodness-of-fit statistics produced by the AUTOREG procedure.

Total R-Square Statistic

The total R-square statistic (Total Rsq) is computed as

$$\mathrm{R}^2_{\mathrm{tot}} = 1 - \frac{\mathrm{SSE}}{\mathrm{SST}}$$

where SST is the sum of squares for the original response variable corrected for the mean and SSE is the final error sum of squares. The Total Rsq is a measure of how well the next value can be predicted using the structural part of the model and the past values of the residuals. If the NOINT option is specified, SST is the uncorrected sum of squares.

Transformed Regression R-Square Statistic

The transformed regression R-square statistic is computed as

$$\mathrm{R}^2_{\mathrm{tr}} = 1 - \frac{\mathrm{TSSE}}{\mathrm{TSST}}$$

where TSST is the total sum of squares of the transformed response variable corrected for the transformed intercept, and TSSE is the error sum of squares for this transformed regression problem. If the NOINT option is requested, no correction for the transformed intercept is made. The transformed regression R-square statistic is a measure of the fit of the structural part of the model after transforming for the autocorrelation and is the R-square for the transformed regression.

Mean Absolute Error and Mean Absolute Percentage Error

The mean absolute error (MAE) is computed as

$$\mathrm{MAE} = \frac{1}{T}\sum_{t=1}^{T}|e_t|$$

where e_t are the estimated model residuals and T is the number of observations.

The mean absolute percentage error (MAPE) is computed as

$$\mathrm{MAPE} = \frac{1}{T'}\sum_{t=1}^{T}\delta_{y_t\neq 0}\frac{|e_t|}{|y_t|}$$

where e_t are the estimated model residuals, y_t are the original response variable observations, $\delta_{y_t\neq 0} = 1$ if $y_t \neq 0$, $\delta_{y_t\neq 0}\,|e_t/y_t| = 0$ if $y_t = 0$, and T' is the number of nonzero original response variable observations.

Calculation of Recursive Residuals and CUSUM Statistics

The recursive residuals w_t are computed as

$$w_t = \frac{e_t}{\sqrt{v_t}}$$

$$e_t = y_t - x_t'\beta^{(t)}$$

$$\beta^{(t)} = \left[\sum_{i=1}^{t-1}\mathbf{x}_i\mathbf{x}_i'\right]^{-1}\left(\sum_{i=1}^{t-1}\mathbf{x}_i y_i\right)$$

$$v_t = 1 + \mathbf{x}'_t\left[\sum_{i=1}^{t-1}\mathbf{x}_i\mathbf{x}_i'\right]^{-1}\mathbf{x}_t$$

Note that the first $\beta^{(t)}$ can be computed for $t = p + 1$, where p is the number of regression coefficients. As a result, first p recursive residuals are not defined. Note also that the forecast error variance of e_t is the scalar multiple of v_t such that $V(e_t) = \sigma^2 v_t$.

The CUSUM and CUSUMSQ statistics are computed using the preceding recursive residuals,

$$\text{CUSUM}_t = \sum_{i=k+1}^{t} \frac{w_i}{\sigma_w}$$

$$\text{CUSUMSQ}_t = \frac{\sum_{i=k+1}^{t} w_i^2}{\sum_{i=k+1}^{T} w_i^2}$$

where w_i are the recursive residuals,

$$\sigma_w = \sqrt{\frac{\sum_{i=k+1}^{T} (w_i - \hat{w})^2}{(T-k-1)}}$$

$$\hat{w} = \frac{1}{T-k} \sum_{i=k+1}^{T} w_i$$

and k is the number of regressors.

The CUSUM statistics can be used to test for misspecification of the model. The upper and lower critical values for CUSUM_t are

$$\pm a \left[\sqrt{T-k} + 2\frac{(t-k)}{(T-k)^{\frac{1}{2}}} \right]$$

where a = 1.143 for a significance level 0.01, 0.948 for 0.05, and 0.850 for 0.10. These critical values are output by the CUSUMLB= and CUSUMUB= options for the significance level specified by the ALPHACSM= option.

The upper and lower critical values of CUSUMSQ_t are given by

$$\pm a + \frac{(t-k)}{T-k}$$

where the value of a is obtained from the table by Durbin (1969) if the $\frac{1}{2}(T-k)-1 \leq 60$. Edgerton and Wells (1994) provided the method of obtaining the value of a for large samples.

These critical values are output by the CUSUMSQLB= and CUSUMSQUB= options for the significance level specified by the ALPHACSM= option.

Information Criteria AIC, AICC, SBC, and HQC

Akaike's information criterion (AIC), the corrected Akaike's information criterion (AICC), Schwarz's Bayesian information criterion (SBC), and the Hannan-Quinn information criterion (HQC) are computed as follows:

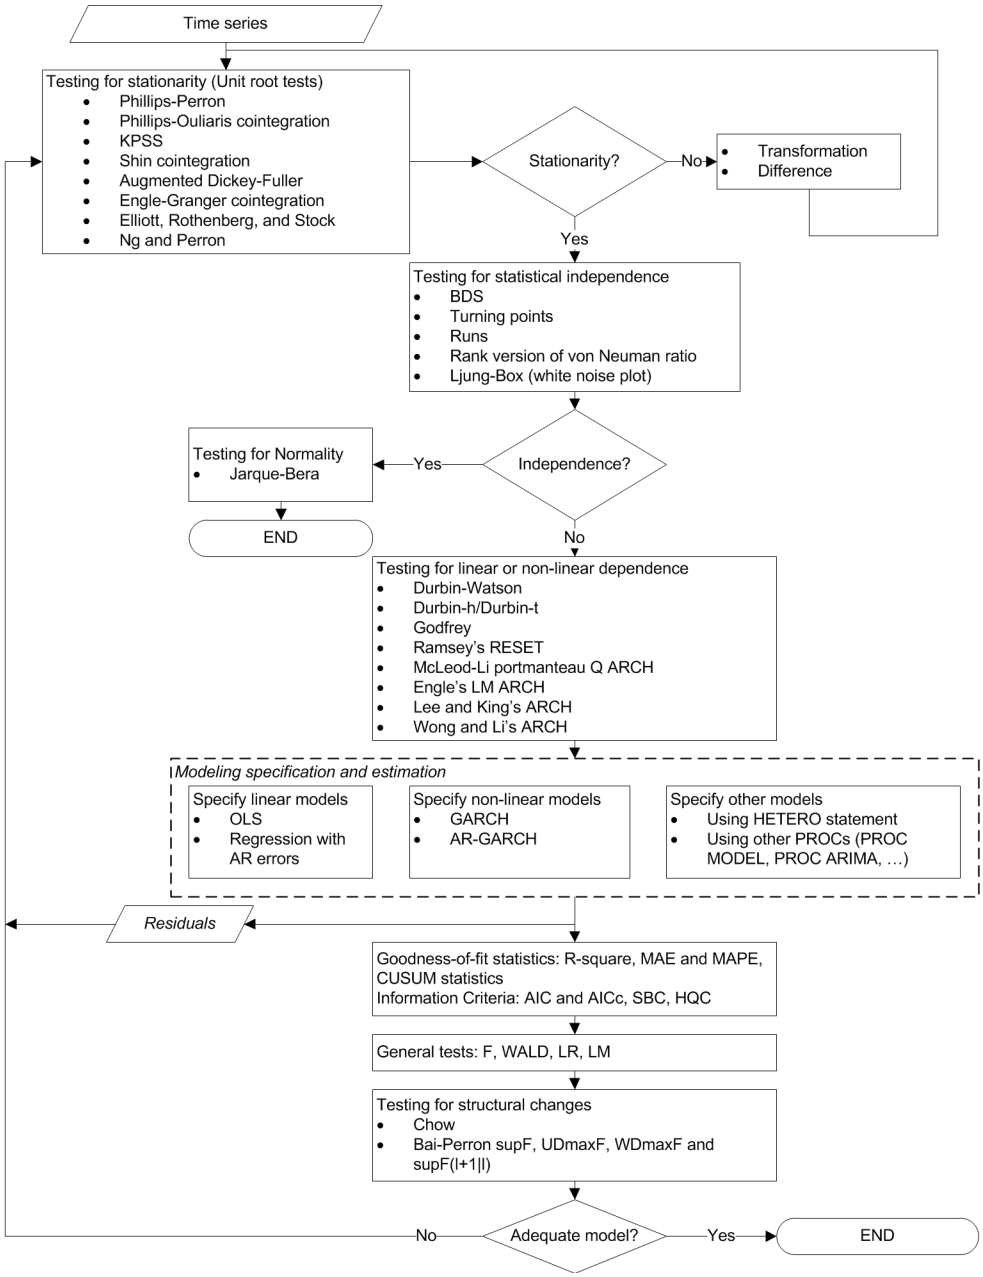
$$\begin{aligned}
\text{AIC} &= -2\ln(L) + 2k \\
\text{AICC} &= \text{AIC} + 2\frac{k(k+1)}{N-k-1} \\
\text{SBC} &= -2\ln(L) + \ln(N)k \\
\text{HQC} &= -2\ln(L) + 2\ln(\ln(N))k
\end{aligned}$$

In these formulas, L is the value of the likelihood function evaluated at the parameter estimates, N is the number of observations, and k is the number of estimated parameters. For more information, see Judge et al. (1985), Hurvich and Tsai (1989), Schwarz (1978) and Hannan and Quinn (1979).

Testing

The modeling process consists of four stages: identification, specification, estimation, and diagnostic checking (Cromwell, Labys, and Terraza 1994). The AUTOREG procedure supports tens of statistical tests for identification and diagnostic checking. Figure 8.17 illustrates how to incorporate these statistical tests into the modeling process.

Figure 8.17 Statistical Tests in the AUTOREG Procedure



Testing for Stationarity

Most of the theories of time series require stationarity; therefore, it is critical to determine whether a time series is stationary. Two nonstationary time series are fractionally integrated time series and autoregressive series with random coefficients. However, more often some time series are nonstationary due to an upward trend over time. The trend can be captured by either of the following two models.

- The *difference stationary* process

  $$(1 - L)y_t = \delta + \psi(L)\epsilon_t$$

  where L is the lag operator, $\psi(1) \neq 0$, and ϵ_t is a white noise sequence with mean zero and variance σ^2. Hamilton (1994) also refers to this model the *unit root* process.

- The *trend stationary* process

  $$y_t = \alpha + \delta t + \psi(L)\epsilon_t$$

When a process has a unit root, it is said to be integrated of order one or I(1). An I(1) process is stationary after differencing once. The trend stationary process and difference stationary process require different treatment to transform the process into stationary one for analysis. Therefore, it is important to distinguish the two processes. Bhargava (1986) nested the two processes into the following general model:

$$y_t = \gamma_0 + \gamma_1 t + \alpha(y_{t-1} - \gamma_0 - \gamma_1(t-1)) + \psi(L)\epsilon_t$$

However, a difficulty is that the right-hand side is nonlinear in the parameters. Therefore, it is convenient to use a different parameterization:

$$y_t = \beta_0 + \beta_1 t + \alpha y_{t-1} + \psi(L)\epsilon_t$$

The test of null hypothesis that $\alpha = 1$ against the one-sided alternative of $\alpha < 1$ is called a *unit root test*.

Dickey-Fuller unit root tests are based on regression models similar to the previous model,

$$y_t = \beta_0 + \beta_1 t + \alpha y_{t-1} + \epsilon_t$$

where ϵ_t is assumed to be white noise. The t statistic of the coefficient α does not follow the normal distribution asymptotically. Instead, its distribution can be derived using the functional central limit theorem. Three types of regression models including the preceding one are considered by the Dickey-Fuller test. The deterministic terms that are included in the other two types of regressions are either null or constant only.

An assumption in the Dickey-Fuller unit root test is that it requires the errors in the autoregressive model to be white noise, which is often not true. There are two popular ways to account for general serial correlation between the errors. One is the augmented Dickey-Fuller (ADF) test, which uses the lagged difference in the regression model. This was originally proposed by Dickey and Fuller (1979) and later studied by Said and Dickey (1984) and Phillips and Perron (1988). Another method is proposed by Phillips and Perron (1988); it is called Phillips-Perron (PP) test. The tests adopt the original Dickey-Fuller regression with intercept, but modify the test statistics to take account of the serial correlation and heteroscedasticity. It is called nonparametric because no specific form of the serial correlation of the errors is assumed.

A problem of the augmented Dickey-Fuller and Phillips-Perron unit root tests is that they are subject to size distortion and low power. It is reported in Schwert (1989) that the size distortion is significant when the

series contains a large moving average (MA) parameter. DeJong et al. (1992) find that the ADF has power around one third and PP test has power less than 0.1 against the trend stationary alternative, in some common settings. Among some more recent unit root tests that improve upon the size distortion and the low power are the tests described by Elliott, Rothenberg, and Stock (1996) and Ng and Perron (2001). These tests involve a step of detrending before constructing the test statistics and are demonstrated to perform better than the traditional ADF and PP tests.

Most testing procedures specify the unit root processes as the null hypothesis. Tests of the null hypothesis of stationarity have also been studied, among which Kwiatkowski et al. (1992) is very popular.

Economic theories often dictate that a group of economic time series are linked together by some long-run equilibrium relationship. Statistically, this phenomenon can be modeled by *cointegration*. When several nonstationary processes $\mathbf{z}_t = (z_{1t}, \ldots, z_{kt})'$ are cointegrated, there exists a $(k \times 1)$ cointegrating vector $\mathbf{c}$ such that $\mathbf{c}'\mathbf{z}_t$ is stationary and $\mathbf{c}$ is a nonzero vector. One way to test the relationship of cointegration is the *residual based cointegration test*, which assumes the regression model

$$y_t = \beta_1 + \mathbf{x}_t'\beta + u_t$$

where $y_t = z_{1t}$, $\mathbf{x}_t = (z_{2t}, \ldots, z_{kt})'$, and $\beta = (\beta_2, \ldots, \beta_k)'$. The OLS residuals from the regression model are used to test for the null hypothesis of no cointegration. Engle and Granger (1987) suggest using ADF on the residuals while Phillips and Ouliaris (1990) study the tests using PP and other related test statistics.

Augmented Dickey-Fuller Unit Root and Engle-Granger Cointegration Testing

Common unit root tests have the null hypothesis that there is an autoregressive unit root $H_0 : \alpha = 1$, and the alternative is $H_a : |\alpha| < 1$, where α is the autoregressive coefficient of the time series

$$y_t = \alpha y_{t-1} + \epsilon_t$$

This is referred to as the zero mean model. The standard Dickey-Fuller (DF) test assumes that errors ϵ_t are white noise. There are two other types of regression models that include a constant or a time trend as follows:

$$y_t = \mu + \alpha y_{t-1} + \epsilon_t$$
$$y_t = \mu + \beta t + \alpha y_{t-1} + \epsilon_t$$

These two models are referred to as the constant mean model and the trend model, respectively. The constant mean model includes a constant mean μ of the time series. However, the interpretation of μ depends on the stationarity in the following sense: the mean in the stationary case when $\alpha < 1$ is the trend in the integrated case when $\alpha = 1$. Therefore, the null hypothesis should be the joint hypothesis that $\alpha = 1$ and $\mu = 0$. However, for the unit root tests, the test statistics are concerned with the null hypothesis of $\alpha = 1$. The joint null hypothesis is not commonly used. This issue is addressed in Bhargava (1986) with a different nesting model.

There are two types of test statistics. The conventional t ratio is

$$DF_\tau = \frac{\hat{\alpha} - 1}{sd(\hat{\alpha})}$$

and the second test statistic, called ρ-test, is

$$T(\hat{\alpha} - 1)$$

For the zero mean model, the asymptotic distributions of the Dickey-Fuller test statistics are

$$T(\hat{\alpha}-1) \Rightarrow \left(\int_0^1 W(r)dW(r)\right)\left(\int_0^1 W(r)^2dr\right)^{-1}$$
$$DF_\tau \Rightarrow \left(\int_0^1 W(r)dW(r)\right)\left(\int_0^1 W(r)^2dr\right)^{-1/2}$$

For the constant mean model, the asymptotic distributions are

$$T(\hat{\alpha}-1) \Rightarrow \left([W(1)^2-1]/2 - W(1)\int_0^1 W(r)dr\right)\left(\int_0^1 W(r)^2dr - \left(\int_0^1 W(r)dr\right)^2\right)^{-1}$$
$$DF_\tau \Rightarrow \left([W(1)^2-1]/2 - W(1)\int_0^1 W(r)dr\right)\left(\int_0^1 W(r)^2dr - \left(\int_0^1 W(r)dr\right)^2\right)^{-1/2}$$

For the trend model, the asymptotic distributions are

$$T(\hat{\alpha}-1) \Rightarrow \left[W(r)dW + 12\left(\int_0^1 rW(r)dr - \frac{1}{2}\int_0^1 W(r)dr\right)\left(\int_0^1 W(r)dr - \frac{1}{2}W(1)\right) - W(1)\int_0^1 W(r)dr\right]D^{-1}$$
$$DF_\tau \Rightarrow \left[W(r)dW + 12\left(\int_0^1 rW(r)dr - \frac{1}{2}\int_0^1 W(r)dr\right)\left(\int_0^1 W(r)dr - \frac{1}{2}W(1)\right) - W(1)\int_0^1 W(r)dr\right]D^{1/2}$$

where

$$D = \int_0^1 W(r)^2dr - 12\left(\int_0^1 r(W(r)dr\right)^2 + 12\int_0^1 W(r)dr\int_0^1 rW(r)dr - 4\left(\int_0^1 W(r)dr\right)^2$$

One problem of the Dickey-Fuller and similar tests that employ three types of regressions is the difficulty in the specification of the deterministic trends. Campbell and Perron (1991) claimed that "the proper handling of deterministic trends is a vital prerequisite for dealing with unit roots." However, the "proper handling" is not obvious since the distribution theory of the relevant statistics about the deterministic trends is not available. Hayashi (2000) suggests using the constant mean model when you think there is no trend, and using the trend model when you think otherwise. However, no formal procedure is provided.

The null hypothesis of the Dickey-Fuller test is a random walk, possibly with drift. The differenced process is not serially correlated under the null of I(1). There is a great need for the generalization of this specification. The augmented Dickey-Fuller (ADF) test, originally proposed in Dickey and Fuller (1979), adjusts for the serial correlation in the time series by adding lagged first differences to the autoregressive model,

$$\Delta y_t = \mu + \delta t + \alpha y_{t-1} + \sum_{j=1}^{p}\alpha_j \Delta y_{t-j} + \epsilon_t$$

where the deterministic terms δt and μ can be absent for the models without drift or linear trend. As previously, there are two types of test statistics. One is the OLS t value

$$\frac{\hat{\alpha}}{sd(\hat{\alpha})}$$

and the other is given by

$$\frac{T\hat{\alpha}}{1-\hat{\alpha}_1-\cdots-\hat{\alpha}_p}$$

The asymptotic distributions of the test statistics are the same as those of the standard Dickey-Fuller test statistics.

Nonstationary multivariate time series can be tested for cointegration, which means that a linear combination of these time series is stationary. Formally, denote the series by $\mathbf{z}_t = (z_{1t}, \ldots, z_{kt})'$. The null hypothesis of cointegration is that there exists a vector $\mathbf{c}$ such that $\mathbf{c}'\mathbf{z}_t$ is stationary. Residual-based cointegration tests were studied in Engle and Granger (1987) and Phillips and Ouliaris (1990). The latter are described in the next subsection. The first step regression is

$$y_t = \mathbf{x}_t'\beta + u_t$$

where $y_t = z_{1t}$, $\mathbf{x}_t = (z_{2t}, \ldots, z_{kt})'$, and $\beta = (\beta_2, \ldots, \beta_k)'$. This regression can also include an intercept or an intercept with a linear trend. The residuals are used to test for the existence of an autoregressive unit root. Engle and Granger (1987) proposed augmented Dickey-Fuller type regression without an intercept on the residuals to test the unit root. When the first step OLS does not include an intercept, the asymptotic distribution of the ADF test statistic DF_τ is given by

$$DF_\tau \Longrightarrow \int_0^1 \frac{Q(r)}{(\int_0^1 Q^2)^{1/2}} dS$$

$$Q(r) = W_1(r) - \int_0^1 W_1 W_2' \left(\int_0^1 W_2 W_2' \right)^{-1} W_2(r)$$

$$S(r) = \frac{Q(r)}{(\kappa'\kappa)^{1/2}}$$

$$\kappa' = \left(1, -\int_0^1 W_1 W_2' \left(\int_0^1 W_2 W_2' \right)^{-1} \right)$$

where $W(r)$ is a k vector standard Brownian motion and

$$W(r) = \Big(W_1(r), W_2(r) \Big)$$

is a partition such that $W_1(r)$ is a scalar and $W_2(r)$ is $k-1$ dimensional. The asymptotic distributions of the test statistics in the other two cases have the same form as the preceding formula. If the first step regression includes an intercept, then $W(r)$ is replaced by the de-meaned Brownian motion $\overline{W}(r) = W(r) - \int_0^1 W(r)dr$. If the first step regression includes a time trend, then $W(r)$ is replaced by the detrended Brownian motion. The critical values of the asymptotic distributions are tabulated in Phillips and Ouliaris (1990) and MacKinnon (1991).

The residual based cointegration tests have a major shortcoming. Different choices of the dependent variable in the first step OLS might produce contradictory results. This can be explained theoretically. If the dependent variable is in the cointegration relationship, then the test is consistent against the alternative that there is cointegration. On the other hand, if the dependent variable is not in the cointegration system, the OLS residual $y_t - \mathbf{x}_t'\beta$ do not converge to a stationary process. Changing the dependent variable is more likely to produce conflicting results in finite samples.

Phillips-Perron Unit Root and Cointegration Testing

Besides the ADF test, there is another popular unit root test that is valid under general serial correlation and heteroscedasticity, developed by Phillips (1987) and Phillips and Perron (1988). The tests are constructed using the AR(1) type regressions, unlike ADF tests, with corrected estimation of the long run variance of Δy_t. In the case without intercept, consider the driftless random walk process

$$y_t = y_{t-1} + u_t$$

where the disturbances might be serially correlated with possible heteroscedasticity. Phillips and Perron (1988) proposed the unit root test of the OLS regression model,

$$y_t = \rho y_{t-1} + u_t$$

Denote the OLS residual by $\hat{u}_t$. The asymptotic variance of $\frac{1}{T}\sum_{t=1}^{T}\hat{u}_t^2$ can be estimated by using the truncation lag l,

$$\hat{\lambda} = \sum_{j=0}^{l} \kappa_j [1 - j/(l+1)]\hat{\gamma}_j$$

where $\kappa_0 = 1, \kappa_j = 2$ for $j > 0$, and $\hat{\gamma}_j = \frac{1}{T}\sum_{t=j+1}^{T}\hat{u}_t\hat{u}_{t-j}$. This is a consistent estimator suggested by Newey and West (1987).

The variance of u_t can be estimated by $s^2 = \frac{1}{T-k}\sum_{t=1}^{T}\hat{u}_t^2$. Let $\hat{\sigma}^2$ be the variance estimate of the OLS estimator $\hat{\rho}$. Then the Phillips-Perron $\hat{Z}_\rho$ test (zero mean case) is written

$$\hat{Z}_\rho = T(\hat{\rho} - 1) - \frac{1}{2}T^2\hat{\sigma}^2(\hat{\lambda} - \hat{\gamma}_0)/s^2$$

The $\hat{Z}_\rho$ statistic is just the ordinary Dickey-Fuller $\hat{Z}_\alpha$ statistic with a correction term that accounts for the serial correlation. The correction term goes to zero asymptotically if there is no serial correlation.

Note that $\mathrm{P}(\hat{\rho} < 1) \approx 0.68$ as $T \to \infty$, which shows that the limiting distribution is skewed to the left.

Let τ_ρ be the τ statistic for $\hat{\rho}$. The Phillips-Perron $\hat{Z}_t$ (defined here as $\hat{Z}_\tau$) test is written

$$\hat{Z}_\tau = (\hat{\gamma}_0/\hat{\lambda})^{1/2}t_{\hat{\rho}} - \frac{1}{2}T\hat{\sigma}(\hat{\lambda} - \hat{\gamma}_0)/(s\hat{\lambda}^{1/2})$$

To incorporate a constant intercept, the regression model $y_t = \mu + \rho y_{t-1} + u_t$ is used (single mean case) and null hypothesis the series is a driftless random walk with nonzero unconditional mean. To incorporate a time trend, the regression model $y_t = \mu + \delta t + \rho y_{t-1} + u_t$ is used, and under the null the series is a random walk with drift.

The limiting distributions of the test statistics for the zero mean case are

$$\hat{\mathrm{Z}}_\rho \Rightarrow \frac{\frac{1}{2}\{B(1)^2 - 1\}}{\int_0^1 [B(s)]^2 ds}$$

$$\hat{\mathrm{Z}}_\tau \Rightarrow \frac{\frac{1}{2}\{[B(1)]^2 - 1\}}{\{\int_0^1 [B(x)]^2 dx\}^{1/2}}$$

where $B(\cdot)$ is a standard Brownian motion.

The limiting distributions of the test statistics for the intercept case are

$$\hat{Z}_\rho \Rightarrow \frac{\frac{1}{2}\{[B(1)]^2 - 1\} - B(1)\int_0^1 B(x)dx}{\int_0^1 [B(x)]^2 dx - \left[\int_0^1 B(x)dx\right]^2}$$

$$\hat{\mathrm{Z}}_\tau \Rightarrow \frac{\frac{1}{2}\{[B(1)]^2 - 1\} - B(1)\int_0^1 B(x)dx}{\{\int_0^1 [B(x)]^2 dx - \left[\int_0^1 B(x)dx\right]^2\}^{1/2}}$$

Finally, the limiting distributions of the test statistics for the trend case are can be derived as

$$\begin{bmatrix} 0 & c & 0 \end{bmatrix} V^{-1} \begin{bmatrix} B(1) \\ \left(B(1)^2 - 1\right)/2 \\ B(1) - \int_0^1 B(x)dx \end{bmatrix}$$

where $c = 1$ for $\hat{\mathrm{Z}}_\rho$ and $c = \frac{1}{\sqrt{Q}}$ for $\hat{\mathrm{Z}}_\tau$,

$$V = \begin{bmatrix} 1 & \int_0^1 B(x)dx & 1/2 \\ \int_0^1 B(x)dx & \int_0^1 B(x)^2 dx & \int_0^1 xB(x)dx \\ 1/2 & \int_0^1 xB(x)dx & 1/3 \end{bmatrix}$$

$$Q = \begin{bmatrix} 0 & c & 0 \end{bmatrix} V^{-1} \begin{bmatrix} 0 & c & 0 \end{bmatrix}^T$$

The finite sample performance of the PP test is not satisfactory (see Hayashi 2000).

When several variables $\mathbf{z}_t = (z_{1t}, \ldots, z_{kt})'$ are cointegrated, there exists a $(k \times 1)$ cointegrating vector $\mathbf{c}$ such that $\mathbf{c}'\mathbf{z}_t$ is stationary and $\mathbf{c}$ is a nonzero vector. The residual based cointegration test assumes the following regression model,

$$y_t = \beta_1 + \mathbf{x}_t'\beta + u_t$$

where $y_t = z_{1t}$, $\mathbf{x}_t = (z_{2t}, \ldots, z_{kt})'$, and $\beta = (\beta_2, \ldots, \beta_k)'$. You can estimate the consistent cointegrating vector by using OLS if all variables are difference stationary—that is, I(1). The estimated cointegrating vector is $\hat{\mathbf{c}} = (1, -\hat{\beta}_2, \ldots, -\hat{\beta}_k)'$. The Phillips-Ouliaris test is computed using the OLS residuals from the preceding regression model, and it uses the PP unit root tests $\hat{\mathrm{Z}}_\rho$ and $\hat{\mathrm{Z}}_\tau$ developed in Phillips (1987), although in Phillips and Ouliaris (1990) the asymptotic distributions of some other leading unit root tests are also derived. The null hypothesis is no cointegration.

You need to refer to the tables by Phillips and Ouliaris (1990) to obtain the p-value of the cointegration test. Before you apply the cointegration test, you might want to perform the unit root test for each variable (see the option STATIONARITY=).

As in the Engle-Granger cointegration tests, the Phillips-Ouliaris test can give conflicting results for different choices of the regressand. There are other cointegration tests that are invariant to the order of the variables, including Johansen (1988), Johansen (1991), Stock and Watson (1988).

ERS and Ng-Perron Unit Root Tests

As mentioned earlier, ADF and PP both suffer severe size distortion and low power. There is a class of newer tests that improve both size and power. These are sometimes called efficient unit root tests, and among them tests by Elliott, Rothenberg, and Stock (1996) and Ng and Perron (2001) are prominent.

Elliott, Rothenberg, and Stock (1996) consider the data generating process

$$y_t = \beta' z_t + u_t$$
$$u_t = \alpha u_{t-1} + v_t, t = 1, \ldots, T$$

where $\{z_t\}$ is either $\{1\}$ or $\{(1, t)\}$ and $\{v_t\}$ is an unobserved stationary zero-mean process with positive spectral density at zero frequency. The null hypothesis is $H_0 : \alpha = 1$, and the alternative is $H_a : |\alpha| < 1$. The key idea of Elliott, Rothenberg, and Stock (1996) is to study the asymptotic power and asymptotic power envelope of some new tests. Asymptotic power is defined with a sequence of local alternatives. For a fixed alternative hypothesis, the power of a test usually goes to one when sample size goes to infinity; however, this says nothing about the finite sample performance. On the other hand, when the data generating process under the alternative moves closer to the null hypothesis as the sample size increases, the power does not necessarily converge to one. The local-to-unity alternatives in ERS are

$$\alpha = 1 + \frac{c}{T}$$

and the power against the local alternatives has a limit as T goes to infinity, which is called asymptotic power. This value is strictly between 0 and 1. Asymptotic power indicates the adequacy of a test to distinguish small deviations from the null hypothesis.

Define

$$y_\alpha = (y_1, (1 - \alpha L)y_2, \ldots, (1 - \alpha L)y_T)$$
$$z_\alpha = (z_1, (1 - \alpha L)z_2, \ldots, (1 - \alpha L)z_T)$$

Let $S(\alpha)$ be the sum of squared residuals from a least squares regression of y_α on z_α. Then the *point optimal test* against the local alternative $\bar{\alpha} = 1 + \bar{c}/T$ has the form

$$P_T^{GLS} = \frac{S(\bar{\alpha}) - \bar{\alpha} S(1)}{\hat{\omega}^2}$$

where $\hat{\omega}^2$ is an estimator for $\omega^2 = \sum_{k=-\infty}^{\infty} E v_t v_{t-k}$. The autoregressive (AR) estimator is used for $\hat{\omega}^2$ (Elliott, Rothenberg, and Stock 1996, equations 13 and 14),

$$\hat{\omega}^2 = \frac{\hat{\sigma}_\eta^2}{(1 - \sum_{i=1}^{p} \hat{a}_i)^2}$$

where $\hat{\sigma}_\eta^2$ and $\hat{a}_i$ are OLS estimates from the regression

$$\Delta y_t = a_0 y_{t-1} + \sum_{i=1}^{p} a_i \Delta y_{t-i} + a_{p+1} + \eta_t$$

where p is selected according to the Schwarz Bayesian information criterion. The test rejects the null when P_T is small. The asymptotic power function for the point optimal test that is constructed with $\bar{c}$ under local alternatives with c is denoted by $\pi(c, \bar{c})$. Then the power envelope is $\pi(c, c)$ because the test formed with $\bar{c}$

is the most powerful against the alternative $c = \bar{c}$. In other words, the asymptotic function $\pi(c, \bar{c})$ is always below the power envelope $\pi(c)$ except that at one point, $c = \bar{c}$, they are tangent. Elliott, Rothenberg, and Stock (1996) show that choosing some specific values for $\bar{c}$ can cause the asymptotic power function $\pi(c, \bar{c})$ of the point optimal test to be very close to the power envelope. The optimal $\bar{c}$ is -7 when $z_t = 1$, and -13.5 when $z_t = (1, t)'$. This choice of $\bar{c}$ corresponds to the tangent point where $\pi = 0.5$. This is also true of the DF-GLS test.

Elliott, Rothenberg, and Stock (1996) also propose the *DF-GLS test*, given by the t statistic for testing $\psi_0 = 0$ in the regression

$$\Delta y_t^d = \psi_0 y_{t-1}^d + \sum_{j=1}^{p} \psi_j \Delta y_{t-j}^d + \epsilon_{tp}$$

where y_t^d is obtained in a first step detrending

$$y_t^d = y_t - \hat{\beta}_{\bar{\alpha}}' z_t$$

and $\hat{\beta}_{\bar{\alpha}}$ is least squares regression coefficient of y_α on z_α. Regarding the lag length selection, Elliott, Rothenberg, and Stock (1996) favor the Schwarz Bayesian information criterion. The optimal selection of the lag length p and the estimation of ω^2 is further discussed in Ng and Perron (2001). The lag length is selected from the interval $[0, p_{max}]$ for some fixed p_{max} by using the modified Akaike's information criterion,

$$\mathrm{MAIC}(p) = \log(\hat{\sigma}_p^2) + \frac{2(\tau_T(p) + p)}{T - p_{max}}$$

where $\tau_T(p) = (\hat{\sigma}_p^2)^{-1} \hat{\psi}_0^2 \sum_{t=p_{max}+1}^{T-1} (y_t^d)^2$ and $\hat{\sigma}_p^2 = (T - p_{max} - 1)^{-1} \sum_{t=p_{max}+1}^{T-1} \hat{\epsilon}_{tp}^2$. For fixed lag length p, an estimate of ω^2 is given by

$$\hat{\omega}^2 = \frac{(T - 1 - p)^{-1} \sum_{t=p+2}^{T} \hat{\epsilon}_{tp}^2}{\left(1 - \sum_{j=1}^{p} \hat{\psi}_j\right)^2}$$

DF-GLS is indeed a superior unit root test, according to Stock (1994), Schwert (1989), and Elliott, Rothenberg, and Stock (1996). In terms of the size of the test, DF-GLS is almost as good as the ADF t test DF_τ and better than the PP $\hat{\mathrm{Z}}_\rho$ and $\hat{\mathrm{Z}}_\tau$ test. In addition, the power of the DF-GLS test is greater than that of both the ADF t test and the ρ-test.

Ng and Perron (2001) also apply GLS detrending to obtain the following M-tests:

$$MZ_\alpha = ((T-1)^{-1}(y_T^d)^2 - \hat{\omega}^2) \left(2(T-1)^{-2} \sum_{t=1}^{T-1} (y_t^d)^2\right)^{-1}$$

$$MSB = \left(\frac{\sum_{t=1}^{T-1} (y_t^d)^2}{(T-1)^2 \hat{\omega}^2}\right)^{1/2}$$

$$MZ_t = MZ_\alpha \times MSB$$

The first one is a modified version of the Phillips-Perron Z_ρ test,

$$MZ_\rho = \mathrm{Z}_\rho + \frac{T}{2}(\hat{\alpha} - 1)^2$$

where the detrended data $\{y_t^d\}$ is used. The second is a modified Bhargava (1986) R_1 test statistic. The third can be perceived as a modified Phillips-Perron Z_τ statistic because of the relationship $Z_\tau = MSB \times Z_\rho$.

The modified point optimal tests that use the GLS detrended data are

$$\begin{aligned} MP_T^{GLS} &= \frac{\bar{c}^2(T-1)^{-2}\sum_{t=1}^{T-1}(y_t^d)^2 - \bar{c}(T-1)^{-1}(y_T^d)^2}{\hat{\omega}^2} && \text{for } z_t = 1 \\ MP_T^{GLS} &= \frac{\bar{c}^2(T-1)^{-2}\sum_{t=1}^{T-1}(y_t^d)^2 + (1-\bar{c})(T-1)^{-1}(y_T^d)^2}{\hat{\omega}^2} && \text{for } z_t = (1,t) \end{aligned}$$

The DF-GLS test and the MZ_t test have the same limiting distribution:

$$\begin{aligned} \text{DF-GLS} \approx MZ_t &\Rightarrow 0.5\frac{(J_c(1)^2-1)}{\left(\int_0^1 J_c(r)^2 dr\right)^{1/2}} && \text{for } z_t = 1 \\ \text{DF-GLS} \approx MZ_t &\Rightarrow 0.5\frac{(V_{c,\bar{c}}(1)^2-1)}{\left(\int_0^1 V_{c,\bar{c}}(r)^2 dr\right)^{1/2}} && \text{for } z_t = (1,t) \end{aligned}$$

The point optimal test and the modified point optimal test have the same limiting distribution,

$$\begin{aligned} P_T^{GLS} \approx MP_T^{GLS} &\Rightarrow \bar{c}^2 \int_0^1 J_c(r)^2 dr - \bar{c} J_c(1)^2 && \text{for } z_t = 1 \\ P_T^{GLS} \approx MP_T^{GLS} &\Rightarrow \bar{c}^2 \int_0^1 V_{c,\bar{c}}(r)^2 dr + (1-\bar{c}) V_{c,\bar{c}}(1)^2 && \text{for } z_t = (1,t) \end{aligned}$$

where $W(r)$ is a standard Brownian motion and $J_c(r)$ is an Ornstein-Uhlenbeck process defined by $dJ_c(r) = cJ_c(r)dr + dW(r)$ with $J_c(0) = 0$, $V_{c,\bar{c}}(r) = J_c(r) - r\left[\lambda J_c(1) + 3(1-\lambda)\int_0^1 sJ_c(s)ds\right]$, and $\lambda = (1-\bar{c})/(1-\bar{c}+\bar{c}^2/3)$.

Overall, the M-tests have the smallest size distortion, with the ADF t test having the next smallest. The ADF ρ-test, $\hat{Z}_\rho$, and $\hat{Z}_\tau$ have the largest size distortion. In addition, the power of the DF-GLS and M-tests is greater than that of the ADF t test and ρ-test. The ADF $\hat{Z}_\rho$ has more severe size distortion than the ADF $\hat{Z}_\tau$, but it has more power for a fixed lag length.

Kwiatkowski, Phillips, Schmidt, and Shin (KPSS) Unit Root Test and Shin Cointegration Test

There are fewer tests available for the null hypothesis of trend stationarity I(0). The main reason is the difficulty of theoretical development. The KPSS test was introduced in Kwiatkowski et al. (1992) to test the null hypothesis that an observable series is stationary around a deterministic trend. For consistency, the notation used here differs from the notation in the original paper. The setup of the problem is as follows: it is assumed that the series is expressed as the sum of the deterministic trend, random walk r_t, and stationary error u_t; that is,

$$\begin{aligned} y_t &= \mu + \delta t + r_t + u_t \\ r_t &= r_{t-1} + e_t \end{aligned}$$

where $e_t \sim$iid $(0, \sigma_e^2)$, and an intercept μ (in the original paper, the authors use r_0 instead of μ; here it is assumed that $r_0 = 0$.) The null hypothesis of trend stationarity is specified by $H_0 : \sigma_e^2 = 0$, while the null of level stationarity is the same as above with the model restriction $\delta = 0$. Under the alternative that $\sigma_e^2 \neq 0$, there is a random walk component in the observed series y_t.

Under stronger assumptions of normality and iid of u_t and e_t, a one-sided LM test of the null that there is no random walk ($e_t = 0, \forall t$) can be constructed as follows:

$$\widehat{LM} = \frac{1}{T^2} \sum_{t=1}^{T} \frac{S_t^2}{s^2(l)}$$

$$s^2(l) = \frac{1}{T} \sum_{t=1}^{T} \hat{u}_t^2 + \frac{2}{T} \sum_{s=1}^{l} w(s,l) \sum_{t=s+1}^{T} \hat{u}_t \hat{u}_{t-s}$$

$$S_t = \sum_{\tau=1}^{t} \hat{u}_\tau$$

Under the null hypothesis, $\hat{u}_t$ can be estimated by ordinary least squares regression of y_t on an intercept and the time trend. Following the original work of Kwiatkowski et al. (1992), under the null ($\sigma_e^2 = 0$), the $\widehat{LM}$ statistic converges asymptotically to three different distributions depending on whether the model is trend-stationary, level-stationary ($\delta = 0$), or zero-mean stationary ($\delta = 0$, $\mu = 0$). The trend-stationary model is denoted by subscript τ and the level-stationary model is denoted by subscript μ. The case when there is no trend and zero intercept is denoted as 0. The last case, although rarely used in practice, is considered in Hobijn, Franses, and Ooms (2004),

$$y_t = u_t : \qquad \widehat{LM}_0 \xrightarrow{D} \int_0^1 B^2(r)dr$$

$$y_t = \mu + u_t : \qquad \widehat{LM}_\mu \xrightarrow{D} \int_0^1 V^2(r)dr$$

$$y_t = \mu + \delta t + u_t : \qquad \widehat{LM}_\tau \xrightarrow{D} \int_0^1 V_2^2(r)dr$$

with

$$V(r) = B(r) - rB(1)$$

$$V_2(r) = B(r) + (2r - 3r^2)B(1) + (-6r + 6r^2) \int_0^1 B(s)ds$$

where $B(r)$ is a Brownian motion (Wiener process) and $\xrightarrow{D}$ is convergence in distribution. $V(r)$ is a standard Brownian bridge, and $V_2(r)$ is a second-level Brownian bridge.

Using the notation of Kwiatkowski et al. (1992), the $\widehat{LM}$ statistic is named as $\hat{\eta}$. This test depends on the computational method used to compute the long-run variance $s(l)$; that is, the window width l and the kernel type $w(\cdot,\cdot)$. You can specify the kernel used in the test by using the KERNEL option:

- Newey-West/Bartlett (KERNEL=NW | BART) (this is the default)

$$w(s,l) = 1 - \frac{s}{l+1}$$

- quadratic spectral (KERNEL=QS)

$$w(s,l) = \tilde{w}\left(\frac{s}{l}\right) = \tilde{w}(x) = \frac{25}{12\pi^2 x^2}\left(\frac{\sin(6\pi x/5)}{6\pi x/5} - \cos\left(\frac{6}{5}\pi x\right)\right)$$

You can specify the number of lags, l, in three different ways:

- Schwert (SCHW = c) (default for NW, c=12)

$$l = \max\left\{1, \text{floor}\left[c\left(\frac{T}{100}\right)^{1/4}\right]\right\}$$

- manual (LAG = l)
- automatic selection (AUTO) (default for QS), from Hobijn, Franses, and Ooms (2004). The number of lags, l, is calculated as in the following table:

KERNEL=NW	**KERNEL=QS**
$l = \min(T, \text{floor}(\hat{\gamma} T^{1/3}))$	$l = \min(T, \text{floor}(\hat{\gamma} T^{1/5}))$
$\hat{\gamma} = 1.1447\left\{\left(\frac{\hat{s}^{(1)}}{\hat{s}^{(0)}}\right)^2\right\}^{1/3}$	$\hat{\gamma} = 1.3221\left\{\left(\frac{\hat{s}^{(2)}}{\hat{s}^{(0)}}\right)^2\right\}^{1/5}$
$\hat{s}^{(j)} = \delta_{0,j}\hat{\gamma}_0 + 2\sum_{i=1}^{n} i^j \hat{\gamma}_i$	$\hat{s}^{(j)} = \delta_{0,j}\hat{\gamma}_0 + 2\sum_{i=1}^{n} i^j \hat{\gamma}_i$
$n = \text{floor}(T^{2/9})$	$n = \text{floor}(T^{2/25})$

where T is the number of observations, $\delta_{0,j} = 1$ if $j = 0$ and 0 otherwise, and $\hat{\gamma}_i = \frac{1}{T}\sum_{t=1}^{T-i} u_t u_{t+i}$.

Simulation evidence shows that the KPSS has size distortion in finite samples. For an example, see Caner and Kilian (2001). The power is reduced when the sample size is large; this can be derived theoretically (see Breitung 1995). Another problem of the KPSS test is that the power depends on the truncation lag used in the Newey-West estimator of the long-run variance $s^2(l)$.

Shin (1994) extends the KPSS test to incorporate the regressors to be a cointegration test. The cointegrating regression becomes

$$y_t = \mu + \delta t + X_t'\beta + r_t + u_t$$
$$r_t = r_{t-1} + e_t$$

where y_t and X_t are scalar and m-vector $I(1)$ variables. There are still three cases of cointegrating regressions: without intercept and trend, with intercept only, and with intercept and trend. The null hypothesis of the cointegration test is the same as that for the KPSS test, $H_0 : \sigma_e^2 = 0$. The test statistics for cointegration in the three cases of cointegrating regressions are exactly the same as those in the KPSS test; these test statistics are then ignored here. Under the null hypothesis, the statistics converge asymptotically to three different distributions,

$$y_t = X_t'\beta + u_t: \qquad \widehat{LM}_0 \xrightarrow{D} \int_0^1 Q_1^2(r)dr$$
$$y_t = \mu + X_t'\beta + u_t: \qquad \widehat{LM}_\mu \xrightarrow{D} \int_0^1 Q_2^2(r)dr$$
$$y_t = \mu + \delta t + X_t'\beta + u_t: \qquad \widehat{LM}_\tau \xrightarrow{D} \int_0^1 Q_3^2(r)dr$$

with

$$Q_1(r) = B(r) - \left(\int_0^r \mathbf{B_m}(x)dx\right)\left(\int_0^1 \mathbf{B_m}(x)\mathbf{B_m}'(x)dx\right)^{-1}\left(\int_0^1 \mathbf{B_m}(x)dB(x)\right)$$
$$Q_2(r) = V(r) - \left(\int_0^r \bar{\mathbf{B}}_\mathbf{m}(x)dx\right)\left(\int_0^1 \bar{\mathbf{B}}_\mathbf{m}(x)\bar{\mathbf{B}}_\mathbf{m}'(x)dx\right)^{-1}\left(\int_0^1 \bar{\mathbf{B}}_\mathbf{m}(x)dB(x)\right)$$
$$Q_3(r) = V_2(r) - \left(\int_0^r \mathbf{B}^*_\mathbf{m}(x)dx\right)\left(\int_0^1 \mathbf{B}^*_\mathbf{m}(x)\mathbf{B}^*_\mathbf{m}'(x)dx\right)^{-1}\left(\int_0^1 \mathbf{B}^*_\mathbf{m}(x)dB(x)\right)$$

where $B(.)$ and $\mathbf{B_m}(.)$ are independent scalar and m-vector standard Brownian motion, and $\xrightarrow{D}$ is convergence in distribution. $V(r)$ is a standard Brownian bridge, $V_2(r)$ is a Brownian bridge of a second-level, $\bar{\mathbf{B}}_\mathbf{m}(r) = \mathbf{B_m}(r) - \int_0^1 \mathbf{B_m}(x)dx$ is an m-vector standard de-meaned Brownian motion, and $\mathbf{B}^*_\mathbf{m}(r) = \mathbf{B_m}(r) + (6r - 4)\int_0^1 \mathbf{B_m}(x)dx + (-12r + 6)\int_0^1 x\mathbf{B_m}(x)dx$ is an m-vector standard de-meaned and detrended Brownian motion.

The p-values that are reported for the KPSS test and Shin test are calculated via a Monte Carlo simulation of the limiting distributions, using a sample size of 2,000 and 1,000,000 replications.

Testing for Statistical Independence

Independence tests are widely used in model selection, residual analysis, and model diagnostics because models are usually based on the assumption of independently distributed errors. If a given time series (for example, a series of residuals) is independent, then no deterministic model is necessary for this completely random process; otherwise, there must exist some relationship in the series to be addressed. In the following section, four independence tests are introduced: the BDS test, the runs test, the turning point test, and the rank version of von Neumann ratio test.

BDS Test

Brock, Dechert, and Scheinkman (1987) propose a test (BDS test) of independence based on the correlation dimension. Brock et al. (1996) show that the first-order asymptotic distribution of the test statistic is independent of the estimation error provided that the parameters of the model under test can be estimated $\sqrt{n}$-consistently. Hence, the BDS test can be used as a model selection tool and as a specification test.

Given the sample size T, the embedding dimension m, and the value of the radius r, the BDS statistic is

$$S_{\mathrm{BDS}}(T, m, r) = \sqrt{T - m + 1}\frac{c_{m,m,T}(r) - c^m_{1,m,T}(r)}{\sigma_{m,T}(r)}$$

where

$$c_{m,n,N}(r) = \frac{2}{(N-n+1)(N-n)} \sum_{s=n}^{N} \sum_{t=s+1}^{N} \prod_{j=0}^{m-1} I_r(z_{s-j}, z_{t-j})$$

$$I_r(z_s, z_t) = \begin{cases} 1 & \text{if } |z_s - z_t| < r \\ 0 & \text{otherwise} \end{cases}$$

$$\sigma^2_{m,T}(r) = 4\left(k^m + 2\sum_{j=1}^{m-1} k^{m-j} c^{2j} + (m-1)^2 c^{2m} - m^2 k c^{2m-2}\right)$$

$$c = c_{1,1,T}(r)$$

$$k = k_T(r) = \frac{6}{T(T-1)(T-2)} \sum_{t=1}^{T} \sum_{s=t+1}^{T} \sum_{l=s+1}^{T} h_r(z_t, z_s, z_l)$$

$$h_r(z_t, z_s, z_l) = \frac{1}{3}\left(I_r(z_t, z_s) I_r(z_s, z_l) + I_r(z_t, z_l) I_r(z_l, z_s) + I_r(z_s, z_t) I_r(z_t, z_l)\right)$$

The statistic has a standard normal distribution if the sample size is large enough. For small sample size, the distribution can be approximately obtained through simulation. Kanzler (1999) has a comprehensive discussion on the implementation and empirical performance of BDS test.

Runs Test and Turning Point Test

The runs test and turning point test are two widely used tests for independence (Cromwell, Labys, and Terraza 1994).

The runs test needs several steps. First, convert the original time series into the sequence of signs, $\{++--\cdots+---\}$, that is, map $\{z_t\}$ into $\{sign(z_t - z_M)\}$ where z_M is the sample mean of z_t and $sign(x)$ is "+" if x is nonnegative and "–" if x is negative. Second, count the number of runs, R, in the sequence. A run of a sequence is a maximal non-empty segment of the sequence that consists of adjacent equal elements. For example, the following sequence contains $R = 8$ runs:

$$\underbrace{+++}_{1}\underbrace{---}_{1}\underbrace{++}_{1}\underbrace{--}_{1}\underbrace{+}_{1}\underbrace{-}_{1}\underbrace{+++++}_{1}\underbrace{--}_{1}$$

Third, count the number of pluses and minuses in the sequence and denote them as N_+ and N_-, respectively. In the preceding example sequence, $N_+ = 11$ and $N_- = 8$. Note that the sample size $T = N_+ + N_-$. Finally, compute the statistic of runs test,

$$S_{\text{runs}} = \frac{R - \mu}{\sigma}$$

where

$$\mu = \frac{2N_+N_-}{T} + 1$$

$$\sigma^2 = \frac{(\mu-1)(\mu-2)}{T-1}$$

The statistic of the turning point test is defined as

$$S_{\text{TP}} = \frac{\sum_{t=2}^{T-1} TP_t - 2(T-2)/3}{\sqrt{(16T-29)/90}}$$

where the indicator function of the turning point TP_t is 1 if $z_t > z_{t\pm1}$ or $z_t < z_{t\pm1}$ (that is, both the previous and next values are greater or less than the current value); otherwise, 0.

The statistics of both the runs test and the turning point test have the standard normal distribution under the null hypothesis of independence.

Rank Version of the von Neumann Ratio Test

Because the runs test completely ignores the magnitudes of the observations, Bartels (1982) proposes a rank version of the von Neumann ratio test for independence,

$$S_{\mathrm{RVN}} = \frac{\sqrt{T}}{2}\left(\frac{\sum_{t=1}^{T-1}(R_{t+1}-R_t)^2}{(T(T^2-1)/12)} - 2\right)$$

where R_t is the rank of tth observation in the sequence of T observations. For large samples, the statistic follows the standard normal distribution under the null hypothesis of independence. For small samples of size between 11 and 100, the critical values that have been simulated would be more precise. For samples of size less than or equal to 10, the exact CDF of the statistic is available. Hence, the VNRRANK=(PVALUE=SIM) option is recommended for small samples whose size is no more than 100, although it might take longer to obtain the p-value than if you use the VNRRANK=(PVALUE=DIST) option.

Testing for Normality

Based on skewness and kurtosis, Jarque and Bera (1980) calculated the test statistic

$$T_N = \left[\frac{N}{6}b_1^2 + \frac{N}{24}(b_2-3)^2\right]$$

where

$$b_1 = \frac{\sqrt{N}\sum_{t=1}^{N}\hat{u}_t^3}{\left(\sum_{t=1}^{N}\hat{u}_t^2\right)^{\frac{3}{2}}}$$

$$b_2 = \frac{N\sum_{t=1}^{N}\hat{u}_t^4}{\left(\sum_{t=1}^{N}\hat{u}_t^2\right)^{2}}$$

The $\chi^2(2)$ distribution gives an approximation to the normality test T_N.

When the GARCH model is estimated, the normality test is obtained using the standardized residuals $\hat{u}_t = \hat{\epsilon}_t/\sqrt{h_t}$. The normality test can be used to detect misspecification of the family of ARCH models.

Testing for Linear Dependence

Generalized Durbin-Watson Tests

Consider the linear regression model

$$\mathbf{Y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\nu}$$

where $\mathbf{X}$ is an $N \times k$ data matrix, β is a $k \times 1$ coefficient vector, and $\boldsymbol{\nu}$ is an $N \times 1$ disturbance vector. The error term $\boldsymbol{\nu}$ is assumed to be generated by the jth-order autoregressive process $\nu_t = \epsilon_t - \varphi_j \nu_{t-j}$ where

$|\varphi_j| < 1$, ϵ_t is a sequence of independent normal error terms with mean 0 and variance σ^2. Usually, the Durbin-Watson statistic is used to test the null hypothesis $H_0 : \varphi_1 = 0$ against $H_1 : -\varphi_1 > 0$. Vinod (1973) generalized the Durbin-Watson statistic,

$$d_j = \frac{\sum_{t=j+1}^{N} (\hat{v}_t - \hat{v}_{t-j})^2}{\sum_{t=1}^{N} \hat{v}_t^2}$$

where $\hat{\mathbf{v}}$ are OLS residuals. Using the matrix notation,

$$d_j = \frac{\mathbf{Y}'\mathbf{M}\mathbf{A}_j'\mathbf{A}_j\mathbf{M}\mathbf{Y}}{\mathbf{Y}'\mathbf{M}\mathbf{Y}}$$

where $\mathbf{M} = \mathbf{I}_N - \mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'$ and $\mathbf{A}_j$ is a $(N - j) \times N$ matrix,

$$\mathbf{A}_j = \begin{bmatrix} -1 & 0 & \cdots & 0 & 1 & 0 & \cdots & 0 \\ 0 & -1 & 0 & \cdots & 0 & 1 & 0 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & -1 & 0 & \cdots & 0 & 1 \end{bmatrix}$$

and there are $j - 1$ zeros between -1 and 1 in each row of matrix $\mathbf{A}_j$.

The QR factorization of the design matrix $\mathbf{X}$ yields an $N \times N$ orthogonal matrix $\mathbf{Q}$,

$$\mathbf{X} = \mathbf{Q}\mathbf{R}$$

where R is an $N \times k$ upper triangular matrix. There exists an $N \times (N - k)$ submatrix of $\mathbf{Q}$ such that $\mathbf{Q}_1\mathbf{Q}_1' = \mathbf{M}$ and $\mathbf{Q}_1'\mathbf{Q}_1 = \mathbf{I}_{N-k}$. Consequently, the generalized Durbin-Watson statistic is stated as a ratio of two quadratic forms,

$$d_j = \frac{\sum_{l=1}^{n} \lambda_{jl} {\xi_l}^2}{\sum_{l=1}^{n} \xi_l^2}$$

where $\lambda_{j1} \ldots \lambda_{jn}$ are upper n eigenvalues of $\mathbf{M}\mathbf{A}'_j\mathbf{A}_j\mathbf{M}$ and ξ_l is a standard normal variate, and $n = \min(N - k, N - j)$. These eigenvalues are obtained by a singular value decomposition of $\mathbf{Q}'_1\mathbf{A}'_j$ (Golub and Van Loan 1989; Savin and White 1978).

The marginal probability (or p-value) for d_j given c_0 is

$$\text{Prob}\left(\frac{\sum_{l=1}^{n} \lambda_{jl}\xi_l^2}{\sum_{l=1}^{n} \xi_l^2} < c_0\right) = \text{Prob}(q_j < 0)$$

where

$$q_j = \sum_{l=1}^{n} (\lambda_{jl} - c_0)\xi_l^2$$

When the null hypothesis $H_0 : \varphi_j = 0$ holds, the quadratic form q_j has the characteristic function

$$\phi_j(t) = \prod_{l=1}^{n} (1 - 2(\lambda_{jl} - c_0)it)^{-1/2}$$

The distribution function is uniquely determined by this characteristic function:

$$F(x) = \frac{1}{2} + \frac{1}{2\pi}\int_0^\infty \frac{e^{itx}\phi_j(-t) - e^{-itx}\phi_j(t)}{it}dt$$

For example, to test $H_0 : \varphi_4 = 0$ given $\varphi_1 = \varphi_2 = \varphi_3 = 0$ against $H_1 : -\varphi_4 > 0$, the marginal probability (p-value) can be used,

$$F(0) = \frac{1}{2} + \frac{1}{2\pi}\int_0^\infty \frac{(\phi_4(-t) - \phi_4(t))}{it}dt$$

where

$$\phi_4(t) = \prod_{l=1}^{n}(1 - 2(\lambda_{4l} - \hat{d}_4)it)^{-1/2}$$

and $\hat{d}_4$ is the calculated value of the fourth-order Durbin-Watson statistic.

In the Durbin-Watson test, the marginal probability indicates positive autocorrelation ($-\varphi_j > 0$) if it is less than the level of significance (α), while you can conclude that a negative autocorrelation ($-\varphi_j < 0$) exists if the marginal probability based on the computed Durbin-Watson statistic is greater than $1 - \alpha$. Wallis (1972) presented tables for bounds tests of fourth-order autocorrelation, and Vinod (1973) has given tables for a 5% significance level for orders two to four. Using the AUTOREG procedure, you can calculate the exact p-values for the general order of Durbin-Watson test statistics. Tests for the absence of autocorrelation of order p can be performed sequentially; at the jth step, test $H_0 : \varphi_j = 0$ given $\varphi_1 = \cdots = \varphi_{j-1} = 0$ against $\varphi_j \neq 0$. However, the size of the sequential test is not known.

The Durbin-Watson statistic is computed from the OLS residuals, while that of the autoregressive error model uses residuals that are the difference between the predicted values and the actual values. When you use the Durbin-Watson test from the residuals of the autoregressive error model, you must be aware that this test is only an approximation. See the section "Autoregressive Error Model" on page 363. If there are missing values, the Durbin-Watson statistic is computed using all the nonmissing values and ignoring the gaps caused by missing residuals. This does not affect the significance level of the resulting test, although the power of the test against certain alternatives may be adversely affected. Savin and White (1978) have examined the use of the Durbin-Watson statistic with missing values.

The Durbin-Watson probability calculations have been enhanced to compute the p-value of the generalized Durbin-Watson statistic for large sample sizes. Previously, the Durbin-Watson probabilities were only calculated for small sample sizes.

Consider the linear regression model

$$\mathbf{Y} = \mathbf{X}\beta + \mathbf{u}$$

$$u_t + \varphi_j u_{t-j} = \epsilon_t, \qquad t = 1, \ldots, N$$

where $\mathbf{X}$ is an $N \times k$ data matrix, β is a $k \times 1$ coefficient vector, $\mathbf{u}$ is an $N \times 1$ disturbance vector, and ϵ_t is a sequence of independent normal error terms with mean 0 and variance σ^2.

The generalized Durbin-Watson statistic is written as

$$\mathrm{DW}_j = \frac{\hat{\mathbf{u}}'\mathbf{A}_j'\mathbf{A}_j\hat{\mathbf{u}}}{\hat{\mathbf{u}}'\hat{\mathbf{u}}}$$

where $\hat{\mathbf{u}}$ is a vector of OLS residuals and $\mathbf{A}_j$ is a $(T-j)\times T$ matrix. The generalized Durbin-Watson statistic DW_j can be rewritten as

$$\mathrm{DW}_j = \frac{\mathbf{Y}'\mathbf{M}\mathbf{A}_j'\mathbf{A}_j\mathbf{M}\mathbf{Y}}{\mathbf{Y}'\mathbf{M}\mathbf{Y}} = \frac{\eta'(\mathbf{Q}_1'\mathbf{A}_j'\mathbf{A}_j\mathbf{Q}_1)\eta}{\eta'\eta}$$

where $\mathbf{Q}_1'\mathbf{Q}_1 = \mathbf{I}_{T-k}$, $\mathbf{Q}_1'\mathbf{X} = 0$, and $\eta = \mathbf{Q}_1'\mathbf{u}$.

The marginal probability for the Durbin-Watson statistic is

$$\Pr(\mathrm{DW}_j < c) = \Pr(h < 0)$$

where $h = \eta'(\mathbf{Q}_1'\mathbf{A}_j'\mathbf{A}_j\mathbf{Q}_1 - c\mathbf{I})\eta$.

The *p*-value or the marginal probability for the generalized Durbin-Watson statistic is computed by numerical inversion of the characteristic function $\phi(u)$ of the quadratic form $h = \eta'(\mathbf{Q}_1'\mathbf{A}_j'\mathbf{A}_j\mathbf{Q}_1 - c\mathbf{I})\eta$. The trapezoidal rule approximation to the marginal probability $\Pr(h<0)$ is

$$\Pr(h<0) = \frac{1}{2} - \sum_{k=0}^{K} \frac{\mathrm{Im}\left[\phi((k+\frac{1}{2})\Delta)\right]}{\pi(k+\frac{1}{2})} + \mathrm{E}_I(\Delta) + \mathrm{E}_T(K)$$

where $\mathrm{Im}\,[\phi(\cdot)]$ is the imaginary part of the characteristic function, $\mathrm{E}_I(\Delta)$ and $\mathrm{E}_T(K)$ are integration and truncation errors, respectively. For numerical inversion of the characteristic function, see Davies (1973).

Ansley, Kohn, and Shively (1992) proposed a numerically efficient algorithm that requires O(N) operations for evaluation of the characteristic function $\phi(u)$. The characteristic function is denoted as

$$\begin{aligned}\phi(u) &= \left|\mathbf{I} - 2iu(\mathbf{Q}_1'\mathbf{A}_j'\mathbf{A}_j\mathbf{Q}_1 - c\mathbf{I}_{N-k})\right|^{-1/2} \\ &= |\mathbf{V}|^{-1/2}\left|\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}\right|^{-1/2}\left|\mathbf{X}'\mathbf{X}\right|^{1/2}\end{aligned}$$

where $\mathbf{V} = (1+2iuc)\mathbf{I} - 2iu\mathbf{A}_j'\mathbf{A}_j$ and $i = \sqrt{-1}$. By applying the Cholesky decomposition to the complex matrix $\mathbf{V}$, you can obtain the lower triangular matrix $\mathbf{G}$ that satisfies $\mathbf{V} = \mathbf{G}\mathbf{G}'$. Therefore, the characteristic function can be evaluated in O(N) operations by using the formula

$$\phi(u) = |\mathbf{G}|^{-1}\left|\mathbf{X}^{*\prime}\mathbf{X}^*\right|^{-1/2}\left|\mathbf{X}'\mathbf{X}\right|^{1/2}$$

where $\mathbf{X}^* = \mathbf{G}^{-1}\mathbf{X}$. For more information about evaluation of the characteristic function, see Ansley, Kohn, and Shively (1992).

Tests for Serial Correlation with Lagged Dependent Variables

When regressors contain lagged dependent variables, the Durbin-Watson statistic (d_1) for the first-order autocorrelation is biased toward 2 and has reduced power. Wallis (1972) shows that the bias in the Durbin-Watson statistic (d_4) for the fourth-order autocorrelation is smaller than the bias in d_1 in the presence of a first-order lagged dependent variable. Durbin (1970) proposes two alternative statistics (Durbin *h* and *t*) that are asymptotically equivalent. The *h* statistic is written as

$$h = \hat{\rho}\sqrt{N/(1-N\hat{V})}$$

where $\hat{\rho} = \sum_{t=2}^{N} \hat{v}_t \hat{v}_{t-1} / \sum_{t=1}^{N} \hat{v}_t^2$ and $\hat{V}$ is the least squares variance estimate for the coefficient of the lagged dependent variable. Durbin's t test consists of regressing the OLS residuals $\hat{v}_t$ on explanatory variables and $\hat{v}_{t-1}$ and testing the significance of the estimate for coefficient of $\hat{v}_{t-1}$.

Inder (1984) shows that the Durbin-Watson test for the absence of first-order autocorrelation is generally more powerful than the h test in finite samples. For information about the Durbin-Watson test in the presence of lagged dependent variables, see Inder (1986) and King and Wu (1991).

Godfrey LM test

The GODFREY= option in the MODEL statement produces the Godfrey Lagrange multiplier test for serially correlated residuals for each equation (Godfrey 1978b, a). r is the maximum autoregressive order, and specifies that Godfrey's tests be computed for lags 1 through r. The default number of lags is four.

Testing for Nonlinear Dependence: Ramsey's Reset Test

Ramsey's reset test is a misspecification test associated with the functional form of models to check whether power transforms need to be added to a model. The original linear model, henceforth called the restricted model, is

$$y_t = \mathbf{x_t}\beta + u_t$$

To test for misspecification in the functional form, the unrestricted model is

$$y_t = \mathbf{x_t}\beta + \sum_{j=2}^{p} \phi_j \hat{y}_t^j + u_t$$

where $\hat{y}_t$ is the predicted value from the linear model and p is the power of $\hat{y}_t$ in the unrestricted model equation starting from 2. The number of higher-ordered terms to be chosen depends on the discretion of the analyst. The RESET option produces test results for $p = 2$, 3, and 4.

The reset test is an F statistic for testing $H_0 : \phi_j = 0$, for all $j = 2, \ldots, p$, against $H_1 : \phi_j \neq 0$ for at least one $j = 2, \ldots, p$ in the unrestricted model and is computed as

$$F_{(p-1,n-k-p+1)} = \frac{(\mathrm{SSE}_R - \mathrm{SSE}_U)/(p-1)}{\mathrm{SSE}_U/(n-k-p+1)}$$

where SSE_R is the sum of squared errors due to the restricted model, SSE_U is the sum of squared errors due to the unrestricted model, n is the total number of observations, and k is the number of parameters in the original linear model.

Ramsey's test can be viewed as a linearity test that checks whether any nonlinear transformation of the specified independent variables has been omitted, but it need not help in identifying a new relevant variable other than those already specified in the current model.

Testing for Nonlinear Dependence: Heteroscedasticity Tests

Portmanteau Q Test

For nonlinear time series models, the portmanteau test statistic based on squared residuals is used to test for independence of the series (McLeod and Li 1983),

$$Q(q) = N(N+2)\sum_{i=1}^{q}\frac{r(i;\hat{\nu}_t^2)}{(N-i)}$$

where

$$r(i;\hat{\nu}_t^2) = \frac{\sum_{t=i+1}^{N}(\hat{\nu}_t^2-\hat{\sigma}^2)(\hat{\nu}_{t-i}^2-\hat{\sigma}^2)}{\sum_{t=1}^{N}(\hat{\nu}_t^2-\hat{\sigma}^2)^2}$$

$$\hat{\sigma}^2 = \frac{1}{N}\sum_{t=1}^{N}\hat{\nu}_t^2$$

This Q statistic is used to test the nonlinear effects (for example, GARCH effects) present in the residuals. The GARCH(p,q) process can be considered as an ARMA$(\max(p,q), p)$ process. See the section "Predicting the Conditional Variance" on page 406. Therefore, the Q statistic calculated from the squared residuals can be used to identify the order of the GARCH process.

Engle's Lagrange Multiplier Test for ARCH Disturbances

Engle (1982) proposed a Lagrange multiplier test for ARCH disturbances. The test statistic is asymptotically equivalent to the test used by Breusch and Pagan (1979). Engle's Lagrange multiplier test for the qth order ARCH process is written

$$LM(q) = \frac{N\mathbf{W}'\mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'\mathbf{W}}{\mathbf{W}'\mathbf{W}}$$

where

$$\mathbf{W} = \left(\frac{\hat{\nu}_1^2}{\hat{\sigma}^2}-1,\ldots,\frac{\hat{\nu}_N^2}{\hat{\sigma}^2}-1\right)'$$

and

$$\mathbf{Z} = \begin{bmatrix} 1 & \hat{\nu}_0^2 & \cdots & \hat{\nu}_{-q+1}^2 \\ \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots \\ 1 & \hat{\nu}_{N-1}^2 & \cdots & \hat{\nu}_{N-q}^2 \end{bmatrix}$$

The presample values ($\nu_0^2,\ldots,\nu_{-q+1}^2$) have been set to 0. Note that the LM(q) tests might have different finite-sample properties depending on the presample values, though they are asymptotically equivalent regardless of the presample values.

Lee and King's Test for ARCH Disturbances

Engle's Lagrange multiplier test for ARCH disturbances is a two-sided test; that is, it ignores the inequality constraints for the coefficients in ARCH models. Lee and King (1993) propose a one-sided test and prove that the test is locally most mean powerful. Let $\varepsilon_t, t = 1, \ldots, T$, denote the residuals to be tested. Lee and King's test checks

$$H_0 : \alpha_i = 0, i = 1, \ldots, q$$

$$H_1 : \alpha_i > 0, i = 1, \ldots, q$$

where $\alpha_i, i = 1, \ldots, q$, are in the following ARCH(q) model:

$$\varepsilon_t = \sqrt{h_t} e_t, e_t \; iid(0, 1)$$

$$h_t = \alpha_0 + \sum_{i=1}^{q} \alpha_i \varepsilon_{t-i}^2$$

The statistic is written as

$$S = \frac{\sum_{t=q+1}^{T} (\frac{\varepsilon_t^2}{h_0} - 1) \sum_{i=1}^{q} \varepsilon_{t-i}^2}{\left[2 \sum_{t=q+1}^{T} (\sum_{i=1}^{q} \varepsilon_{t-i}^2)^2 - \frac{2(\sum_{t=q+1}^{T} \sum_{i=1}^{q} \varepsilon_{t-i}^2)^2}{T-q} \right]^{1/2}}$$

Wong and Li's Test for ARCH Disturbances

Wong and Li (1995) propose a rank portmanteau statistic to minimize the effect of the existence of outliers in the test for ARCH disturbances. They first rank the squared residuals; that is, $R_t = rank(\varepsilon_t^2)$. Then they calculate the rank portmanteau statistic

$$Q_R = \sum_{i=1}^{q} \frac{(r_i - \mu_i)^2}{\sigma_i^2}$$

where r_i, μ_i, and σ_i^2 are defined as follows:

$$r_i = \frac{\sum_{t=i+1}^{T} (R_t - (T+1)/2)(R_{t-i} - (T+1)/2)}{T(T^2-1)/12}$$

$$\mu_i = -\frac{T-i}{T(T-1)}$$

$$\sigma_i^2 = \frac{5T^4 - (5i+9)T^3 + 9(i-2)T^2 + 2i(5i+8)T + 16i^2}{5(T-1)^2 T^2 (T+1)}$$

The Q, Engle's LM, Lee and King's, and Wong and Li's statistics are computed from the OLS residuals, or residuals if the NLAG= option is specified, assuming that disturbances are white noise. The Q, Engle's LM, and Wong and Li's statistics have an approximate $\chi_{(q)}^2$ distribution under the white-noise null hypothesis, while the Lee and King's statistic has a standard normal distribution under the white-noise null hypothesis.

Testing for Structural Change

Chow Test

Consider the linear regression model

$$\mathbf{y} = \mathbf{X}\beta + \mathbf{u}$$

where the parameter vector β contains k elements.

Split the observations for this model into two subsets at the break point specified by the CHOW= option, so that

$$\begin{aligned} \mathbf{y} &= (\mathbf{y'}_1, \mathbf{y'}_2)' \\ \mathbf{X} &= (\mathbf{X'}_1, \mathbf{X'}_2)' \\ \mathbf{u} &= (\mathbf{u'}_1, \mathbf{u'}_2)' \end{aligned}$$

Now consider the two linear regressions for the two subsets of the data modeled separately,

$$\mathbf{y}_1 = \mathbf{X}_1\beta_1 + \mathbf{u}_1$$

$$\mathbf{y}_2 = \mathbf{X}_2\beta_2 + \mathbf{u}_2$$

where the number of observations from the first set is n_1 and the number of observations from the second set is n_2.

The Chow test statistic is used to test the null hypothesis $H_0 : \beta_1 = \beta_2$ conditional on the same error variance $V(\mathbf{u}_1) = V(\mathbf{u}_2)$. The Chow test is computed using three sums of square errors,

$$\mathrm{F}_{chow} = \frac{(\hat{\mathbf{u}}'\hat{\mathbf{u}} - \hat{\mathbf{u}}'_1\hat{\mathbf{u}}_1 - \hat{\mathbf{u}}'_2\hat{\mathbf{u}}_2)/k}{(\hat{\mathbf{u}}'_1\hat{\mathbf{u}}_1 + \hat{\mathbf{u}}'_2\hat{\mathbf{u}}_2)/(n_1 + n_2 - 2k)}$$

where $\hat{\mathbf{u}}$ is the regression residual vector from the full set model, $\hat{\mathbf{u}}_1$ is the regression residual vector from the first set model, and $\hat{\mathbf{u}}_2$ is the regression residual vector from the second set model. Under the null hypothesis, the Chow test statistic has an F distribution with k and $(n_1 + n_2 - 2k)$ degrees of freedom, where k is the number of elements in β.

Chow (1960) suggested another test statistic that tests the hypothesis that the mean of prediction errors is 0. The predictive Chow test can also be used when $n_2 < k$.

The PCHOW= option computes the predictive Chow test statistic

$$\mathrm{F}_{pchow} = \frac{(\hat{\mathbf{u}}'\hat{\mathbf{u}} - \hat{\mathbf{u}}'_1\hat{\mathbf{u}}_1)/n_2}{\hat{\mathbf{u}}'_1\hat{\mathbf{u}}_1/(n_1 - k)}$$

The predictive Chow test has an F distribution with n_2 and $(n_1 - k)$ degrees of freedom.

Bai and Perron's Multiple Structural Change Tests

Bai and Perron (1998) propose several kinds of multiple structural change tests: (1) the test of no break versus a fixed number of breaks ($supF$ test), (2) the equal and unequal weighted versions of double maximum tests of no break versus an unknown number of breaks given some upper bound ($UDmaxF$ test and $WDmaxF$ test), and (3) the test of l versus $l + 1$ breaks ($supF_{l+1|l}$ test). Bai and Perron (2003a, b, 2006) also show how to implement these tests, the commonly used critical values, and the simulation analysis on these tests.

Consider the following partial structural change model with m breaks ($m+1$ regimes):

$$y_t = x_t'\beta + z_t'\delta_j + u_t, \qquad t = T_{j-1}+1, \ldots, T_j,\ j = 1, \ldots, m$$

Here, y_t is the dependent variable observed at time t, $x_t(p \times 1)$ is a vector of covariates with coefficients β unchanged over time, and $z_t(q \times 1)$ is a vector of covariates with coefficients δ_j at regime j, $j = 1, \ldots, m$. If $p = 0$ (that is, there are no x regressors), the regression model becomes the pure structural change model. The indices $(T_1, \ldots, T_m)$ (that is, the break dates or break points) are unknown, and the convenient notation $T_0 = 0$ and $T_{m+1} = T$ applies. For any given m-partition $(T_1, \ldots, T_m)$, the associated least squares estimates of β and δ_j, $j = 1, \ldots, m$, are obtained by minimizing the sum of squared residuals (SSR),

$$S_T(T_1, \ldots, T_m) = \sum_{i=1}^{m+1} \sum_{t=T_{i-1}+1}^{T_i} (y_t - x_t'\beta - z_t'\delta_i)^2$$

Let $\hat{S}_T(T_1, \ldots, T_m)$ denote the minimized SSR for a given $(T_1, \ldots, T_m)$. The estimated break dates $(\hat{T}_1, \ldots, \hat{T}_m)$ are such that

$$(\hat{T}_1, \ldots, \hat{T}_m) = \arg \min_{T_1, \ldots, T_m} \hat{S}_T(T_1, \ldots, T_m)$$

where the minimization is taken over all partitions $(T_1, \ldots, T_m)$ such that $T_i - T_{i-1} \geq T\epsilon$. Bai and Perron (2003a) propose an efficient algorithm, based on the principle of dynamic programming, to estimate the preceding model.

In the case that the data are nontrending, as stated in Bai and Perron (1998), the limiting distribution of the break dates is

$$\frac{(\Delta_i' Q_i \Delta_i)^2}{(\Delta_i' \Omega_i \Delta_i)}(\hat{T}_i - T_i^0) \Rightarrow \arg\max_s V^{(i)}(s), \qquad i = 1, \ldots, m$$

where

$$V^{(i)}(s) = \begin{cases} W_1^{(i)}(-s) - |s|/2 & \text{if } s \leq 0 \\ \sqrt{\eta_i}(\phi_{i,2}/\phi_{i,1}) W_2^{(i)}(s) - \eta_i |s|/2 & \text{if } s > 0 \end{cases}$$

and

$$\begin{aligned} \Delta T_i^0 &= T_i^0 - T_{i-1}^0 \\ \Delta_i &= \delta_{i+1}^0 - \delta_i^0 \\ Q_i &= \lim (\Delta T_i^0)^{-1} \sum_{t=T_{i-1}^0+1}^{T_i^0} E(z_t z_t') \\ \Omega_i &= \lim (\Delta T_i^0)^{-1} \sum_{r=T_{i-1}^0+1}^{T_i^0} \sum_{t=T_{i-1}^0+1}^{T_i^0} E(z_r z_t' u_r u_t) \\ \eta_i &= \Delta_i' Q_{i+1} \Delta_i / \Delta_i' Q_i \Delta_i \\ \phi_{i,1}^2 &= \Delta_i' \Omega_i \Delta_i / \Delta_i' Q_i \Delta_i \\ \phi_{i,2}^2 &= \Delta_i' \Omega_{i+1} \Delta_i / \Delta_i' Q_{i+1} \Delta_i \end{aligned}$$

Also, $W_1^{(i)}(s)$ and $W_2^{(i)}(s)$ are independent standard Weiner processes that are defined on $[0, \infty)$, starting at the origin when $s = 0$; these processes are also independent across i. The cumulative distribution function of $\arg\max_s V^{(i)}(s)$ is shown in Bai (1997). Hence, with the estimates of Δ_i, Q_i, and Ω_i, the relevant critical values for confidence interval of break dates T_i can be calculated. The estimate of Δ_i is $\hat{\delta}_{i+1} - \hat{\delta}_i$. The estimate of Q_i is either

$$\hat{Q}_i = (\Delta \hat{T}_i)^{-1} \sum_{t=\hat{T}_{i-1}^0+1}^{\hat{T}_i^0} z_t z_t'$$

if the regressors are assumed to have heterogeneous distributions across regimes (that is, the HQ option is specified), or

$$\hat{Q}_i = \hat{Q} = (T)^{-1} \sum_{t=1}^{T} z_t z_t'$$

if the regressors are assumed to have identical distributions across regimes (that is, the HQ option is not specified). The estimate of Ω_i can also be constructed with data over regime i only or the whole sample, depending on whether the vectors $z_t \hat{u}_t$ are heterogeneously distributed across regimes (that is, the HO option is specified). If the HAC option is specified, $\hat{\Omega}_i$ is estimated through the heteroscedasticity- and autocorrelation-consistent (HAC) covariance matrix estimator applied to vectors $z_t \hat{u}_t$.

The $supF$ test of no structural break ($m = 0$) versus the alternative hypothesis that there are a fixed number, $m = k$, of breaks is defined as

$$supF(k) = \frac{1}{T}\left(\frac{T - (k+1)q - p}{kq}\right)(R\hat{\theta})'(R\hat{V}(\hat{\theta})R')^{-1}(R\hat{\theta})$$

where

$$R_{(kq)\times(p+(k+1)q)} = \begin{pmatrix} 0_{q\times p} & I_q & -I_q & 0 & 0 & \cdots & 0 \\ 0_{q\times p} & 0 & I_q & -I_q & 0 & \cdots & 0 \\ \vdots & \cdots & \ddots & \ddots & \ddots & \ddots & \cdots \\ 0_{q\times p} & 0 & \cdots & \cdots & 0 & I_q & -I_q \end{pmatrix}$$

and I_q is the $q \times q$ identity matrix; $\hat{\theta}$ is the coefficient vector $(\hat{\beta}'\hat{\delta}_1' \ldots \hat{\delta}_{k+1})'$, which together with the break dates $(\hat{T}_1 \ldots \hat{T}_k)$ minimizes the global sum of squared residuals; and $\hat{V}(\hat{\theta})$ is an estimate of the variance-covariance matrix of $\hat{\theta}$, which could be estimated by using the HAC estimator or another way, depending on how the HAC, HR, and HE options are specified. The output $supF$ test statistics are scaled by q, the number of regressors, to be consistent with the limiting distribution; Bai and Perron (2003b, 2006) take the same action.

There are two versions of double maximum tests of no break against an unknown number of breaks given some upper bound M: the $UDmaxF$ test,

$$UDmaxF(M) = \max_{1\le m\le M} supF(m)$$

and the $WDmaxF$ test,

$$WDmaxF(M, \alpha) = \max_{1\le m\le M} \frac{c_\alpha(1)}{c_\alpha(m)} supF(m)$$

where α is the significance level and $c_\alpha(m)$ is the critical value of $supF(m)$ test given the significance level α. Four kinds of $WDmaxF$ tests that correspond to $\alpha = 0.100, 0.050, 0.025$, and 0.010 are implemented.

The $supF(l+1|l)$ test of l versus $l+1$ breaks is calculated in two ways that are asymptotically the same. In the first calculation, the method amounts to the application of $(l+1)$ tests of the null hypothesis of no structural change versus the alternative hypothesis of a single change. The test is applied to each segment that contains the observations $\hat{T}_{i-1}$ to $\hat{T}_i$ $(i = 1, \ldots, l+1)$. The $supF(l+1|l)$ test statistics are the maximum of these $(l+1)$ $supF$ test statistics. In the second calculation, for the given l breaks $(\hat{T}_1, \ldots, \hat{T}_l)$, the new break $\hat{T}^{(N)}$ is to minimize the global SSR:

$$\hat{T}^{(N)} = \arg\min_{T^{(N)}} SSR(\hat{T}_1, \ldots, \hat{T}_l; T^{(N)})$$

Then,

$$supF(l+1|l) = (T - (l+1)q - p)\frac{SSR(\hat{T}_1, \ldots, \hat{T}_l) - SSR(\hat{T}_1, \ldots, \hat{T}_l; \hat{T}^{(N)})}{SSR(\hat{T}_1, \ldots, \hat{T}_l)}$$

The p-value of each test is based on the simulation of the limiting distribution of that test.

Predicted Values

The AUTOREG procedure can produce two kinds of predicted values for the response series and corresponding residuals and confidence limits. The residuals in both cases are computed as the actual value minus the predicted value. In addition, when GARCH models are estimated, the AUTOREG procedure can output predictions of the conditional error variance.

Predicting the Unconditional Mean

The first type of predicted value is obtained from only the structural part of the model, $\mathbf{x}_t'\mathbf{b}$. These are useful in predicting values of new response time series, which are assumed to be described by the same model as the current response time series. The predicted values, residuals, standard errors, and upper and lower confidence limits for the structural predictions are requested by specifying the PREDICTEDM=, RESIDUALM=, STDERRM=, UCLM=, or LCLM= option in the OUTPUT statement. The ALPHACLM= option controls the confidence level for UCLM= and LCLM=. These confidence limits are for estimation of the mean of the dependent variable, $\mathbf{x}_t'\mathbf{b}$, where $\mathbf{x}_t$ is the column vector of independent variables at observation t.

The predicted values are computed as

$$\hat{y}_t = \mathbf{x}_t'\mathbf{b}$$

and the upper and lower confidence limits as

$$\hat{u}_t = \hat{y}_t + t_{\alpha/2}\mathrm{v}$$

$$\hat{l}_t = \hat{y}_t - t_{\alpha/2}\mathrm{v}$$

where v^2 is an estimate of the variance of $\hat{y}_t$ and $t_{\alpha/2}$ is the upper $\alpha/2$ percentage point of the t distribution.

$$\text{Prob}(T > t_{\alpha/2}) = \alpha/2$$

where T is an observation from a t distribution with q degrees of freedom. The value of α can be set with the ALPHACLM= option. The degrees of freedom parameter, q, is taken to be the number of observations minus the number of free parameters in the final model. For the YW estimation method, the value of v is calculated as

$$\text{v} = \sqrt{s^2 \mathbf{x}_t' (\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1} \mathbf{x}_t}$$

where s^2 is the error sum of squares divided by q. For the ULS and ML methods, it is calculated as

$$\text{v} = \sqrt{s^2 \mathbf{x}_t' \mathbf{W} \mathbf{x}_t}$$

where $\mathbf{W}$ is the $k \times k$ submatrix of $(\mathbf{J}'\mathbf{J})^{-1}$ that corresponds to the regression parameters. For more information, see the section "Computational Methods" on page 365.

Predicting Future Series Realizations

The other predicted values use both the structural part of the model and the predicted values of the error process. These conditional mean values are useful in predicting future values of the current response time series. The predicted values, residuals, standard errors, and upper and lower confidence limits for future observations conditional on past values are requested by the PREDICTED=, RESIDUAL=, STDERR=, UCL=, or LCL= option in the OUTPUT statement. The ALPHACLI= option controls the confidence level for UCL= and LCL=. These confidence limits are for the predicted value,

$$\tilde{y}_t = \mathbf{x}_t' \mathbf{b} + \nu_{t|t-1}$$

where $\mathbf{x}_t$ is the vector of independent variables if all independent variables at time t are nonmissing, and $\nu_{t|t-1}$ is the minimum variance linear predictor of the error term, which is defined in the following recursive way given the autoregressive model, AR(m) model, for ν_t,

$$\nu_{s|t} = \begin{cases} -\sum_{i=1}^{m} \hat{\varphi}_i \nu_{s-i|t} & s > t \text{ or observation } s \text{ is missing} \\ y_s - \mathbf{x}_s' \mathbf{b} & 0 < s \leq t \text{ and observation } s \text{ is nonmissing} \\ 0 & s \leq 0 \end{cases}$$

where $\hat{\varphi}_i, i = 1, \ldots, m$, are the estimated AR parameters. Observation s is considered to be missing if the dependent variable or at least one independent variable is missing. If some of the independent variables at time t are missing, the predicted $\tilde{y}_t$ is also missing. With the same definition of $\nu_{s|t}$, the prediction method can be easily extended to the multistep forecast of $\tilde{y}_{t+d}, d > 0$:

$$\tilde{y}_{t+d} = \mathbf{x}_{t+d}' \mathbf{b} + \nu_{t+d|t-1}$$

The prediction method is implemented through the Kalman filter.

If $\tilde{y}_t$ is not missing, the upper and lower confidence limits are computed as

$$\tilde{u}_t = \tilde{y}_t + t_{\alpha/2} \text{v}$$

$$\tilde{l}_t = \tilde{y}_t - t_{\alpha/2} \text{v}$$

where v, in this case, is computed as

$$\mathrm{v} = \sqrt{\mathbf{z}_t' \mathbf{V}_\beta \mathbf{z}_t + s^2 r}$$

where $\mathbf{V}_\beta$ is the variance-covariance matrix of the estimation of regression parameter β; $\mathbf{z}_t$ is defined as

$$\mathbf{z}_t = \mathbf{x}_t + \sum_{i=1}^{m} \hat{\varphi}_i \mathbf{x}_{t-i|t-1}$$

and $\mathbf{x}_{s|t}$ is defined in a similar way as $v_{s|t}$:

$$\mathbf{x}_{s|t} = \begin{cases} -\sum_{i=1}^{m} \hat{\varphi}_i \mathbf{x}_{s-i|t} & s > t \text{ or observation } s \text{ is missing} \\ \mathbf{x}_s & 0 < s \leq t \text{ and observation } s \text{ is nonmissing} \\ 0 & s \leq 0 \end{cases}$$

The formula for computing the prediction variance v is deducted based on Baillie (1979).

The value $s^2 r$ is the estimate of the conditional prediction error variance. At the start of the series, and after missing values, r is usually greater than 1. For the computational details of r, see the section "Predicting the Conditional Variance" on page 406. The plot of residuals and confidence limits in Example 8.4 illustrates this behavior.

Except to adjust the degrees of freedom for the error sum of squares, the preceding formulas do not account for the fact that the autoregressive parameters are estimated. In particular, the confidence limits are likely to be somewhat too narrow. In large samples, this is probably not an important effect, but it might be appreciable in small samples. For some discussion of this problem for AR(1) models, see Harvey (1981).

At the beginning of the series (the first m observations, where m is the value of the NLAG= option) and after missing values, these residuals do not match the residuals obtained by using OLS on the transformed variables. This is because, in these cases, the predicted noise values must be based on less than a complete set of past noise values and, thus, have larger variance. The GLS transformation for these observations includes a scale factor in addition to a linear combination of past values. Put another way, the $\mathbf{L}^{-1}$ matrix defined in the section "Computational Methods" on page 365 has the value 1 along the diagonal, except for the first m observations and after missing values.

Predicting the Conditional Variance

The GARCH process can be written as

$$\epsilon_t^2 = \omega + \sum_{i=1}^{n} (\alpha_i + \gamma_i) \epsilon_{t-i}^2 - \sum_{j=1}^{p} \gamma_j \eta_{t-j} + \eta_t$$

where $\eta_t = \epsilon_t^2 - h_t$ and $n = \max(p, q)$. This representation shows that the squared residual ϵ_t^2 follows an ARMA(n, p) process. Then for any $d > 0$, the conditional expectations are as follows:

$$\mathbf{E}(\epsilon_{t+d}^2 | \Psi_t) = \omega + \sum_{i=1}^{n} (\alpha_i + \gamma_i) \mathbf{E}(\epsilon_{t+d-i}^2 | \Psi_t) - \sum_{j=1}^{p} \gamma_j \mathbf{E}(\eta_{t+d-j} | \Psi_t)$$

The d-step-ahead prediction error, $\xi_{t+d} = y_{t+d} - y_{t+d|t}$, has the conditional variance

$$\mathbf{V}(\xi_{t+d} | \Psi_t) = \sum_{j=0}^{d-1} g_j^2 \sigma_{t+d-j|t}^2$$

where

$$\sigma^2_{t+d-j|t} = \mathbf{E}(\epsilon^2_{t+d-j}|\Psi_t)$$

Coefficients in the conditional d-step prediction error variance are calculated recursively using the formula

$$g_j = -\varphi_1 g_{j-1} - \cdots - \varphi_m g_{j-m}$$

where $g_0 = 1$ and $g_j = 0$ if $j < 0$; $\varphi_1, \ldots, \varphi_m$ are autoregressive parameters. Since the parameters are not known, the conditional variance is computed using the estimated autoregressive parameters. The d-step-ahead prediction error variance is simplified when there are no autoregressive terms:

$$\mathbf{V}(\xi_{t+d}|\Psi_t) = \sigma^2_{t+d|t}$$

Therefore, the one-step-ahead prediction error variance is equivalent to the conditional error variance defined in the GARCH process:

$$h_t = \mathbf{E}(\epsilon^2_t|\Psi_{t-1}) = \sigma^2_{t|t-1}$$

The multistep forecast of conditional error variance of the EGARCH, QGARCH, TGARCH, PGARCH, and GARCH-M models cannot be calculated using the preceding formula for the GARCH model. The following formulas are recursively implemented to obtain the multistep forecast of conditional error variance of these models:

- for the EGARCH(p, q) model:

$$\ln(\sigma^2_{t+d|t}) = \omega + \sum_{i=d}^{q} \alpha_i g(z_{t+d-i}) + \sum_{j=1}^{d-1} \gamma_j \ln(\sigma^2_{t+d-j|t}) + \sum_{j=d}^{p} \gamma_j \ln(h_{t+d-j})$$

  where

$$g(z_t) = \theta z_t + |z_t| - E|z_t|$$

$$z_t = \epsilon_t / \sqrt{h_t}$$

- for the QGARCH(p, q) model:

$$\begin{aligned}\sigma^2_{t+d|t} = \omega &+ \sum_{i=1}^{d-1} \alpha_i (\sigma^2_{t+d-i|t} + \psi_i^2) + \sum_{i=d}^{q} \alpha_i (\epsilon_{t+d-i} - \psi_i)^2 \\ &+ \sum_{j=1}^{d-1} \gamma_j \sigma^2_{t+d-j|t} + \sum_{j=d}^{p} \gamma_j h_{t+d-j}\end{aligned}$$

- for the TGARCH(p, q) model:

$$\begin{aligned}\sigma^2_{t+d|t} = \omega &+ \sum_{i=1}^{d-1} (\alpha_i + \psi_i/2) \sigma^2_{t+d-i|t} + \sum_{i=d}^{q} (\alpha_i + 1_{\epsilon_{t+d-i}<0} \psi_i) \epsilon^2_{t+d-i} \\ &+ \sum_{j=1}^{d-1} \gamma_j \sigma^2_{t+d-j|t} + \sum_{j=d}^{p} \gamma_j h_{t+d-j}\end{aligned}$$

- for the PGARCH(p, q) model:

$$
\begin{aligned}
(\sigma^2_{t+d|t})^\lambda = \omega \quad &+ \quad \sum_{i=1}^{d-1} \alpha_i ((1+\psi_i)^{2\lambda} + (1-\psi_i)^{2\lambda})(\sigma^2_{t+d-i|t})^\lambda / 2 \\
&+ \quad \sum_{i=d}^{q} \alpha_i (|\epsilon_{t+d-i}| - \psi_i \epsilon_{t+d-i})^{2\lambda} \\
&+ \quad \sum_{j=1}^{d-1} \gamma_j (\sigma^2_{t+d-j|t})^\lambda + \sum_{j=d}^{p} \gamma_j h^\lambda_{t+d-j}
\end{aligned}
$$

- for the GARCH-M model: ignoring the mean effect and directly using the formula of the corresponding GARCH model.

If the conditional error variance is homoscedastic, the conditional prediction error variance is identical to the unconditional prediction error variance

$$\mathbf{V}(\xi_{t+d}|\Psi_t) = \mathbf{V}(\xi_{t+d}) = \sigma^2 \sum_{j=0}^{d-1} g_j^2$$

since $\sigma^2_{t+d-j|t} = \sigma^2$. You can compute $s^2 r$ (which is the second term of the variance for the predicted value $\tilde{y}_t$ explained in the section "Predicting Future Series Realizations" on page 405) by using the formula $\sigma^2 \sum_{j=0}^{d-1} g_j^2$, and r is estimated from $\sum_{j=0}^{d-1} g_j^2$ by using the estimated autoregressive parameters.

Consider the following conditional prediction error variance:

$$\mathbf{V}(\xi_{t+d}|\Psi_t) = \sigma^2 \sum_{j=0}^{d-1} g_j^2 + \sum_{j=0}^{d-1} g_j^2 (\sigma^2_{t+d-j|t} - \sigma^2)$$

The second term in the preceding equation can be interpreted as the noise from using the homoscedastic conditional variance when the errors follow the GARCH process. However, it is expected that if the GARCH process is covariance stationary, the difference between the conditional prediction error variance and the unconditional prediction error variance disappears as the forecast horizon d increases.

OUT= Data Set

The output SAS data set produced by the OUTPUT statement contains all the variables in the input data set and the new variables specified by the OUTPUT statement options. For information about the output variables that can be created, see the section "OUTPUT Statement" on page 357. The output data set contains one observation for each observation in the input data set.

OUTEST= Data Set

The OUTEST= data set contains all the variables used in any MODEL statement. Each regressor variable contains the estimate for the corresponding regression parameter in the corresponding model. In addition, the OUTEST= data set contains the following variables:

_A_*i*	the *i*th order autoregressive parameter estimate. There are *m* such variables _A_1 through _A_*m*, where *i*s the value of the NLAG= option.
_AH_*i*	the *i*th order ARCH parameter estimate, if the GARCH= option is specified. There are *q* such variables _AH_1 through _AH_*q*, where *q* is the value of the Q= option. The variable _AH_0 contains the estimate of ω.
_AHP_*i*	the estimate of the ψ_i parameter in the PGARCH model, if a PGARCH model is specified. There are *q* such variables _AHP_1 through _AHP_*q*, where *q* is the value of the Q= option.
_AHQ_*i*	the estimate of the ψ_i parameter in the QGARCH model, if a QGARCH model is specified. There are *q* such variables _AHQ_1 through _AHQ_*q*, where *q* is the value of the Q= option.
_AHT_*i*	the estimate of the ψ_i parameter in the TGARCH model, if a TGARCH model is specified. There are *q* such variables _AHT_1 through _AHT_*q*, where *q* is the value of the Q= option.
DELTA	the estimated mean parameter for the GARCH-M model if a GARCH-in-mean model is specified
DEPVAR	the name of the dependent variable
_GH_*i*	the *i*th order GARCH parameter estimate, if the GARCH= option is specified. There are *p* such variables _GH_1 through _GH_*p*, where *p* is the value of the P= option.
_HET_*i*	the *i*th heteroscedasticity model parameter specified by the HETERO statement
INTERCEPT	the intercept estimate. INTERCEPT contains a missing value for models for which the NOINT option is specified.
METHOD	the estimation method that is specified in the METHOD= option
MODEL	the label of the MODEL statement if one is given, or blank otherwise
MSE	the value of the mean square error for the model
NAME	the name of the row of covariance matrix for the parameter estimate, if the COVOUT option is specified
LAMBDA	the estimate of the power parameter λ in the PGARCH model, if a PGARCH model is specified.
LIKLHD	the log-likelihood value of the GARCH model
SSE	the value of the error sum of squares
START	the estimated start-up value for the conditional variance when GARCH= (STARTUP=ESTIMATE) option is specified

STATUS	This variable indicates the optimization status. _STATUS_ = 0 indicates that there were no errors during the optimization and the algorithm converged. _STATUS_ = 1 indicates that the optimization could not improve the function value and means that the results should be interpreted with caution. _STATUS_ = 2 indicates that the optimization failed due to the number of iterations exceeding either the maximum default or the specified number of iterations or the number of function calls allowed. _STATUS_ = 3 indicates that an error occurred during the optimization process. For example, this error message is obtained when a function or its derivatives cannot be calculated at the initial values or during the iteration process, when an optimization step is outside of the feasible region or when active constraints are linearly dependent.
STDERR	standard error of the parameter estimate, if the COVOUT option is specified.
TDFI	the estimate of the inverted degrees of freedom for Student's t distribution, if DIST=T is specified.
THETA	the estimate of the θ parameter in the EGARCH model, if an EGARCH model is specified.
TYPE	PARM for observations containing parameter estimates, or COV for observations containing covariance matrix elements.

The OUTEST= data set contains one observation for each MODEL statement giving the parameter estimates for that model. If the COVOUT option is specified, the OUTEST= data set includes additional observations for each MODEL statement giving the rows of the covariance of parameter estimates matrix. For covariance observations, the value of the _TYPE_ variable is COV, and the _NAME_ variable identifies the parameter associated with that row of the covariance matrix.

Printed Output

The AUTOREG procedure prints the following items:

1. the name of the dependent variable
2. the ordinary least squares estimates
3. estimates of autocorrelations, which include the estimates of the autocovariances, the autocorrelations, and (if there is sufficient space) a graph of the autocorrelation at each LAG
4. if the PARTIAL option is specified, the partial autocorrelations
5. the preliminary MSE, which results from solving the Yule-Walker equations. This is an estimate of the final MSE.
6. the estimates of the autoregressive parameters (Coefficient), their standard errors (Standard Error), and the ratio of estimate to standard error (t Value)
7. the statistics of fit for the final model. These include the error sum of squares (SSE), the degrees of freedom for error (DFE), the mean square error (MSE), the mean absolute error (MAE), the mean absolute percentage error (MAPE), the root mean square error (Root MSE), the Schwarz information criterion (SBC), the Hannan-Quinn information criterion (HQC), Akaike's information criterion (AIC), the corrected Akaike's information criterion (AICC), the Durbin-Watson statistic (Durbin-Watson), the

transformed regression R^2 (Transformed Regress R-Square), and the total R^2 (Total R-Square). For GARCH models, the following additional items are printed:

- the value of the log-likelihood function (Log Likelihood)
- the number of observations that are used in estimation (Observations)
- the unconditional variance (Uncond Var)
- the normality test statistic and its p-value (Normality Test and Pr > ChiSq)

8. the parameter estimates for the structural model (Estimate), a standard error estimate (Standard Error), the ratio of estimate to standard error (t Value), and an approximation to the significance probability for the parameter being 0 (Approx Pr > |t|)

9. If the NLAG= option is specified with METHOD=ULS or METHOD=ML, the regression parameter estimates are printed again, assuming that the autoregressive parameter estimates are known. In this case, the Standard Error and related statistics for the regression estimates will, in general, be different from the case when they are estimated. Note that from a standpoint of estimation, Yule-Walker and iterated Yule-Walker methods (NLAG= with METHOD=YW, ITYW) generate only one table, assuming AR parameters are given.

10. If you specify the NORMAL option, the Jarque-Bera normality test statistics are printed. If you specify the LAGDEP option, Durbin's h or Durbin's t is printed.

ODS Table Names

PROC AUTOREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the Table 8.6.

Table 8.6 ODS Tables Produced in PROC AUTOREG

ODS Table Name	Description	Option
ODS Tables Created by the MODEL Statement

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

This section describes the use of ODS for creating graphics with the AUTOREG procedure.

To request these graphs, you must specify the ODS GRAPHICS statement. By default, only the residual, predicted versus actual, and autocorrelation of residuals plots are produced. If, in addition to the ODS GRAPHICS statement, you also specify the ALL option in either the PROC AUTOREG statement or MODEL statement, all plots are created. For HETERO, GARCH, and AR models studentized residuals are replaced by standardized residuals. For the autoregressive models, the conditional variance of the residuals is computed as described in the section "Predicting Future Series Realizations" on page 405. For the GARCH and HETERO models, residuals are assumed to have h_t conditional variance invoked by the HT= option of the OUTPUT statement. For all these cases, the Cook's D plot is not produced.

ODS Graph Names

PROC AUTOREG assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 8.7.

Table 8.7 ODS Graphics Produced in PROC AUTOREG

ODS Table Name	Description	PLOTS= Option
DiagnosticsPanel	All applicable plots	
ACFPlot	Autocorrelation of residuals	ACF
AutoCorrPlot	Estimates of autocorrelations	AutoCorrPlot
FitPlot	Predicted versus actual plot	FITPLOT, default
CooksD	Cook's D plot	COOKSD (no NLAG=)
IACFPlot	Inverse autocorrelation of residuals	IACF
QQPlot	Q-Q plot of residuals	QQ
PACFPlot	Partial autocorrelation of residuals	PACF
ResidualHistogram	Histogram of the residuals	RESIDUALHISTOGRAM or RESIDHISTOGRAM
ResidualPlot	Residual plot	RESIDUAL or RES, default
StudentResidualPlot	Studentized residual plot	STUDENTRESIDUAL (no NLAG=, GARCH=, or HETERO)
StandardResidualPlot	Standardized residual plot	STANDARDRESIDUAL
WhiteNoiseLogProbPlot	Tests for white noise residuals	WHITENOISE

Examples: AUTOREG Procedure

Example 8.1: Analysis of Real Output Series

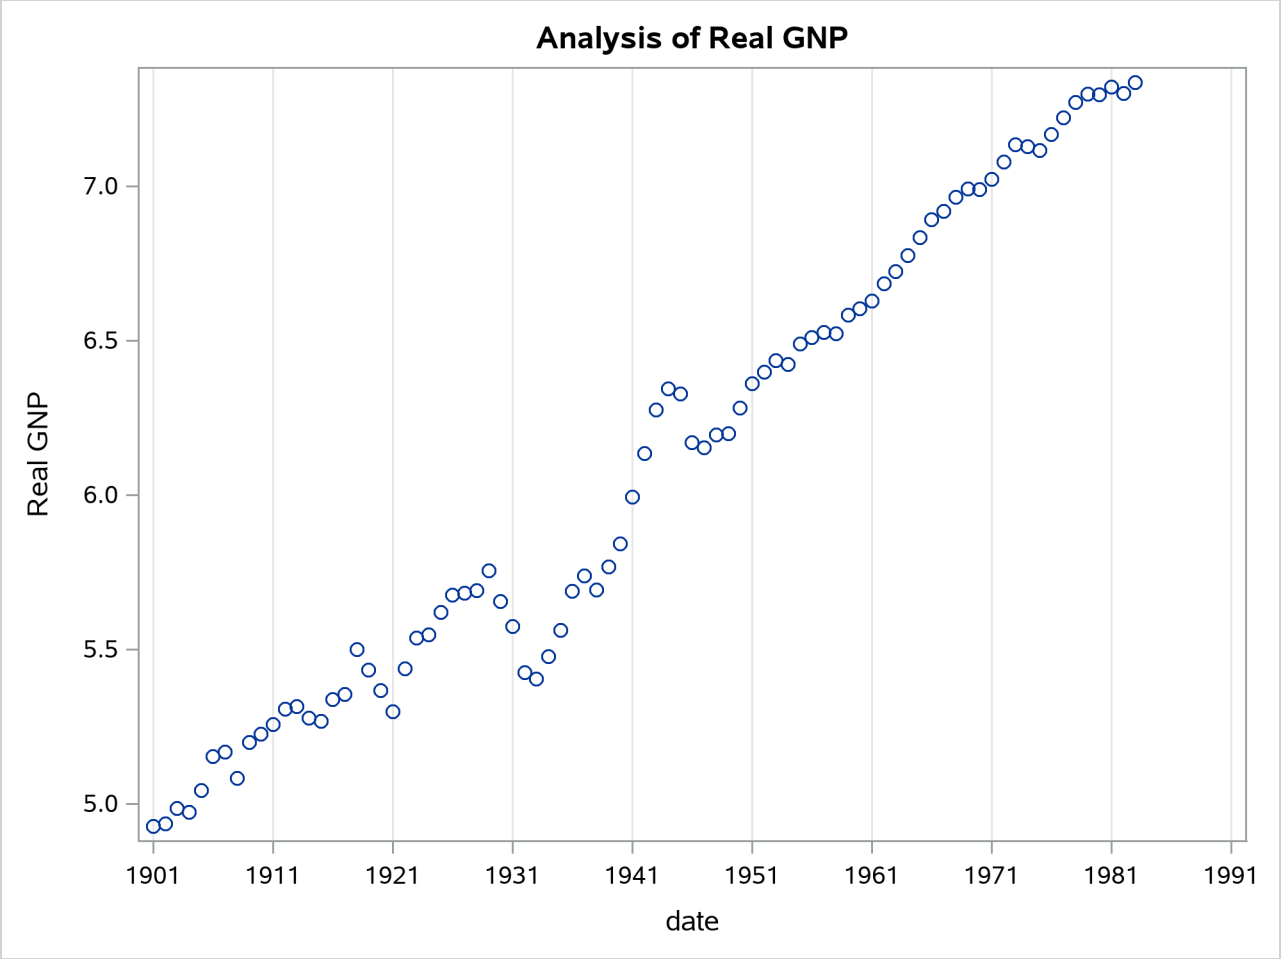
In this example, the annual real output series is analyzed over the period 1901 to 1983 (Balke and Gordon 1986, pp. 581–583). With the following DATA step, the original data are transformed using the natural logarithm, and the differenced series DY is created for further analysis. The log of real output is plotted in Output 8.1.1.

```
title 'Analysis of Real GNP';
data gnp;
   date = intnx( 'year', '01jan1901'd, _n_-1 );
   format date year4.;
   input x @@;
   y  = log(x);
   dy = dif(y);
   t  = _n_;
   label y  = 'Real GNP'
         dy = 'First Difference of Y'
         t  = 'Time Trend';
datalines;
  137.87  139.13  146.10  144.21  155.04  172.97  175.61  161.22

   ... more lines ...

proc sgplot data=gnp noautolegend;
   scatter x=date y=y;
   xaxis grid values=('01jan1901'd '01jan1911'd '01jan1921'd '01jan1931'd
             '01jan1941'd '01jan1951'd '01jan1961'd '01jan1971'd
             '01jan1981'd '01jan1991'd);
run;
```

Output 8.1.1 Real Output Series: 1901–1983



The (linear) trend-stationary process is estimated using the form

$$y_t = \beta_0 + \beta_1 t + \nu_t$$

where

$$\nu_t = \epsilon_t - \varphi_1 \nu_{t-1} - \varphi_2 \nu_{t-2}$$

$$\epsilon_t \sim \mathrm{IN}(0, \sigma_\epsilon)$$

The preceding trend-stationary model assumes that uncertainty over future horizons is bounded since the error term, ν_t, has a finite variance. The maximum likelihood AR estimates from the statements that follow are shown in Output 8.1.2:

```
proc autoreg data=gnp;
   model y = t / nlag=2 method=ml;
run;
```

t	1	0.0302	0.001346	22.45	<.0001	Time Trend

Nelson and Plosser (1982) failed to reject the hypothesis that macroeconomic time series are nonstationary and have no tendency to return to a trend line. In this context, the simple random walk process can be used as an alternative process,

$$y_t = \beta_0 + y_{t-1} + v_t$$

where $v_t = \epsilon_t$ and $y_0 = 0$. In general, the difference-stationary process is written as

$$\phi(L)(1-L)y_t = \beta_0\phi(1) + \theta(L)\epsilon_t$$

where L is the lag operator. You can observe that the class of a difference-stationary process should have at least one unit root in the AR polynomial $\phi(L)(1-L)$.

The Dickey-Fuller procedure is used to test the null hypothesis that the series has a unit root in the AR polynomial. Consider the following equation for the augmented Dickey-Fuller test,

$$\Delta y_t = \beta_0 + \delta t + \beta_1 y_{t-1} + \sum_{i=1}^{m} \gamma_i \Delta y_{t-i} + \epsilon_t$$

where $\Delta = 1 - L$. The test statistic τ_τ is the usual t ratio for the parameter estimate $\hat{\beta}_1$, but the τ_τ does not follow a t distribution.

The following code performs the augmented Dickey-Fuller test with $m = 3$. The test results in the linear time trend case are of interest because the previous plot reveals that there is a linear trend.

```
proc autoreg data = gnp;
   model y = / stationarity =(adf =3);
run;
```

The augmented Dickey-Fuller test indicates that the output series may have a difference-stationary process. The statistic Tau with linear time trend has a value of -2.6190 and its p-value is 0.2732. The statistic Rho has a p-value of 0.0817, which also indicates the null of unit root is accepted at the 5% level. (See Output 8.1.3.)

Output 8.1.3 Augmented Dickey-Fuller Test Results

Analysis of Real GNP

The AUTOREG Procedure

Augmented Dickey-Fuller Unit Root Tests							
Type	Lags	Rho	Pr < Rho	Tau	Pr < Tau	F	Pr > F
Zero Mean	3	0.3827	0.7732	3.3342	0.9997		
Single Mean	3	-0.1674	0.9465	-0.2046	0.9326	5.7521	0.0211
Trend	3	-18.0246	0.0817	-2.6190	0.2732	3.4472	0.4957

The AR(1) model for the differenced series DY is estimated using the maximum likelihood method for the period 1902 to 1983. The difference-stationary process is written

$$\Delta y_t = \beta_0 + \nu_t$$

$$\nu_t = \epsilon_t - \varphi_1 \nu_{t-1}$$

The estimated value of φ_1 is -0.297 and that of β_0 is 0.0293. All estimated values are statistically significant. The PROC step follows:

```
proc autoreg data=gnp;
   model dy = / nlag=1 method=ml;
run;
```

The printed output produced by the PROC step is shown in Output 8.1.4.

Example 8.2: Comparing Estimates and Models

In this example, the Grunfeld series are estimated using different estimation methods. For information about the Grunfeld investment data set, see Maddala (1977). For comparison, the Yule-Walker method, ULS method, and maximum likelihood method estimates are shown. With the DWPROB option, the *p*-value of the Durbin-Watson statistic is printed. The Durbin-Watson test indicates the positive autocorrelation of the regression residuals. The DATA and PROC steps follow:

```
title 'Grunfeld''s Investment Models Fit with Autoregressive Errors';
data grunfeld;
   input year gei gef gec;
   label gei = 'Gross investment GE'
         gec = 'Lagged Capital Stock GE'
         gef = 'Lagged Value of GE shares';
datalines;
1935     33.1      1170.6     97.8

   ... more lines ...

Example 8.3: Lack-of-Fit Study

Many time series exhibit high positive autocorrelation, having the smooth appearance of a random walk. This behavior can be explained by the partial adjustment and adaptive expectation hypotheses.

Short-term forecasting applications often use autoregressive models because these models absorb the behavior of this kind of data. In the case of a first-order AR process where the autoregressive parameter is exactly 1 (a *random walk*), the best prediction of the future is the immediate past.

PROC AUTOREG can often greatly improve the fit of models, not only by adding additional parameters but also by capturing the random walk tendencies. Thus, PROC AUTOREG can be expected to provide good short-term forecast predictions.

However, good forecasts do not necessarily mean that your structural model contributes anything worthwhile to the fit. In the following example, random noise is fit to part of a sine wave. Notice that the structural model does not fit at all, but the autoregressive process does quite well and is very nearly a first difference (AR(1) = −.976). The DATA step, PROC AUTOREG step, and PROC SGPLOT step follow:

```
title1 'Lack of Fit Study';
title2 'Fitting White Noise Plus Autoregressive Errors to a Sine Wave';

data a;
   pi=3.14159;
   do time = 1 to 75;
      if time > 75 then y = .;
      else y = sin( pi * ( time / 50 ) );
      x = ranuni( 1234567 );
      output;
   end;
run;

proc autoreg data=a plots;
   model y = x / nlag=1;
   output out=b p=pred pm=xbeta;
run;

proc sgplot data=b;
   scatter y=y x=time / markerattrs=(color=black);
   series y=pred x=time / lineattrs=(color=blue);
   series y=xbeta x=time / lineattrs=(color=red);
run;
```

The printed output produced by PROC AUTOREG is shown in Output 8.3.1 and Output 8.3.2. Plots of observed and predicted values are shown in Output 8.3.3 and Output 8.3.4. Note: the plot Output 8.3.3 can be viewed in the Autoreg.Model.FitDiagnosticPlots category by selecting **View►Results**.

Example 8.4: Missing Values

In this example, a pure autoregressive error model with no regressors is used to generate 50 values of a time series. Approximately 15% of the values are randomly chosen and set to missing. The following statements generate the data:

```
title  'Simulated Time Series with Roots:';
title2 ' (X-1.25)(X**4-1.25)';
title3 'With 15% Missing Values';
data ar;
   do i=1 to 550;
      e = rannor(12345);
      n = sum( e, .8*n1, .8*n4, -.64*n5 );  /* ar process  */
      y = n;
      if ranuni(12345) > .85 then y = .;    /* 15% missing */
      n5=n4; n4=n3; n3=n2; n2=n1; n1=n;     /* set lags    */
      if i>500 then output;
   end;
run;
```

The model is estimated using maximum likelihood, and the residuals are plotted with 99% confidence limits. The PARTIAL option prints the partial autocorrelations. The following statements fit the model:

```
proc autoreg data=ar partial;
   model y = / nlag=(1 4 5) method=ml;
   output out=a predicted=p residual=r ucl=u lcl=l alphacli=.01;
run;
```

The printed output produced by the AUTOREG procedure is shown in Output 8.4.1 and Output 8.4.2. Note: the plot Output 8.4.2 can be viewed in the Autoreg.Model.FitDiagnosticPlots category by selecting **View►Results**.

5	-0.3816	-0.0855

The following statements plot the residuals and confidence limits:

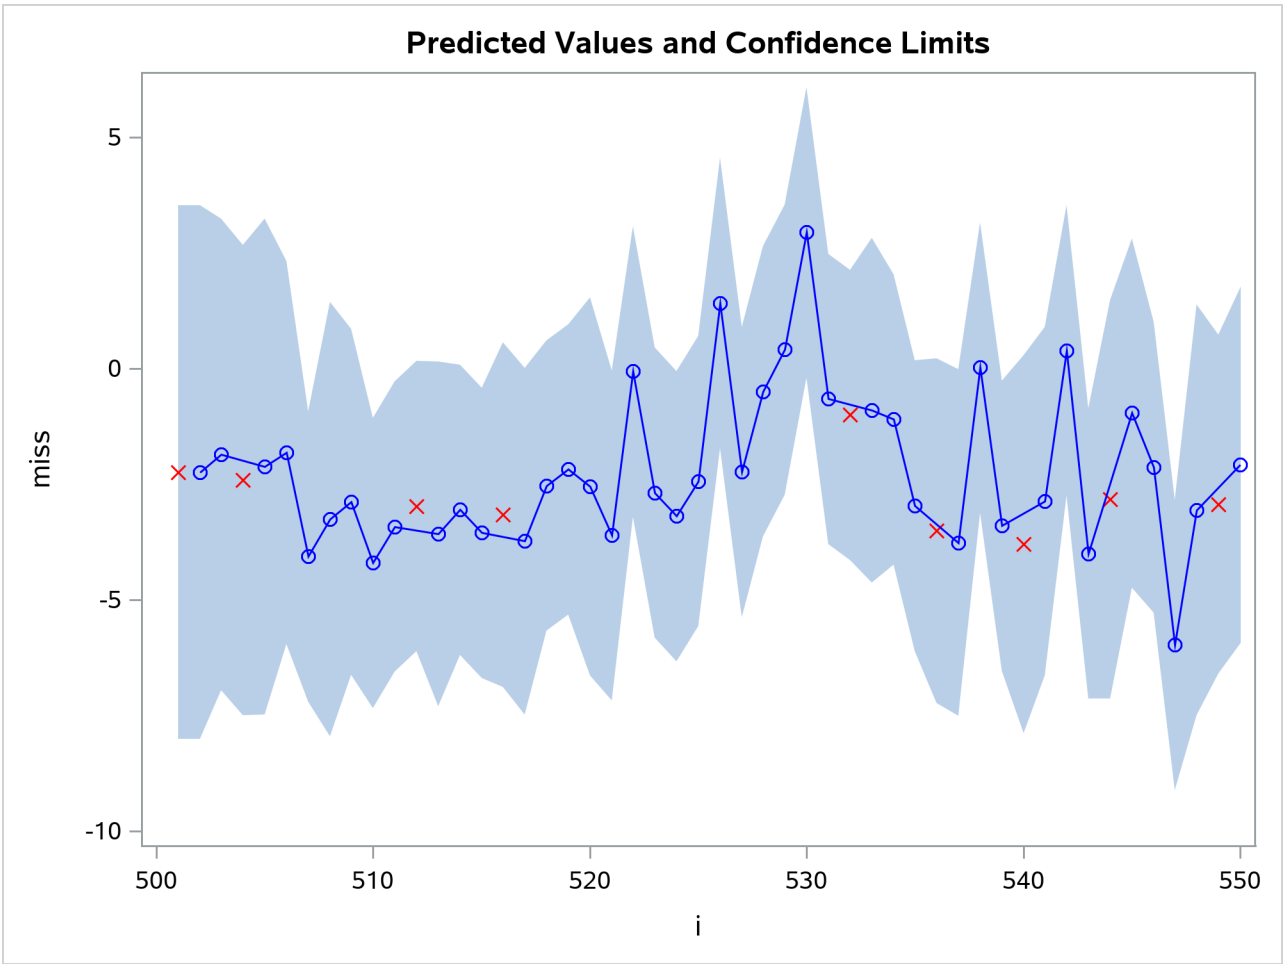
```
data reshape1;
   set a;
   miss = .;
   if r=. then do;
      miss = p;
      p = .;
   end;
run;

title 'Predicted Values and Confidence Limits';

proc sgplot data=reshape1 NOAUTOLEGEND;
   band x=i upper=u lower=l;
   scatter y=miss x=i/ MARKERATTRS =(symbol=x color=red);
   series y=p x=i/markers MARKERATTRS =(color=blue) lineattrs=(color=blue);
run;
```

The plot of the predicted values and the upper and lower confidence limits is shown in Output 8.4.4. Note that the confidence interval is wider at the beginning of the series (when there are no past noise values to use in the forecast equation) and after missing values where, again, there is an incomplete set of past residuals.

Output 8.4.4 Plot of Predicted Values and Confidence Interval



Example 8.5: Money Demand Model

This example estimates the log-log money demand equation by using the maximum likelihood method. The money demand model contains four explanatory variables. The lagged nominal money stock M1 is divided by the current price level GDF to calculate a new variable M1CP since the money stock is assumed to follow the partial adjustment process. The variable M1CP is then used to estimate the coefficient of adjustment. All variables are transformed using the natural logarithm with a DATA step. For a data description, see Balke and Gordon (1986).

The first eight observations are printed using the PRINT procedure and are shown in Output 8.5.1. Note that the first observation of the variables M1CP and INFR are missing. Therefore, the money demand equation is estimated for the period 1968:2 to 1983:4 since PROC AUTOREG ignores the first missing observation. The DATA step that follows generates the transformed variables:

```
   title 'Partial Adjustment Money Demand Equation';
   title2 'Quarterly Data - 1968:2 to 1983:4';
data money;
   date = intnx( 'qtr', '01jan1968'd, _n_-1 );
   format date yyqc6.;
   input m1 gnp gdf ycb @@;
   m = log( 100 * m1 / gdf );
   m1cp = log( 100 * lag(m1) / gdf );
   y = log( gnp );
   intr = log( ycb );
   infr = 100 * log( gdf / lag(gdf) );
   label m    = 'Real Money Stock (M1)'
         m1cp = 'Lagged M1/Current GDF'
         y    = 'Real GNP'
         intr = 'Yield on Corporate Bonds'
         infr = 'Rate of Prices Changes';

   ... more lines ...
```

Output 8.5.1 Money Demand Data Series – First 8 Observations

8	1969:4	206.10	1085.53	88.62	8.22	5.44917	5.43981	6.98982	2.10657	1.28331

The money demand equation is first estimated using OLS. The DW=4 option produces generalized Durbin-Watson statistics up to the fourth order. Their exact marginal probabilities (*p*-values) are also calculated with

the DWPROB option. The Durbin-Watson test indicates positive first-order autocorrelation at, say, the 10% confidence level. You can use the Durbin-Watson table, which is available only for 1% and 5% significance points. The relevant upper (d_U) and lower (d_L) bounds are $d_U = 1.731$ and $d_L = 1.471$, respectively, at 5% significance level. However, the bounds test is inconvenient, since sometimes you may get the statistic in the inconclusive region while the interval between the upper and lower bounds becomes smaller with the increasing sample size. The PROC step follows:

```
proc autoreg data=money outest=est covout;
   model m = m1cp y intr infr / dw=4 dwprob;
run;
```

Output 8.5.2 OLS Estimation of the Partial Adjustment Money Demand Equation

Parameter Estimates

Variable	DF	Estimate	Standard Error	t Value	Approx Pr > |t|	Variable Label
Intercept	1	0.3084	0.2359	1.31	0.1963	
m1cp	1	0.8952	0.0439	20.38	<.0001	Lagged M1/Current GDF
y	1	0.0476	0.0122	3.89	0.0003	Real GNP
intr	1	-0.0238	0.007933	-3.00	0.0040	Yield on Corporate Bonds
infr	1	-0.005646	0.001584	-3.56	0.0007	Rate of Prices Changes

The autoregressive model is estimated using the maximum likelihood method. Though the Durbin-Watson test statistic is calculated after correcting the autocorrelation, it should be used with care since the test based on this statistic is not justified theoretically. The PROC step follows:

```
proc autoreg data=money;
   model m = m1cp y intr infr / nlag=1 method=ml maxit=50;
   output out=a p=p pm=pm r=r rm=rm ucl=ucl lcl=lcl
               uclm=uclm lclm=lclm;
run;

proc print data=a(obs=8);
   var p pm r rm ucl lcl uclm lclm;
run;
```

A difference is shown between the OLS estimates in Output 8.5.2 and the AR(1)-ML estimates in Output 8.5.3. The estimated autocorrelation coefficient is significantly negative (−0.88345). Note that the negative coefficient of AR(1) should be interpreted as a positive autocorrelation.

Two predicted values are produced: predicted values computed for the structural model and predicted values computed for the full model. The full model includes both the structural and error-process parts. The predicted values and residuals are stored in the output data set A, as are the upper and lower 95% confidence limits for the predicted values. Part of the data set A is shown in Output 8.5.4. The first observation is missing since the explanatory variables, M1CP and INFR, are missing for the corresponding observation.

Example 8.6: Estimation of ARCH(2) Process

Stock returns show a tendency for small changes to be followed by small changes while large changes are followed by large changes. The plot of daily price changes of IBM common stock (Box and Jenkins 1976, p. 527) is shown in Output 8.6.1. The time series look serially uncorrelated, but the plot makes us skeptical of their independence.

With the following DATA step, the stock (capital) returns are computed from the closing prices. To forecast the conditional variance, an additional 46 observations with missing values are generated.

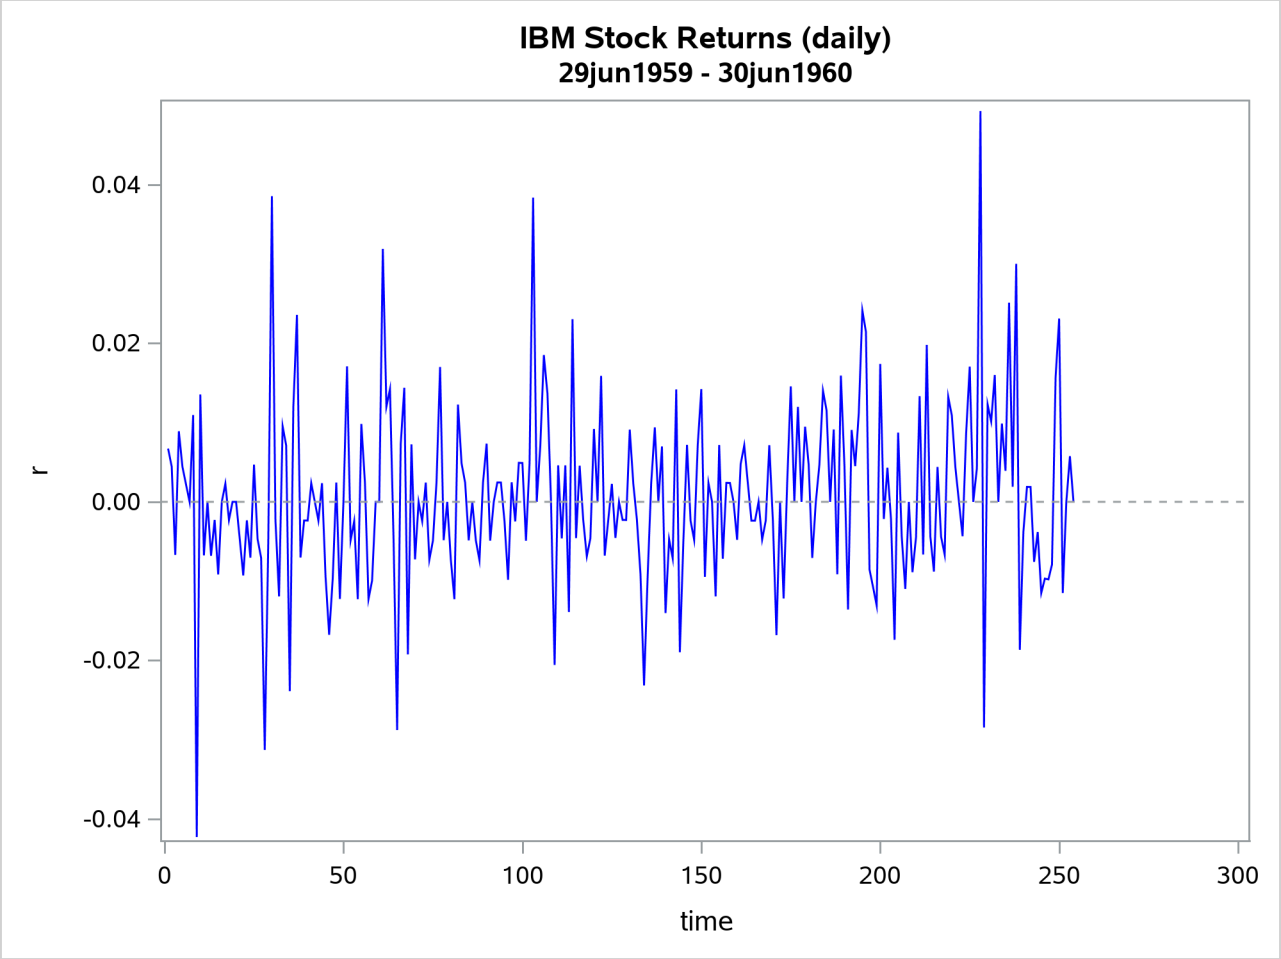
```
title 'IBM Stock Returns (daily)';
title2 '29jun1959 - 30jun1960';

data ibm;
   infile datalines eof=last;
   input x @@;
   r = dif( log( x ) );
   time = _n_-1;
   output;
   return;
last:
   do i = 1 to 46;
      r = .;
      time + 1;
      output;
   end;
   return;
datalines;
445 448 450 447 451 453 454 454 459 440 446 443 443 440

   ... more lines ...

proc sgplot data=ibm;
   series y=r x=time/lineattrs=(color=blue);
         refline 0/ axis = y LINEATTRS = (pattern=ShortDash);
run;
```

Output 8.6.1 IBM Stock Returns: Daily



The simple ARCH(2) model is estimated using the AUTOREG procedure. The MODEL statement option GARCH=(Q=2) specifies the ARCH(2) model. The OUTPUT statement with the CEV= option produces the conditional variances V. The conditional variance and its forecast are calculated using parameter estimates,

$$h_t = \hat{\omega} + \hat{\alpha}_1 \epsilon_{t-1}^2 + \hat{\alpha}_2 \epsilon_{t-2}^2$$

$$\mathbf{E}(\epsilon_{t+d}^2 | \Psi_t) = \hat{\omega} + \sum_{i=1}^{2} \hat{\alpha}_i \mathbf{E}(\epsilon_{t+d-i}^2 | \Psi_t)$$

where $d > 1$. This model can be estimated as follows:

```
proc autoreg data=ibm maxit=50;
   model r = / noint garch=(q=2);
   output out=a cev=v;
run;
```

The parameter estimates for ω, α_1, and α_2 are 0.00011, 0.04136, and 0.06976, respectively. The normality test indicates that the conditional normal distribution may not fully explain the leptokurtosis in the stock returns (Bollerslev 1987).

The ARCH model estimates are shown in Output 8.6.2, and conditional variances are also shown in Output 8.6.3. The following code generates Output 8.6.3:

```
data b; set a;
   length type $ 8.;
   if r ^= . then do;
      type = 'ESTIMATE'; output; end;
   else do;
      type = 'FORECAST'; output; end;
run;
proc sgplot data=b;
   series x=time y=v/group=type;
   refline 254/ axis = x LINEATTRS = (pattern=ShortDash);
run;
```

The table shown in Output 8.7.2 is convenient for reporting the estimation result of multiple models and their comparison.

The following statements merge multiple tables that contain fit statistics for each estimated model, leaving only columns of interest, and rename them:

```
/* Merging ODS output tables and extracting AIC and SBC measures */
data sbc_aic;
   set fitsum_arch_2 fitsum_garch_1_1 fitsum_st_garch_1_1
       fitsum_ar_1 fitsum_ar_1_garch_1_1 fitsum_igarch_1_1
       fitsum_egarch_1_1 fitsum_garchm_1_1
       fitsum_tgarch_1_1 fitsum_pgarch_1_1 fitsum_qgarch_1_1;
   keep Model SBC AIC;
   if Label1="SBC" then do; SBC=input(cValue1,BEST12.4); end;
   if Label2="SBC" then do; SBC=input(cValue2,BEST12.4); end;
   if Label1="AIC" then do; AIC=input(cValue1,BEST12.4); end;
   if Label2="AIC" then do; AIC=input(cValue2,BEST12.4); end;
   if not (SBC=.) then output;
run;
```

Next, sort the models by one of the criteria—for example, by AIC:

```
/* Sorting data by AIC criterion */
proc sort data=sbc_aic;
   by AIC;
run;
```

Finally, print the sorted data set:

```
title "Selection Criteria for Different Models";
proc print data=sbc_aic;
   format _NUMERIC_ BEST12.4;
run;
title;
```

The result is given in Output 8.7.3.

Output 8.7.3 GARCH-Family Model Selection on the Basis of AIC and SBC

Selection Criteria for Different Models

Obs	Model	SBC	AIC
1	pgarch_1_1	42907.7292	42870.7722
2	egarch_1_1	42905.9616	42876.3959
3	tgarch_1_1	42995.4893	42965.9236
4	qgarch_1_1	43023.106	42993.5404
5	garchm_1_1	43158.4139	43128.8483
6	garch_1_1	43176.5074	43154.3332
7	ar_1_garch_1_1	43185.5226	43155.957
8	st_garch_1_1	43178.2497	43156.0755
9	arch_2	44605.4332	44583.259
10	ar_1	45922.0721	45914.6807
11	igarch_1_1	45925.5828	45918.1914

According to the smaller-is-better rule for the information criteria, the PGARCH(1,1) model is the leader by AIC while the EGARCH(1,1) is the model of choice according to SBC.

Next, check whether the power GARCH model is misspecified, especially, if dependence exists in the standardized residuals that correspond to the assumed independently and identically distributed (iid) disturbance. The following statements reestimate the power GARCH model and use the BDS test to check the independence of the standardized residuals:

```
proc autoreg data=ibm_long;
   model r = / noint garch=(p=1,q=1,type=pgarch) BDS=(Z=SR,D=2.0);
run;
```

The partial results listing of the preceding statements is given in Output 8.7.4.

Output 8.7.4 Diagnostic Checking of the PGARCH(1,1) Model

The AUTOREG Procedure

BDS Test for Independence			
Distance	Embedding Dimension	BDS	Pr > |BDS|
2.0000	2	2.9691	0.0030
	3	3.3810	0.0007
	4	3.1299	0.0017
	5	3.3805	0.0007
	6	3.3368	0.0008
	7	3.1888	0.0014
	8	2.9576	0.0031
	9	2.7386	0.0062
	10	2.5553	0.0106
	11	2.3510	0.0187
	12	2.1520	0.0314
	13	1.9373	0.0527
	14	1.7210	0.0852
	15	1.4919	0.1357
	16	1.2569	0.2088
	17	1.0647	0.2870
	18	0.9635	0.3353
	19	0.8678	0.3855
	20	0.7660	0.4437

The results in Output 8.7.4 indicate that when embedded size is greater than 9, you fail to reject the null hypothesis of independence at 1% significance level, which is a good indicator that the PGARCH model is not misspecified.

Example 8.8: Illustration of ODS Graphics

This example illustrates the use of ODS GRAPHICS. This is a continuation of the section "Forecasting Autoregressive Error Models" on page 315.

These graphical displays are requested by specifying the ODS GRAPHICS statement. For information about the graphs available in the AUTOREG procedure, see the section "ODS Graphics" on page 414.

The following statements show how to generate ODS GRAPHICS plots with the AUTOREG procedure. In this case, all plots are requested using the ALL option in the PROC AUTOREG statement, in addition to the ODS GRAPHICS statement. The plots are displayed in Output 8.8.1 through Output 8.8.8. Note: these plots can be viewed in the Autoreg.Model.FitDiagnosticPlots category by selecting **View►Results**.

```
data a;
   ul = 0; ull = 0;
   do time = -10 to 36;
      u = + 1.3 * ul - .5 * ull + 2*rannor(12346);
      y = 10 + .5 * time + u;
      if time > 0 then output;
```

```
      ull = ul; ul = u;
   end;
run;

Overview: COMPUTAB Procedure

The COMPUTAB (computing and tabular reporting) procedure produces tabular reports generated using a programmable data table.

The COMPUTAB procedure is especially useful when you need both the power of a programmable spreadsheet and a report generation system, but you want to set up a program to run in a batch mode and generate routine reports.

With PROC COMPUTAB, you can select a subset of observations from the input data set, define the format of a table, operate on its row and column values, and create new columns and rows. Access to individual table values is available when needed.

The COMPUTAB procedure can tailor reports to almost any desired specification and provide consolidation reports over summarization variables. The generated report values can be stored in an output data set. PROC COMPUTAB is especially useful in creating tabular reports such as income statements, balance sheets, and other row and column reports.

Getting Started: COMPUTAB Procedure

The following example shows the different types of reports that can be generated by PROC COMPUTAB.

Suppose a company has monthly expense data on three of its divisions and wants to produce the year-to-date expense report shown in Figure 9.1. This section starts out with the default report produced by the COMPUTAB procedure and modifies it until the desired report is achieved.

Figure 9.1 Year-to-Date Expense Report

Year to Date Expenses

	Division A	Division B	Division C	All Divisions
Travel Expenses within U.S.	18700	211000	12800	$242,500
Advertising	18500	176000	34500	$229,000
Permanent Staff Salaries	186000	1270000	201000	$1,657,000
Benefits Including Insurance	3900	11100	17500	$32,500
Total	227100	1668100	265800	$2,161,000

Producing a Simple Report

Without any specifications, the COMPUTAB procedure transposes and prints the input data set. The variables in the input data set become rows in the report, and the observations in the input data set become columns. The variable names are used as the row titles. The column headings default to COL1 through COLn. For example, the following input data set contains the monthly expenses reported by different divisions of the company:

```
data report;
   length compdiv $ 1;
   input compdiv $ date:date7. salary travel insure advrtise;
   format date date7.;
   label travel   = 'Travel Expenses within U.S.'
         advrtise = 'Advertising'
         salary   = 'Permanent Staff Salaries'
         insure   = 'Benefits Including Insurance';
datalines;
A 31JAN1989 95000  10500  2000 6500
B 31JAN1989 668000 112000 5600 90000
C 31JAN1989 105000 6800   9000 18500
A 28FEB1989 91000  8200   1900 12000
B 28FEB1989 602000 99000  5500 86000
C 28FEB1989 96000  6000   8500 16000
;
```

You can get a listing of the data set by using the PRINT procedure, as follows:

```
title 'Listing of Monthly Divisional Expense Data';
proc print data=report;
run;
```

Figure 9.2 Listing of Data Set by PROC PRINT

Listing of Monthly Divisional Expense Data

Obs	compdiv	date	salary	travel	insure	advrtise
1	A	31JAN89	95000	10500	2000	6500
2	B	31JAN89	668000	112000	5600	90000
3	C	31JAN89	105000	6800	9000	18500
4	A	28FEB89	91000	8200	1900	12000
5	B	28FEB89	602000	99000	5500	86000
6	C	28FEB89	96000	6000	8500	16000

To get a simple, transposed report of the same data set, use the following PROC COMPUTAB statement:

```
title 'Monthly Divisional Expense Report';
proc computab data=report;
run;
```

Figure 9.3 Listing of Data Set by PROC COMPUTAB

Monthly Divisional Expense Report

	COL1	COL2	COL3	COL4	COL5	COL6
compdiv	A	B	C	A	B	C
date	31JAN89	31JAN89	31JAN89	28FEB89	28FEB89	28FEB89
salary	95000.00	668000.00	105000.00	91000.00	602000.00	96000.00
travel	10500.00	112000.00	6800.00	8200.00	99000.00	6000.00
insure	2000.00	5600.00	9000.00	1900.00	5500.00	8500.00
advrtise	6500.00	90000.00	18500.00	12000.00	86000.00	16000.00

Using PROC COMPUTAB

The COMPUTAB procedure is best understood by examining the following features:

- definition of the report layout with ROWS and COLUMNS statements
- input block
- row blocks
- column blocks

PROC COMPUTAB builds a table according to the specifications in the ROWS and COLUMNS statements. Row names and column names define the rows and columns of the table. Options in the ROWS and COLUMNS statements control titles, spacing, and formatting.

The input block places input observations into the appropriate columns of the report. It consists of programming statements used to select observations to be included in the report, to determine the column into which the observation should be placed, and to calculate row and column values that are not in the input data set.

Row blocks and column blocks perform operations on the values of rows and columns of the report after the input block has executed. Row blocks are a block of programming statements labeled ROW*xxxxx*: that create or modify row values; column blocks are a block of programming statements labeled COL*xxxxx*: that create or modify column values. Row and column blocks can make multiple passes through the report for final calculations.

For most reports, these features are sufficient. More complicated applications might require knowledge of the program data vector and the COMPUTAB data table. These topics are discussed in the section "Details: COMPUTAB Procedure" on page 477.

Defining Report Layout

ROWS and COLUMNS statements define the rows and columns of the report. The order of row and column names in these statements determines the order of rows and columns in the report. Additional ROWS and COLUMNS statements can be used to specify row and column formatting options.

The following statements select and order the variables from the input data set and produce the report in Figure 9.4:

```
proc computab data=report;
   rows travel advrtise salary;
run;
```

Figure 9.4 Report Produced Using a ROWS Statement

	COL1	COL2	COL3	COL4	COL5	COL6
TRAVEL	10500.00	112000.00	6800.00	8200.00	99000.00	6000.00
ADVRTISE	6500.00	90000.00	18500.00	12000.00	86000.00	16000.00
SALARY	95000.00	668000.00	105000.00	91000.00	602000.00	96000.00

When a COLUMNS statement is not specified, each observation becomes a new column. If you use a COLUMNS statement, you must specify to which column each observation belongs by using program statements for column selection. When more than one observation is selected for the same column, values are summed.

The following statements produce Figure 9.5:

```
proc computab data= report;
   rows travel advrtise salary insure;
   columns a b c;
   *----select column for company division,
        based on value of compdiv----*;
   a = compdiv = 'A';
   b = compdiv = 'B';
   c = compdiv = 'C';
run;
```

The statement A=COMPDIV='A'; illustrates the use of logical operators as a selection technique. If COMPDIV='A', then the current observation is added to the A column. For more information, see *SAS Language: Reference, Version 6, First Edition*.

Figure 9.5 Report Produced Using ROWS and COLUMNS Statements

	A	B	C
TRAVEL	18700.00	211000.00	12800.00
ADVRTISE	18500.00	176000.00	34500.00
SALARY	186000.00	1270000.0	201000.00
INSURE	3900.00	11100.00	17500.00

Adding Computed Rows and Columns

In addition to the variables and observations in the input data set, you can create additional rows or columns by using SAS programming statements in PROC COMPUTAB. You can do the following:

- modify input data and select columns in the input block
- create or modify columns in column blocks
- create or modify rows in row blocks

The following statements add one computed row (SUM) and one computed column (TOTAL) to the report in Figure 9.5. In the input block the logical operators indicate the observations that correspond to each column of the report. After the input block reads in the values from the input data set, the column block creates the column variable TOTAL by summing the columns A, B, and C. The additional row variable, SUM, is calculated as the sum of the other rows. The result is shown in Figure 9.6.

```
proc computab data= report;
   rows travel advrtise salary insure sum;
   columns a b c total;
   a = compdiv = 'A';
   b = compdiv = 'B';
   c = compdiv = 'C';
   colblk: total = a + b + c;
   rowblk: sum   = travel + advrtise + salary + insure;
run;
```

Figure 9.6 Report Produced Using Row and Column Blocks

	A	B	C	TOTAL
TRAVEL	18700.00	211000.00	12800.00	242500.00
ADVRTISE	18500.00	176000.00	34500.00	229000.00
SALARY	186000.00	1270000.0	201000.00	1657000.0
INSURE	3900.00	11100.00	17500.00	32500.00
SUM	227100.00	1668100.0	265800.00	2161000.0

Enhancing the Report

To enhance the appearance of the final report, you can use the following:

- TITLE and LABEL statements
- column headings
- row titles
- row and column spacing control
- overlining and underlining

- formats

The following example enhances the report in the previous example. The enhanced report is shown in Figure 9.7.

The TITLE statement assigns the report title. The column headings in Figure 9.7 (Division A, Division B, and Division C) are assigned in the first COLUMNS statement by "Division" _name_ specification. The second COLUMNS statement assigns the column heading ("All" "Divisions"), sets the spacing (+4), and formats the values in the TOTAL column.

Similarly, the first ROWS statement uses previously assigned variable labels for row labels by specifying the _LABEL_ option. The DUL option in the second ROWS statement double-underlines the INSURE row. The third ROWS statement assigns the row label TOTAL to the SUM row.

```
title 'Year to Date Expenses';

proc computab cwidth=8 cdec=0;

   columns a  b  c / 'Division' _name_;
   columns total / 'All' 'Divisions' +4 f=dollar10.0;

   rows travel advrtise salary insure / _label_;
   rows insure / dul;
   rows sum / 'Total';

   a = compdiv = 'A';
   b = compdiv = 'B';
   c = compdiv = 'C';

   colblk: total = a + b + c;
   rowblk: sum   = travel + advrtise + salary + insure;
run;
```

Figure 9.7 Report Produced by PROC COMPUTAB Using Enhancements

Year to Date Expenses

	Division A	Division B	Division C	All Divisions
Travel Expenses within U.S.	18700	211000	12800	$242,500
Advertising	18500	176000	34500	$229,000
Permanent Staff Salaries	186000	1270000	201000	$1,657,000
Benefits Including Insurance	3900	11100	17500	$32,500
Total	227100	1668100	265800	$2,161,000

Syntax: COMPUTAB Procedure

The following statements are used with the COMPUTAB procedure:

PROC COMPUTAB *options* **;**
BY *variables* **;**
COLUMNS *column-list / options* **;**
ROWS *row-list / options* **;**
CELL *cell-names* / **FORMAT=** *format* **;**
INIT *anchor-name locator-name values locator-name values* **;**
programming *statements* **;**
SUMBY *variables* **;**

The PROC COMPUTAB statement is the only required statement. The COLUMNS, ROWS, and CELL statements define the COMPUTAB table. The INIT statement initializes the COMPUTAB table values. Programming statements process COMPUTAB table values. The BY and SUMBY statements provide BY-group processing and consolidation (roll up) tables.

Functional Summary

Table 9.1 summarizes the COMPUTAB procedure statements and options.

Table 9.1 COMPUTAB Functional Summary

Description	Statement	Option
Statements		
Specify BY-group processing	BY	
Specify the format for printing a particular cell	CELL	
Define columns of the report	COLUMNS	
Initialize values in the COMPUTAB data table	INIT	
Define rows of the report	ROWS	
Produce consolidation tables	SUMBY	
Data Set Options		
Specify the input data set	COMPUTAB	DATA=
Specify an output data set	COMPUTAB	OUT=
Input Options		
Specify a value to use when testing for 0	COMPUTAB	FUZZ=
Initialize the data table to missing	COMPUTAB	INITMISS
Prevent the transposition of the input data set	COMPUTAB	NOTRANS
Printing Control Options		
Suppress printing of the listed columns	COLUMNS	NOPRINT
Suppress all printed output	COMPUTAB	NOPRINT
Suppress printing of the listed rows	ROWS	NOPRINT

Table 9.1 *continued*

Description	Statement	Option
Suppress columns with all 0 or missing values	COLUMNS	NOZERO
Suppress rows with all 0 or missing values	ROWS	NOZERO
List option values	COMPUTAB	OPTIONS
Overprint titles, values, overlining, and underlining associated with listed rows	ROWS	OVERPRINT
Print only consolidation tables	COMPUTAB	SUMONLY
Report Formatting Options		
Specify number of decimal places to print	COMPUTAB	CDEC=
Specify number of spaces between columns	COMPUTAB	CSPACE=
Specify column width for the report	COMPUTAB	CWIDTH=
Overline the listed rows with double lines	ROWS	DOL
Underline the listed rows with double lines	ROWS	DUL
Specify a format for printing the cell values	CELL	FORMAT=
Specify a format for printing column values	COLUMNS	FORMAT=
Specify a format for printing the row values	ROWS	FORMAT=
Left-align the column headings	COLUMNS	LJC
Left-justify character rows in each column	ROWS	LJC
Specify indention from the margin	ROWS	+n
Suppress printing of row titles on later pages	COMPUTAB	NORTR
Overline the listed rows with a single line	ROWS	OL
Start a new page before printing the listed rows	ROWS	_PAGE_
Specify number of spaces before row titles	COMPUTAB	RTS=
Print a blank row	ROWS	SKIP
Underline the listed rows with a single line	ROWS	UL
Specify text to print if column is 0 or missing	COLUMNS	ZERO=
Specify text to print if row is 0 or missing	ROWS	ZERO=
Row and Column Type Options		
Specify that columns contain character data	COLUMNS	CHAR
Specify that rows contain character data	ROWS	CHAR
Options for Column Headings		
Specify literal column headings	COLUMNS	‘column heading’
Use variable labels in column headings	COLUMNS	_LABEL_
Specify a master title centered over columns	COLUMNS	MTITLE=
Use column names in column headings	COLUMNS	_NAME_
Options for Row Titling		
Use labels in row titles	ROWS	_LABEL_
Use row names in row titles	ROWS	_NAME_
Specify literal row titles	ROWS	‘row title’

The following sections describe the PROC COMPUTAB statement and then describe the other statements in

alphabetical order.

PROC COMPUTAB Statement

PROC COMPUTAB *options* **;**

The following options can be used in the PROC COMPUTAB statement.

Input Options

DATA=*SAS-data-set*
names the SAS data set that contains the input data. If this option is not specified, the last created data set is used. If you are not reading a data set, use DATA=_NULL_.

FUZZ=*value*
specifies the criterion to use when testing for 0. If a number is within the FUZZ= value of 0, the number is set to 0.

INITMISS
initializes the COMPUTAB data table to missing rather than to 0. The COMPUTAB data table is discussed further in the section "Details: COMPUTAB Procedure" on page 477.

NOTRANSPOSE
NOTRANS
prevents the transposition of the input data set in building the COMPUTAB report tables. The NOTRANS option causes input data set variables to appear among the columns of the report rather than among the rows.

Report Formatting Options

The formatting options specify default values. Many of the formatting options can be modified for specific columns in COLUMNS statements and for rows in ROWS statements.

CDEC=*d*
specifies the default number of decimal places for printing. The default is CDEC=2. See the FORMAT= option in the sections on the COLUMN, ROWS, and CELL statements later in this chapter.

CSPACE=*n*
specifies the default number of spaces to insert between columns. The value of the CSPACE= option is used as the default value for the +*n* option in the COLUMNS statement. The default is CSPACE=2.

CWIDTH=*w*
specifies a default column width for the report. The default is CWIDTH=9. The width must be in the range of 1–32.

NORTR
suppresses the printing of row titles on each page. The NORTR (no row-title repeat) option is useful to suppress row titles when report pages are to be joined together in a larger report.

RTS=*n*
specifies the default number of spaces to be inserted before row titles when row titles appear after the first printed column. The default row-title spacing is RTS=2.

Output Options

NOPRINT
suppresses all printed output. Use the NOPRINT option with the OUT= option to produce an output data set but no printed reports.

OPTIONS
lists PROC COMPUTAB option values. The option values appear on a separate page preceding the procedure's normal output.

OUT=*SAS-data-set*
names the SAS data set to contain the output data. For a description of the structure of the output data set, see the section "Details: COMPUTAB Procedure" on page 477.

SUMONLY
suppresses printing of detailed reports. When the SUMONLY option is used, PROC COMPUTAB generates and prints only consolidation tables as specified in the SUMBY statement.

BY Statement

BY *variables* **;**

A BY statement can be used with PROC COMPUTAB to obtain separate reports for observations in groups defined by the BY variables. At the beginning of each BY group, before PROC COMPUTAB reads any observations, all table values are set to 0 unless the INITMISS option or an INIT statement is specified.

CELL Statement

CELL *cell-names* / **FORMAT=***format* **;**

The CELL statement specifies the format for printing a particular cell in the COMPUTAB data table. Cell variable names are compound SAS names of the form *name1.name2*, where *name1* is the name of a row variable and *name2* is the name of a column variable. Formats specified with the FORMAT= option in CELL statements override formats specified in ROWS and COLUMNS statements.

COLUMNS Statement

COLUMNS *column-list / options* **;**

COLUMNS statements define the columns of the report. The COLUMNS statement can be abbreviated COLUMN, COLS, or COL.

The specified column names must be valid SAS names. Abbreviated lists, as described in *SAS Language: Reference*, can also be used.

You can use as many COLUMNS statements as you need. A COLUMNS statement can describe more than one column, and one column of the report can be described with several different COLUMNS statements. The order of the columns on the report is determined by the order of appearance of column names in COLUMNS statements. The first occurrence of the name determines where in the sequence of columns a particular column is located.

The following options can be used in the COLUMNS statement.

Option for Column Type

CHAR
indicates that the columns contain character data.

Options for Column Headings

You can specify as many lines of column headings as needed. If no options are specified, the column names from the COLUMNS statement are used as column headings. Any or all of the following options can be used in a column heading:

"column heading"
specifies that the characters enclosed in quotes are to be used in the column heading for the variable or variables listed in the COLUMNS statement. Each quoted string appears on a separate line of the heading.

LABEL
uses labels, if provided, in the heading for the column or columns listed in the COLUMNS statement. If a label has not been provided, the name of the column is used. For information about the LABEL statement, see *SAS Language: Reference*.

MTITLE=*"text"*
specifies that the string of characters enclosed in quotes is a master title to be centered over all the columns listed in the COLUMNS statement. The list of columns must be consecutive. Special characters ("+", "*", "=", and so forth) placed on either side of the text expand to fill the space. The MTITLE= option can be abbreviated M=.

NAME
uses column names in column headings for the columns listed in the COLUMNS statement. This option allows headings (*"text"*) and names to be combined in a heading.

Options for Column Print Control

+n

inserts *n* spaces before each column listed in the COLUMNS statement. The default spacing is given by the CSPACE= option in the PROC COMPUTAB statement.

NOPRINT

suppresses printing of columns listed in the COLUMNS statement. This option enables you to create columns to be used for intermediate calculations without having those columns printed.

NOZERO

suppresses printing of columns when all the values in a column are 0 or missing. Numbers within the FUZZ= value of 0 are treated as 0.

PAGE

starts a new page of the report before printing each of the columns in the list that follows.

TITLES

prints row titles before each column in the list. The _TITLES_ option can be abbreviated as _TITLE_.

Options for Column Formatting

Column formats override row formats for particular table cells only when the input data set is not transposed (when the NOTRANS option is specified).

FORMAT=*format*

specifies a format for printing the values of the columns listed in the COLUMNS statement. The FORMAT= option can be abbreviated F=.

LJC

left-justifies the column headings for the columns listed. By default, columns are right-justified. When the LJC (left-justify character) option is used, any character row values in the column are also left-justified rather than right-justified.

ZERO=*"text"*

substitutes *"text"* when the value in the column is 0 or missing.

INIT Statement

INIT *anchor-name [locator-name] values [locator-name values]* **;**

The INIT statement initializes values in the COMPUTAB data table at the beginning of each execution of the procedure and at the beginning of each BY group if a BY statement is present.

The INIT statement in the COMPUTAB procedure is similar in function to the RETAIN statement in the DATA step, which initializes values in the program data vector. The INIT statement can be used at any point after the variable to which it refers has been defined in COLUMNS or ROWS statements. Each INIT statement initializes one row or column. Any number of INIT statements can be used.

The first term after the keyword INIT, *anchor-name*, anchors initialization to a row or column. If *anchor-name* is a row name, then all *locator-name* values in the statement are columns of that row. If *anchor-name* is a column name, then all *locator-name* values in the statement are rows of that column.

The following terms appear in the INIT statement:

anchor-name names the row or column in which values are to be initialized. This term is required.

locator-name identifies the starting column in the row (or starting row in the column) into which values are to be placed. For example, in a table with a row SALES and a column for each month of the year, the following statement initializes values for columns JAN, FEB, and JUN:

```
init sales jan 500 feb 600 jun 800;
```

If you do not specify *locator-name* values, the first value is placed into the first row or column, the second value into the second row or column, and so on. For example, the following statement assigns 500 to column JAN, 600 to FEB, and 450 to MAR:

```
init sales 500 600 450;
```

+n specifies the number of columns in a row (or rows in a column) that are to be skipped when initializing values. For example, the following statement assigns 500 to JAN and 900 to JUL:

```
init sales jan 500 +5 900;
```

*n*value* assigns *value* to *n* columns in the row (or rows in the column). For example, both of the following statements assign 500 to columns JAN through JUN and 1000 to JUL through DEC:

```
init sales jan 6*500 jul 6*1000;
```

```
init sales 6*500 6*1000;
```

ROWS Statement

ROWS *row-list / options* **;**

ROWS statements define the rows of the report. The ROWS statement can be abbreviated ROW.

The specified row names must be valid SAS names. Abbreviated lists, as described in *SAS Language: Reference*, can also be used.

You can use as many ROWS statements as you need. A ROWS statement can describe more than one row, and one row of the report can be described with several different ROWS statements. The order of the rows in the report is determined by the order of appearance of row names in ROWS statements. The first occurrence of the name determines where the row is located.

The following options can be used in the ROWS statement.

Option for Row Type

CHAR
indicates that the rows contain character data.

Options for Row Titling

You can specify as many lines of row titles as needed. If no options are specified, the names from the ROWS statement are used as row titles. Any or all of the following options can be used in a row title:

LABEL
uses labels as row titles for the row or rows listed in the ROWS statement. If a label is not provided, the name of the row is substituted. For more information about the LABEL statement, see *SAS Language: Reference*.

NAME
uses row names in row titles for the row or rows listed in the ROWS statement.

"row title"
specifies that the string of characters enclosed in quotes is to be used in the row title for the row or rows listed in the ROWS statement. Each quoted string appears on a separate line of the heading.

Options for Row Print Control

+n
indents *n* spaces from the margin for the rows in the ROWS statement.

DOL
overlines the rows listed in the ROWS statement with double lines. Overlines are printed on the line before any row titles or data for the row.

DUL
underlines the rows listed in the ROWS statement with double lines. Underlines are printed on the line after the data for the row. A row can have both an underline and an overline option.

NOPRINT
suppresses printing of the rows listed in the ROWS statement. This option enables you to create rows to be used for intermediate calculations without having those rows printed.

NOZERO
suppresses the printing of a row when all the values are 0 or missing.

OL
overlines the rows listed in the ROWS statement with a single line. Overlines are printed on the line before any row titles or data for the row.

OVERPRINT
overprints titles, values, overlining, and underlining associated with rows listed in the ROWS statement. The OVERPRINT option can be abbreviated OVP. This option is valid only when the system option OVP is in effect. For more information about the OVP option, see *SAS Language: Reference*.

PAGE
starts a new page of the report before printing these rows.

SKIP
prints a blank line after the data lines for these rows.

UL
underlines the rows listed in the ROWS statement with a single line. Underlines are printed on the line after the data for the row. A row can have both an underline and an overline option.

Options for Row Formatting

Row formatting options take precedence over column-formatting options when the input data set is transposed. Row print width can never be wider than column width. Character values are truncated on the right.

FORMAT=*format*
specifies a format for printing the values of the rows listed in the ROWS statement. The FORMAT= option can be abbreviated as F=.

LJC
left-justifies character rows in each column.

ZERO=*"text"*
substitutes *"text"* when the value in the row is 0 or missing.

SUMBY Statement

SUMBY *variables* **;**

The SUMBY statement produces consolidation tables for variables whose names are in the SUMBY list. Only one SUMBY statement can be used.

To use a SUMBY statement, you must use a BY statement. The SUMBY and BY variables must be in the same relative order in both statements. For example:

```
by a b c;
sumby a b;
```

This SUMBY statement produces tables that consolidate over values of C within levels of B and over values of B within levels of A. Suppose A has values 1, 2; B has values 1, 2; and C has values 1, 2, 3. Table 9.2 indicates the consolidation tables produced by the SUMBY statement.

Table 9.2 Consolidation Tables Produced by the SUMBY Statement

SUMBY Consolidations	Consolidated BY Groups		
A=1, B=1	C=1	C=2	C=3
A=1, B=2	C=1	C=2	C=3
A=1	B=1, C=1 B=2, C=1	B=1, C=2 B=2, C=2	B=1, C=3 B=2, C=3
A=2, B=1	C=1	C=2	C=3
A=2, B=2	C=1	C=2	C=3
A=2	B=1, C=1 B=2, C=1	B=1, C=2 B=2, C=2	B=1, C=3 B=2, C=3

Two consolidation tables for B are produced for each value of A. The first table consolidates the three tables produced for the values of C while B is 1; the second table consolidates the three tables produced for C while B is 2.

Tables are similarly produced for values of A. Nested consolidation tables are produced for B (as described previously) for each value of A. Thus, this SUMBY statement produces a total of six consolidation tables in addition to the tables produced for each BY group.

To produce a table that consolidates the entire data set (the equivalent of using PROC COMPUTAB with neither BY nor SUMBY statements), use the special name _TOTAL_ as the first entry in the SUMBY variable list. For example:

```
sumby _total_ a b;
```

PROC COMPUTAB then produces consolidation tables for SUMBY variables as well as a consolidation table for all observations.

To produce only consolidation tables, use the SUMONLY option in the PROC COMPUTAB statement.

Programming Statements

You can use most SAS programming statements the same way you use them in the DATA step. Also, all DATA step functions can be used in the COMPUTAB procedure.

Lines written by the PUT statement are not integrated with the COMPUTAB report. PUT statement output is written to the SAS log.

The automatic variable _N_ can be used; its value is the number of observations read or the number read in the current BY group, if a BY statement is used. FIRST.*variable* and LAST.*variable* references cannot be used.

The following statements are also available in PROC COMPUTAB:

```
ABORT                    FORMAT
ARRAY                    GOTO
ATTRIB                   IF-THEN/ELSE
assignment statement     LABEL
CALL                     LINK
DELETE                   PUT
DO                       RETAIN
iterative DO             SELECT
DO UNTIL                 STOP
DO WHILE                 sum statement
END                      TITLE
FOOTNOTE
```

The programming statements can be assigned labels ROW*xxxxx*: or COL*xxxxx*: to indicate the start of a row and column block, respectively. Statements in a row block create or change values in all the columns in the specified rows. Similarly, statements in a column block create or change values in all the rows in the specified columns.

There is an implied RETURN statement before each new row or column block. Thus, the flow of execution does not leave the current row (column) block before the block repeats for all columns (rows.) Row and column variables and nonretained variables are initialized prior to each execution of the block.

The next COL*xxxxx*: label, ROW*xxxxx*: label, or the end of the PROC COMPUTAB step signals the end of a row (column) block. Column blocks and row blocks can be mixed in any order. In some cases, performing calculations in different orders can lead to different results.

For more information, see the sections “Program Flow Example” on page 477, “Order of Calculations” on page 480, and “Controlling Execution within Row and Column Blocks” on page 483.

Details: COMPUTAB Procedure

Program Flow Example

This example shows how the COMPUTAB procedure processes observations in the program working storage and the COMPUTAB data table (CDT).

Assume you have three years of figures for sales and cost of goods sold (CGS), and you want to determine total sales and cost of goods sold and calculate gross profit and the profit margin.

```
title 'Program Flow Example for PROC COMPUTAB';

data example;
   input year sales cgs;
datalines;
1988    83      52
1989   106      85
1990   120     114
;

proc computab data=example;

   columns c88 c89 c90 total;
   rows sales cgs gprofit pctmarg;

   /* calculate gross profit */
   gprofit = sales - cgs;

   /* select a column */
   c88 = year = 1988;
   c89 = year = 1989;
   c90 = year = 1990;

   /* calculate row totals for sales */
   /* and cost of goods sold */
   col: total = c88 + c89 + c90;

   /* calculate profit margin */
   row: pctmarg = gprofit / cgs * 100;
run;
```

Table 9.3 shows the CDT before any observation is read in. All the columns and rows are defined with the values initialized to 0.

Table 9.3 CDT before Any Input

	C88	C89	C90	TOTAL
SALES	0	0	0	0
CGS	0	0	0	0
GPROFIT	0	0	0	0
PCTMARG	0	0	0	0

When the first input is read in (YEAR=1988, SALES=83, and CGS=52), the input block puts the values for SALES and CGS in the C88 column since year=1988. Also the value for the gross profit for that year (GPROFIT) is calculated as indicated in the following statements:

```
gprofit = sales-cgs;
c88 = year = 1988;
c89 = year = 1989;
c90 = year = 1990;
```

Table 9.4 shows the CDT after the first observation is input.

Table 9.4 CDT after First Observation Input (C88=1)

	C88	C89	C90	TOTAL
SALES	83	0	0	0
CGS	52	0	0	0
GPROFIT	31	0	0	0
PCTMARG	0	0	0	0

Similarly, the second observation (YEAR=1989, SALES=106, CGS=85) is put in the second column, and the GPROFIT is calculated to be 21. The third observation (YEAR=1990, SALES=120, CGS=114) is put in the third column, and the GPROFIT is calculated to be 6. Table 9.5 shows the CDT after all observations are input.

Table 9.5 CDT after All Observations Input

	C88	C89	C90	TOTAL
SALES	83	106	120	0
CGS	52	85	114	0
GPROFIT	31	21	6	0
PCTMARG	0	0	0	0

After the input block is executed for each observation in the input data set, the first row or column block is processed. In this case, the column block is

```
col: total = c88 + c89 + c90;
```

The column block executes for each row, calculating the TOTAL column for each row. Table 9.6 shows the CDT after the column block has executed for the first row (TOTAL=83 + 106 + 120). The total sales for the three years is 309.

Table 9.6 CDT after Column Block Executed for First Row

	C88	C89	C90	TOTAL
SALES	83	106	120	309
CGS	52	85	114	0
GPROFIT	31	21	6	0
PCTMARG	0	0	0	0

Table 9.7 shows the CDT after the column block has executed for all rows and the values for total cost of goods sold and total gross profit have been calculated.

Table 9.7 CDT after Column Block Executed for All Rows

	C88	C89	C90	TOTAL
SALES	83	106	120	309
CGS	52	85	114	251
GPROFIT	31	21	6	58
PCTMARG	0	0	0	0

After the column block has been executed for all rows, the next block is processed. The row block is

```
row: pctmarg = gprofit / cgs * 100;
```

The row block executes for each column, calculating the PCTMARG for each year and the total (TOTAL column) for three years. Table 9.8 shows the CDT after the row block has executed for all columns.

Table 9.8 CDT after Row Block Executed for All Columns

	C88	C89	C90	TOTAL
SALES	83	106	120	309
CGS	52	85	114	251
GPROFIT	31	21	6	58
PCTMARG	59.62	24.71	5.26	23.11

Order of Calculations

The COMPUTAB procedure provides alternative programming methods for performing most calculations. New column and row values are formed by adding values from the input data set, directly or with modification, into existing columns or rows. New columns can be formed in the input block or in column blocks. New rows can be formed in the input block or in row blocks.

This example illustrates the different ways to collect totals. Table 9.9 is the total sales report for two products, SALES1 and SALES2, during the years 1988–1990. The values for SALES1 and SALES2 in columns C88, C89, and C90 come from the input data set.

Table 9.9 Total Sales Report

	C88	C89	C90	SALESTOT
SALES1	15	45	80	140
SALES2	30	40	50	120
YRTOT	45	85	130	260

The new column SALESTOT, which is the total sales for each product over three years, can be computed in several different ways:

- in the input block by selecting SALESTOT for each observation:

```
salestot = 1;
```

- in a column block:

```
coltot: salestot = c88 + c89 + c90;
```

In a similar fashion, the new row YRTOT, which is the total sales for each year, can be formed as follows:

- in the input block:

```
yrtot = sales1 + sales2;
```

- in a row block:

```
rowtot: yrtot = sales1 + sales2;
```

Performing some calculations in PROC COMPUTAB in different orders can yield different results, because many operations are not commutative. Be sure to perform calculations in the proper sequence. It might take several column and row blocks to produce the desired report values.

Notice that in the previous example, the grand total for all rows and columns is 260 and is the same whether it is calculated from row subtotals or column subtotals. It makes no difference in this case whether you compute the row block or the column block first.

However, consider the example in Table 9.10, where a new column and a new row are formed.

Table 9.10 Report Sensitive to Order of Calculations

	STORE1	STORE2	STORE3	MAX
PRODUCT1	12	13	27	27
PRODUCT2	11	15	14	15
TOTAL	23	28	41	?

The new column MAX contains the maximum value in each row, and the new row TOTAL contains the column totals. MAX is calculated in a column block:

```
col: max = max(store1,store2,store3);
```

TOTAL is calculated in a row block:

```
row: total = product1 + product2;
```

Notice that either of two values, 41 or 42, is possible for the element in column MAX and row TOTAL. If the row block is first, the value is the maximum of the column totals (41). If the column block is first, the value is the sum of the MAX values (42). Whether to compute a column block before a row block can be a critical decision.

Column Selection

The following discussion assumes that the NOTRANS option has not been specified. When NOTRANS is specified, this section applies to rows rather than columns.

If a COLUMNS statement appears in PROC COMPUTAB, a target column must be selected for the incoming observation. If there is no COLUMNS statement, a new column is added for each observation. When a COLUMNS statement is present and the selection criteria fail to designate a column, the current observation is ignored. Faulty column selection can result in columns or entire tables of 0s (or missing values if the INITMISS option is specified).

During execution of the input block, when an observation is read, its values are copied into row variables in the program data vector (PDV).

To select columns, use either the column variable names themselves or the special variable _COL_. Use the column names by setting a column variable equal to some nonzero value. The example in the section "Getting Started: COMPUTAB Procedure" on page 460 uses the logical expression COMPDIV= *value*, and the result is assigned to the corresponding column variable.

```
a = compdiv = 'A';
b = compdiv = 'B';
c = compdiv = 'C';
```

IF statements can also be used to select columns. The following statements are equivalent to the preceding example:

```
if      compdiv = 'A' then a = 1;
else if compdiv = 'B' then b = 1;
else if compdiv = 'C' then c = 1;
```

At the end of the input block for each observation, PROC COMPUTAB multiplies numeric input values by any nonzero selector values and adds the result to selected columns. Character values simply overwrite the contents already in the table. If more than one column is selected, the values are added to each of the selected columns.

Use the _COL_ variable to select a column by assigning the column number to it. The COMPUTAB procedure automatically initializes column variables and sets the _COL_ variable to 0 at the start of each execution of the input block. At the end of the input block for each observation, PROC COMPUTAB examines the value of _COL_. If the value is nonzero and within range, the row variable values are added to the CDT cells of the _COL_th column. For example:

```
title 'Column Selection Example for PROC COMPUTAB';

   data rept;
      input div sales cgs;
   datalines;
   2   106    85
   3   120   114
   1    83    52
   ;

proc computab data=rept;
   row div sales cgs;
   columns div1 div2 div3;
   _col_ = div;
run;
```

The code in this example places the first observation (DIV=2) in column 2 (DIV2), the second observation (DIV=3) in column 3 (DIV3), and the third observation (DIV=1) in column 1 (DIV1).

Controlling Execution within Row and Column Blocks

Row names, column names, and the special variables _ROW_ and _COL_ can be used to limit the execution of programming statements to selected rows or columns. A row block operates on all columns of the table for a specified row unless restricted in some way. Likewise, a column block operates on all rows for a specified column. Use column names or _COL_ in a row block to execute programming statements conditionally; use row names or _ROW_ in a column block.

For example, consider a simple column block that consists of only one statement:

```
col: total = qtr1 + qtr2 + qtr3 + qtr4;
```

This column block assigns a value to each row in the TOTAL column. As each row participates in the execution of a column block, the following changes occur:

- Its row variable in the program data vector is set to 1.
- The value of _ROW_ is the number of the participating row.
- The value from each column of the row is copied from the COMPUTAB data table to the program data vector.

To avoid calculating TOTAL on particular rows, use row names or _ROW_. For example:

```
col: if sales|cost then total = qtr1 + qtr2 + qtr3 + qtr4;
```

or

```
col: if _row_ < 3  then total = qtr1 + qtr2 + qtr3 + qtr4;
```

Row and column blocks can appear in any order, and rows and columns can be selected in each block.

Program Flow

This section describes in detail the different steps in PROC COMPUTAB execution.

Step 1: Define Report Organization and Set Up the COMPUTAB Data Table

Before the COMPUTAB procedure reads in data or executes programming statements, the columns list from the COLUMNS statements and the rows list from the ROWS statements are used to set up a matrix of all columns and rows in the report. This matrix is called the COMPUTAB data table (CDT). When you define columns and rows of the CDT, the COMPUTAB procedure also sets up corresponding variables in working storage called the program data vector (PDV) for programming statements. Data values reside in the CDT but are copied into the program data vector as they are needed for calculations.

Step 2: Select Input Data with Input Block Programming Statements

The input block copies input observations into rows or columns of the CDT. By default, observations go to columns; if the data set is not transposed (the NOTRANS option is specified), observations go to rows of the report table. The input block consists of all executable statements before any ROW*xxxxx*: or COL*xxxxx*: statement label. Use programming statements to perform calculations and select a given observation to be added into the report.

Input Block

The input block is executed once for each observation in the input data set. If there is no input data set, the input block is not executed. The program logic of the input block is as follows:

1. Determine which variables, row or column, are selector variables and which are data variables. Selector variables determine which rows or columns receive values at the end of the block. Data variables contain the values that the selected rows or columns receive. By default, column variables are selector variables and row variables are data variables. If the input data set is not transposed (the NOTRANS option is specified), the roles are reversed.
2. Initialize nonretained program variables (including selector variables) to 0 (or missing if the INITMISS option is specified). Selector variables are temporarily associated with a numeric data item supplied by the procedure. Using these variables to control row and column selection does not affect any other data values.
3. Transfer data from an observation in the data set to data variables in the PDV.
4. Execute the programming statements in the input block by using values from the PDV and storing results in the PDV.
5. Transfer data values from the PDV into the appropriate columns of the CDT. If a selector variable for a row or column has a nonmissing and nonzero value, multiply each PDV value for variables used in the report by the selector variable and add the results to the selected row or column of the CDT.

Step 3: Calculate Final Values by Using Column Blocks and Row Blocks

Column Blocks

A column block is executed once for each row of the CDT. The program logic of a column block is as follows:

1. Indicate the current row by setting the corresponding row variable in the PDV to 1 and the other row variables to missing. Assign the current row number to the special variable _ROW_.
2. Move values from the current row of the CDT to the respective column variables in the PDV.
3. Execute programming statements in the column block by using the column values in the PDV. Here new columns can be calculated and old ones adjusted.
4. Move the values back from the PDV to the current row of the CDT.

Row Blocks

A row block is executed once for each column of the CDT. The program logic of a row block is as follows:

1. Indicate the current column by setting the corresponding column variable in the PDV to 1 and the other column variables to missing. Assign the current column number to the special variable _COL_.
2. Move values from the current column of the CDT to the respective row variables in the PDV.
3. Execute programming statements in the row block by using the row values in the PDV. Here new rows can be calculated and old ones adjusted.
4. Move the values back from the PDV to the current column of the CDT.

See the section "Controlling Execution within Row and Column Blocks" on page 483.

Any number of column blocks and row blocks can be used. Each can include any number of programming statements.

The values of row variables and column variables are determined by the order in which different row-block and column-block programming statements are processed. These values can be modified throughout the COMPUTAB procedure, and final values are printed in the report.

Direct Access to Table Cells

You can insert or retrieve numeric values from specific table cells by using the special reserved name TABLE with row and column subscripts. References to the TABLE have the form

```
TABLE[ row-index, column-index ]
```

where *row-index* and *column-index* can be numbers, character literals, numeric variables, character variables, or expressions that produce a number or a name. If an index is numeric, it must be within range; if it is character, it must name a row or column.

References to TABLE elements can appear on either side of an equal sign in an assignment statement and can be used in a SAS expression.

Reserved Words

Certain words are reserved for special use by the COMPUTAB procedure, and using these words as variable names can lead to syntax errors or warnings. The reserved words are as follows:

- COLUMN
- COLUMNS
- COL
- COLS

- _COL_
- ROW
- ROWS
- _ROW_
- INIT
- _N_
- TABLE

Missing Values

Missing values for variables in programming statements are treated in the same way that missing values are treated in the DATA step; that is, missing values used in expressions propagate missing values to the result. For more information about missing values, see *SAS Language: Reference*.

Missing values in the input data are treated as follows in the COMPUTAB report table. At the end of the input block, either one or more rows or one or more columns can have been selected to receive values from the program data vector (PDV). Numeric data values from variables in the PDV are added into selected report table rows or columns. If a PDV value is missing, the values already in the selected rows or columns for that variable are unchanged by the current observation. Other values from the current observation are added to table values as usual.

OUT= Data Set

The output data set contains the following variables:

- BY variables
- a numeric variable _TYPE_
- a character variable _NAME_
- the column variables from the COMPUTAB data table

The BY variables contain values for the current BY group. For observations in the output data set from consolidation tables, the consolidated BY variables have missing values.

The special variable _TYPE_ is a numeric variable that can have one of three values: 1, 2, or 3. _TYPE_ = 1 indicates observations from the normal report table produced for each BY group; _TYPE_ = 2 indicates observations from the _TOTAL_ consolidation table; _TYPE_ = 3 indicates observations from other consolidation tables. _TYPE_ = 2 and _TYPE_ = 3 observations have one or more BY variables with missing values.

The special variable _NAME_ is a character variable of length 8 that contains the row or column name associated with the observation from the report table. If the input data set is transposed, _NAME_ contains column names; otherwise, _NAME_ contains row names.

If the input data set is transposed, the remaining variables in the output data set are row variables from the report table. They are column variables if the input data set is not transposed.

NOTRANS Option

The NOTRANS option in the PROC COMPUTAB statement prevents the transposition of the input data set. The NOTRANS option affects the input block, the precedence of row and column options, and the structure of the output data set if the OUT= option is specified.

When the input data set is transposed, input variables are among the rows of the COMPUTAB report, and observations compose columns. The reverse is true if the data set is not transposed; therefore, the input block must select rows to receive data values, and input variables are among the columns.

Variables from the input data set dominate the format specification and data type. When the input data set is transposed, input variables are among the rows of the report, and row options take precedence over column options. When the input data set is not transposed, input variables are among the columns, and column options take precedence over row options.

Variables for the output data set are taken from the dimension (row or column) that contains variables from the input data set. When the input data set is transposed, this dimension is the row dimension; otherwise, the output variables come from the column dimension.

Examples: COMPUTAB Procedure

Example 9.1: Using Programming Statements

This example illustrates two ways of operating on the same input variables and producing the same tabular report. To simplify the example, no report enhancements are shown.

The manager of a hotel chain wants a report that shows the number of bookings at its hotels in each of four cities, the total number of bookings in the current quarter, and the percentage of the total coming from each location for each quarter of the year. Input observations contain the following variables: REPTDATE (report date), LA (number of bookings in Los Angeles), ATL (number of bookings in Atlanta), CH (number of bookings in Chicago), and NY (number of bookings in New York).

The following DATA step creates the SAS data set BOOKINGS:

```
title 'Using Programming Statements in PROC COMPUTAB';

data bookings;
   input reptdate date9. la atl ch ny;
datalines;
```

```
01JAN1989 100 110 120 130
01FEB1989 140 150 160 170
01MAR1989 180 190 200 210
01APR1989 220 230 240 250
01MAY1989 260 270 280 290
01JUN1989 300 310 320 330
01JUL1989 340 350 360 370

```

The following PROC COMPUTAB statements select columns by setting _COL_ to an appropriate value. The PCT1, PCT2, PCT3, and PCT4 columns represent the percentage contributed by each city to the total for the quarter. These statements produce Output 9.1.1.

```
proc computab data=bookings cspace=1 cwidth=6;

   columns qtr1 pct1 qtr2 pct2 qtr3 pct3 qtr4 pct4;
   columns qtr1-qtr4 / format=6.;
   columns pct1-pct4 / format=6.2;
   rows la atl ch ny total;

   /* column selection */
   _col_ = qtr( reptdate ) * 2 - 1;

   /* copy qtr column values temporarily into pct columns */
   colcopy:
      pct1 = qtr1;
      pct2 = qtr2;
      pct3 = qtr3;
      pct4 = qtr4;

   /* calculate total row for all columns */
   /* calculate percentages for all rows in pct columns only  */
   rowcalc:
      total = la + atl + ch + ny;
      if mod( _col_, 2 ) = 0 then do;
         la  = la  / total * 100;
         atl = atl / total * 100;
         ch  = ch  / total * 100;
         ny  = ny  / total * 100;
         total = 100;
         end;
run;
```

Output 9.1.1 Quarterly Report of Hotel Bookings

Using Programming Statements in PROC COMPUTAB

	QTR1	PCT1	QTR2	PCT2	QTR3	PCT3	QTR4	PCT4
LA	420	22.58	780	23.64	1140	24.05	1500	24.27
ATL	450	24.19	810	24.55	1170	24.68	1530	24.76
CH	480	25.81	840	25.45	1200	25.32	1560	25.24
NY	510	27.42	870	26.36	1230	25.95	1590	25.73
TOTAL	1860	100.00	3300	100.00	4740	100.00	6180	100.00

Using the same input data, the next set of statements shows the usefulness of arrays in allowing PROC COMPUTAB to work in two directions at once. Arrays in larger programs can both reduce the amount of program source code and simplify otherwise complex methods of referring to rows and columns. The same report as in Output 9.1.1 is produced.

```
proc computab data=bookings cspace=1 cwidth=6;

   columns qtr1 pct1 qtr2 pct2 qtr3 pct3 qtr4 pct4;
   columns qtr1-qtr4 / format=6.;
   columns pct1-pct4 / format=6.2;
   rows la atl ch ny total;

   array pct[4] pct1-pct4;
   array qt[4] qtr1-qtr4;
   array rowlist[5] la atl ch ny total;

   /* column selection */
   _col_ = qtr(reptdate) * 2 - 1;

   /* copy qtr column values temporarily into pct columns */
   colcopy:
      do i = 1 to 4;
         pct[i] = qt[i];
         end;

   /* calculate total row for all columns */
   /* calculate percentages for all rows in pct columns only */

   rowcalc:
      total = la + atl + ch + ny;
      if mod(_col_,2) = 0 then
         do i = 1 to 5;
            rowlist[i] = rowlist[i] / total * 100;
         end;
run;
```

Example 9.2: Enhancing a Report

This example shows how a report can be enhanced from a simple listing to a complex report. The simplest COMPUTAB report is a transposed listing of the data in the SAS data set INCOMREP shown in Output 9.2.1. To produce this output, nothing is specified except the PROC COMPUTAB statement and a TITLE statement.

```
title 'Enhancing a Report in PROC COMPUTAB';

data incomrep;
   length type $ 8;
   input type :$8. date :monyy7.
         sales retdis tcos selling randd
         general admin deprec other taxes;
   format date monyy7.;
datalines;

taxes	510.00	480.00	520.00	500.00	490.00

To exclude the budgeted values from your report, select columns for ACTUAL observations only. To remove unwanted variables, specify the variables you want in a ROWS statement.

```
title 'Column Selection by Month';

proc computab data=incomrep;
   rows sales--other;
```

```
   columns jana feba mara;
   mnth = month(date);
   if type = 'ACTUAL';
      jana = mnth = 1;
      feba = mnth = 2;
      mara = mnth = 3;
run;
```

The report is shown in Output 9.2.2.

Output 9.2.2 Report That Uses Column Selection Techniques

Column Selection by Month

	JANA	FEBA	MARA
sales	4900.00	5100.00	0.00
retdis	505.00	480.00	0.00
tcos	2100.00	2400.00	0.00
selling	430.00	510.00	0.00
randd	130.00	110.00	0.00
general	410.00	390.00	0.00
admin	200.00	230.00	0.00
deprec	14.00	15.00	0.00
other	-8.00	2.00	0.00

To complete the report, compute new rows from existing rows. This is done in a row block (although it can also be done in the input block). Add a new column (QTR1) that accumulates all the actual data. The NOZERO option suppresses the zero column for March. The output produced by these statements is shown in Output 9.2.3.

```
title 'Completing the Report';

proc computab data=incomrep;

   /* add a new column to be selected */
   /* qtr1 column will be selected several times */
   columns actual1-actual3 qtr1 / nozero;
   array collist[3] actual1-actual3;
   rows sales retdis netsales tcos grosspft selling randd general
        admin deprec operexp operinc other taxblinc taxes netincom;

   if type='ACTUAL';
   i = month(date);
   if i <= 3 then qtr1 = 1;
   collist[i]=1;

   rowcalc:
      if sales = . then return;
      netsales = sales - retdis;
      grosspft = netsales - tcos;
      operexp  = selling + randd + general + admin + deprec;
      operinc  = grosspft - operexp;
      taxblinc = operinc + other;
```

```
      netincom = taxblinc - taxes;
run;
```

Output 9.2.3 Report That Uses Techniques to Compute New Rows

Completing the Report

	ACTUAL1	ACTUAL2	QTR1
SALES	4900.00	5100.00	10000.00
RETDIS	505.00	480.00	985.00
NETSALES	4395.00	4620.00	9015.00
TCOS	2100.00	2400.00	4500.00
GROSSPFT	2295.00	2220.00	4515.00
SELLING	430.00	510.00	940.00
RANDD	130.00	110.00	240.00
GENERAL	410.00	390.00	800.00
ADMIN	200.00	230.00	430.00
DEPREC	14.00	15.00	29.00
OPEREXP	1184.00	1255.00	2439.00
OPERINC	1111.00	965.00	2076.00
OTHER	-8.00	2.00	-6.00

Example 9.3: Comparison of Actual and Budget

This example shows a more complex report that compares the actual data with the budgeted values. The same input data as in the previous example is used.

The report produced by these statements is shown in Output 9.3.1. The report shows the values for the current month and the year-to-date totals for budgeted amounts, actual amounts, and the actuals as a percentage of the budgeted amounts. The data have the values for January and February. Therefore, the CURMO variable (current month) in the RETAIN statement is set to 2. The values for the observations where the month of the year is 2 (February) are accumulated for the current month values. The year-to-date values are accumulated from those observations where the month of the year is less than or equal to 2 (January and February).

Example 9.4: Consolidations

This example consolidates product tables by region and region tables by corporate division. Output 9.4.1 shows the North Central and Northeast regional summaries for the Equipment division for the first quarter. Output 9.4.2 shows the profit summary for the Equipment division. Similar tables for the Publishing division are produced but not shown here.

Example 9.5: Creating an Output Data Set

This example uses data and reports similar to those in Example 9.3 to illustrate the creation of an output data set.

```
title 'Creating an Output Data Set in PROC COMPUTAB';

data product;
   input pcode div region month sold revenue recd cost;
datalines;
1 1 1 1 56 5600 29 2465
1 1 1 2 13 1300 30 2550
1 1 1 3 17 1700 65 5525

   ... more lines ...

proc sort data=product out=sorted;
   by div region;
run;
```

```
/* create data set, profit */
proc computab data=sorted notrans out=profit noprint;
   by div region;
   sumby div;

   /* specify order of rows and row titles */
   row     jan feb mar qtr1;
   row     apr may jun qtr2;
   row     jul aug sep qtr3;
   row     oct nov dec qtr4;

   /* specify order of columns and column titles */
   columns sold revenue recd cost profit pctmarg;

   /* select row for appropriate month */
   _row_ = month + ceil( month / 3 ) - 1;

   /* calculate quarterly summary rows */
   rowcalc:
      qtr1 = jan + feb + mar;
      qtr2 = apr + may + jun;
      qtr3 = jul + aug + sep;
      qtr4 = oct + nov + dec;

   /* calculate profit columns */
   colcalc:
      profit = revenue - cost;
      if cost > 0 then pctmarg = profit / cost * 100;
run;

/* make a partial listing of the output data set */
options linesize=96;
proc print data=profit(obs=10) noobs;
run;
```

Because the NOTRANS option is specified, column names become variables in the data set. REGION has missing values in the output data set for observations associated with consolidation tables. The output data set PROFIT, in conjunction with the option NOPRINT, illustrates how you can use the computational features of PROC COMPUTAB for creating additional rows and columns as in a spreadsheet without producing a report. Output 9.5.1 shows a partial listing of the output data set PROFIT.

Output 9.5.1 Partial Listing of the PROFIT Data Set

Example 9.6: Cash Flows

The COMPUTAB procedure can be used to model cash flows from one time period to the next. The RETAIN statement is useful for enabling a row or column to contribute one of its values to its successor. Financial functions such as IRR (internal rate of return) and NPV (net present value) can be used on PROC COMPUTAB table values to provide a more comprehensive report. The following statements produce Output 9.6.1:

```

Overview: COPULA Procedure

A multivariate distribution for a random vector contains a description of both the marginal distributions and their dependence structure. A copula approach to formulating a multivariate distribution provides a way to isolate the description of the dependence structure from the marginal distributions. A copula is a function that combines marginal distributions of variables into a specific multivariate distribution. All of the one-dimensional marginals in the multivariate distribution are the cumulative distribution functions of the factors. Copulas help perform large-scale multivariate simulation from separate models, each of which can be fitted using different, even nonnormal, distributional specifications.

The COPULA procedure enables you to fit multivariate distributions or copulas from a given sample data set. You can do the following:

- estimate the parameters for a specified copula type
- simulate a given copula
- plot dependent relationships among the variables

The following types of copulas are supported:

- normal copula
- *t* copula
- Clayton copula
- Gumbel copula
- Frank copula

Getting Started: COPULA Procedure

The following example illustrates the use of PROC COPULA. The data used are daily returns on several major stocks. The main purpose of this example is to estimate the joint distribution of stock returns and then simulate from this distribution a new sample of specified size.

Figure 10.1 shows the first 10 observations of the daily stock return data set.

Figure 10.1 First 10 Observations of Daily Returns

10	01/16/2008	-0.022587	-0.015021	-0.001955	0.002316	-0.021336

The following statements fit a normal copula to the returns data (with the FIT statement) and create a new SAS data set that contains parameter estimates of the model. The VAR statement specifies the list of variables, which in this case are the daily returns of five large company stocks.

```
/* Copula estimation */
proc copula data = returns;
   var ret_ibm ret_msft ret_bp ret_ko ret_duk;
   fit normal / outcopula=estimates;
run;
```

The first table in Figure 10.2 shows some general information about the copula fitting procedure: the number of observations, the name of the input data set, the type of model, and the correlation matrix.

Figure 10.2 Copula Estimation: Fit Summary and Correlation Matrix

The COPULA Procedure

Model Fit Summary	
Number of Observations	603
Data Set	WORK.RETURNS
Copula Type	Normal

Correlations Matrix					
	ret_ibm	ret_msft	ret_bp	ret_ko	ret_duk
ret_ibm	1.0000	0.6232	0.5294	0.4725	0.4902
ret_msft	0.6232	1.0000	0.5229	0.5015	0.4567
ret_bp	0.5294	0.5229	1.0000	0.3980	0.4378
ret_ko	0.4725	0.5015	0.3980	1.0000	0.5283
ret_duk	0.4902	0.4567	0.4378	0.5283	1.0000

Next, the following statements restrict the data set to only those columns that contain correlation parameter estimates:

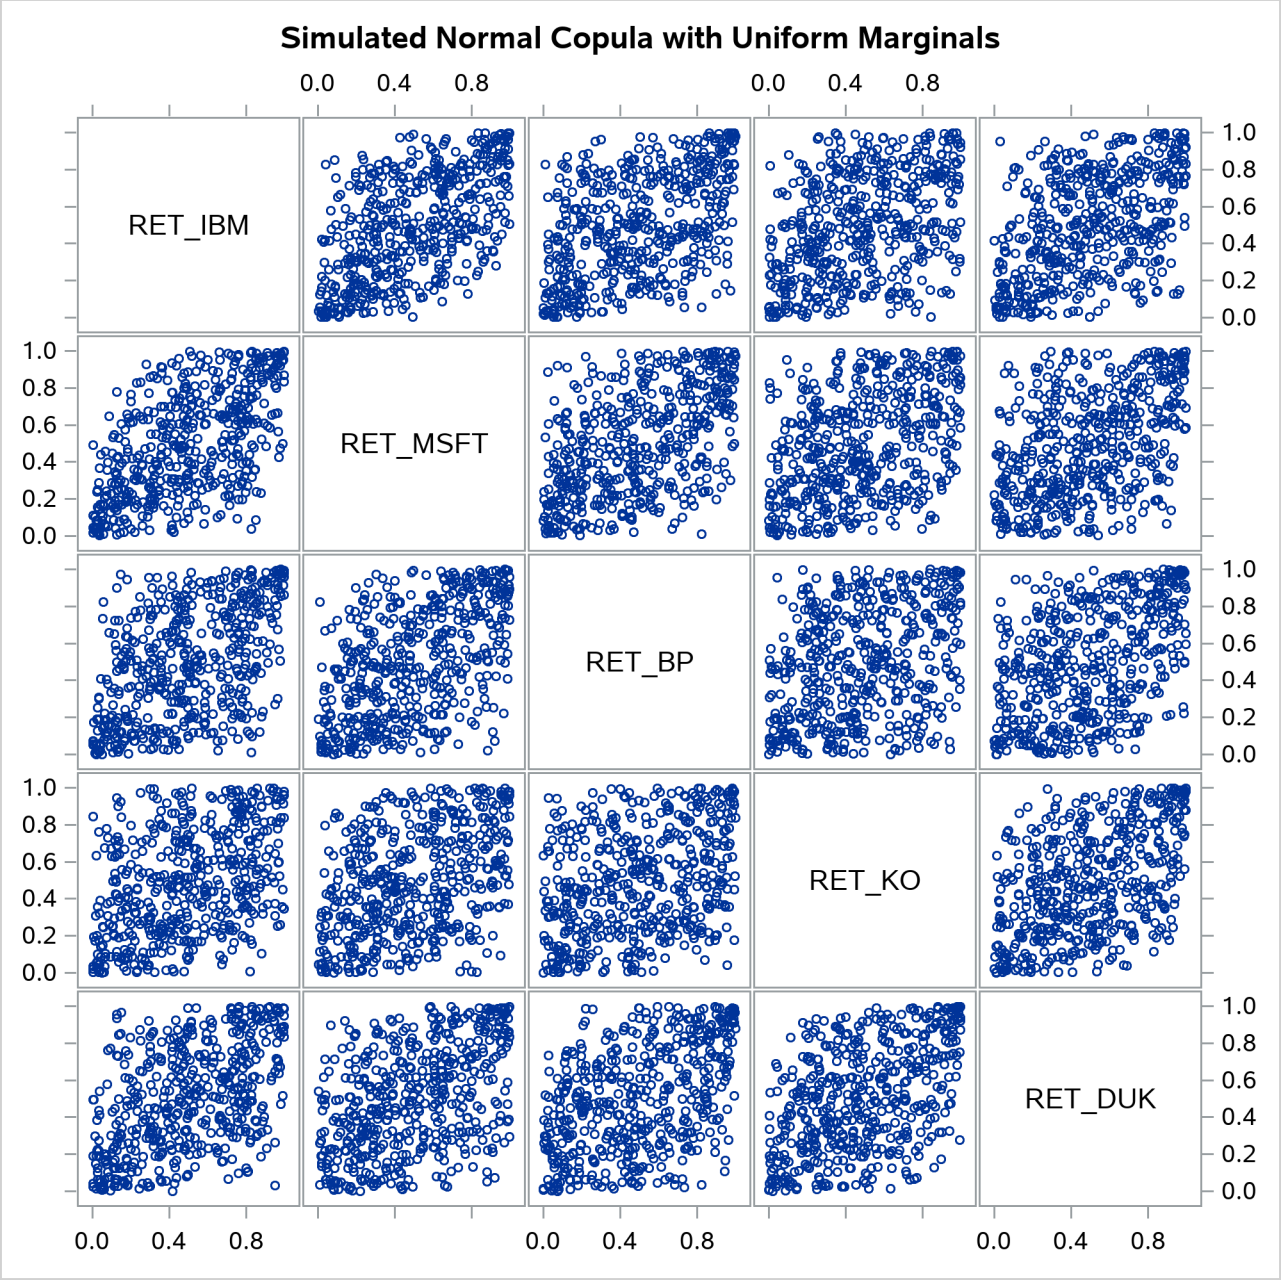
```
/* keep only correlation estimates */
data estimates;
   set estimates;
   keep ret_ibm ret_msft ret_bp ret_ko ret_duk;
run;
```

Then, in the following statements, the DEFINE statement specifies a normal copula named COP, and the CORR= option specifies that the data set Estimates be used as the source for the model parameters. The NDRAWS=500 option in the SIMULATE statement generates 500 observations from the normal copula. The OUTUNIFORM= option specifies the name of SAS data set to contain the simulated sample with uniform marginal distributions. Note that this syntax does not require the DATA= option.

```
/* Copula simulation of uniforms */
proc copula;
   var ret_ibm ret_msft ret_bp ret_ko ret_duk;
   define cop normal (corr = estimates);
   simulate cop / ndraws     = 500
                  seed       = 1234
                  outuniform = simulated_uniforms
                  plots=(datatype=uniform);
run;
```

The simulated data are contained in the new SAS data set, Simulated_Uniforms. A scatter plot matrix of uniform marginals contained in the data set is shown in Output 10.3.

Figure 10.3 Simulated Data, Uniform Marginals



The preceding sequence of PROC COPULA usage—first fit, then simulate given estimated parameters—is a legitimate sequence but has a limitation in that the second COPULA call does not generate the sample according to the empirical distribution of the raw data. It generates only marginally uniform series.

In the following statements, the FIT statement fits a *t* copula to the returns data and at the same time simulates the sample according to empirical marginal distributions:

```
/* Copula estimation and simulation of returns */
proc copula data = returns;
   var ret_ibm ret_msft ret_bp ret_ko ret_duk;
   fit T;
   simulate / ndraws = 1000
              seed   = 1234
              out    = simulated_returns;
run;
```

The output of the statements is similar in structure to the output displayed in Figure 10.2 with the addition of parameter estimates and inference statistics that are specific to the copula model as shown in Figure 10.4. For a *t* copula, the degrees of freedom are displayed (as in Figure 10.4); for Archimedean copulas, the parameter "theta" is displayed; and for a normal copula, this table is not printed.

Figure 10.4 Copula Estimation: Specific Parameter Estimates

The COPULA Procedure

Parameter Estimates

Parameter	Estimate	Standard Error	t Value	Approx Pr > |t|
DF	3.659299	0.320583	11.41	<.0001

The simulated data are contained in the new SAS data set, Simulated_Returns.

Syntax: COPULA Procedure

The COPULA procedure is controlled by the following statements:

PROC COPULA < **DATA=***SAS-data-set*> ;
VAR *variables* ;
DEFINE *name copula-type* < *(parameter-value-options . . .)* > ;
FIT *type* < **NAME=***name* > < **INIT=***(parameter-value-options)* > */ options* ;
BOUNDS *bound1* < *, bound2 . . .* > ;
SIMULATE < *copula-name-list* > */ options* ;
BY *variables* ;

Functional Summary

Table 10.1 summarizes the statements and options used with the COPULA procedure.

PROC COPULA Statement

PROC COPULA < **DATA=***SAS-data-set*> **;**

The PROC COPULA statement has the following option:

DATA= < *libref.*>*SAS-data-set*

specifies the input data set used to estimate parameters for the FIT statement. When the procedure is used for simulation only, the input data set is not required to run the procedure. If you do not specify *libref*, then the Work library is used. Work is the default temporary library that is automatically defined by SAS at the beginning of each SAS session or job.

BOUNDS Statement

BOUNDS *bound1* < *, bound2 . . .* > **;**

The BOUNDS statement specifies the lower and upper bounds for the parameters. You can use this statement only when maximum likelihood estimation is used for the specified copula. Each bound is composed of parameters, constants, and inequality operators in the following format:

item operator item < *operator item operator item . . .* >

Each *item* is a constant, parameter, or list of parameters. Parameters associated with a regressor variable are referred to by the name of the corresponding regressor variable. Each *operator* is <, >, <=, or >=. The following example indicates that the lower and upper bounds for the parameter THETA are –5 and 10, respectively:

```
bounds -5 < THETA < 10;
```

If you do not specify bounds, the internal default values are used; the default values are described in the section "Details: COPULA Procedure" on page 522. For the normal and *t* copulas, the correlation matrix uses only the default parameter bounds, which are –1 and 1 for lower bound and upper bound, respectively.

BY Statement

BY *variables* **;**

The BY statement specifies groups in which separate FIT analyses for copula are performed. The *variables* must be present in the input data set and are excluded from the model fitting. The BY statement requires the VAR statement to be present.

A SIMULATE statement can also be used with a BY statement, provided that a FIT statement precedes the SIMULATE statement. Multiple FIT and SIMULATE statements can be used with a BY statement. If a FIT statement and a SIMULATE statement both specify the same name, then the fitting results of the FIT statement with that name are used to initialize the simulation of the same name. If no names are specified in a sequence of FIT and SIMULATE statements, then the simulation requested by a particular SIMULATE statement is initialized using the fitting results from the FIT statement that immediately precedes the SIMULATE statement.

DEFINE Statement

DEFINE *name copula-type* < **(** *parameter-value-options . . .* **)** > **;**

The DEFINE statement specifies the relevant information of copula used for the simulation.

name specifies the name of the copula definition, which can be used later in the SIMULATE statement.

copula-type specifies one of the following types of copula:

CLAYTON specifies the Clayton copula.

FRANK specifies the Frank copula.

GUMBEL specifies the Gumbel copula.

HACCLAYTON specifies the hierarchical Clayton copula.

HACFRANK specifies the hierarchical Frank copula.

HACGUMBEL specifies the hierarchical Gumbel copula.

NORMAL specifies the normal copula.

T specifies the *t* copula.

These copula models are also described in the section "Details: COPULA Procedure" on page 522.

parameter-value-options

specify the input parameters used to simulate the specified copula. These options must be appropriate for the type of copula specified. You can specify the following options:

CORR=*SAS-data-set*

specifies the data set that contains the correlation matrix to use for elliptical copulas. If the correlation matrix is valid but its elements are not submitted in order, then you must provide the variable names in the first column of the matrix, and these names must match the variable names in the VAR statement. For an example of a correlation matrix input in this form, see Output 10.2.1. If the correlation matrix elements are submitted in order, the first column of variable names is not required. You can use this option for normal and *t* copulas.

DF=*value*

specifies the degrees of freedom. You can use this option for *t* copulas.

HIERARCHY=(*name***=(***HAC-specification* **)(THETA=***value* **))** (Experimental)

specifies the hierarchy for hierarchical Archimedean copulas. The argument usually consists of multiple specification lines, where each line specifies one copula in the hierarchy. The *name* can be user-defined symbols, with the exception of the copula at the top of the hierarchy, which must be named ROOT. The *HAC-specification* is a list of symbols that can be either defined copula names or variable names from the VAR statement, depending on whether the element of the copula is a variable or an inner copula in the hierarchy. For example, you can use the following code to define a hierarchical Archimedean copula, with the hierarchy shown in Figure 10.5:

```
var u1-u4;
define cop hacclayton hierarchy=(
root = (c1 c2)(theta=1)
c1 = (u1 u2)(theta=3)
c2 = (u3 u4)(theta=5));
```

Note that as long as the specification is valid, the order of the specification lines does not matter. In the previous example, you could first list $c1$ and $c2$, and then define $root$.

KENDALL=*SAS-data-set*
specifies the data set that contains the correlation matrix defined in Kendall's tau. If the correlation matrix is valid but its elements are not submitted in order, then you must provide the variable names in the first column of the matrix, and these names must match the variable names in the VAR statement. If the correlation matrix elements are submitted in order, the first column of variable names is not required. You can use this option for normal and *t* copulas.

SPEARMAN=*SAS-data-set*
specifies the data set that contains the correlation matrix defined in Spearman's rho. If the correlation matrix is valid but its elements are not submitted in order, then you must provide the variable names in the first column of the matrix, and these names must match the variable names in the VAR statement. If the correlation matrix elements are submitted in order, the first column of variable names is not required. You can use this option for normal copulas.

THETA=*value*
specifies the parameter value for Archimedean copulas.

The DEFINE statement is used with the SIMULATE statement. The FIT statement can also be used with the SIMULATE statement. The results of the FIT statement can be the input of the SIMULATE statement. Therefore, the SIMULATE statement can follow the FIT statement. If there is no FIT statement, then the DEFINE statement must precede the SIMULATE statement. However, you cannot use both the FIT and DEFINE statements in the same procedure.

FIT Statement

FIT *type* < **NAME=***name* >< **INIT=(***parameter-value-options***)** > */options* **;**

The FIT statement estimates the parameters for a specified copula type.

type
specifies the type of the copula to be estimated, which is one of the following:

CLAYTON	fits the Clayton copula.
FRANK	fits the Frank copula.
GUMBEL	fits the Gumbel copula.
NORMAL	fits the normal copula.
T	fits the *t* copula.

INIT=(*parameter-value-options***)**
provides the initial values for the numerical optimization.

[*parameter-value-options*]
specify the input parameters that are used to initialize the specified copula. These options must be appropriate for the type of copula that you specify. You can specify the following options:

CORR=*SAS-data-set*
specifies the data set that contains the Pearson correlation matrix to use for elliptical copulas. If the correlation matrix is valid but its elements are not submitted in order, then you must provide the variable names in the first column of the matrix, and these names must match the variable names in the VAR statement. For an example of a correlation matrix input in this form, see Output 10.2.1. If the correlation matrix elements are submitted in order, the first column of variable names is not required. You can use this option for *t* copulas.

DF=*value*
specifies the degrees of freedom. You can use this option for *t* copulas.

KENDALL=*SAS-data-set*
specifies the data set that contains the correlation matrix defined in Kendall's tau. If the correlation matrix is valid but its elements are not submitted in order, then you must provide the variable names in the first column of the matrix, and these names must match the variable names in the VAR statement. If the correlation matrix elements are submitted in order, the first column of variable names is not required. You can use this option for *t* copulas.

THETA=*value*
specifies the parameter value for Archimedean copulas.

For Archimedean copulas, the default initial values of the parameter are computed using the calibration method. The default initial value for the degrees-of-freedom parameter in the *t* copula is set to 2.0. The following statement shows an initialization for Student's *t* copula, where the Kendall's tau correlation matrix is stored in the corrmat data set and the DF is set to 2.5:

```
fit t init=(df=2.5 kendall=corrmat);
```

NAME=*name*
specifies an identifier for the fit, which is stored as an ID variable in the OUTCOPULA= data set.

You can specify the following *options* after a slash (/):

MARGINALS=UNIFORM | EMPIRICAL
specifies the marginal distribution of the individual variables. You can specify the following values:

EMPIRICAL uses the marginal empirical CDF to transform the data and uses the transformed data to fit the copula.

UNIFORM uses the input data without transformation to fit the copula.

METHOD=MLE | CAL
specifies the method used to estimate parameters. You can specify the following values:

CAL specifies the calibration method that uses the correlation matrix (only Kendall's tau is implemented in this procedure).

MLE represents canonical maximum likelihood estimation (CMLE) or maximum likelihood estimation (MLE).

For the *t* copula, if METHOD=CAL, then the correlation matrix is estimated using the calibration method with Kendall's tau and the degrees of freedom are estimated by the MLE. For the normal copula, only METHOD=MLE is supported and METHOD=CAL is ignored. By default for all copula types, METHOD=MLE.

OUTCOPULA < (KENDALL | SPEARMAN) >=*SAS-data-set*
specifies the name of the output data set. Each fitted copula is written to the specified *SAS-data-set*. The data set is not created if this option is not specified.

You can specify one of the following options, which must be appropriate for the type of copula that you specify:

KENDALL also writes a Kendall correlation matrix to the *SAS-data-set*.

SPEARMAN also writes a Spearman correlation matrix to the *SAS-data-set*.

OUTPSEUDO=*SAS-data-set*
specifies the output data set for saving the pseudo-samples with uniform marginal distributions. The pseudo-samples are obtained by transforming the individual variables of the original data with the empirical cumulative distribution functions (CDFs). The data set is not created if this option is not specified.

PLOTS<(*global-plot-options***)> < = *(specific-plot-options)*>**
controls the plots that are produced by the COPULA procedure. By default, PROC COPULA produces a scatter plot matrix for variables (that is, it displays a symmetric matrix plot with the variables that are specified in the VAR statement).

You can specify the following *global-plot-options*:

NVAR=ALL | *n*
specifies the maximum number of variables specified in the VAR statement to be displayed in the matrix plot. The NVAR=ALL option uses all variables that are specified in the VAR statement. By default, NVAR=5.

TAIL | CHI
requests that tail dependence plots (chi-plots) be plotted. If you specify this option with the UNPACK option on, PROC COPULA displays a chi-plot for each applicable pair of distinct variables that are specified in the VAR statement. If you specify this option without the UNPACK option, PROC COPULA displays a scatter plot matrix, the lower triangular section shows regular scatter plots between distinct pairs of variables that are specified in the VAR statement, the upper triangular section shows chi-plots for corresponding pairs of variables.

UNPACKPANEL | UNPACK
requests scatter plots for pairs of variables. If you specify this option, PROC COPULA displays a scatter plot for each applicable pair of distinct variables that are specified in the VAR statement.

You can specify the following *specific-plot-options*:

DATATYPE=ORIGINAL | UNIFORM | BOTH
requests the data type to be plotted. DATATYPE=ORIGINAL presents the data in their original marginal distribution; DATATYPE=UNIFORM shows the transformed data with uniform marginal distribution; and DATATYPE=BOTH plots both the original and uniform data types. If MARGINALS=UNIFORM, then the transformation is omitted and the DATATYPE= option is ignored.

NONE
suppresses all plots.

Printing Options

ITPRINT
prints a summary iteration listing.

NOCORR
suppresses the correlation matrix.

NOPRINT
suppresses all output.

PRINTALL
default option.

SIMULATE Statement

SIMULATE < *copula-name-list* >/*options* **;**

The SIMULATE statement simulates data from a specified copula model. The copula name specification can be either the name of a defined copula as specified by *name* in the DEFINE statement or the name of a fitted copula specified in the NAME= option in the FIT statement copula specification.

MARGINALS=UNIFORM | EMPIRICAL
specifies how the marginal distributions are computed. If MARGINALS=UNIFORM, then the samples are drawn from the copula distribution and marginal distributions are uniform.

MARGINALS=EMPIRICAL can be used to explicitly specify that the marginal distributions are empirical CDF computed from the DATA= option in the PROC COPULA statement.

If the MARGINALS= option is not specified in the SIMULATE statement, then the marginal distributions used in the simulation depend on whether a preceding FIT statement was used: If there is no FIT statement, the marginal distributions depend on whether the PROC COPULA statement includes a DATA= option. If there is a preceding FIT statement, then the marginal distributions from that fit are used. If there is no FIT statement and there is no DATA= option, then MARGINALS=UNIFORM.

NDRAWS=*integer*
specifies the number of draws to generate for this simulation. The default is 100.

OUT=*SAS-data-set*
specifies the output data set for the random samples from the simulation. This data set is the SAS data set in the OUTUNIFORM= option transformed by the inverse empirical CDF. This option is useful only when an input data exists and MARGINALS=EMPIRICAL. The data set is not created if this option is not specified.

OUTUNIFORM=*SAS-data-set*
specifies the output data set for the result of the simulation in uniforms. This option can be used when MARGINALS=UNIFORM or when MARGINALS=EMPIRICAL. If MARGINALS=EMPIRICAL, then this option enables you to obtain the samples simulated from the joint distribution specified by the copula, with all marginal distributions being uniform. The data are not created if this option is not specified.

PLOTS<**(***global-plot-options***)**> **< = ***(specific-plot-options)***>**
controls the plots that are produced by the COPULA procedure. By default, the PROC COPULA produces a scatter plot matrix for variables. You can specify any of the following *global-plot-options*:

NVAR=ALL | *n*
specifies the maximum number of variables specified in the VAR statement to be displayed in the matrix plot. The NVAR=ALL option uses all variables that are specified in the VAR statement. By default, NVAR=5.

TAIL | **CHI**
requests that tail dependence plots (chi-plots) be plotted. If you specify this option with the UNPACK option on, PROC COPULA displays a chi-plot for each applicable pair of distinct variables that are specified in the VAR statement. If you specify this option without the UNPACK option, PROC COPULA displays a scatter plot matrix, the lower triangular section shows regular scatter plots between distinct pairs of variables that are specified in the VAR statement, the upper triangular section shows chi-plots for corresponding pairs of variables.

UNPACKPANEL | **UNPACK**
requests scatter plots for pairs of variables. If you specify this option, PROC COPULA displays a scatter plot for each applicable pair of distinct variables that are specified in the VAR statement.

You can specify the following *specific-plot-options*:

DATATYPE=ORIGINAL | **UNIFORM** | **BOTH**
requests the data type to be plotted. DATATYPE=ORIGINAL presents the data in their original marginal distribution; DATATYPE=UNIFORM shows the transformed data with uniform marginal distribution; and DATATYPE=BOTH plots both the original and uniform data types. If MARGINALS=UNIFORM, then the transformation is omitted and the DATATYPE= option is ignored. If there are no input data, then the simulated data can only have uniform marginal distributions; in this case, the DATATYPE= option is ignored.

DISTRIBUTION=PDF | CDF
requests distributional graphs for the case of two variables. DISTRIBUTION=PDF specifies that the theoretical probability density function is provided with both a contour plot and a surface plot. DISTRIBUTION=CDF requests the graph for the theoretical cumulative distribution function of the copula.

NONE
suppresses all plots.

SEED=*integer*
specifies the seed for generating random numbers for the simulation. If the seed is not provided, a random number is used as the seed.

VAR Statement

VAR *variables* **;**

The VAR statement specifies the variable names in the input data set specified by the DATA= option in the PROC COPULA statement. The subset of variables in the data set is used for the copula models in the FIT statement. When there is no input data set, the VAR statement creates the names of the list of variables for the SIMULATE statement.

Details: COPULA Procedure

Sklar's Theorem

The copula models are tools for studying the dependence structure of multivariate distributions. The usual joint distribution function contains the information both about the marginal behavior of the individual random variables and about the dependence structure between the variables. The copula is introduced to decouple the marginal properties of the random variables and the dependence structures. An m-dimensional *copula* is a joint distribution function on $[0,1]^m$ with all marginal distributions being standard uniform. The common notation for a copula is $C(u_1,\ldots,u_m)$.

The Sklar (1959) theorem shows the importance of copulas in modeling multivariate distributions. The first part claims that a copula can be derived from any joint distribution functions, and the second part asserts the opposite: that is, any copula can be combined with any set of marginal distributions to result in a multivariate distribution function.

- Let F be a joint distribution function and F_j, $j = 1,\ldots,m$, be the marginal distributions. Then there exists a copula $C : [0,1]^m \rightarrow [0,1]$ such that

  $$F(x_1,\ldots,x_m) = C(F_1(x_1),\ldots,F_m(x_m))$$

  for all $x_1,\ldots,x_m$ in $[-\infty,\infty]$. Moreover, if the margins are continuous, then C is unique; otherwise C is uniquely determined on $\mathrm{Ran}F_1 \times \cdots \times \mathrm{Ran}F_m$, where $\mathrm{Ran}F_j = F_j([-\infty,\infty])$ is the range of F_j.

- The converse is also true. That is, if C is a copula and $F_1, \ldots, F_m$ are univariate distribution functions, then the multivariate function defined in the preceding equation is a joint distribution function with marginal distributions $F_j, j = 1, \ldots, m$.

Dependence Measures

There are three basic types of measures: linear correlation, rank correlation, and tail dependence. Linear correlation is given by

$$\rho \equiv \text{corr}(X, Y) = \frac{\text{cov}(X, Y)}{\sqrt{\text{var}(X)}\sqrt{\text{var}(Y)}}$$

The linear correlation coefficient carries very limited information about the joint properties of the variables. A well-known property is that uncorrelatedness does not imply independence, while independence implies noncorrelation. In addition, there exist distinct bivariate distributions that have the same marginal distribution and the same correlation coefficient. These results suggest that caution must be used when interpreting the linear correlation.

Another statistical measure of dependence is called rank correlation, which is nonparametric. Kendall's tau, for example, is the covariance between the sign statistic $X_1 - \tilde{X}_1$ and $X_2 - \tilde{X}_2$, where $(\tilde{X}_1, \tilde{X}_2)$ is an independent copy of (X_1, X_2):

$$\rho_\tau \equiv E[\text{sign}(X_1 - \tilde{X}_1)(X_2 - \tilde{X}_2)]$$

The sign function (sometimes written as sgn) is defined by

$$\text{sign}(x) = \begin{cases} -1 & \text{if} x \leq 0 \\ 0 & \text{if} x = 0 \\ 1 & \text{if} x \geq 0 \end{cases}$$

Spearman's *rho* is the correlation between the transformed random variables:

$$\rho_S(X_1, X_2) \equiv \rho(F_1(X_1), F_2(X_2))$$

The variables are transformed by their distribution functions so that the transformed variables are uniformly distributed on $[0, 1]$. The rank correlations depend only on the copula of the random variables and are indifferent to the marginal distributions. Like linear correlation, the rank correlations have their limitations. In particular, there are different copulas that result in the same rank correlation.

A third measure focuses on only part of the joint properties between the variables. Tail dependence measures the dependence when both variables are at extreme values. Formally, they can be defined as the conditional probabilities of quantile exceedances. There are two types of tail dependence:

- The upper tail dependence, denoted λ_u, is

$$\lambda_u(X_1, X_2) \equiv \lim_{q->1^-} P(X_2 > F_2^{-1}(q) | X_1 > F_1^{-1}(q))$$

when the limit exists $\lambda_u \in [0, 1]$. Here F_j^{-1} is the quantile function (that is, the inverse of the CDF).

- The lower tail dependence is defined symmetrically.

Tail dependence is hard to detect by looking at a scatter plot of realizations of two random variables. One graphical way to detect tail dependence between two variables is by creating the chi plot of those two variables. The chi plot, as defined in Fisher and Switzer (2001), has characteristic patterns that depend on the dependence structure between the variables. The chi plot for the random variables X and Y is a scatter plot of the pairs (λ_i, χ_i) for each data point (x_i, y_i). λ_i is a measure of the distance of the data point (x_i, y_i) from the center of the data as measured by the median values of (x_i, y_i), and χ_i is a correlation coefficient between dichotomized values of X and Y. A positive λ_i means that x_i and y_i are either both large with respect to their median values or both small. A negative λ_i means that x_i or y_i is large with respect to its median, whereas the other value is small. Signs of tail dependence manifest as clusters of points that are significantly far from the χ axis around λ values of ± 1. If X and Y are uncorrelated, the χ values cluster around the λ axis.

Normal Copula

Let $u_j \sim U(0,1)$ for $j = 1, \ldots, m$, where $U(0,1)$ represents the uniform distribution on the $[0,1]$ interval. Let Σ be the correlation matrix with $m(m-1)/2$ parameters satisfying the positive semidefiniteness constraint. The normal copula can be written as

$$C_\Sigma(u_1, u_2, \ldots, u_m) = \mathbf{\Phi}_\Sigma\Big(\Phi^{-1}(u_1), \ldots, \Phi^{-1}(u_m)\Big)$$

where Φ is the distribution function of a standard normal random variable and $\mathbf{\Phi}_\Sigma$ is the m-variate standard normal distribution with mean vector 0 and covariance matrix Σ. That is, the distribution $\mathbf{\Phi}_\Sigma$ is $N_m(0, \Sigma)$.

Simulation

For the normal copula, the input of the simulation is the correlation matrix Σ. The normal copula can be simulated by the following steps, in which $\boldsymbol{U} = (U_1, \ldots, U_m)$ denotes one random draw from the copula:

1. Generate a multivariate normal vector $\boldsymbol{Z} \sim N(0, \Sigma)$ where Σ is an m-dimensional correlation matrix.
2. Transform the vector $\boldsymbol{Z}$ into $\boldsymbol{U} = (\Phi(Z_1), \ldots, \Phi(Z_m))^T$, where Φ is the distribution function of univariate standard normal.

The first step can be achieved by Cholesky decomposition of the correlation matrix $\Sigma = LL^T$ where L is a lower triangular matrix with positive elements on the diagonal. If $\tilde{\boldsymbol{Z}} \sim N(0, I)$, then $L\tilde{\boldsymbol{Z}} \sim N(0, \Sigma)$.

Fitting

To fit a normal copula is to estimate the covariance matrix Σ from an input sample data set. Given a random sample $\boldsymbol{u}_i = (u_{i,1}, \ldots, u_{i,m})^\top$ where $i = 1, \ldots, n$, the log-likelihood function is

$$\begin{aligned}&\log L(\Sigma; \boldsymbol{u}_1, \ldots, \boldsymbol{u}_n)\\ &= \sum_{t=1}^{n} \log f_\Sigma(\Phi^{-1}(u_{t,1}), \ldots, \Phi^{-1}(u_{t,m})) - \sum_{t=1}^{n}\sum_{j=1}^{m} \log \phi(\Phi^{-1}(u_{t,j}))\end{aligned}$$

Here f_Σ is the joint density of the multivariate normal with mean zero and variance Σ, and ϕ is the univariate density of the standard normal distribution. Note that the second term is not related to the parameters Σ and, therefore, can be ignored during the optimization. The restriction that Σ is a correlation matrix is very inconvenient, and it is common practice to circumvent this problem by first assuming that Σ has the covariance form. Therefore, Σ can be estimated by

$$\widehat{\Sigma} = \frac{1}{n}\sum_{i=1}^{n} \zeta_i \zeta_i^T$$

where

$$\zeta_i = \left(\Phi^{-1}(u_{i,1}), \Phi^{-1}(u_{i,2}), \ldots, \Phi^{-1}(u_{i,m})\right)^T$$

This estimate is consistent with the form of a covariance matrix but not necessarily with the form of a correlation matrix. The approximation to the original MLE problem can be obtained using the normalizing operator defined as follows:

$$\Delta(\Sigma) = \text{diag}(\sigma_{11}^{1/2}, \ldots, \sigma_{mm}^{1/2})$$
$$\mathcal{P}(\Sigma) = (\Delta(\Sigma))^{-1}\Sigma(\Delta(\Sigma))^{-1}$$

Student's *t* Copula

Let $\Theta = \{(\nu, \Sigma) : \nu \in (1, \infty), \Sigma \in \mathbb{R}^{m\times m}\}$and let t_ν be a univariate t distribution with ν degrees of freedom.

The Student's t copula can be written as

$$C_\Theta(u_1, u_2, \ldots, u_m) = \boldsymbol{t}_{\nu,\Sigma}\left(t_\nu^{-1}(u_1), t_\nu^{-1}(u_2), \ldots, t_\nu^{-1}(u_m)\right)$$

where $\boldsymbol{t}_{\nu,\Sigma}$ is the multivariate Student's t distribution with a correlation matrix Σ with ν degrees of freedom.

Simulation

The input parameters for the simulation are (ν, Σ). The t copula can be simulated by the following two steps:

1. Generate a multivariate vector $\boldsymbol{X} \sim t_m(\nu, 0, \Sigma)$ following the centered t distribution with ν degrees of freedom and correlation matrix Σ.
2. Transform the vector $\boldsymbol{X}$ into $\boldsymbol{U} = (t_\nu(X_1), \ldots, t_\nu(X_m))^T$, where t_ν is the distribution function of univariate t distribution with ν degrees of freedom.

To simulate centered multivariate t random variables, you can use the property that $\boldsymbol{X} \sim t_m(\nu, 0, \Sigma)$ if $\boldsymbol{X} = \sqrt{\nu/s}\boldsymbol{Z}$, where $\boldsymbol{Z} \sim N(0, \Sigma)$ and the univariate random variable $s \sim \chi^2_\nu$.

Fitting

To fit a t copula is to estimate the covariance matrix Σ and degrees of freedom ν from a given multivariate data set. Given a random sample $\boldsymbol{u}_i = (u_{i,1}, \ldots, u_{i,m})^\top$, $i = 1, \ldots, n$ that has uniform marginal distributions, the log likelihood is

$$\begin{aligned}&\log L(\nu, \Sigma; u_{i,1}, \ldots, u_{i,m})\\ &= \sum_{i=1}^{n} \log g_{\nu,\Sigma}(t_\nu^{-1}(u_{i,1}), \ldots, t_\nu^{-1}(u_{i,m})) - \sum_{i=1}^{n}\sum_{j=1}^{m} \log g_\nu(t_\nu^{-1}(u_{i,j}))\end{aligned}$$

where ν denotes the degrees of freedom of the t copula, $g_{\nu,\Sigma}$ denotes the joint density function of the centered multivariate t distribution with parameters (ν, Σ), t_ν is the distribution function of a univariate t distribution with ν degrees of freedom, Σ is a correlation matrix, and g_ν is the density function of univariate t distribution with ν degrees of freedom.

The log likelihood can be maximized with respect to the parameters $\theta = (\nu, \Sigma) \in \Theta$ using numerical optimization. If you allow the parameters in Σ to be such that Σ is symmetric and with ones on the diagonal, then the MLE estimate for Σ might not be positive semidefinite. In that case, you need to apply the adjustment to convert the estimated matrix to positive semidefinite, as shown by McNeil, Frey, and Embrechts (2005), Algorithm 5.55.

When the dimension of the data m increases, the numerical optimization quickly becomes infeasible. It is common practice to estimate the correlation matrix Σ by calibration using Kendall's tau. Then, using this fixed Σ, the single parameter ν can be estimated by MLE. By proposition 5.37 in McNeil, Frey, and Embrechts (2005),

$$\rho_\tau(U_i, U_j) = \frac{2}{\pi}\arcsin\rho_{ij}$$

where ρ_τ is the Kendall's tau and ρ_{ij} is the off-diagonal elements of the correlation matrix Σ of the t copula. Therefore, an estimate for the correlation is

$$\hat{\rho}_{ij} = \sin\left(\frac{1}{2}\pi\hat{\rho}^\tau_{i,j}\right)$$

where $\hat{\rho}$ and $\hat{\rho}^\tau$ are the estimates of the sample correlation matrix and Kendall's tau, respectively. However, it is possible that the estimate of the correlation matrix $\hat{\Sigma}$ is not positive definite. In this case, there is a standard procedure that uses the eigenvalue decomposition to transform the correlation matrix into one that is positive definite. Let Σ be a symmetric matrix with ones on the diagonal, with off-diagonal entries in $[-1, 1]$. If Σ is not positive semidefinite, use Algorithm 5.55 from McNeil, Frey, and Embrechts (2005):

1. Compute the eigenvalue decomposition $\Sigma = EDE^T$, where D is a diagonal matrix that contains all the eigenvalues and E is an orthogonal matrix that contains the eigenvectors.
2. Construct a diagonal matrix $\tilde{D}$ by replacing all negative eigenvalues in D by a small value $\delta > 0$.
3. Compute $\tilde{\Sigma} = E\tilde{D}E^T$, which is positive definite but not necessarily a correlation matrix.
4. Apply the normalizing operator $\mathcal{P}$ on the matrix $\tilde{\Sigma}$ to obtain the correlation matrix desired.

The log-likelihood function and its gradient function for a single observation are listed as follows, where $\boldsymbol{\zeta} = (\zeta_1, \ldots, \zeta_m)$, with $\zeta_j = t_\nu^{-1}(u_j)$, and g is the derivative of the $\log\Gamma$ function:

$$
\begin{aligned}
l = \log(c) &= -\frac{1}{2}\log(|\Sigma|) + \log\Gamma\left(\frac{\nu+m}{2}\right) + (m-1)\log\Gamma\left(\frac{\nu}{2}\right) - m\log\Gamma\left(\frac{\nu+1}{2}\right) \\
&\quad - \frac{\nu+m}{2}\log(1+\zeta^T\Sigma^{-1}\zeta/\nu) + \frac{\nu+1}{2}\sum_{j=1}^{m}\log\left(1+\frac{\zeta_j^2}{\nu}\right) \\
\frac{\partial l}{\partial \nu} &= \frac{1}{2}g\left(\frac{\nu+m}{2}\right) + \frac{m-1}{2}g\left(\frac{\nu}{2}\right) - \frac{m}{2}g\left(\frac{\nu+1}{2}\right) \\
&\quad - \frac{1}{2}\log(1+\zeta^T\Sigma^{-1}\zeta/\nu) + \frac{\nu+m}{2\nu^2}\frac{\zeta^T\Sigma^{-1}\zeta}{1+\zeta^T\Sigma^{-1}\zeta/\nu} \\
&\quad + \frac{1}{2}\sum_{j=1}^{m}\log(1+\zeta_j^2/\nu) - \frac{\nu+1}{2\nu^2}\sum_{j=1}^{m}\frac{\zeta_j^2}{1+\zeta_j^2/\nu} \\
&\quad - \frac{(\nu+m)}{\nu}\frac{\zeta^T\Sigma^{-1}(d\zeta/d\nu)}{1+\zeta^T\Sigma^{-1}\zeta/\nu} + \frac{\nu+1}{\nu}\sum\frac{\zeta_j(d\zeta_j/d\nu)}{1+\zeta_j^2/\nu}
\end{aligned}
$$

The derivative of the likelihood with respect to the correlation matrix Σ follows:

$$
\begin{aligned}
\frac{\partial l}{\partial \Sigma} &= -\frac{1}{2}(\Sigma^{-1})^T + \frac{\nu+m}{2}\frac{\Sigma^{-T}\zeta\zeta^T\Sigma^{-T}/\nu}{1+\zeta^T\Sigma^{-1}\zeta/\nu} \\
&= -\frac{1}{2}(\Sigma^{-1})^T + \frac{\nu+m}{2}\frac{\Sigma^{-T}\zeta\zeta^T\Sigma^{-T}}{\nu+\zeta^T\Sigma^{-1}\zeta}
\end{aligned}
$$

Archimedean Copulas

Overview of Archimedean Copulas

Let function $\phi : [0,1] \to [0,\infty)$ be a strict Archimedean copula generator function and suppose its inverse ϕ^{-1} is completely monotonic on $[0,\infty)$. A strict generator is a decreasing function $\phi : [0,1] \to [0,\infty)$ that satisfies $\phi(0) = \infty$ and $\phi(1) = 0$. A decreasing function $f(t) : [a,b] \to (-\infty,\infty)$ is completely monotonic if it satisfies

$$(-1)^k \frac{d^k}{dt^k} f(t) \geq 0, k \in \mathbb{N}, t \in (a,b)$$

An Archimedean copula is defined as follows:

$$C(u_1, u_2, \ldots, u_m) = \phi^{-1}\Big(\phi(u_1) + \cdots + \phi(u_m)\Big)$$

The Archimedean copulas available in the COPULA procedure are the Clayton copula, the Frank copula, and the Gumbel copula.

Clayton Copula

Let the generator function $\phi(u) = \theta^{-1}\left(u^{-\theta} - 1\right)$. A Clayton copula is defined as

$$C_\theta(u_1, u_2, \ldots, u_m) = \left[\sum_{i=1}^{m} u_i^{-\theta} - m + 1\right]^{-1/\theta}$$

with $\theta > 0$.

Frank Copula

Let the generator function be

$$\phi(u) = -\log\left[\frac{\exp(-\theta u) - 1}{\exp(-\theta) - 1}\right]$$

A Frank copula is defined as

$$C_\theta(u_1, u_2, \ldots, u_m) = \frac{1}{\theta}\log\left\{1 + \frac{\prod_{i=1}^{m}[\exp(-\theta u_i) - 1]}{[\exp(-\theta) - 1]^{m-1}}\right\}$$

with $\theta \in (-\infty, \infty)\backslash\{0\}$ for $m = 2$ and $\theta > 0$ for $m \geq 3$.

Gumbel Copula

Let the generator function $\phi(u) = (-\log u)^\theta$. A Gumbel copula is defined as

$$C_\theta(u_1, u_2, \ldots, u_m) = \exp\left\{-\left[\sum_{i=1}^{m}(-\log u_i)^\theta\right]^{1/\theta}\right\}$$

with $\theta > 1$.

Simulation

Suppose the generator of the Archimedean copula is ϕ. Then the simulation method using the Laplace-Stieltjes transformation of the distribution function is given by Marshall and Olkin (1988) where $\tilde{F}(t) = \int_0^\infty e^{-tx} dF(x)$:

1. Generate a random variable V with the distribution function F such that $\tilde{F}(t) = \phi^{-1}(t)$.
2. Draw samples from independent uniform random variables $X_1, \ldots, X_m$.
3. Return $\boldsymbol{U} = (\tilde{F}(-\log(X_1)/V), \ldots, \tilde{F}(-\log(X_m)/V))^T$.

The Laplace-Stieltjes transformations are as follows:

- For the Clayton copula, $\tilde{F} = (1 + t)^{-1/\theta}$, and the distribution function F is associated with a Gamma random variable with shape parameter θ^{-1} and scale parameter one.

- For the Gumbel copula, $\tilde{F} = \exp(-t^{1/\theta})$, and F is the distribution function of the stable variable $\text{St}(\theta^{-1}, 1, \gamma, 0)$ with $\gamma = [\cos(\pi/(2\theta))]^{\theta}$.
- For the Frank copula with $\theta > 0$, $\tilde{F} = -\log\{1 - \exp(-t)[1 - \exp(-\theta)]\}/\theta$, and F is a discrete probability function $P(V = k) = (1 - \exp(-\theta))^k/(k\theta)$. This probability function is related to a logarithmic random variable with parameter value $1 - e^{-\theta}$.

For more information about simulating a random variable from a stable distribution, see Theorem 1.19 in Nolan (2010). For more information about simulating a random variable from a logarithmic series, see Chapter 10.5 in Devroye (1986).

For a Frank copula with $m = 2$ and $\theta < 0$, the simulation can be done through conditional distributions as follows:

1 Draw independent v_1, v_2 from a uniform distribution.

2 Let $u_1 = v_1$.

3 Let $u_2 = -\frac{1}{\theta}\log\left(1 + \frac{v_2(1-e^{-\theta})}{v_2(e^{-\theta v_1}-1)-e^{-\theta v_1}}\right)$.

Fitting

One method to estimate the parameters is to calibrate with Kendall's tau. The relation between the parameter θ and Kendall's tau is summarized in Table 10.5 for the three Archimedean copulas.

Table 10.2 Calibration Using Kendall's Tau

Copula Type	τ	**Formula for** θ
Clayton	$\theta/(\theta + 2)$	$2\tau/(1 - \tau)$
Gumbel	$1 - 1/\theta$	$1/(1 - \tau)$
Frank	$1 - 4\theta^{-1}(1 - D_1(\theta))$	No closed form

In Table 10.2, $D_1(\theta) = \theta^{-1}\int_0^{\theta} t/(\exp(t) - 1)dt$ for $\theta > 0$, and $D_1(\theta) = D_1(\theta) + 0.5\theta$ for $\theta < 0$. In addition, for the Frank copula, the formula for θ has no closed form. The numerical algorithm for root finding can be used to invert the function $\tau(\theta)$ to obtain θ as a function of τ.

Alternatively, you can use the MLE or the CMLE method to estimate the parameter θ given the data $\mathbf{u} = \{u_{i,j}\}$ and $i = 1, \ldots, n$, $j = 1, \ldots, m$. The log-likelihood function for each type of Archimedean copula is provided in the following sections.

Fitting the Clayton Copula

For the Clayton copula, the log-likelihood function is as follows (Cherubini, Luciano, and Vecchiato 2004, Chapter 7):

$$l = n\left[m\log(\theta) + \log\left(\Gamma\left(\frac{1}{\theta}+m\right)\right) - \log\left(\Gamma\left(\frac{1}{\theta}\right)\right)\right] - (\theta+1)\sum_{i,j}\log u_{ij}$$
$$-\left(\frac{1}{\theta}+m\right)\sum_{i}\log\left(\sum_{j}u_{ij}^{-\theta} - m + 1\right)$$

Let $g(\cdot)$ be the derivative of $\log(\Gamma(\cdot))$. Then the first-order derivative is

$$\frac{dl}{d\theta} = n\left[\frac{m}{\theta} + g\left(\frac{1}{\theta}+m\right)\frac{-1}{\theta^2} - g\left(\frac{1}{\theta}\right)\frac{-1}{\theta^2}\right]$$
$$-\sum_{i,j}\log(u_{ij}) + \frac{1}{\theta^2}\sum_{i}\log\left(\sum_{j}u_{ij}^{-\theta} - m + 1\right)$$
$$-\left(\frac{1}{\theta}+m\right)\sum_{i}\frac{-\sum_j u_{ij}^{-\theta}\log(u_{ij})}{\sum_j u_{ij}^{-\theta} - m + 1}$$

The second-order derivative is

$$\frac{d^2l}{d\theta^2} = n\left\{\frac{-m}{\theta^2} + g'\left(\frac{1}{\theta}+m\right)\frac{1}{\theta^4} + g\left(\frac{1}{\theta}+m\right)\frac{2}{\theta^3} - g'\left(\frac{1}{\theta}\right)\frac{1}{\theta^4} - g\left(\frac{1}{\theta}\right)\frac{2}{\theta^3}\right\}$$
$$-\frac{2}{\theta^3}\sum_{i}\log\left(\sum_{j}u_{ij}^{-\theta} - m + 1\right)$$
$$+\frac{2}{\theta^2}\sum_{i}\frac{-\sum_j u_{ij}^{-\theta}\log u_{ij}}{\sum_j u_{ij}^{-\theta} - m + 1}$$
$$-\left(\frac{1}{\theta}+m\right)\sum_{i}\left\{\frac{\sum_j u_{ij}^{-\theta}(\log u_{ij})^2}{\sum_j u_{ij}^{-\theta} - m + 1} - \left(\frac{\sum_j u_{ij}^{-\theta}\log u_{ij}}{\sum_j u_{ij}^{-\theta} - m + 1}\right)^2\right\}$$

Fitting the Gumbel Copula

A different parameterization $\alpha = \theta^{-1}$ is used for the following part, which is related to the fitting of the Gumbel copula. For the Gumbel copula, you need to compute $\phi^{-1(m)}$. It turns out that for $k = 1, 2, \ldots, m$,

$$\phi^{-1(k)}(u) = (-1)^k\alpha\exp(-u^\alpha)u^{-k+\alpha}\Psi_{k-1}(u^\alpha)$$

where Ψ_{k-1} is a function that is described later. The copula density is given by

$$\begin{aligned} c &= \phi^{-1(m)}(x)\prod_k \phi'(u_k) \\ &= (-1)^m\alpha\exp\left(-x^\alpha\right)x^{-k+\alpha}\Psi_{m-1}\left(x^\alpha\right)\prod_k\phi'(u_k) \\ &= (-1)^m f_1 f_2 f_3 f_4 f_5 \end{aligned}$$

where $x = \sum_k \phi(u_k)$, $f_1 = \alpha$, $f_2 = \exp(-x^\alpha), f_3 = x^{-k+\alpha}, f_4 = \Psi_{m-1}(x^\alpha)$, and $f_5 = (-1)^m \prod_k \phi'(u_k)$.

The log density is

$$\begin{aligned} l &= \log(c) \\ &= \log(f_1) + \log(f_2) + \log(f_3) + \log(f_4) + \log\left((-1)^m f_5\right) \end{aligned}$$

Now the first-order derivative of the log density has the decomposition

$$\frac{dl}{d\alpha} = \frac{1}{c}\frac{dc}{d\alpha} = \sum_{j=1}^{4} \frac{1}{f_j}\frac{df_j}{d\alpha} + \frac{d\sum_k \log(-\phi'(u_k))}{d\alpha}$$

Some of the terms are given by

$$\begin{aligned} \frac{1}{f_1}\frac{df_1}{d\alpha} &= \frac{1}{\alpha} \\ \frac{1}{f_2}\frac{df_2}{d\alpha} &= -x^\alpha \log(x) - \alpha x^{\alpha-1}\frac{dx}{d\alpha} \\ \frac{1}{f_3}\frac{df_3}{d\alpha} &= \log(x) + (-k+\alpha)x^{-1}\frac{dx}{d\alpha} \end{aligned}$$

where

$$\frac{dx}{d\alpha} = \sum (-\log u_k)^{1/\alpha} \log(-\log u_k)\left(\frac{-1}{\alpha^2}\right)$$

The last term in the derivative of the $dl/d\alpha$ is

$$\begin{aligned} \log\left(-\phi'(u_k)\right) &= \log\left(\frac{1}{\alpha}(-\log u_k)^{\frac{1}{\alpha}-1}\frac{1}{u_k}\right) \\ &= -\log\alpha - \log(u_k) + \left(\frac{1}{\alpha} - 1\right)\log(-\log(u_k)) \\ \frac{d\sum_k \log(-\phi'(u_k))}{d\alpha} &= \sum_{k=1}^{m} -\frac{1}{\alpha} - \frac{1}{\alpha^2}\log(-\log(u_k)) \\ &= -\frac{m}{\alpha} - \frac{1}{\alpha^2}\sum_{k=1}^{m}\log(-\log(u_k)) \end{aligned}$$

Now the only remaining term is f_4, which is related to Ψ_{m-1}. Wu, Valdez, and Sherris (2007) show that $\Psi_k(x)$ satisfies a recursive equation

$$\Psi_k(x) = [\alpha(x-1)+k]\Psi_{k-1}(x) - \alpha x \Psi'_{k-1}(x)$$

with $\Psi_0(x) = 1$.

The preceding equation implies that $\Psi_{k-1}(x)$ is a polynomial of x and therefore can be represented as

$$\Psi_{k-1}(x) = \sum_{j=0}^{k-1} a_j(k-1,\alpha)\, x^j$$

In addition, its coefficient, denoted by $a_j(k-1,\alpha)$, is a polynomial of α. For simplicity, use the notation $a_j(\alpha) \equiv a_j(m-1,\alpha)$. Therefore,

$$f_4 = \Psi_{m-1}\left(x^\alpha\right) = \sum_{j=0}^{m-1} a_j(\alpha)\, x^{j\alpha}$$

$$\begin{aligned}\frac{df_4}{d\alpha} &= \frac{d\,\Psi_{m-1}\left(x^\alpha\right)}{d\alpha} \\ &= \sum_{j=0}^{m-1}\left[\frac{da_j(\alpha)}{d\alpha}x^{j\alpha} + a_j(\alpha)\,x^{j\alpha}\log(x)\,j + a_j(\alpha)\,(j\alpha)\,x^{j\alpha-1}\frac{dx}{d\alpha}\right]\end{aligned}$$

Fitting the Frank Copula

For the Frank copula,

$$\phi^{-1(k)}(u) = -\frac{1}{\theta}\Psi_{k-1}\left((1+e^{-u}(e^{-\theta}-1))^{-1}\right)$$

When $\theta > 0$, a Frank copula has a probability density function

$$\begin{aligned}c &= \varphi^{-1(m)}(x)\prod_k \varphi'(u_k) \\ &= \frac{-1}{\theta}\Psi_{m-1}\left(\frac{1}{1+e^{-x}\left(e^{-\theta}-1\right)}\right)\prod_k \varphi'(u_k)\end{aligned}$$

where $x = \sum_k \varphi(u_k)$.

The log likelihood is

$$\log c = -\log(\theta) + \log\left(\Psi_{m-1}\left(\frac{1}{1+e^{-x}\left(e^{-\theta}-1\right)}\right)\right) + \sum \log\left(\varphi'(u_k)\right)$$

Denote

$$y = \frac{1}{1+e^{-x}\left(e^{-\theta}-1\right)}$$

Then the derivative of the log likelihood is

$$\frac{d\log c}{d\theta} = -\frac{1}{\theta} + \frac{1}{\Psi_{m-1}(y)}\frac{d\,\Psi_{m-1}}{d\theta} + \sum_k \frac{1}{\varphi'(u_k)}\frac{d\varphi'(u_k)}{d\theta}$$

The term in the last summation is

$$\frac{1}{\varphi'(u_k)}\frac{d\varphi'(u_k)}{d\theta} = \frac{1}{\theta\left(1-e^{\theta u_k}\right)}\left[1-e^{\theta u_k}+\theta u e^{\theta u_k}\right]$$

The function Ψ_{m-1} satisfies a recursive relation

$$\Psi_k(x) = x(x-1)\Psi'_{k-1}(x)$$

with $\Psi_0(x) = x-1$. Note that Ψ_{m-1} is a polynomial whose coefficients do not depend on θ; therefore,

$$\begin{aligned}\frac{d\Psi_{m-1}}{d\theta} &= \frac{d\Psi_{m-1}}{dy}\frac{dy}{d\theta}\\ &= \frac{d\Psi_{m-1}}{dy}\left[\frac{dy}{d\theta}+\frac{dy}{dx}\frac{dx}{d\theta}\right]\\ &= \frac{d\Psi_{m-1}}{dy}\left[\frac{e^{-x}e^{-\theta}}{\left[1+e^{-x}\left(e^{-\theta}-1\right)\right]^2}+\frac{e^{-x}\left(e^{-\theta}-1\right)}{\left[1+e^{-x}\left(e^{-\theta}-1\right)\right]^2}\frac{dx}{d\theta}\right]\end{aligned}$$

where

$$\begin{aligned}\frac{dx}{d\theta} &= \sum_k \frac{d\varphi(u_k)}{d\theta} = \sum_k\left[-\frac{u_k e^{-\theta u_k}}{1-e^{-\theta u_k}}+\frac{e^{-\theta}}{1-e^{\theta}}\right]\\ &= \sum_k\left[-\frac{u_k}{e^{\theta u_k}-1}+\frac{1}{e^{\theta}-1}\right]\end{aligned}$$

For the case of $m = 2$ and $\theta < 0$, the bivariate density is

$$\log c = \log(\theta(1-e^{-\theta})) - \theta(u_1+u_2) - \log((1-e^{-\theta}-(1-e^{-\theta u_1})(1-e^{-\theta u_2}))^2)$$

Hierarchical Archimedean Copula (HAC) (Experimental)

Adopting the notations of Savu and Trede (2010), let L denote the total level of hierarchies and let D denote the dimension of the HAC. There are n_l distinct copulas at each level $l, l = 1,\ldots,L$. These copulas are indexed by (l,j), $j = 1,\ldots,n_l$. At each level, there are also d_l variables, $0 \le d_l \le D$ and $\sum_l d_l = D$. In the first step, all the variables at the lowest level are grouped into n_1 subsets, each subset being an ordinary multivariate Archimedean copula

$$C_{1,j}(\boldsymbol{u}_{1,j}) = \phi_{1,j}^{-1}\left(\sum_{\boldsymbol{u}_{1,j}}\phi_{1,j}(\boldsymbol{u}_{1,j})\right), j = 1,\ldots,n_1$$

where $\phi_{1,j}$ is the generator of copula $C_{1,j}$, $\boldsymbol{u}_{1,j}$ denotes the variables that belong to copula $C_{1,j}$, and the sum $\sum_{u_{1,j}}$ is the sum over each variable in the subset $\boldsymbol{u}_{1,j}$. The copulas $C_{1,j}$ can be different Archimedean

copulas for $j = 1, \ldots, n_1$. Then at the second level, the copulas $C_{1,j}$ that are derived in the first level are aggregated as if they are individual variables. Suppose there are n_2 copulas and d_2 variables,

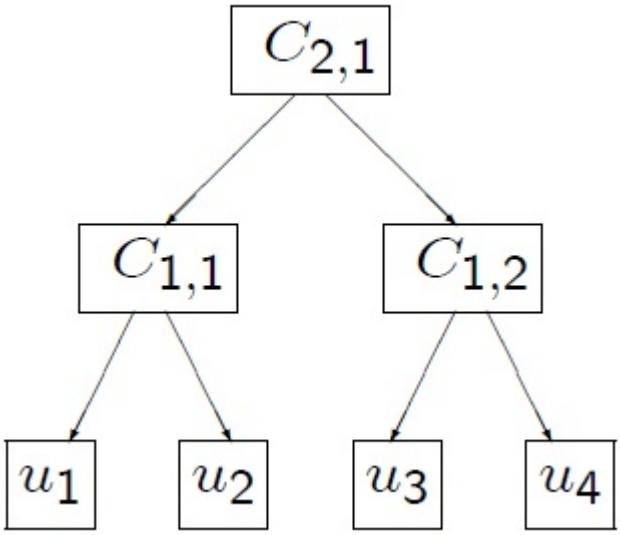
$$C_{2,j}(\boldsymbol{C}_{1,j}, \boldsymbol{u}_{2,j}) = \phi_{2,j}^{-1}\left(\sum_{\boldsymbol{C}_{1,j}} \phi_{2,j}(\boldsymbol{C}_{1,j}) + \sum_{\boldsymbol{u}_{2,j}} \phi_{2,j}(\boldsymbol{u}_{2,j})\right)$$

where $\phi_{2,j}$ denotes the generator of $C_{2,j}$ and $\boldsymbol{C}_{1,j}$ represents the subset of copulas in $C_{1,h}, h = 1, \ldots, n_1$, that is aggregated for copula $C_{2,j}$ for $j = 1, \ldots, n_2$. This structure continues until at level $l = L$ a single copula $C_{L,1}$ aggregates all the copulas at its previous level, $l = L - 1$.

A four-dimensional example that has total levels $L = 2$ and a structure shown in Figure 10.5 is defined as follows:

$$\begin{aligned} C_{2,1}(u_1, u_2, u_3, u_4) &= C_{2,1}\left(C_{1,1}(u_1, u_2), C_{1,2}(u_3, u_4)\right) \\ &= \phi_{2,1}^{-1}\left(\phi_{2,1} \circ \phi_{1,1}^{-1}\left(\phi_{1,1}(u_1) + \phi_{1,1}(u_2)\right) + \phi_{2,1} \circ \phi_{1,2}^{-1}\left(\phi_{1,2}(u_3) + \phi_{1,2}(u_4)\right)\right) \end{aligned}$$

Figure 10.5 Example Four-Dimensional Hierarchical Structure with Two Levels



Theorem 4.4 of McNeil (2008) states that the sufficient condition for a general hierarchical Archimedean structure to be a proper copula is that all appearing nodes of the form $\phi_{m,j} \circ \phi_{n,j}^{-1}$ have completely monotone derivatives. This condition places certain constraints on the copula parameters. In particular, if all the copulas in a hierarchical structure come from the Frank, Clayton, or Gumbel family, then $\theta_{m,j} \leq \theta_{n,j}$ for all j when $m < n$. Intuitively, this means that rank correlation must be increasing as you move down the hierarchical structure.

The hierarchical Archimedean copulas available in the COPULA procedure are the hierarchical versions of the Clayton, Frank, and Gumbel copulas.

Simulation

A slightly modified version of the recursive algorithm from McNeil (2008) works for all valid hierarchical structures that have Clayton, Frank, or Gumbel generators:

1. Start at $l = L$, and generate a random variable V with the distribution function F with Laplace transform $\phi_{L,1}^{-1}$.
2. For $l = L-1, \ldots, 1$, generate $u_{l,j}$ from its parent hierarchy. For $C_{l,j}$, recursively call this algorithm with the proper inner generators that correspond to the copula family.
3. Return $\boldsymbol{U} = (\phi_{L,1}^{-1}(-\log(u_1)/V), \ldots, \phi_{L,1}^{-1}(-\log(u_D)/V))^T$.

Let ϕ_1 be the outer generator and ϕ_2 the nested generator, and let θ_1 and θ_2 be the respective generator parameters. Let v be a draw from distribution function F with Laplace transform ϕ_1^{-1}. The inner copula generators $\phi_{12}(\cdot; v) = \exp(-v\phi_1 \circ \phi_2^{-1}(\cdot))$ and their corresponding Laplace transform distributions for the Clayton, Frank, and Gumbel family are summarized in Table 10.3.

Table 10.3 Inner Generators and Corresponding Distributions

Copula Type	$\phi_{12}(x; v)$	**Distribution with LT** $\phi_{12}(\cdot; v)$
Clayton	$\exp\left(v - v(1+x)^{\theta_1/\theta_2}\right)$	Tiled stable
Gumbel	$\exp(-vx^{\theta_1/\theta_2})$	$\text{Stable}\left(\frac{\theta_1}{\theta_2}, 1, \left(v\cos\frac{\theta_1\pi}{2\theta_2}\right)^{\theta_2/\theta_1}, 0\right)$
Frank	$\left(\frac{1}{1-e^{-\theta_1}}\left(1-\left(1-(1-e^{-\theta_2})\exp(-x)\right)^{\theta_1/\theta_2}\right)\right)^v$	No closed form

Note that when $\theta_1 = \theta_2$, the inner generators for the Clayton and Gumbel family both simplify to the generator of the independence copula, $\exp(-vx)$. For more information about simulating from the distribution with the Laplace transform given by the inner generator for the Frank family, see Hofert (2011). For more information about how to simulate from a tilted stable distribution, see McNeil (2008).

Canonical Maximum Likelihood Estimation (CMLE)

In the canonical maximum likelihood estimation (CMLE) method, it is assumed that the sample data $\boldsymbol{x}_i = (x_{i1}, x_{i2}, \ldots, x_{im})^\top$, $i = 1, \ldots, n$, have been transformed into uniform variates $\hat{\boldsymbol{u}}_i = (\hat{u}_{i1}, \ldots, \hat{u}_{im})$, $i = 1, \ldots, n$. One commonly used transformation is the nonparametric estimation of the CDF of the marginal distributions, which is closely related to empirical CDF,

$$\hat{u}_{i,j} = \hat{F}_{j,n}(x_{i,j})$$

where

$$\hat{F}_{j,n}(x) = \frac{1}{n+1}\sum_{i=1}^{n} I_{[x_{i,j} \le x]}$$

The transformed data $\hat{u}_{i,j}$ are used as if they had uniform marginal distributions; hence, they are called pseudo-samples. The function $\hat{F}_{j,n}$ is different from the standard empirical CDF in the scalar $1/(n+1)$, which is to ensure that the transformed data cannot be on the boundary of the unit interval $[0, 1]$. It is clear that

$$\hat{u}_{i,j} = \frac{1}{n+1}\text{rank}(x_{i,j})$$

where $\text{rank}(x_{i,j})$ is the rank among $i = 1, \ldots, n$ in increasing order.

Let $c(u_1, u_2, \ldots, u_m; \theta)$ be the density function of a copula $C(u_1, u_2, \ldots, u_m; \theta)$, and let θ be the parameter vector to be estimated. The parameter θ is estimated by maximum likelihood:

$$\hat{\theta} = \arg\max_{\theta \in \Theta} \sum_{i=1}^{n} \log c(\hat{u}_{i1}, \ldots, \hat{u}_{im}; \theta)$$

Exact Maximum Likelihood Estimation (MLE)

Suppose that the marginal distributions of vector elements $\boldsymbol{x}_i = (x_{i1}, x_{i2}, \ldots, x_{im})^\top$, $i = 1, \ldots, n$ are already known to be uniform. Then the parameter θ is estimated by exact maximum likelihood:

$$\hat{\theta} = \arg\max_{\theta \in \Theta} \sum_{i=1}^{n} \log c(x_{i1}, x_{i2}, \ldots, x_{im}; \theta)$$

Calibration Estimation

Instead of fitting the whole distribution as in MLE methods, you can directly use empirical estimates of distribution parameters. The unknown parameter that you want to estimate can be obtained by calibration using Kendall's tau. There exists a one-to-one map between the parameter at interest and Kendall's tau. Therefore, after you estimate the Kendall's tau, you can use the map to compute the parameter value. For example, the parameter matrix Σ in a t copula and the parameter θ in Archimedean copulas can be estimated in this manner. The most frequently used estimator of Kendall's tau is the rank correlation coefficient:

$$\hat{\rho}_\tau\left(X_i, X_j\right) = \binom{n}{2}^{-1} \sum_{1 \le t < s \le n} \text{sign}\left(\left(x_{t,i} - x_{s,i}\right)\left(x_{t,j} - x_{s,j}\right)\right)$$

The preceding formula is analogous to its population counterpart

$$\rho_\tau\left(X_i, X_j\right) = E\left[\text{sign}\left(\left(X_i - \tilde{X}_i\right)\left(X_j - \tilde{X}_j\right)\right)\right]$$

where $(\tilde{X}_i, \tilde{X}_j)$ has the same distribution but is independent of (X_i, X_j).

For Archimedean multivariate copulas there is only one parameter to estimate, τ (or its function θ), although for m variables there are $m(m-1)/2$ unique pairwise correlation coefficients. Denote the map from ρ_τ to θ by $\theta = \hat{\theta}(\rho_\tau)$. To aggregate the map, take simple arithmetic average:

$$\hat{\theta} = \frac{2}{m(m-1)} \sum_{1 \le i < j \le m} \hat{\theta}\left[\hat{\rho}_\tau\left(X_i, X_j\right)\right]$$

Nonlinear Optimization Options

PROC COPULA uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. In the PROC COPULA statement, you can specify nonlinear optimization options that are then passed to the NLO subsystem. For a list of all the nonlinear optimization options, see Chapter 6, "Nonlinear Optimization Methods."

Displayed Output

PROC COPULA produces displayed output described in the following sections.

Optimization Start and Resulting Parameter Estimates

If you specify the ITPRINT option in the PROC COPULA statement, PROC COPULA displays two tables, "Optimization Start Parameter Estimates" and "Optimization Results Parameter Estimates." Each table contains the following information for each model parameter:

- parameter number
- parameter name
- parameter estimate
- gradient of the objective function at the initial parameter values

In addition to this information, the table "Optimization Start Parameter Estimates" contains the following columns:

- lower-bound constraint
- upper-bound constraint

The value of the objective function at the parameter values is displayed below each table.

Iteration History for Parameter Estimates

If you specify the ITPRINT option in the PROC COPULA statement, PROC COPULA displays a table that contains the following information for each iteration. Note that some information is specific to the model-fitting method chosen (for example, Newton-Raphson, trust region, or quasi-Newton method).

- iteration number
- number of restarts since the fitting began
- number of function calls
- number of active constraints at the current solution

- value of the objective function (–1 times the log-likelihood value) at the current solution
- change in the objective function from previous iteration
- value of the maximum absolute gradient element
- step size (for Newton-Raphson and quasi-Newton methods)
- slope of the current search direction (for Newton-Raphson and quasi-Newton methods)
- lambda (for trust region method)
- radius value at current iteration (for trust region method)

Model Fit Summary

The "Model Fit Summary" table contains the following information:

- number of observations used
- number of missing values in data set, if any
- data set name
- type of model that was fit
- log-likelihood value at solution
- maximum absolute gradient at solution
- number of iterations
- optimization method
- value of Akaike's information criterion (AIC) at the solution (a smaller value indicates better fit)
- value of Schwarz Bayesian criterion (SBC) at the solution (a smaller value indicates better fit)

Below the "Model Fit Summary" table is a statement about whether the algorithm successfully converged.

Parameter Estimates

The "Parameter Estimates" table contains the estimates of the model parameters. For the normal copula, this table is not displayed because the only parameters are in the correlation matrix, which is displayed in the "Correlation Matrix" table. For the *t* copula, the parameter is the number of degrees of freedom; in the table it is called "DF." For Archimedean copulas such as Clayton, Frank, and Gumbel, the parameter is called "theta."

Correlation Matrix

The "Correlation Matrix" table contains the estimates of the model correlation matrix. This table is displayed only for elliptical copulas such as the normal and *t* copulas. Row and column names come from the list of variables defined in the VAR statement.

OUTCOPULA= Data Set

The OUTCOPULA= data set consists of several rows. The first row (with _TYPE_='PARM') contains the parameter estimates in the model. For a *t* copula, the estimate is the number of degrees of freedom; for Archimedean copulas, the estimate is "theta." The second row (with _TYPE_='STD') contains the standard error for the parameter estimate in the model. These two rows do not appear for the normal copula.

If you use one of the elliptical copulas, *t* or normal, the rest of the data set contains the correlation matrix estimates. The correlation matrix appears in the observations with _TYPE_='CORR', and the _VARIABLE_ column contains the parameter names.

If METHOD=MLE and the nonlinear optimization subsystem is used, a _STATUS_ column is created that contains a character variable that indicates whether the optimization process reached convergence or failed to converge:

- 0 indicates that the convergence was reached
- 1 indicates that the maximum number of iterations allowed was exceeded
- 2 indicates a failure to improve the function value
- 3 indicates a failure to converge for one of the following reasons:
  - The objective function or its derivatives could not be evaluated or improved.
  - Linear constraints are dependent.
  - The algorithm failed to return to feasible region.
  - The number of iterations is greater than prespecified.

OUTPSEUDO=, OUT=, and OUTUNIFORM= Data Sets

The OUTPSEUDO=, OUT=, and OUTUNIF= data sets contain the same number of columns as specified in the VAR statement. The names of the columns are taken from the same VAR statement list.

ODS Table Names

PROC COPULA assigns a name to each table it creates. You can use these names to denote the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 10.4.

Table 10.4 ODS Tables Produced in PROC COPULA

ODS Table Name	Description	Option
ODS Tables Created by the FIT Statement		
ConvergenceStatus	Convergence status	Default
Correlation	Correlation matrix estimates	Default with elliptical copulas
KendallCorrelation	Kendall correlation matrix estimates	Default with elliptical copulas
SpearmanCorrelation	Spearman correlation matrix estimates	Default with normal copula
FitSummary	Summary of nonlinear estimation	Default
ParameterEstimates	Parameter estimates	Default
ConvergenceStatus	Convergence status	ITPRINT
InputOptions	Input options	ITPRINT
IterHist	Iteration history	ITPRINT
IterStart	Optimization start	ITPRINT
IterStop	Optimization results	ITPRINT
ParameterEstimatesResults	Parameter estimates	ITPRINT
ParameterEstimatesStart	Parameter estimates	ITPRINT
ProblemDescription	Problem description	ITPRINT

ODS Graph Names

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

PROC COPULA assigns a name to each graph it creates by using ODS. You can use these names to refer to the graphs when you use ODS. The names are listed in Table 10.5.

Table 10.5 ODS Graphics Produced by PROC COPULA

ODS Graph Name	Plot Description	Statement	PLOTS= Option
MatrixPlotOrig	Matrix panel of pairwise scatter plots of the original data	FIT	DATATYPE=BOTH, DATATYPE=ORIGINAL
MatrixPlotUnif	Matrix panel of pairwise scatter plots of the original data transformed into uniform marginals	FIT	DATATYPE=BOTH, DATATYPE=UNIFORM
MatrixPlotSOrig	Matrix panel of pairwise scatter plots of the simulated data	SIMULATE	DATATYPE=BOTH, DATATYPE=ORIGINAL
MatrixPlotSUnif	Matrix panel of pairwise scatter plots of the simulated data transformed into uniform marginals	SIMULATE	DATATYPE=BOTH, DATATYPE=UNIFORM

Examples: COPULA Procedure

Example 10.1: Copula-Based VaR Estimation

Value-at-risk (VaR) has become a de facto standard in financial risk management. The purpose of this measure is to give some quantitative insight to the riskiness of an asset portfolio. This measure is expressed generically in the following terms: What is the probability of losing no more than given percentage of a portfolio in a certain period of time? Or, what are the maximum possible losses at a given confidence level? The most simple and clearly wrong answer to this question is to compute the empirical quantile of past portfolio returns. The problem of this approach is that it does not take into account the dynamic nature of asset returns, the possibility of changing distribution, time memory, and, most importantly, cross-sectional dependence between individual assets in the portfolio.

This simple example of VaR computation takes into account at least cross-sectional dependence of the data. The end result is the prediction of the next-day maximum possible loss on the portfolio of stocks.

This example uses the daily returns on large stocks such as IBM, Microsoft, British Petroleum, Coca-Cola, and Duke Energy. Output 10.1.1 shows the first 10 observations of the data.

Output 10.1.1 First 10 Observations of Daily Returns

Obs	date	ret_msft	ret_ko	ret_ibm	ret_duk	ret_bp
1	01/03/2008	0.004182	0.010367	0.002002	0.003503	0.019114

9	01/15/2008	-0.011318	-0.010851	-0.010689	-0.017075	-0.040925
10	01/16/2008	-0.022587	-0.015021	-0.001955	0.002316	-0.021336

The purpose of this exercise is to estimate one-day future losses of a stock portfolio. The simplest approach is to assume that the joint distribution of individual asset returns does not change with time. This might be close to the truth if only a small time interval is used. Then, a copula approach is used to estimate the joint distribution. Next, the new large sample of daily individual asset returns is simulated from the fitted joint distribution. These assets are then combined into a portfolio and its daily returns are computed. Finally, quantiles of simulated portfolio returns (which simply represent possible next-day losses of the portfolio) are examined.

The first step is to cut off a small number of past return observations as in the following SAS DATA step:

```
/* Keep only the last 250 observations of the data */
data returns;
   set returns nobs=observ;
   if (_N_ > observ-250);
run;
```

The following statements fit a *t* copula to the returns data and at the same time simulate the sample from the fitted joint distribution:

```
/* Copula estimation and simulation of returns */
proc copula data = returns;
   var ret_ibm ret_msft ret_bp ret_ko ret_duk;
   * fit T-copula to stock returns;
   fit T /
          marginals = empirical
          method    = MLE
          plots      = (datatype = both);
   * simulate 10000 observations;
   * independent in time, dependent in cross-section;
   simulate /
            ndraws = 10000
            seed   = 1234
            out    = simulated_returns
            plots(unpack) = (datatype = original);
run;
```

The first line of the COPULA procedure uses a VAR statement to specify the list of variables. In this example, these are daily returns of five large-company stocks.The next statement, FIT, requires some options. First, Student's *t* copula (T) is specified. After the slash, the MARGINALS=EMPIRICAL option specifies that an

empirical distribution be fit. The choice of fitting method is MLE. The PLOTS=BOTH option requests that both original and transformed data graphs be organized into a symmetric panel.

Then, given the estimation results, the NDRAWS= option in the SIMULATE statement simulates 10,000 new observations for each asset return series. The SEED= option fixes the random number generator, the OUT= option specifies the name of SAS data set to contain the simulated sample, and the PLOT= option requests scatter plots of simulated returns in the original data scale.

The output of these statements is shown in Output 10.1.2.

Output 10.1.2 Copula Estimation

The COPULA Procedure

Model Fit Summary	
Number of Observations	250
Data Set	WORK.RETURNS
Copula Type	T
Log Likelihood	171.52667
Maximum Absolute Gradient	1.21421E-6
Number of Iterations	9
Optimization Method	Newton-Raphson
AIC	-321.05333
SBC	-282.31726

Parameter Estimates

Parameter	Estimate	Standard Error	t Value	Approx Pr > |t|
DF	6.713594	1.327879	5.06	<.0001

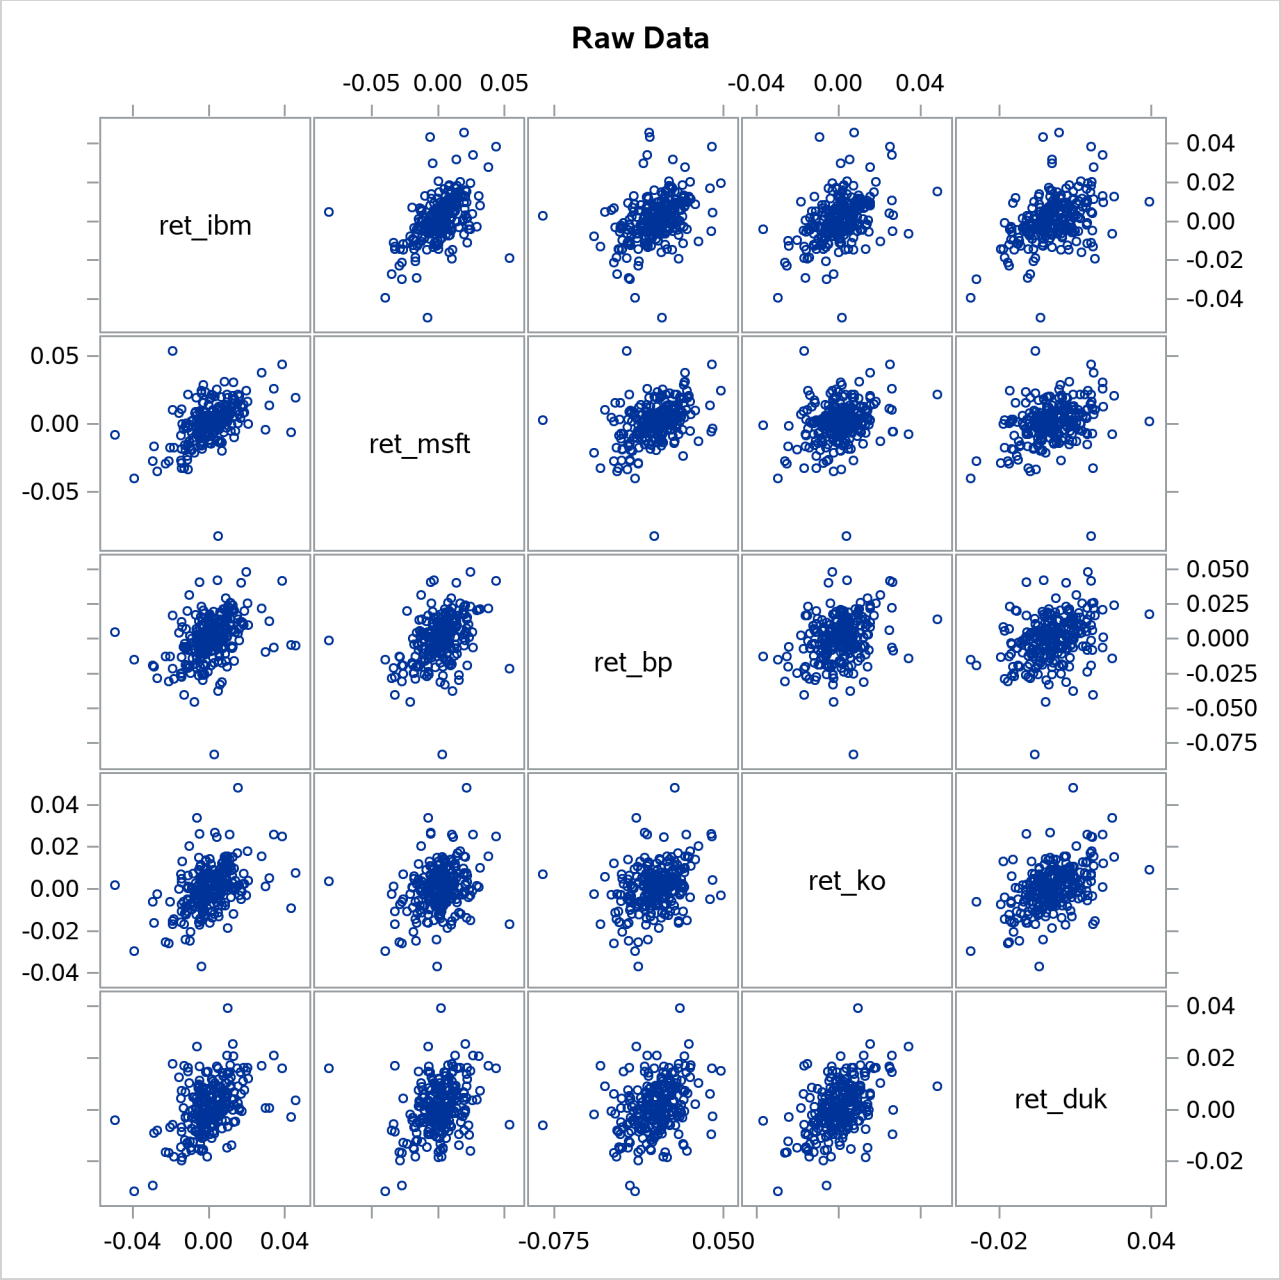
Correlations Matrix

	ret_ibm	ret_msft	ret_bp	ret_ko	ret_duk
ret_ibm	1.0000	0.5657	0.4663	0.4548	0.4740
ret_msft	0.5657	1.0000	0.4585	0.3234	0.3658
ret_bp	0.4663	0.4585	1.0000	0.3459	0.3576
ret_ko	0.4548	0.3234	0.3459	1.0000	0.4742
ret_duk	0.4740	0.3658	0.3576	0.4742	1.0000

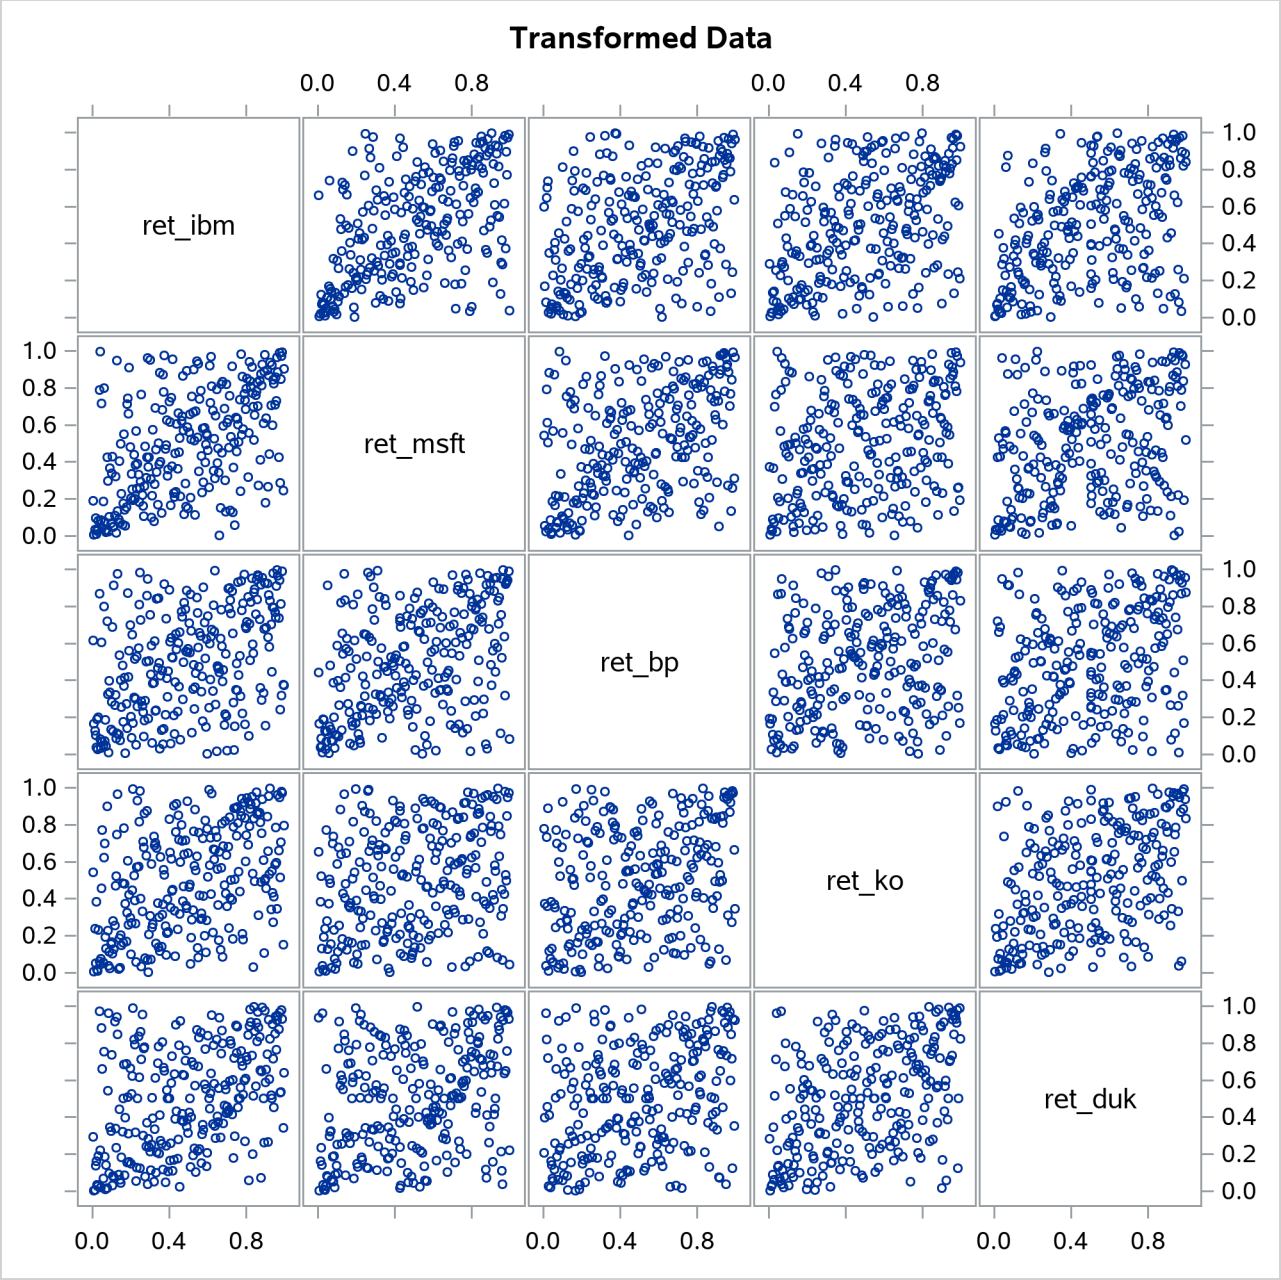
The first table in Output 10.1.2, "Model Fit Summary," provides some general description of copula model estimation. The second table, "Parameter Estimates," provides point estimates and inference on copula parameters. In this example the only parameter in this table is the number of degrees of freedom in the multivariate *t* distribution. The last table, "Correlation Matrix," contains estimates of copula model parameters.

The graphical output of the preceding statements is in Output 10.1.3 and in Output 10.1.4.

Output 10.1.3 Original Data



Output 10.1.4 Original Data Transformed into Uniform Marginals



Note that in Output 10.1.3 the most elliptical scatter plot, between IBM and MSFT, indicates the strongest dependence. Similarly, in Output 10.1.4 those graphs that are denser along the diagonal indicate the same thing.

Now the equally weighted next day portfolio return is computed. Each individual return is transformed into nominal scale first, then all returns are added up with equal weights, and the result is transformed into a net return by subtracting one.

```
/* compute equally weighted portfolio return */
data port_ret (drop = i ret);
   set simulated_returns;
   array returns{5} ret_ibm ret_msft ret_bp ret_ko ret_duk;
   ret =0;
   do i =1 to 5;
      ret = ret+ 0.2*exp(returns[i]);
   end;
   port_ret = ret-1;
run;
```

The final step is to compute empirical quantiles of simulated daily portfolio return. This is done with the help of PROC UNIVARIATE in the following statements:

```
/* compute descriptive statistics */
/* quantile table will give Value-at-Risk estimates for the portfolio */
proc univariate data = port_ret;
   var port_ret;
run;
```

Output 10.1.5 shows that with 99% confidence the potential loss on an equally weighted portfolio over the next day does not exceed 2.6% (the number in table is multiplied by 100). You can also say that there is no more than a 5% chance of losing 1.5% of the portfolio value. These percentage measures are exactly the value-at-risk.

Output 10.1.5 Return Quantiles

The UNIVARIATE Procedure
Variable: port_ret

Quantiles (Definition 5)	
Level	**Quantile**
100% Max	0.048144752
99%	0.026628639
95%	0.015538196
90%	0.011573916
75% Q3	0.005801203
50% Median	0.000688897
25% Q1	-0.004953729
10%	-0.010636997
5%	-0.014677062
1%	-0.026629716
0% Min	-0.052757770

Example 10.2: Simulating Default Times

Suppose the correlation structure required for a normal copula function is already given. For example, it can be estimated from the historic data on default times in some set of industries, but this stage is not in the scope of this example. The correlation structure is saved in a SAS data set called inparm. The following statements and their output in Output 10.2.1 show that the correlation parameter is set at 0.8:

```
proc print data = inparm;
run;
```

Output 10.2.1 Copula Correlation Matrix

Obs	name	Y1	Y2
1	Y1	1.0	0.8
2	Y2	0.8	1.0

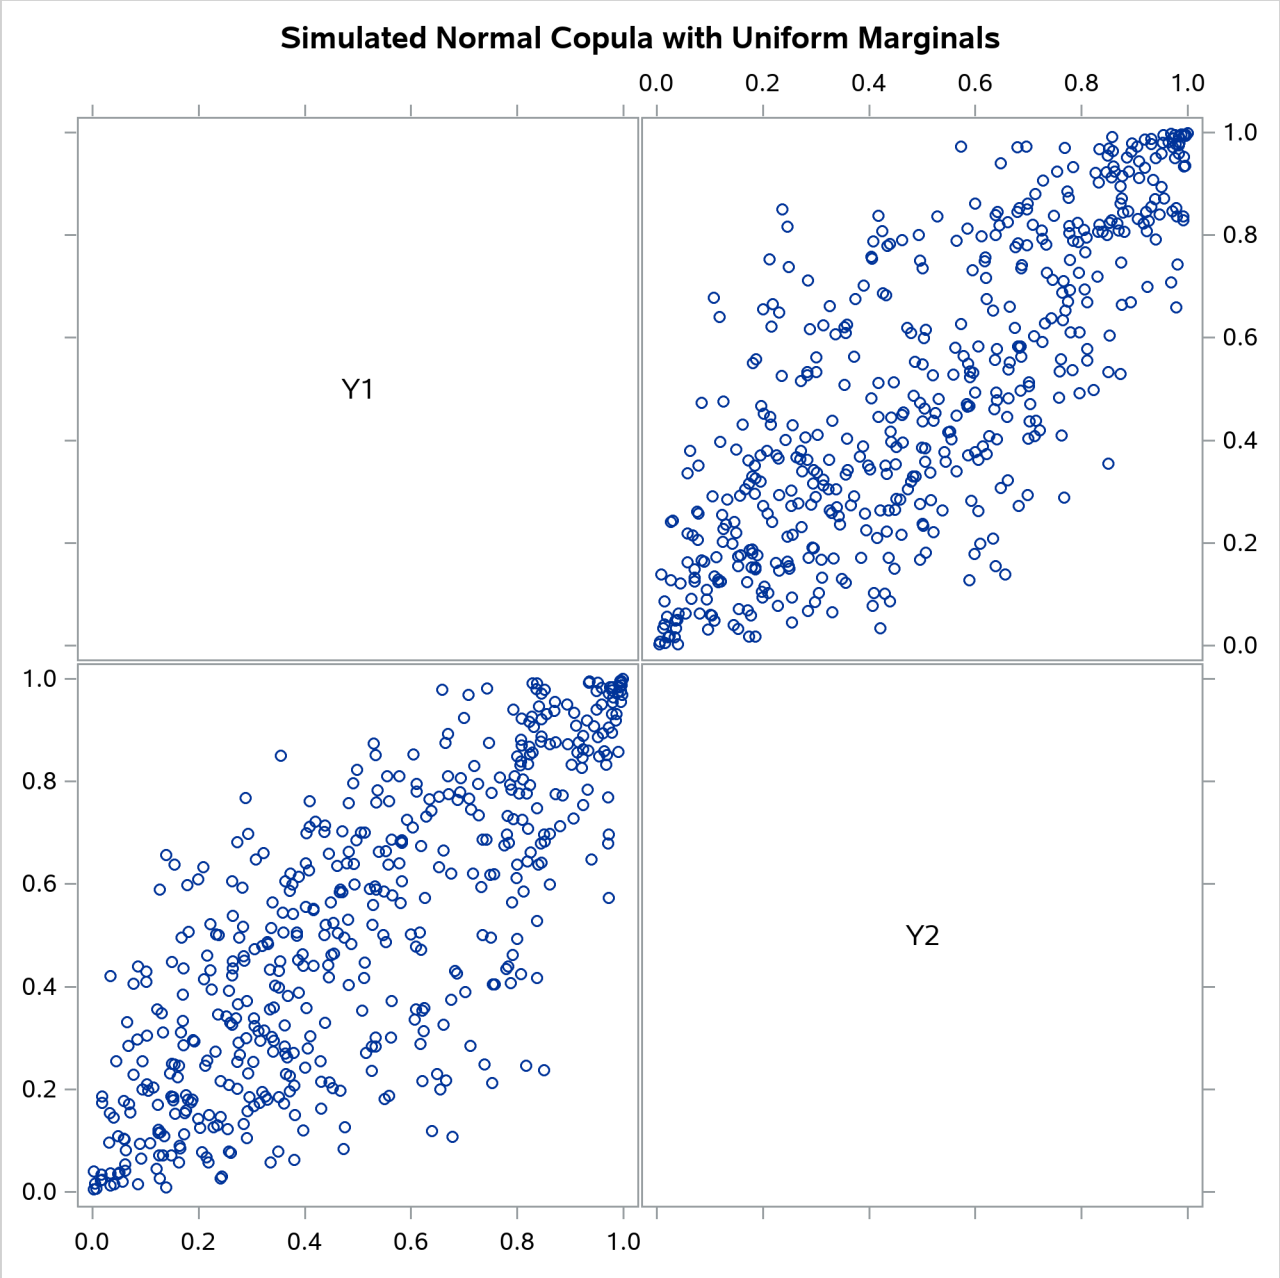
Now you use PROC COPULA to simulate the data. The VAR statement specifies the list of variables to contain simulated data. The DEFINE statement assigns the name COP and specifies a normal copula that reads the correlation matrix from the inparm data set.

The SIMULATE statement refers to the COP label defined in the VAR statement and specifies some options: the NDRAWS= option specifies a sample size, the SEED= option specifies 1234 as the random number generator seed, the OUTUNIFORM=NORMAL_UNIFDATA option names the output data set for the result of simulation in uniforms, and the PLOTS= option requests the matrix of data scatter plots and marginal distributions (DATATYPE=ORIGINAL) and theoretical cumulative distribution function contour and surface plots (DISTRIBUTION=CDF). Theoretical distribution graphs work only for the bivariate case.

```
/* simulate the data from bivariate normal copula */
proc copula ;
   var Y1-Y2;
   define cop normal (corr=inparm);
   simulate cop /
            ndraws     = 500
            seed       = 1234
            outuniform = normal_unifdata
            plots      = (datatype = original
                          distribution = cdf);
run;
```

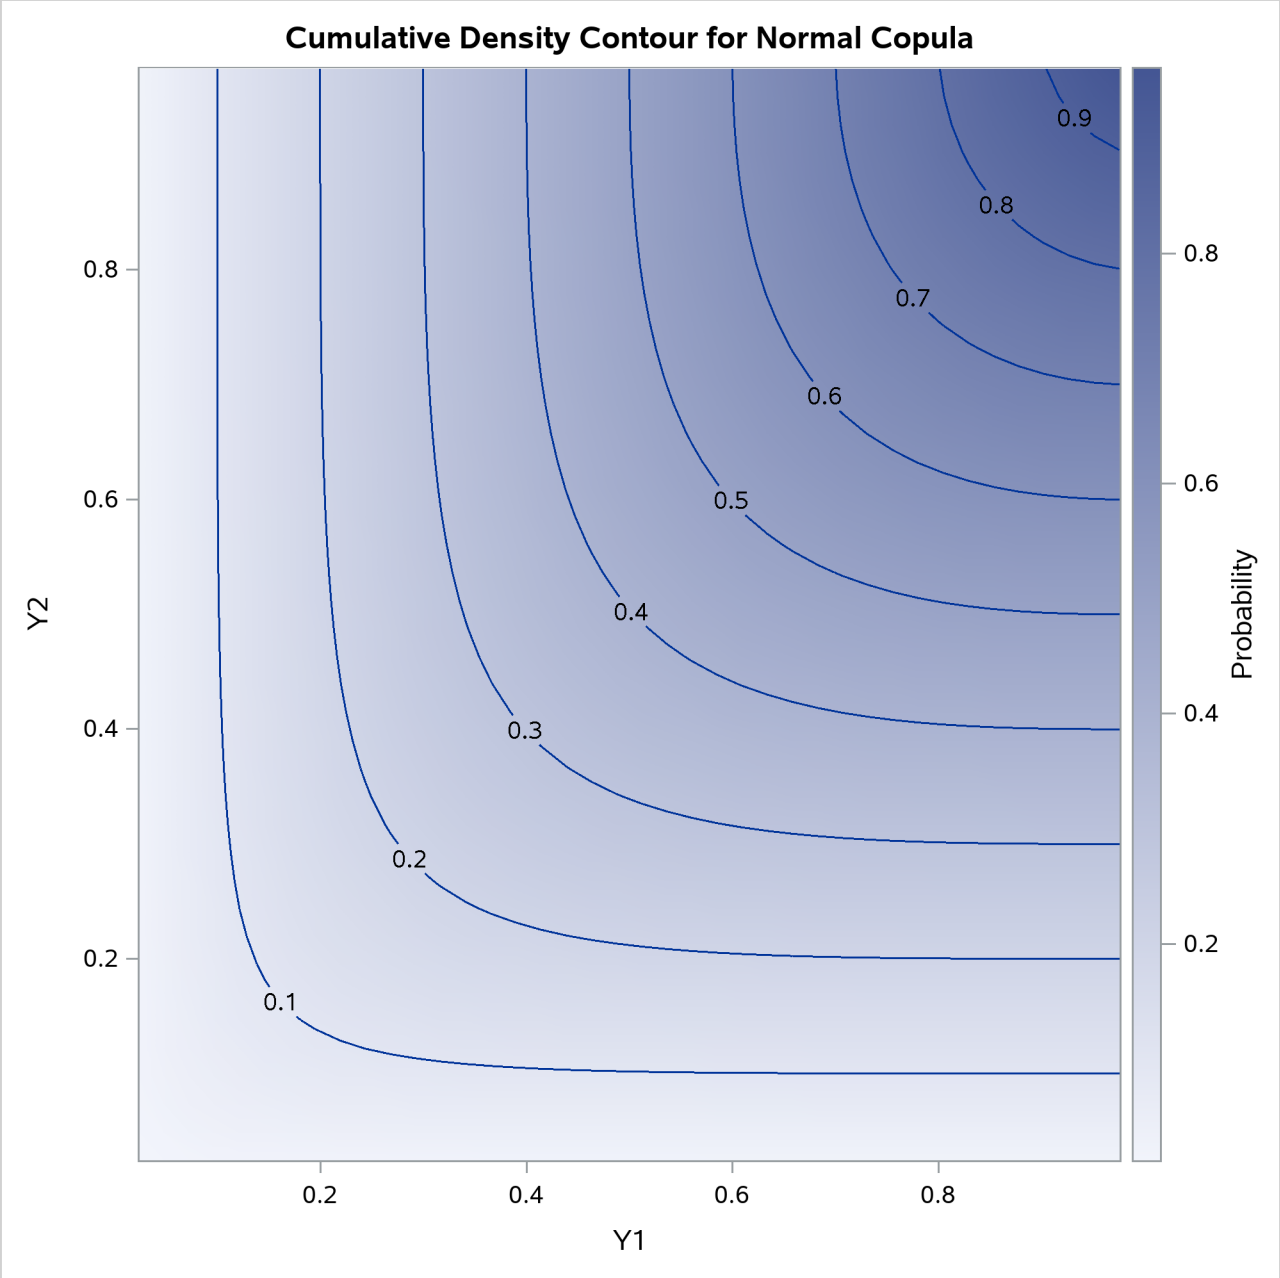
The graphical output is shown in Output 10.2.2 and in Output 10.2.3.

Output 10.2.2 Simulated Data, Uniform Marginals



Output 10.2.2 shows bivariate scatter plots of the simulated data. Also note that due to the high correlation parameter (0.8), the scatter plots are most dense around the 45 degree line, which indicates high dependence between the two variables.

Output 10.2.3 Joint Cumulative Distribution



Output 10.2.3 shows the theoretical CDF contour plot. If the correlation parameter were set to 0, then knowing copula properties you would expect perfectly parallel straight lines with the slope of –45 degrees. On the other hand, if the parameter were set to 1, you would expect perpendicular lines with corners lying on the diagonal.

The next DATA step transforms the variables from zero-one uniformly distributed to nonnegative exponentially distributed with parameter 0.5. Three indicator variables are added to the data set as well. SURVIVE1 and SURVIVE2 are equal to 1 if a respective company has remained in business for more than three years. SURVIVE is equal to 1 if both companies survived the same period together.

```
/* default time has exponential marginal distribution with parameter 0.5 */
data default;
   set normal_unifdata;
   array arr{2} Y1-Y2;
   array time{2} time1-time2;
   array surv{2} survive1-survive2;
   lambda = 0.5;
   do i=1 to 2;
      time[i] = -log(1-arr[i])/lambda;
      surv[i] = 0;
      if (time[i] >3) then surv[i]=1;
   end;
   survive = 0;
   if (time1 >3) && (time2 >3) then survive = 1;
run;
```

The first analysis step is to look at correlations between survival times of two companies. This step is performed with the following CORR procedure:

```
proc corr data = default plot=matrix kendall;
   var time1 time2;
run;
```

The output of this code is given in Output 10.2.4 and in Output 10.2.5.

Output 10.2.4 shows some descriptive statistics and two measures of correlation: Pearson and Kendall. Both of these measures indicate high and statistically significant dependence between life spans of two companies.

Output 10.2.4 Default Time Descriptive Statistics and Correlations

The CORR Procedure

2 Variables:	time1	time2

Simple Statistics

Variable	N	Mean	Std Dev	Median	Minimum	Maximum
time1	500	2.08347	2.23677	1.26496	0.00449	13.08462
time2	500	2.07547	2.19756	1.37603	0.01076	16.85567

Pearson Correlation Coefficients, N = 500
Prob > |r| under H0: Rho=0

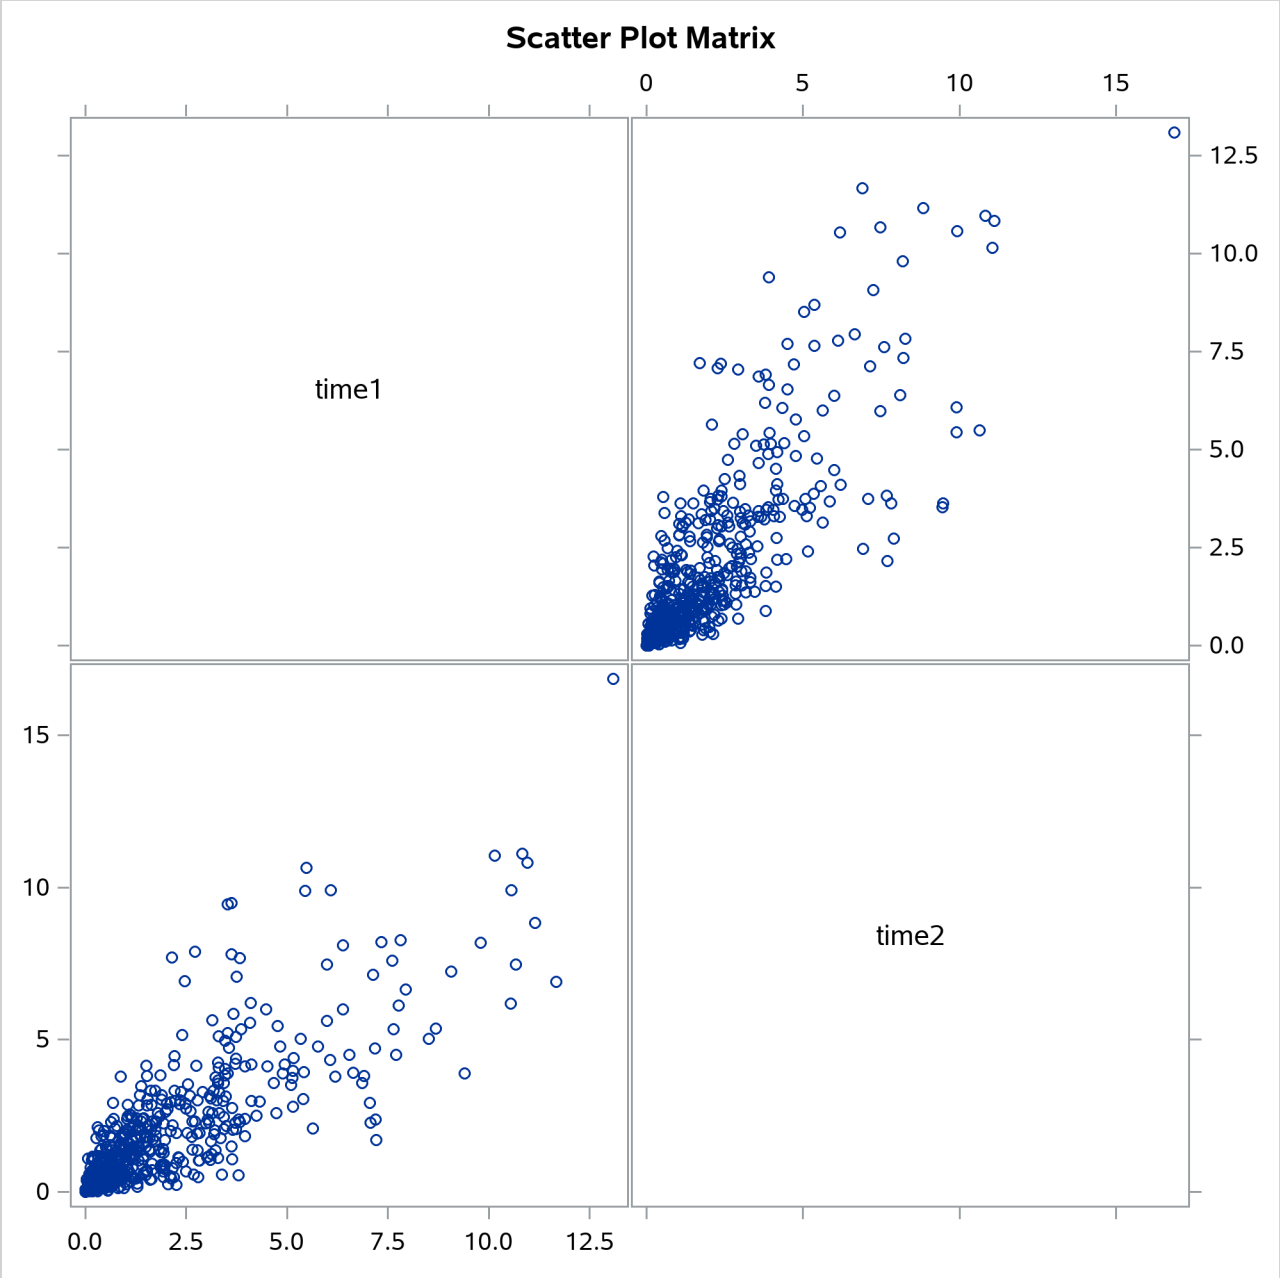
	time1	time2
time1	1.00000	0.80268 <.0001
time2	0.80268 <.0001	1.00000

Kendall Tau b Correlation Coefficients, N = 500
Prob > |tau| under H0: Tau=0

	time1	time2
time1	1.00000	0.59566 <.0001
time2	0.59566 <.0001	1.00000

Output 10.2.5 shows marginal distributions and scatter plots of simulated data. Distributions are noticeably close to exponential and scatter plots show a high degree of dependence.

Output 10.2.5 Default Times



The second and final step is to empirically estimate the default probabilities of two companies. This is done using the FREQ procedure as follows:

```
proc freq data=default;
   table survive survive1-survive2;
run;
```

The result is shown in Output 10.2.6.

Output 10.2.6 Probabilities of Default

The FREQ Procedure

survive	Frequency	Percent	Cumulative Frequency	Cumulative Percent
0	415	83.00	415	83.00
1	85	17.00	500	100.00

survive1	Frequency	Percent	Cumulative Frequency	Cumulative Percent
0	374	74.80	374	74.80
1	126	25.20	500	100.00

survive2	Frequency	Percent	Cumulative Frequency	Cumulative Percent
0	390	78.00	390	78.00
1	110	22.00	500	100.00

Output 10.2.6 shows that the empirical default probabilities are 75% and 78%. Assuming that these companies are independent gives the probability estimate of both companies defaulting during the period of three years as: 0.75*0.78=0.59 (59%). Comparing this naive estimate with the much higher actual 83% joint default probability illustrates that neglecting the correlation between the two companies significantly underestimates the probability of default.

Overview: COUNTREG Procedure

The COUNTREG (count regression) procedure analyzes regression models in which the dependent variable takes nonnegative integer or count values. The dependent variable is usually an *event count*, which refers to the number of times an event occurs. For example, an event count might represent the number of ship accidents per year for a given fleet. In count regression, the conditional mean $E(y_i|\mathbf{x}_i)$ of the dependent variable y_i is assumed to be a function of a vector of covariates $\mathbf{x}_i$.

The Poisson (log-linear) regression model is the most basic model that explicitly takes into account the nonnegative integer-valued aspect of the outcome. With this model, the probability of an event count is determined by a Poisson distribution, where the conditional mean of the distribution is a function of a vector of covariates. However, the basic Poisson regression model is limited because it forces the conditional mean of the outcome to equal the conditional variance. This assumption is often violated in real-life data. Negative binomial regression is an extension of Poisson regression in which the conditional variance can exceed the conditional mean. Also, a common characteristic of count data is that the number of zeros in the sample exceeds the number of zeros that are predicted by either the Poisson or negative binomial model. Zero-inflated

Poisson (ZIP) and zero-inflated negative binomial (ZINB) models explicitly model the production of zero counts to account for excess zeros and also enable the conditional variance of the outcome to differ from the conditional mean.

In zero-inflated models, additional zeros occur with probability φ_i, which is determined by a separate model, $\varphi_i = F(\mathbf{z}_i'\boldsymbol{\gamma})$, where F is the normal or logistic distribution function that results in a probit or logistic model and $\mathbf{z}_i$ is a set of covariates.

PROC COUNTREG supports the following models for count data:

- Poisson regression
- Conway-Maxwell-Poisson regression
- negative binomial regression with quadratic (NEGBIN2) and linear (NEGBIN1) variance functions (Cameron and Trivedi 1986)
- zero-inflated Poisson (ZIP) model (Lambert 1992)
- zero-inflated Conway-Maxwell-Poisson (ZICMP) model
- zero-inflated negative binomial (ZINB) model
- fixed-effects and random-effects Poisson models for panel data
- fixed-effects and random-effects negative binomial models for panel data
- all models in this list (except panel data models) that have spatial effects

The count data models have been used extensively in economics, political science, and sociology. For example, Hausman, Hall, and Griliches (1984) examine the effects of research and development expenditures on the number of patents obtained by US companies. Cameron and Trivedi (1986) study factors that affect the number of doctor visits that a group made during a two-week period. Greene (1994) studies the number of derogatory reports to a credit reporting agency for a group of credit card applicants. As a final example, Long (1997) analyzes the number of publications by PhD candidates in science in the final three years of their doctoral studies.

The COUNTREG procedure can use the maximum likelihood method and the Bayesian method. Initial starting values for the nonlinear optimizations are typically calculated by OLS. When a model that contains a dependent count variable is estimated using linear ordinary least squares (OLS) regression, the count nature of the dependent variable is ignored. This can lead to negative predicted counts and to parameter estimates that have undesirable properties in terms of statistical efficiency, consistency, and unbiasedness unless the mean of the counts is high, in which case the Gaussian approximation and linear regression might be satisfactory.

Getting Started: COUNTREG Procedure

The COUNTREG procedure is similar in use to other SAS regression model procedures. For example, the following statements are used to estimate a Poisson regression model:

```
proc countreg data=one;
   model y = x / dist=poisson;
run;
```

The response variable *y* is numeric and has nonnegative integer values. To allow for variance greater than the mean, specify the DIST=NEGBIN option to fit the negative binomial model instead of the Poisson.

The following example illustrates the use of PROC COUNTREG. The data are taken from Long (1997) and can be found in the SAS/ETS Sample Library. This study examines how factors such as gender (fem), marital status (mar), number of young children (kid5), prestige of the graduate program (phd), and number of articles published by the mentor (ment) of a doctoral candidate in science affect the number of articles (art) published by the scientist.

The first 10 observations are shown in Figure 11.1.

Figure 11.1 Article Count Data

Obs	art	fem	mar	kid5	phd	ment
1	3	0	1	2	1.38000	8.0000
2	0	0	0	0	4.29000	7.0000
3	4	0	0	0	3.85000	47.0000
4	1	0	1	1	3.59000	19.0000
5	1	0	1	0	1.81000	0.0000
6	1	0	1	1	3.59000	6.0000
7	0	0	1	1	2.12000	10.0000
8	0	0	1	0	4.29000	2.0000
9	3	0	1	2	2.58000	2.0000
10	3	0	1	1	1.80000	4.0000

The following SAS statements estimate the Poisson regression model:

```
proc countreg data=long97data;
   model art = fem mar kid5 phd ment / dist=poisson;
run;
```

The "Model Fit Summary" table, shown in Figure 11.2, lists several details about the model. By default, the COUNTREG procedure uses the Newton-Raphson optimization technique. The maximum log-likelihood value is shown, in addition to two information measures, Akaike's information criterion (AIC) and Schwarz's Bayesian information criterion (SBC), which can be used to compare competing Poisson models. Smaller values of these criteria indicate better models.

Figure 11.2 Estimation Summary Table for a Poisson Regression

The COUNTREG Procedure

Model Fit Summary	
Dependent Variable	art
Number of Observations	915
Data Set	WORK.LONG97DATA
Model	Poisson
Log Likelihood	-1651
Maximum Absolute Gradient	3.57426E-9
Number of Iterations	5
Optimization Method	Newton-Raphson
AIC	3314
SBC	3343

The parameter estimates of the model and their standard errors are shown in Figure 11.3. All covariates are significant predictors of the number of articles, except for the prestige of the program (phd), which has a p-value of 0.6271.

Figure 11.3 Parameter Estimates of Poisson Regression

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	0.304617	0.102982	2.96	0.0031
fem	1	-0.224594	0.054614	-4.11	<.0001
mar	1	0.155243	0.061375	2.53	0.0114
kid5	1	-0.184883	0.040127	-4.61	<.0001
phd	1	0.012823	0.026397	0.49	0.6271
ment	1	0.025543	0.002006	12.73	<.0001

The following statements fit the negative binomial model. Although the Poisson model requires that the conditional mean equal the conditional variance, the negative binomial model allows for overdispersion; that is, the conditional variance can exceed the conditional mean.

```
proc countreg data=long97data;
   model art = fem mar kid5 phd ment / dist=negbin(p=2) method=qn;
run;
```

The fit summary is shown in Figure 11.4, and parameter estimates are listed in Figure 11.5.

Figure 11.4 Estimation Summary Table for a Negative Binomial Regression

The COUNTREG Procedure

Model Fit Summary	
Dependent Variable	art
Number of Observations	915
Data Set	WORK.LONG97DATA
Model	NegBin(p=2)
Log Likelihood	-1561
Maximum Absolute Gradient	5.72014E-7
Number of Iterations	16
Optimization Method	Quasi-Newton
AIC	3136
SBC	3170

Figure 11.5 Parameter Estimates of Negative Binomial Regression

Parameter Estimates					
Parameter	**DF**	**Estimate**	**Standard Error**	**t Value**	**Approx Pr > |t|**
Intercept	1	0.256144	0.138560	1.85	0.0645
fem	1	-0.216418	0.072672	-2.98	0.0029
mar	1	0.150489	0.082106	1.83	0.0668
kid5	1	-0.176415	0.053060	-3.32	0.0009
phd	1	0.015271	0.036040	0.42	0.6718
ment	1	0.029082	0.003470	8.38	<.0001
_Alpha	1	0.441620	0.052967	8.34	<.0001

The parameter estimate for _Alpha of 0.4416 is an estimate of the dispersion parameter in the negative binomial distribution. A t test for the hypothesis $H_0 : \alpha = 0$ is provided. It is highly significant, indicating overdispersion ($p < 0.0001$).

The null hypothesis $H_0 : \alpha = 0$ can be also tested against the alternative $\alpha > 0$ by using the likelihood ratio test, as described by Cameron and Trivedi (1998, pp. 45, 77–78). The likelihood ratio test statistic is equal to $-2(\mathcal{L}_P - \mathcal{L}_{NB}) = -2(-1651 + 1561) = 180$, where $\mathcal{L}_P$ and $\mathcal{L}_{NB}$ are the log likelihoods for the Poisson and negative binomial models, respectively. The likelihood ratio test is highly significant, providing strong evidence of overdispersion.

Syntax: COUNTREG Procedure

The following statements are available in the COUNTREG procedure:

PROC COUNTREG < *options* > ;
BAYES < *options* > ;
BOUNDS *bound1* < , *bound2* . . . > ;
BY *variables* ;
CLASS *variable* < *options* > . . . < *variable* < *options* > > < */global-options* > ;
DISPMODEL *dependent-variable* ∼ < *dispersion-related-regressors* >< */option* > ;
FREQ *variable* ;
INIT *initvalue1* < , *initvalue2* . . . > ;
MODEL *dependent-variable* ∼ < *dispersion-related-regressors* ></ *option*> ;
NLOPTIONS < *options* > ;
OUTPUT < **OUT=***SAS-data-set* >< *output-options* > ;
PERFORMANCE < *performance-options* > ;
PRIOR **_REGRESSORS** | *parameter-list* ∼ *distribution* ;
RESTRICT *restriction1* < , *restriction2* . . . > ;
TEST *equation1* < , *equation2*. . . > / *test-options* ;
SCORE < **OUT=***SAS-data-set* > < *output-options* > ;
SHOW *options* ;
STORE < **OUT=** >*item-store-name* ;
WEIGHT *variable* < */options* > ;
ZEROMODEL *dependent-variable* ∼ < *zero-inflated-regressors* > < */options* > ;
SPATIALEFFECTS < *model-spatial-effect-regressors* > < */options* > ;
SPATIALDISPEFFECTS < *dispersion-spatial-effect-regressors* > < */options* > ;
SPATIALZEROEFFECTS < *zero-inflation-spatial-effect-regressors* > < */option* > ;
SPATIALID *variable* ;

You can specify multiple MODEL statements. The CLASS statement must precede the MODEL statement. If you include the ZEROMODEL statement, it must appear after the MODEL statement. If you specify more than one FREQ or WEIGHT statement, the variable that is specified in the first instance is used.

Functional Summary

Table 11.1 summarizes the statements that you can use in the COUNTREG procedure.

Table 11.1 PROC COUNTREG Functional Summary

Description	Statement	Option
Data Set Options		
Specifies the input data set	PROC COUNTREG	DATA=
Specifies the input spatial weights data set	PROC COUNTREG	WMAT=
Specifies the identification variable for panel data analysis	PROC COUNTREG	GROUPID=
Does not row-normalize the spatial weights matrix	PROC COUNTREG	NONORMALIZE

Table 11.1 *continued*

Description	Statement	Option
Writes parameter estimates to an output data set	PROC COUNTREG	OUTEST=
Requests that the procedure produce graphics via the Output Delivery System	PROC COUNTREG	PLOTS=
Writes estimates to an output data set	OUTPUT	OUT=
Declaring the Role of Variables		
Specifies BY-group processing	BY	
Specifies classification variables	CLASS	
Specifies a frequency variable	FREQ	
Specifies a weight variable	WEIGHT	
Specifies a spatial ID variable	SPATIALID	
Item Store Control Options		
Displays the contents of the item store	SHOW	
Stores the model in an item store	STORE	
Restores the model from the item store	PROC COUNTREG	RESTORE=
Printing Control Options		
Prints the correlation matrix of the estimates	MODEL	CORRB
Prints the covariance matrix of the estimates	MODEL	COVB
Prints a summary iteration listing	MODEL	ITPRINT
Suppresses the normal printed output	PROC COUNTREG	NOPRINT
Requests all printing options	MODEL	PRINTALL
Option Process Control Options		
Specifies maximum number of iterations allowed	MODEL	MAXITER=
Selects the iterative minimization method to use	PROC COUNTREG	METHOD=
Sets boundary restrictions on parameters	BOUNDS	
Sets initial values for parameters	INIT	
Sets linear restrictions on parameters	RESTRICT	
Sets the number of threads to use	PERFORMANCE	
Specifies the optimization options	NLOPTIONS	See Chapter 6, "Nonlinear Optimization Methods."
Model Estimation Options		
Specifies the dispersion variables	DISPMODEL	
Specifies the type of model	PROC COUNTREG	DIST=
Specifies the type of covariance matrix	MODEL	COVEST=
Specifies the type of error components model for panel data	MODEL	ERRORCOMP=
Suppresses the intercept parameter	MODEL	NOINT
Specifies the offset variable	MODEL	OFFSET=

Table 11.1 *continued*

Description	Statement	Option
Specifies the parameterization for the Conway-Maxwell-Poisson (CMP) model	MODEL	PARAMETER=
Specifies the zero-inflated offset variable	ZEROMODEL	OFFSET=
Specifies the zero-inflated link function	ZEROMODEL	LINK=
Specifies variable selection	MODEL	SELECT=( )
Specifies variable selection	DISPMODEL	SELECT=( )
Specifies variable selection	ZEROMODEL	SELECT=( )
Specifies the spatial effects to be added to MODEL statement	SPATIALEFFECTS	
Specifies variable selection	SPATIALEFFECTS	SELECT=( )
Specifies the spatial effects for dispersion	SPATIALDISPEFFECTS	
Specifies variable selection	SPATIALDISPEFFECTS	SELECT=( )
Specifies the spatial effects for zero-inflation	SPATIALZEROEFFECTS	
Specifies variable selection	SPATIALZEROEFFECTS	SELECT=( )
Bayesian MCMC Options		
Controls the aggregation of multiple posterior chains	BAYES	AGGREGATION=
Automates the initialization of the MCMC algorithm	BAYES	AUTOMCMC()
Specifies the initial values of the MCMC algorithm	INIT	
Requests evaluation of the marginal likelihood	BAYES	MARGINLIKE
Specifies the maximum number of tuning phases	BAYES	MAXTUNE=
Specifies the minimum number of tuning phases	BAYES	MINTUNE=
Specifies the number of burn-in iterations	BAYES	NBI=
Specifies the number of iterations during the sampling phase	BAYES	NMC=
Specifies the number of threads to use during the sampling phase	BAYES	NTRDS=
Specifies the number of iterations during the tuning phase	BAYES	NTU=
Controls options for constructing the initial proposal covariance matrix	BAYES	PROPCOV=
Specifies the sampling scheme	BAYES	SAMPLING=
Specifies the random number generator seed	BAYES	SEED=
Prints the time required for the MCMC sampling	BAYES	SIMTIME
Controls the thinning of the Markov chain	BAYES	THIN=
Bayesian Summary Statistics and Convergence Diagnostics		
Displays convergence diagnostics	BAYES	DIAGNOSTICS=
Displays summary statistics of the posterior samples	BAYES	STATISTICS=

Table 11.1 *continued*

Description	Statement	Option
Bayesian Prior and Posterior Samples		
Specifies a SAS data set for the posterior samples	BAYES	OUTPOST=
Bayesian Analysis		
Specifies normal prior distribution	PRIOR	NORMAL(MEAN=, VAR=)
Specifies gamma prior distribution	PRIOR	GAMMA(SHAPE=, SCALE=)
Specifies inverse gamma prior distribution	PRIOR	IGAMMA(SHAPE=, SCALE=)
Specifies uniform prior distribution	PRIOR	UNIFORM(MIN=, MAX=)
Specifies beta prior distribution	PRIOR	BETA(SHAPE1=, SHAPE2=, MIN=, MAX=)
Specifies *t* prior distribution	PRIOR	T(LOCATION=, DF=)
Output Control Options		
Includes covariances in the OUTEST= data set	PROC COUNTREG	COVOUT
Outputs the estimates of dispersion for the CMP model	OUTPUT	DISPERSION
Outputs the estimates of $\mathbf{g}_i'\boldsymbol{\delta}$ for the CMP model	OUTPUT	GDELTA=
Outputs the estimates of λ for the CMP model	OUTPUT	LAMBDA=
Outputs the estimates of ν for the CMP model	OUTPUT	NU=
Outputs the estimates of μ for the CMP model	OUTPUT	MU=
Outputs the estimates of mode for the CMP model	OUTPUT	MODE=
Outputs the probability that the response variable will take the current value	OUTPUT	PROB=
Outputs probabilities for particular response values	OUTPUT	PROBCOUNT( )
Outputs the expected value of the response variable	OUTPUT	PRED=
Outputs the estimates of variance for the CMP model	OUTPUT	VARIANCE=
Outputs estimates of $\mathbf{x}_i'\boldsymbol{\beta}$	OUTPUT	XBETA=
Outputs estimates of $\mathbf{z}_i'\boldsymbol{\gamma}$	OUTPUT	ZGAMMA=
Outputs the probability that the response variable will take a zero value as a result of the zero-generating process	OUTPUT	PROBZERO=
Specifies the output data set for scoring	SCORE	OUT=
Outputs the estimates of dispersion for the CMP model	SCORE	DISPERSION
Outputs the estimates of $\mathbf{g}_i'\boldsymbol{\delta}$ for the CMP model	SCORE	GDELTA=
Outputs the estimates of λ for the CMP model	SCORE	LAMBDA=
Outputs the estimates of ν for the CMP model	SCORE	NU=
Outputs the estimates of μ for the CMP model	SCORE	MU=

Outputs expected value of response variable	SCORE	PRED=
Outputs the estimates of variance for the CMP model	SCORE	VARIANCE=
Outputs estimates of $\mathbf{x}_i'\boldsymbol{\beta}$	SCORE	XBETA=
Outputs estimates of $\mathbf{z}_i'\boldsymbol{\gamma}$	SCORE	ZGAMMA=
Outputs the probability that the response variable will take a value of zero as a result of the zero-generating process	SCORE	PROBZERO=
Test Request Options		
Requests Wald, Lagrange multiplier, and likelihood ratio tests	TEST	ALL
Requests the Wald test	TEST	WALD
Requests the Lagrange multiplier test	TEST	LM
Requests the likelihood ratio test	TEST	LR

PROC COUNTREG Statement

PROC COUNTREG < *options* > **;**

You can specify the following *options* in the PROC COUNTREG statement.

Data Set Options

DATA=*SAS-data-set*

specifies the input SAS data set. If the DATA= option is not specified, PROC COUNTREG uses the most recently created SAS data set.

GROUPID=*variable*

specifies an identification variable when a panel data model is estimated. The identification variable is used as a cross-sectional ID variable.

NONORMALIZE

does not row-normalize the spatial weights matrix that is specified in the WMAT= option. By default, the spatial weights matrix is required to be row-normalized; that is, the spatial weights matrix has unit row sum. Equivalently, this means that $w(\mathrm{s}_i, \mathrm{s}_j)$ is normalized by multiplying it by $\frac{1}{\sum_{j=1}^{n} w(\mathrm{s}_i, \mathrm{s}_j)}$, where n is the total number of spatial units. If the NONORMALIZE option is specified, spatial weights are used "as is" except for $w(\mathrm{s}_i, \mathrm{s}_i)$, which is always treated as 0. This implies that a spatial weight $w(\mathrm{s}_i, \mathrm{s}_j)$ cannot be missing for $i \neq j$ if the NONOMALIZE option is specified. If the NONOMALIZE option is not specified, missing spatial weights are replaced with 0.

WMAT=*SAS-data-set*

specifies the input SAS data set that contains spatial weights matrix. The spatial weights matrix is often known as the W matrix. The spatial weights $w(\mathrm{s}_i, \mathrm{s}_j)$ for two locations s_i and s_j must satisfy the following: $w(\mathrm{s}_i, \mathrm{s}_j) \geq 0$ and $w(\mathrm{s}_i, \mathrm{s}_i) = 0$, where $i, j = 1, 2, \ldots, n$ and n is the total number of spatial locations. However, it is not necessary that $w(\mathrm{s}_i, \mathrm{s}_j) = w(\mathrm{s}_j, \mathrm{s}_i)$. In addition, any nonzero $w(\mathrm{s}_i, \mathrm{s}_i)$ is replaced with 0. For more information about missing spatial weights in W, see the section "NONORMALIZE" on page 565.

For a spatial weights data set that has n spatial units, the number of columns must be $n + 1$ if the SPATIALID statement specifies a spatial ID variable for the purpose of matching observations. For more information, see the section "SPATIALID Statement" on page 592. However, if the SPATIALID statement is not specified, the number of rows and columns in the spatial weights data set must be equal.

Item Store Control Options

RESTORE=*item-store-name*

specifies the source item store for processing. An *item-store-name* consists of a one- or two-level name, as with SAS data sets. As with data sets, an item store is associated by default with the Work library, and any item stores that are created in this library are deleted when the SAS session concludes.

Output Data Set Options

OUTEST=*SAS-data-set*

writes the parameter estimates to the specified output data set.

COVOUT

writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid only if the OUTEST= option is specified.

Printing Options

CORRB

prints the correlation matrix of the parameter estimates. This option can also be specified in the MODEL statement.

COVB

prints the covariance matrix of the parameter estimates. This option can also be specified in the MODEL statement.

NOPRINT

suppresses all printed output.

Estimation Control Options

COVEST=HESSIAN | OP | QML
specifies the type of covariance matrix of the parameter estimates. The quasi-maximum-likelihood estimates are computed using COVEST=QML. By default, COVEST=HESSIAN. You can specify the following values:

HESSIAN	specifies the covariance from the Hessian matrix.
OP	specifies the covariance from the outer product matrix.
QML	specifies the covariance from the outer product and Hessian matrices.

Plot Control Options

PLOTS<*(global-plot-options)*> **< =** *plot-request* **|** **(***plot-requests***)>**
requests that the COUNTREG procedure produce statistical graphics via the Output Delivery System, provided that ODS GRAPHICS has been enabled. For general information about ODS Graphics, see Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*). The *global-plot-options* apply to all relevant plots that are generated by the COUNTREG procedure.

You can specify the following *global-plot-options*:

COUNTS(*value1* **<***value2***. . . >)**
supplies the plots PREDPROB and PREDPROFILE with particular values of the response variable. Each *value* should be a nonnegative integer. Nonintegers are rounded to the nearest integer. The *value* can also be a list of the form X TO Y BY Z. For example, COUNTS(0 1 2 TO 10 BY 2 15) specifies plotting for counts 0, 1, 2, 4, 6, 8, 10, and 15.

ONLY
suppresses the default plots. Only the plots that are specifically requested are produced.

UNPACKPANEL

UNPACK
displays each graph separately. (By default, some graphs can appear together in a single panel.)

You can specify the following *plot-requests*:

ALL
requests that all plots appropriate for the particular analysis be produced.

AUTOCORR< (LAGS=*n***) >**
displays the autocorrelation function plots of the parameters. This *plot-request* is available only for Bayesian analysis. The optional LAGS= suboption specifies the number (up to lag *n*) of autocorrelations to be plotted in the AUTOCORR plot. If this suboption is not specified, autocorrelations are plotted up to lag 50.

BAYESDIAG
displays the TRACE, AUTOCORR, and DENSITY plots. This *plot-request* is available only for Bayesian analysis.

BAYESSUM
displays the posterior distribution, prior distribution, and maximum likelihood estimates. This *plot-request* is available only for Bayesian analysis.

DENSITY< (FRINGE) >
displays the kernel density plots of the parameters. This *plot-request* is available only for Bayesian analysis. If you specify the FRINGE suboption, a fringe plot is created on the X axis of the kernel density plot.

DISPERSION
produces the overdispersion diagnostic plot.

NONE
suppresses all plots.

PREDPROB
produces the overall predictive probabilities of the specified count levels. You must also specify COUNTS in *global-plot-options*.

PREDPROFILE
produces the predictive probability profiles of specified count levels against model regressors. The regressor on the X axis is varied, whereas all other regressors are fixed at the mean of the observed data set.

PROFILELIKE
produces the profile likelihood functions of the model parameters. The model parameter on the X axis is varied, whereas all other parameters are fixed at their estimated maximum likelihood estimates.

TRACE< (SMOOTH) >
displays the trace plots of the parameters. This *plot-request* is available only for Bayesian analysis. The SMOOTH suboption displays a fitted penalized B-spline curve for each trace plot.

ZEROPROFILE | ZPPRO
produces the probability profiles of zero-inflation process selection and zero count prediction against model regressors. The regressor on the X axis is varied, whereas all other regressors are fixed at the mean of the observed data set.

Optimization Process Control Options

PROC COUNTREG uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. All the NLO options are available in the NLOPTIONS statement. For more information, see the "NLOPTIONS Statement" on page 583. In addition, you can specify the following option in the PROC COUNTREG statement:

METHOD=CONGRA | DBLDOG | NMSIMP | NRA | NRRIDG | QN | TR
specifies the iterative minimization method to use.

You can specify the following values:

CONGRA	specifies the conjugate-gradient method.
DBLDOG	specifies the double-dogleg method.
NMSIMP	specifies the Nelder-Mead simplex method.
NONE	specifies that no optimization be performed beyond using the ordinary least squares.
NRA	specifies the Newton-Raphson method.
NRRIDG	specifies the Newton-Raphson ridge method.
QN	specifies the quasi-Newton method.
TR	specifies the trust region method.

By default, METHOD=NRA.

BAYES Statement

BAYES < *options* > **;**

The BAYES statement controls the Metropolis sampling scheme that is used to obtain samples from the posterior distribution of the underlying model and data. You can specify the following *options*.

AGGREGATION=WEIGHTED | NOWEIGHTED (Experimental)
specifies how multiple posterior samples should be aggregated. You can specify the following values:

WEIGHTED	implements a weighted resampling scheme for the aggregation of multiple posterior chains. You can use this option when the posterior distribution is characterized by several very distinct posterior modes.
NOWEIGHTED	aggregates multiple posterior chains without any adjustment. You can use this option when the posterior distribution is characterized by one or few relatively close posterior modes.

By default, AGGREGATION=NOWEIGHTED. For more information, see the section "Aggregation of Multiple Chains" on page 640.

AUTOMCMC< =(*automcmc-options***) >**
specifies an algorithm for the automated initialization of the MCMC sampling algorithm. For more information, see the section "Automated Initialization of MCMC" on page 641. You can specify the following *automcmc-options*:

ACCURACY=(*accuracy-options***)**
customizes the behavior of the AUTOMCMC algorithm when you are searching for an accurate representation of the posterior distribution. By default, it implements the TARGETSTATS option. You can specify the following *accuracy-options*:

ATTEMPTS=*number*
specifies the maximum number of attempts that are required in order to obtain accurate samples from the posterior distribution. By default, ATTEMPTS=10.

TARGETESS=*number*
requests that the accuracy search be based on the effective sample size (ESS) analysis and specifies the minimum number of effective samples.

TARGETSTATS<=(*targetstats-option***)>**
requests that the accuracy search be based on the analysis of the posterior mean and a posterior quantile of interest. You can customize the behavior of the analysis of the posterior mean by adjusting the HEIDELBERGER suboptions. You can customize the behavior of the analysis of the posterior quantile by adjusting the RAFTERY suboptions. If you specify TARGETSTATS, you can also specify how the Raftery-Lewis test should be interpreted by using the following option:

RLLIMITS=(LB=*number* **UB=***number***)**
specifies a region where the search for the optimal sample size depends directly on the Raftery-Lewis test. By default, RLLIMITS=(LB=10000 UB=300000).

TOL=*value*
specifies the proportion of parameters that are required to be accurate. By default, TOL=0.95.

MAXNMC=*number*
specifies the maximum number of posterior samples that the AUTOMCMC option allows. By default, MAXNMC=700000.

RANDINIT< =(*randinit-options***) >**
specifies random starting points for the MCMC algorithm. The starting points can be sampled around the maximum likelihood estimate and around the prior mean. You can specify the following *randinit-options*:

MULTIPLIER=(*value***)**
specifies the radius of the area where the starting points are sampled. For the starting points that are sampled around the maximum likelihood estimate, the radius equals the standard deviation of the maximum likelihood estimate multiplied by the multiplier value. For the starting points that are sampled around the prior mean, the radius equals the standard deviation of the prior distribution multiplied by the multiplier value. By default, MULTIPLIER=2.

PROPORTION=(*value***)**
specifies the proportion of starting points that are sampled around the maximum likelihood estimate and around the prior mean. By default, PROPORTION=0, which implies that all the initial points are sampled around the maximum likelihood estimate. If you choose to sample starting points around the prior mean, the convergence of the MCMC algorithm could be very slow.

STATIONARITY=(*stationarity-options***)**
customizes the behavior of the AUTOMCMC algorithm when you are trying to sample from the posterior distribution. You can specify the following *stationarity-options*:

ATTEMPTS=*number*
specifies the maximum number of attempts that are required in order to obtain stationary samples from the posterior distribution. By default, ATTEMPTS=10.

TOL=*value*
specifies the proportion of parameters whose samples must be stationary. By default, TOL=0.95.

DIAGNOSTICS=ALL | NONE | *(keyword-list)*
DIAG=ALL | NONE | *(keyword-list)*
controls which diagnostics are produced. All the following diagnostics are produced by using DIAGNOSTICS=ALL. If you do not want any of these diagnostics, specify DIAGNOSTICS=NONE. If you want some but not all of the diagnostics, or if you want to change certain settings of these diagnostics, specify a subset of the following keywords. You can specify the following values; by default, DIAGNOSTICS=NONE.

AUTOCORR< (LAGS=*numeric-list***) >**
computes the autocorrelations at lags that are specified in the *numeric-list*. Elements in the *numeric-list* are truncated to integers, and repeated values are removed. If you do not specify the LAGS= option, autocorrelations of lags 1, 5, and 10 are computed.

AUTOMCMCSUM
produces a summary table for the AUTOMCMC (automatic MCMC) sampling tool is used.

ESS
computes Carlin's estimate of the effective sample size, the correlation time, and the efficiency of the chain for each parameter.

GEWEKE< (*geweke-options***) >**
computes the Geweke spectral density diagnostics, which are essentially a two-sample t test between the first f_1 portion and the last f_2 portion of the chain. The default is $f_1 = 0.1$ and $f_2 = 0.5$, but you can choose other fractions by using the following *geweke-options*:

FRAC1=*value*
specifies the fraction f_1 for the first window.

FRAC2=*value*
specifies the fraction f_2 for the second window.

HEIDELBERGER< (*heidel-options***) >**
computes the Heidelberger-Welch diagnostic for each variable, which consists of a stationarity test of the null hypothesis that the sample values form a stationary process. If the stationarity test is not rejected, a halfwidth test is then performed. Optionally, you can specify one or more of the following *heidel-options*:

SALPHA=*value*
specifies the α level ($0 < \alpha < 1$) for the stationarity test. By default, SALPHA=0.05.

HALPHA=*value*
specifies the α level ($0 < \alpha < 1$) for the halfwidth test. By default, HALPHA=0.1.

EPS=*value*
specifies a positive number ϵ such that if the halfwidth is less than ϵ times the sample mean of the retained iterates, the halfwidth test is passed. By default, EPS=0.05.

MCSE

MCERROR
computes the Monte Carlo standard error for each parameter. The Monte Carlo standard error, which measures the simulation accuracy, is the standard error of the posterior mean estimate and is calculated as the posterior standard deviation divided by the square root of the effective sample size.

RAFTERY<(*raftery-options***)>**
computes the Raftery-Lewis diagnostics, which evaluate the accuracy of the estimated quantile ($\hat{\theta}_Q$ for a given $Q \in (0, 1)$) of a chain. $\hat{\theta}_Q$ can achieve any degree of accuracy when the chain is allowed to run for a long time. The computation is stopped when the estimated probability $\hat{P}_Q = \Pr(\theta \leq \hat{\theta}_Q)$ reaches within $\pm R$ of the value Q with probability S; that is, $\Pr(Q - R \leq \hat{P}_Q \leq Q + R) = S$. The following *raftery-options* enable you to specify Q, R, S, and a precision level ϵ for the test:

ACCURACY=*value*

R=*value*
specifies a small positive number as the margin of error for measuring the accuracy of estimation of the quantile. By default, R=0.005.

EPSILON=*value*

EPS=*value*
specifies the tolerance level (a small positive number) for the stationary test. By default, EPS=0.001.

PROBABILITY*value*

S=*value*
specifies the probability of attaining the accuracy of the estimation of the quantile. By default, S=0.95.

QUANTILE*value*

Q=*value*
specifies the order (a value between 0 and 1) of the quantile of interest. By default, Q=0.025.

MARGINLIKE< (NSIM=*number***) >**
requests evaluation of the logarithm of the marginal likelihood. Two estimates are produced: the cross-entropy estimate and the harmonic mean. The cross-entropy estimate is based on an importance sampling algorithm for which you can specify the *number* of importance samples in the NSIM= suboption. The default is 10,000. For more information, see the section "Marginal Likelihood" on page 648.

MAXTUNE=*number*
specifies the maximum number of tuning phases. By default, MAXTUNE=24.

MINTUNE=*number*
specifies the minimum number of tuning phases. By default, MINTUNE=2.

NBI=*number*
specifies the number of burn-in iterations before the chains are saved. By default, NBI=1000.

NMC=*number*
specifies the number of iterations after the burn-in for Metropolis sampling scheme. By default, NMC=1000.

NTRDS=*number*
THREADS=*number*
specifies the number of threads to be used. The number of threads cannot exceed the number of computer cores available. Each core samples the number of iterations that is specified by the NMC= option. By default, NTRDS=1.

NTU=*number*
specifies the number of samples for each tuning phase for Metropolis sampling schemes. By default, NTU=500.

OUTPOST=*SAS-data-set*
names the SAS data set to contain the posterior samples. Alternatively, you can create the output data set by specifying an ODS OUTPUT statement as follows:

```
ods output posteriorsample=<SAS-data-set>;
```

PROPCOV=CONGRA | DBLDOG | NEWRAP | NMSIMP | NRRIDG | QUANEW | TUREG
specifies the method to use in constructing the initial covariance matrix for the Metropolis-Hastings algorithm. The quasi-Newton (PROPCOV=QUANEW) and Nelder-Mead simplex (PROPCOV=NMSIMP) methods find numerically approximated covariance matrices at the optimum of the posterior density function with respect to all continuous parameters. The tuning phase starts at the optimized values; in some problems, this can greatly increase convergence performance. If the approximated covariance matrix is not positive definite, then an identity matrix is used instead.

You can specify the following *values*:

CONGRA performs a conjugate-gradient optimization.

DBLDOG performs a version of double-dogleg optimization.

NEWRAP performs a Newton-Raphson optimization that combines a line-search algorithm with ridging.

NMSIMP performs a Nelder-Mead simplex optimization.

NRRIDG performs a Newton-Raphson optimization with ridging.

QUANEW performs a quasi-Newton optimization.

TRUREG performs a trust-region optimization.

SAMPLING=*value*

specifies how to sample from the posterior distribution. You can specify the following values:

MULTIMETROPOLIS

implements a Metropolis sampling scheme on a single block that contains all the parameters of the model. SAMPLING=MULTIMETROPOLIS is the default option.

UNIMETROPOLIS

implements a Metropolis sampling scheme on multiple blocks, one for each parameter of the model.

SEED=*number*

specifies an integer seed in the range 1 to $2^{31} - 1$ for the random number generator in the simulation. Specifying a seed enables you to reproduce identical Markov chains for the same specification. If you do not specify the SEED= option, or if you specify SEED=0, a random seed is derived from the time of day, which is read from the computer's clock.

SIMTIME

prints the time required for the MCMC sampling.

STATISTICS< (*global-options***) >=ALL | NONE |** *keyword* **|** *(keyword-list)*

STATS< (*global-options***) >=ALL | NONE |** *keyword* **|** *(keyword-list)*

controls the number of posterior statistics that are produced. Specifying STATISTICS=ALL is equivalent to specifying STATISTICS=(CORR COV INTERVAL PRIOR SUMMARY). If you do not want any posterior statistics, specify STATISTICS=NONE. By default, STATISTICS=(SUMMARY INTERVAL).

You can specify the following *global-options*:

ALPHA=*numeric-list*

controls the probabilities of the credible intervals. The values in the *numeric-list* must be between 0 and 1. Each ALPHA= value produces a pair of 100(1–ALPHA)% equal-tail and HPD intervals for each parameter. By default, ALPHA=0.05, which yields the 95% credible intervals for each parameter.

PERCENT=*numeric-list*

requests the percentile points of the posterior samples. The values in the *numeric-list* must be between 0 and 100. By default, PERCENT=25, 50, 75, which yields the 25th, 50th, and 75th percentile points, respectively, for each parameter.

You can specify the following *keywords*:

CORR
produces the posterior correlation matrix.

COV
produces the posterior covariance matrix.

INTERVAL
produces equal-tail credible intervals and HPD intervals. The default is to produce the 95% equal-tail credible intervals and 95% HPD intervals, but you can use the ALPHA= *global-option* to request intervals of any probabilities.

NONE
suppresses printing of all summary statistics.

PRIOR
produces a summary table of the prior distributions that are used in the Bayesian analysis.

SUMMARY
produces the means, standard deviations, and percentile points (25th, 50th, and 75th) of the posterior samples. You can use the global PERCENT= *global-option* to request specific percentile points.

THIN=*number*

THINNING=*number*
controls the thinning of the Markov chain. Only one in every k samples is used when THIN=k, and if NBI=n_0 and NMC=n, the number of samples that are kept is

$$\left\lfloor \frac{n_0 + n}{k} \right\rfloor - \left\lfloor \frac{n_0}{k} \right\rfloor$$

where $\lfloor a \rfloor$ represents the integer part of the number a. By default, THIN=1.

BOUNDS Statement

BOUNDS *bound1* < *, bound2 . . .* > **;**

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. You can specify any number of BOUNDS statements as follows.

Each *bound* is composed of parameter names, constants, and inequality operators as follows:

item operator item [*operator item* [*operator item . . .*]]

Each *item* is a constant, a parameter name, or a list of parameter names. Each *operator* is <, >, <=, or >=.

Parameter names are as shown in the Parameter column of the "Parameter Estimates" table. If a parameter name contains a blank or some other special character (such as '*', '-','(', or ')'), then you must use the internal name of the parameter in order to refer to that parameter in the BOUNDS statement.

For more information about how parameters are named in the BOUNDS statement, see the section "Parameter Naming Conventions for the RESTRICT, TEST, BOUNDS, and INIT Statements" on page 631.

You can use both the BOUNDS statement and the RESTRICT statement to impose boundary constraints; however, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints. See also the section "RESTRICT Statement" on page 586.

The following BOUNDS statement constrains the estimates of the parameter for z to be negative, the parameters for x1 through x10 to be between zero and one, and the parameter for x1 in the zero-inflation model to be less than one:

```
bounds z < 0,
       0 < x1-x10 < 1,
       Inf_x1 < 1;
```

The BOUNDS statement is not supported if a BAYES statement is also specified. In Bayesian analysis, the restrictions on parameters are usually introduced through the prior distribution.

BY Statement

BY *variables* **;**

A BY statement can be used with PROC COUNTREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the input data set should be sorted in the order of the BY variables.

CLASS Statement

CLASS *variable* < *(options)* > . . . < *variable* < *(options)* > > < */global-options* > **;**

The CLASS statement names the classification variables that are used to group (classify) data in the analysis. Classification variables can be either character or numeric.

Class levels are determined from the formatted values of the CLASS *variables*. Thus, you can use formats to group values into levels. For more information, see the discussion of the FORMAT procedure in the *Base SAS Procedures Guide*. The CLASS statement must precede the MODEL statement.

Most options can be specified either as individual variable *options* or as *global-options*. You can specify *options* for each variable by enclosing the options in parentheses after the variable name. You can also specify *global-options* for the CLASS statement by placing them after a slash (/). *Global-options* are applied to all the variables that are specified in the CLASS statement. If you specify more than one CLASS statement, the *global-options* specified in any one CLASS statement apply to all CLASS statements. However, individual CLASS variable *options* override the *global-options*. You can specify the following values for either an *option* or a *global-option*:

MISSING
: treats missing values (., ._, .A, . . . , .Z for numeric variables and blanks for character variables) as valid values for the CLASS variable.

ORDER=DATA | FORMATTED | FREQ | INTERNAL
specifies the sort order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data. You can specify the following values:

DATA sorts levels by the order of appearance in the input data set.

FORMATTED sorts levels by external formatted values, except for numeric variables that have no explicit format. Those variables are sorted by their unformatted (internal) values. Ths sort order is machine-dependent.

FREQ sorts levels by descending frequency count; levels that have more observations come earlier in the order.

INTERNAL sorts levels by unformatted value. Ths sort order is machine-dependent.

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Programmers Guide: Essentials*. By default, ORDER=FORMATTED.

PARAM=EFFECT | GLM | REFERENCE
specifies the parameterization method for the classification variable or variables. You can specify the following values:

EFFECT uses effect coding to create design matrix columns from the CLASS variables.

GLM uses less-than-full-rank reference cell coding to create design matrix columns from the CLASS variables. This value can be used only as a global option.

REFERENCE uses reference cell coding to create design matrix columns from the CLASS variables. You can abbreviate this value as REF.

All parameterizations are full rank, except for the GLM parameterization. The REF= option in the CLASS statement determines the reference level for effect and reference coding and for their orthogonal parameterizations. It also indirectly determines the reference level for a singular GLM parameterization through the order of levels. By default, PARAM=GLM.

REF=*'level'* | FIRST | LAST
specifies the reference level for PARAM=EFFECT, PARAM=REFERENCE, and their orthogonalizations. When PARAM=GLM, the REF= option specifies a level of the classification variable to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the linear estimates with a singular parameterization.

For an individual variable REF= option (but not for a global REF= option), you can specify the *level* of the variable to use as the reference level. Specify the formatted value of the variable if a format is assigned. For a global or individual variable REF= option, you can use one of the following keywords.

FIRST designates the first-ordered level as reference.

LAST designates the last-ordered level as reference.

By default, REF=LAST.

DISPMODEL Statement

DISPMODEL *dependent-variable* ∼ < *dispersion-related-regressors* ></ *option*> **;**

The DISPMODEL statement specifies the *dispersion-related-regressors* that are used to model dispersion. This statement is ignored unless you specify DIST=COMPOISSON in the MODEL statement. The *dependent-variable* in the DISPMODEL statement must be the same as the *dependent-variable* in the MODEL statement.

The *dependent-variable* that appears in the DISPMODEL statement is directly used to model dispersion. Each of the q variables to the right of the tilde (∼) has a parameter to be estimated in the regression. For example, let $\mathbf{g}_i'$ be the ith observation's $1 \times (q+1)$ vector of values of the q dispersion explanatory variables (q_0 is set to 1 for the intercept term). Then the dispersion is a function of $\mathbf{g}_i'\boldsymbol{\delta}$, where $\boldsymbol{\delta}$ is the $(q+1)\times 1$ vector of parameters to be estimated, the dispersion model intercept is δ_0, and the coefficients for the q dispersion covariates are $\delta_1, \ldots, \delta_q$. If you specify DIST=COMPOISSON in the MODEL statement but do not include a DISPMODEL statement, then only the intercept term δ_0 is estimated. The "Parameter Estimates" table in the displayed output shows the estimates for the dispersion intercept and dispersion explanatory variables; they are labeled with the prefix "Dsp_". For example, the dispersion intercept is labeled "Dsp_Intercept". If you specify Age (a variable in your data set) as a dispersion explanatory variable, then the "Parameter Estimates" table labels the corresponding parameter estimate "Dsp_Age". The following statements fit a Conway-Maxwell-Poisson model by using the regressors SEX, ILLNESS, and INCOME and by using AGE as a dispersion-related regressor:

```
proc countreg data=docvisit;
   model doctorvisits=sex illness income / dist=compoisson;
   dispmodel doctorvisits ~ age;
run;
```

You can specify the following *option* after a slash (/):

SELECT=INFO=<(*selection-options***)>**

SELECTVAR=INFO=<(*selection-options***)>**

requests that the variable selection method be based on an information criterion. For a list of *selection-options*, see the section "Options for Variable Selection Based on an Information Criterion" on page 580. For more information about this type of variable selection, see the section "Variable Selection Using an Information Criterion" on page 616.

FREQ Statement

FREQ *variable* **;**

The FREQ statement specifies a variable whose values represent the frequency of occurrence of each observation. PROC COUNTREG treats each observation as if it appears n times, where n is the value of the FREQ variable for the observation. If the frequency value is not an integer, it is truncated to an integer; if it is less than 1 or missing, the observation is not used in the model fitting. When the FREQ statement is not specified, each observation is assigned a frequency of 1. If you specify more than one FREQ statement, then the first statement is used.

INIT Statement

INIT *initialization1* < *, initialization2 . . .* > **;**

The INIT statement sets initial values for parameters in the optimization.

Each *initialization* is written as a parameter or parameter list, followed by an optional equal sign (=), followed by a number:

parameter <=> number

Parameter names are as shown in the Parameter column of the "Parameter Estimates" table. If a parameter name contains a blank or some other special character (such as '*', '-','(', or ')'), then you must use the internal name of the parameter in order to refer to that parameter in the INIT statement. For more information about how parameters are named in the INIT statement, see the section "Parameter Naming Conventions for the RESTRICT, TEST, BOUNDS, and INIT Statements" on page 631.

By default, initial values are determined by OLS regression. Initial values can be displayed with the ITPRINT option in the PROC statement.

If you also specify the BAYES statement, the INIT statement also initializes the Markov chain Monte Carlo (MCMC) algorithm. In particular, the INIT statement does one of the following:

- initializes the tuning phase (this also includes the PROPCOV= option)
- initializes the sampling phase, if there is no tuning phase

MODEL Statement

MODEL *dependent-variable = <regressors> </ options>* **;**

The MODEL statement specifies the *dependent-variable* and independent covariates (*regressors*) for the regression model. If you specify no *regressors*, PROC COUNTREG fits a model that contains only an intercept. The dependent count variable should take on only nonnegative integer values in the input data set. PROC COUNTREG rounds any positive noninteger count values to the nearest integer and ignores any observations that have a negative count.

You can specify only one MODEL statement. You can specify the following *options* after a slash (/):

DIST=*value*
specifies the type of model to be analyzed. If you specify this option in both the MODEL statement and the PROC COUNTREG statement, then only the value in the MODEL statement is used. You can specify the following *values*:

COMPOISSON | C | CMP specifies a Conway-Maxwell-Poisson regression model.

NEGBIN(P=1) specifies a negative binomial regression model that uses a linear variance function.

NEGBIN(P=2) | NEGBIN specifies a negative binomial regression model that uses a quadratic variance function.

POISSON | P specifies a Poisson regression model.

ZICOMPOISSON | ZICMP specifies a zero-inflated Conway-Maxwell-Poisson regression. You must also specify the ZEROMODEL statement when you specify this model type.

ZINEGBIN | *ZINB* specifies a zero-inflated negative binomial regression. You must also specify the ZEROMODEL statement when you specify this model type.

ZIPOISSON | ZIP specifies a zero-inflated Poisson regression. You must also specify the ZEROMODEL statement when you specify this model type.

ERRORCOMP=FIXED | RANDOM
specifies the type of conditional panel model to be analyzed. You can specify the following values:

FIXED specifies a fixed-effect error component regression model.

RANDOM specifies a random-effect error component regression model.

NOINT
suppresses the intercept parameter.

OFFSET=*variable*
specifies a *variable* in the input data set to be used as an offset variable. The offset variable appears as a covariate in the model with its parameter restricted to 1. The offset variable cannot be the response variable, the zero-inflation offset variable (if any), or one of the explanatory variables. The "Model Fit Summary" table gives the name of the data set variable used as the offset variable; it is labeled as "Offset."

PARAMETER=MU | LAMBDA
specifies the parameterization for the Conway-Maxwell-Poisson model. The following parameterizations are supported:

LAMBDA estimates the original Conway-Maxwell-Poisson model (Shmueli et al. 2005).

MU reparameterizes λ as documented by Guikema and Coffelt (2008), where $\mu = \lambda^{1/\nu}$ and the integral part of μ represents the mode, which can be considered a measure of central tendency (mean).

By default, PARAMETER=MU.

Options for Variable Selection Based on an Information Criterion

For modeling statements (MODEL, ZEROMODEL, DISPMODEL, SPATIALEFFECTS, SPATIALDISPEFFECTS, and SPATIALZEROEFFECTS), you can specify the following *option* after a slash (/) to control the variable selection process:

SELECT=INFO< (*selection-options*) >
SELECTVAR=INFO< (*selection-options*) >
requests that the variable selection method be based on an information criterion. For more information, see the section "Variable Selection Using an Information Criterion" on page 616. You can specify one or more of the following *selection-options*:

CRITER=AIC | SBC
specifies the information criterion to use in the variable selection. You can specify the following values:

AIC uses Akaike's information criterion to determine whether the current model is better than the previous model.

SBC uses the Schwarz-Bayesian information criterion to determine whether the current model is better than the previous model.

By default, CRITER=SBC.

DIRECTION=FORWARD | BACKWARD
specifies the search algorithm to use in the variable selection method. You can specify the following values:

FORWARD specifies the search algorithm that starts with a base model and adds an additional variable at each step until either the model cannot be improved or one of the criteria for stopping has been met.

BACKWARD specifies the search algorithm that starts with the original model and removes a variable at each step until either the model cannot be improved or one of the criteria for stopping has been met.

By default, DIRECTION=FORWARD.

LSTOP=*percentage*
specifies the *percentage* of decrease or increase in the AIC or SBC that is required for the algorithm to proceed; *percentage* must be a nonnegative number less than 1. By default, LSTOP=0.

MAXSTEPS=*number*
specifies the maximum *number* of steps to allow in the search algorithm. The default is infinite; that is, the algorithm does not stop until the stopping criterion is satisfied.

NOSPLITEFFECTS
specifies that effects that involve class variables should not be split into individual effects that correspond to class levels. If you specify this option and some effect in your model involves a class variable, then each candidate model contains either no levels or all levels of the class variable. By default, NOSPLITEFFECTS is turned off. Thus, unless you specify the NOSPLITEFFECTS option, if some effect in your model involves a class variable, then some candidate models will contain some but not all of the levels of the class variable.

RETAIN(*variable1* **<***variable2***...>)**
requests that the variables named within parentheses be retained during the variable selection process. Each name in the RETAIN list is the name of some parameter associated with the statement that contains the RETAIN list. This option is ignored if the NOSPLITEFFECTS option is specified.

RETAINEFFECT(*variable1* **<***variable2***...>)**
requests that the specified *variables* be retained during the variable selection process. Each *variable* is the name of some effect (*regressor*) that is associated with the modeling statement that contains the *variables*. This option is ignored if the NOSPLITEFFECTS option is not specified.

Options for Penalized Variable Selection

For the MODEL statement, you can specify the following option instead of the SELECT=INFO option:

SELECT=PEN< (*selection-options***) >**
requests the penalized variable selection method. For more information, see the section "Variable Selection Using an Information Criterion" on page 616. You can specify one or more of the following *selection-options*:

GCV
specifies the generalized cross-validation (GCV) approach. For more information, see the section "The GCV Approach" on page 621.

GCV1
specifies the GCV1 approach. For more information, see the section "The GCV1 Approach" on page 622.

GCVLENGTH=*value*
specifies the number of different values to use for the generalized cross validation (GCV) tuning parameter. The value corresponds to λ

LAMBDA=*value*
specifies the *value* of lambda to use as the shrinkage parameter. When LAMBDA=0, no shrinkage is performed. As the value of LAMBDA increases, the coefficients are shrunk ever more strongly. By default, LAMBDA=0.

LLASTEPS=*value*
specifies the maximum number of iterations in the algorithm of local linear approximations. By default, LLASTEPS=5.

When SELECT=PEN, GCV1 is the default.

Printing Options

CORRB
prints the correlation matrix of the parameter estimates. The CORRB option can also be specified in the PROC COUNTREG statement.

COVB
prints the covariance matrix of the parameter estimates. The COVB can also be specified in the PROC COUNTREG statement.

ITPRINT
prints the objective function and parameter estimates at each iteration. The objective function is the negative log-likelihood function. The ITPRINT option can also be specified in the PROC COUNTREG statement.

PRINTALL
requests all printing options. The PRINTALL option can also be specified in the PROC COUNTREG statement.

NLOPTIONS Statement

NLOPTIONS < *options* > **;**

The NLOPTIONS statement provides the options to control the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. For a list of all the options of the NLOPTIONS statement, see Chapter 6, "Nonlinear Optimization Methods."

OUTPUT Statement

OUTPUT < **OUT=***SAS-data-set* > < *output-options* > **;**

The OUTPUT statement creates a new SAS data set that contains all the variables in the input data set and, optionally, the estimates of $\mathbf{x}_i'\boldsymbol{\beta}$, the expected value of the response variable, and the probability of the response variable taking on the current value or other values that you specify. In a zero-inflated model, you can additionally request that the output data set contain the estimates of $\mathbf{z}_i'\boldsymbol{\gamma}$ and the probability that the response is zero as a result of the zero-generating process. For the Conway-Maxwell-Poisson model, the estimates of $\mathbf{g}_i'\boldsymbol{\delta}$, λ, ν, μ, mode, variance, and dispersion are also available. Except for the probability of the current value, these statistics can be computed for all observations in which the regressors are not missing, even if the response is missing. By adding observations that have missing response values to the input data set, you can compute these statistics for new observations or for settings of the regressors that are not present in the data without affecting the model fit.

You can specify only one OUTPUT statement. You can specify the following *output-options*:

DISPERSION=*name*
names the variable that contains the value of dispersion for the Conway-Maxwell-Poisson distribution.

GDELTA=*name*
names the variable that contains estimates of $\mathbf{g}_i'\boldsymbol{\delta}$ for the Conway-Maxwell-Poisson distribution.

LAMBDA=*name*
names the variable that contains the estimate of λ for the Conway-Maxwell-Poisson distribution.

MODE=*name*
names the variable that contains the integral part of μ (mode) for the Conway-Maxwell-Poisson distribution.

MU=*name*
names the variable that contains the estimate of μ for the Conway-Maxwell-Poisson distribution.

NU=*name*
names the variable that contains the estimate of ν for the Conway-Maxwell-Poisson distribution.

OUT=*SAS-data-set*
names the output data set.

PRED=*name*

MEAN=*name*
names the variable that contains the predicted value of the response variable.

PROB=*name*
names the variable that contains the probability of the response variable taking the current value, $\Pr(Y = y_i)$.

PROBCOUNT(*value1* **<***value2***...>)**
outputs the probability that the response variable will take particular values. Each *value* should be a nonnegative integer. If you specify a noninteger, it is rounded to the nearest integer. The *value* can also be a list of the form X TO Y BY Z. For example, PROBCOUNT(0 1 2 TO 10 BY 2 15) requests predicted probabilities for counts 0, 1, 2, 4, 5, 6, 8, 10, and 15. This option is not available for the fixed-effects and random-effects panel models.

PROBZERO=*name*
names the variable that contains the value of φ_i, the probability of the response variable taking on the value of zero as a result of the zero-generating process. It is written to the output file only if the model is zero-inflated. This is not the overall probability of a zero response; that is provided by the PROBCOUNT(0) option.

VARIANCE=*name*
names the variable that contains the estimate of variance.

XBETA=*name*
names the variable that contains estimates of $\mathbf{x}_i'\boldsymbol{\beta}$.

ZGAMMA=*name*
names the variable that contains estimates of $\mathbf{z}_i'\boldsymbol{\gamma}$.

PERFORMANCE Statement

PERFORMANCE < *performance-options* > **;**

The PERFORMANCE statement controls the number of threads that are used in the optimization phase. You can also specify that multithreading not be used in the optimization phase by using the NOTHREADS option.

You can specify only one PERFORMANCE statement. The PERFORMANCE statement supports the following *performance-options*:

NTHREADS=*number*
specifies the number of threads to be used during optimization of the model.

NOTHREADS
specifies that no threads should be used during optimization of the model.

DETAILS
specifies that a timing table be included in the output.

If you use both the NTHREADS= and NOTHREADS options, then the NTHREADS= option is ignored. If you use a PERFORMANCE statement, then it overrides any global threading settings that might have been set using the CPUCOUNT=, THREADS, or NOTHREADS system option.

PRIOR Statement

PRIOR _REGRESSORS | *parameter-list* ~ *distribution* **;**

The PRIOR statement specifies the prior distribution of the model parameters. You must specify a single parameter or a list of parameters, a tilde (~), and then a distribution with its parameters. Multiple PRIOR statements are allowed.

You can specify the following *distributions*:

BETA(SHAPE1=*a*, SHAPE2=*b*, MIN=*m*, MAX=*M*)
specifies a beta distribution that has the parameters SHAPE1 and SHAPE2 and is defined between MIN and MAX.

GAMMA(SHAPE=*a*, SCALE=*b*)
specifies a gamma distribution that has the parameters SHAPE and SCALE.

IGAMMA(SHAPE=*a*, SCALE=*b*)
specifies an inverse gamma distribution that has the parameters SHAPE and SCALE.

NORMAL(MEAN=μ, VAR=σ^2)
specifies a normal distribution that has the parameters MEAN and VAR.

T(LOCATION=μ, DF=ν)
specifies a noncentral t distribution that has DF degrees of freedom and a location parameter equal to LOCATION.

UNIFORM(MIN=m, MAX=M)
specifies a uniform distribution that is defined between MIN and MAX.

For more information about how to specify *distributions*, see the section "Standard Distributions" on page 649.

You can specify the special keyword _REGRESSORS to select all the parameters that are used in the linear regression component of the model.

RESTRICT Statement

RESTRICT *restriction1 < , restriction2 . . . >* **;**

The RESTRICT statement imposes linear restrictions on the parameter estimates. You can specify any number of RESTRICT statements.

Each *restriction* is written either as a single linear *equation* or as a comma-separated list of two or more linear *equations*. A restriction *equation* consists of an *expression*, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

expression operator expression

The *operator* can be =, <, >, <=, or >=.

RESTRICT Statement Expressions

A restriction *expression* is composed of parameter names, constants, and the operators times ($*$), plus ($+$), and minus ($-$). Each restriction expression must be a linear function of the parameters in the model. In addition, no grouping symbols (such as parentheses) are allowed and the constant factor in any product can only appear on the left-hand side of the times ($*$) operator.

In the following example, we assume that we have a data set in which y is the count variable and x1-x3 are continuous variables. The PROC COUNTREG program below uses a RESTRICT statement to impose a restriction on the estimate for the parameter associated with the variable x2. Thus, in any solution found by the optimizer, the solution must satisfy the condition that the parameter associated with the variable x2 is equal to 1.5:

```
proc countreg data=mycas.exrestrict;
   model y = x1-x3;
   restrict x2=1.5;
run;
```

It is important to keep in mind that the parameters associated with the variables are restricted, not the variables themselves. Thus, in the RESTRICT statement above, we use the variable name "x2" to refer to the parameter associated with the variable x2, and not the variable itself.

Parameter names are shown in the Parameter column of the "Parameter Estimates" table. If a parameter name contains a blank or some other special character (such as '*', '-','(', or ')'), then you must use the internal name of the parameter in order to refer to that parameter in the RESTRICT statement. For more

information about how parameters are named in the RESTRICT statement, see the section "Parameter Naming Conventions for the RESTRICT, TEST, BOUNDS, and INIT Statements" on page 631.

Restrictions should be consistent and not redundant. All restriction equations in all RESTRICT statements are applied jointly.

RESTRICT Statement Examples

Examples of valid RESTRICT statements include the following:

```
restrict x1=0.1;
restrict a+b=1;
restrict a-b=0, b+c=1.5;
restrict 2*f=g+h, intercept+f=0;
```

Examples of invalid RESTRICT statements include the following:

```
restrict x1^2=4;
restrict x1*x3=4;
restrict x1/x3=2;
restrict sin(a)=0;
restrict a*0.5=1;
restrict 2*(f+h)=1;
```

In the first four examples, the equation is non-linear. The fifth example is invalid because the constant factor (0.5) cannot appear on the right-hand side of the times ($*$) operator. The last example is invalid because grouping symbols are not allowed.

The set of restrictions must be consistent. For example, you cannot specify

```
restrict f-g=0,
         f-intercept=0,
         g-intercept=1;
```

because the three restrictions are not consistent.

Lagrange multipliers are reported in the "Parameter Estimates" table for all the active linear constraints. They are identified with the names Restrict1, Restrict2, and so on. The probabilities of these Lagrange multipliers are computed using a beta distribution (LaMotte 1994). Nonactive (nonbinding) restrictions have no effect on the estimation results and are not noted in the output.

The following RESTRICT statement constrains the negative binomial dispersion parameter α to 1, which restricts the conditional variance to be $\mu + \mu^2$:

```
restrict _Alpha = 1;
```

The RESTRICT statement is not supported if you also specify a BAYES statement. In Bayesian analysis, the restrictions on parameters are usually introduced through the prior distribution.

SCORE Statement

SCORE <**OUT=***SAS-data-set*> <*output-options*> **;**

The SCORE statement enables you to compute predicted values and other statistics for a SAS data set. As with the OUTPUT statement, the new data set that is created contains all the variables in the input data set and, optionally, the estimates of $\mathbf{x}_i'\boldsymbol{\beta}$, the expected value of the response variable, and the probability that the response variable will take the current value or other values that you specify. In a zero-inflated model, you can additionally request that the output data set contain the estimates of $\mathbf{z}_i'\boldsymbol{\gamma}$ and the probability that the response is zero as a result of the zero-generating process. For the Conway-Maxwell-Poisson model, the estimates of $\mathbf{g}_i'\boldsymbol{\delta}$, λ, ν, μ, mode, variance, and dispersion are also available. Except for the probability of the current value, these statistics can be computed for all observations in which the regressors are not missing, even if the response is missing.

The following statements fit a Poisson model by using the DocVisit data set. Additional observations in the additionalPatients data set are used to compute expected values by using the SCORE statement. The data in the additionalPatients data set are not used during the fitting stage and are used only for scoring.

You score a data set in two separate steps. In the first step, you fit the model and use the STORE statement to preserve it in the DocVisitPoisson item store, as shown in the following statements:

```
proc countreg data=docvisit;
   model doctorvisits=sex illness income / dist=poisson;
   store docvisitPoisson;
run;
```

In the second step, you retrieve the content of the DocVisitPoisson item store and use it to calculate expected values by using the SCORE statement for the additionalPatients data set as follows:

```
proc countreg restore=docvisitPoisson data=additionalPatients;
score out=outScores mean=meanPoisson probability=prob;
run;
```

By retrieving the model from the item store and using it in a postprocessing step, you can separate the fitting and scoring stages and use data for scoring that might not be available at the time when the model was fitted.

You can specify only one SCORE statement. You can specify the following *output-options*:

DISPERSION=*name*
names the variable that contains the value of dispersion for the Conway-Maxwell-Poisson distribution.

GDELTA=*name*
names the variable that contains estimates of $\mathbf{g}_i'\boldsymbol{\delta}$ for the Conway-Maxwell-Poisson distribution.

LAMBDA=*name*
names the variable that contains the estimate of λ for the Conway-Maxwell-Poisson distribution.

MODE=*name*
names the variable that contains the integral part of μ (mode) for the Conway-Maxwell-Poisson distribution.

MU=*name*
names the variable that contains the estimate of μ for the Conway-Maxwell-Poisson distribution.

NU=*name*
names the variable that contains the estimate of ν for the Conway-Maxwell-Poisson distribution.

OUT=*SAS-data-set*
names the output data set.

PRED=*name*

MEAN=*name*
names the variable that contains the predicted value of the response variable.

PROB=*name*
names the variable that contains the probability that the response variable will take the current value, $\Pr(Y = y_i)$.

PROBCOUNT(*value1* **<***value2***...>)**
outputs the probability that the response variable will take particular values. Each value should be a nonnegative integer. Nonintegers are rounded to the nearest integer. The *value* can also be a list of the form X TO Y BY Z. For example, PROBCOUNT(0 1 2 TO 10 BY 2 15) requests predicted probabilities for counts 0, 1, 2, 4, 5, 6, 8, 10, and 15. This option is not available for the fixed-effects and random-effects panel models.

PROBZERO=*name*
names the variable that contains the value of φ_i, the probability of the response variable taking on the value of zero as a result of the zero-generating process. It is written to the output file only if the model is zero-inflated. This is not the overall probability of a zero response; that is provided by the PROBCOUNT(0) option.

VARIANCE=*name*
names the variable that contains the estimate of variance for the Conway-Maxwell-Poisson distribution.

XBETA=*name*
names the variable that contains estimates of $\mathbf{x}_i'\boldsymbol{\beta}$.

ZGAMMA=*name*
names the variable that contains estimates of $\mathbf{z}_i'\boldsymbol{\gamma}$.

SHOW Statement

SHOW *options* **;**

The SHOW statement displays the contents of the item store. You can use the SHOW statement to verify the contents of the item store before proceeding with the analysis.

Table 11.2 summarizes the *options* available in the SHOW statement.

Table 11.2 SHOW Statement Options

Option	Description
ALL	Displays all applicable contents
CLASSLEVELS	Displays the "Class Level Information" table
CORRELATION	Produces the correlation matrix of the parameter estimates
COVARIANCE	Produces the covariance matrix of the parameter estimates
EFFECTS	Displays information about the constructed effects
FITSTATS	Displays the fit statistics
PARAMETERS	Displays the parameter estimates
PROGRAM	Displays the SAS program that generates the item store

You can specify the following *options* after the SHOW statement:

ALL | _ALL_
displays all applicable contents.

CLASSLEVELS | CLASS
displays the "Class Level Information" table. This table is produced by the COUNTREG procedure by default if the model contains effects that depend on classification variables.

CORRELATION | CORR | CORRB
produces the correlation matrix of the parameter estimates.

COVARIANCE | COV | COVB
produces the covariance matrix of the parameter estimates.

EFFECTS
displays information about the effects in the model.

FITSTATS | FIT | FITSUMMARY
displays the fit statistics from the item store.

PARAMETERS
PARMS
displays the parameter estimates table from the item store.

PROGRAM

PROG

displays the SAS program that generates the item store, provided that this was stored at store generation time. The program does not include comments, titles, or some other global statements.

SPATIALDISPEFFECTS Statement

SPATIALDISPEFFECTS < *dispersion-spatial-effect-regressors* > < */options* > **;**

The SPATIALDISPEFFECTS statement adds the spatially weighted *dispersion-spatial-effect-regressors* to regressors that are specified in the DISPMODEL statement. For example, if you specify q variables $z_1, \ldots, z_q$ in the SPATIALDISPEFFECTS statement, then each of q spatially weighted variables $\mathbf{W}z_1, \ldots, \mathbf{W}z_q$ has a parameter to be estimated in the regression. Here, $\mathbf{W}z_1, \ldots, \mathbf{W}z_q$ denotes the matrix and vector product between $\mathbf{W}$ and a column vector whose entries are the values of $z_1, \ldots, z_q$, respectively. The spatial weights matrix $\mathbf{W}$ comes from the data set that is specified in the WMAT= option in the PROC COUNTREG statement.

The "Parameter Estimates" table in the displayed output shows the estimates for spatially weighted explanatory variables; they are labeled with the prefix "Dsp_W_". For example, if you specify z (a variable in your data set) as a spatial effect explanatory variable, then the "Parameter Estimates" table labels the corresponding parameter estimate "Dsp_W_z".

You can specify the following *option* after a slash (/):

SELECT=INFO=< (*selection-options***) >**

SELECTVAR=INFO=< (*selection-options***) >**

requests that the variable selection method be based on an information criterion. For a list of *selection-options*, see the section "Options for Variable Selection Based on an Information Criterion" on page 580. For more information about this type of variable selection, see the section "Variable Selection Using an Information Criterion" on page 616.

SPATIALEFFECTS Statement

SPATIALEFFECTS < *model-spatial-effect-regressors* > < */options* > **;**

The SPATIALEFFECTS statement adds the spatially weighted *model-spatial-effect-regressors* to regressors that are specified in the MODEL statement. For example, if you specify q variables $z_1, \ldots, z_q$ in the SPATIALEFFECTS statement, then each of q spatially weighted variables $\mathbf{W}z_1, \ldots, \mathbf{W}z_q$ has a parameter to be estimated in the regression. Here, $\mathbf{W}z_1, \ldots, \mathbf{W}z_q$ denotes the matrix and vector product between $\mathbf{W}$ and a column vector whose entries are the values of $z_1, \ldots, z_q$, respectively. The spatial weights matrix $\mathbf{W}$ comes from the data set that is specified in the WMAT= option in the PROC COUNTREG statement.

The "Parameter Estimates" table in the displayed output shows the estimates for spatially weighted *model-spatial-effect-regressors*; they are labeled with the prefix "W_". For example, if you specify z (a variable in your data set) as a spatial effect explanatory variable, then the "Parameter Estimates" table labels the corresponding parameter estimate "W_z".

You can specify the following *option* after a slash (/):

SELECT=INFO=<(*selection-options***)>**

SELECTVAR=INFO=<(*selection-options***)>**

requests that the variable selection method be based on an information criterion. For a list of *selection-options*, see the section "Options for Variable Selection Based on an Information Criterion" on page 580. For more information about this type of variable selection, see the section "Variable Selection Using an Information Criterion" on page 616.

SPATIALID Statement

SPATIALID *variable* **;**

For a spatial lag of X model, the SPATIALID statement specifies a variable that identifies a spatial unit for each observation in the two data sets that are provided by the DATA= and WMAT= options in the PROC COUNTREG statement. The variable also identifies the rows and columns of the WMAT= data set. The values of the spatial ID variable cannot be missing in either the DATA= data set or the WMAT= data set. When there are multiple SPATIALID statements, the first SPATIALID statement takes precedence over others that follow. In such a circumstance, the first SPATIALID statement applies to all spatial lag of X models.

The variable in the SPATIALID statement can be either numeric or character. However, the type of spatial ID variable in both the primary data set (specified in the DATA= option) and the spatial weights data set (specified in the WMAT= option) must be the same. When the spatial ID variable is numeric, its value needs to be an integer. If you specify a number that is not an integer, PROC COUNTREG uses the integer part of that number for matching. When the variable is numeric, the first letter of column names in the WMAT= data set (which specifies a spatial unit) is discarded because a valid SAS variable name must start with a letter or an underscore. When a numeric column name (such as, 11) is in the WMAT= data set, the IMPORT procedure (in Base SAS) appends an underscore to the column name in order to make it a valid name (for example, 11 becomes _11).

SPATIALZEROEFFECTS Statement

SPATIALZEROEFFECTS *< zero-inflation-spatial-effect-regressors > < /option >* **;**

The SPATIALZEROEFFECTS statement adds the spatially weighted *zero-inflation-spatial-effect-regressors* to regressors that are specified in the ZEROMODEL statement. For example, if you specify q variables $z_1, \ldots, z_q$ in the SPATIALZEROEFFECTS statement, then each of q spatially weighted variables $\mathbf{W}z_1, \ldots, \mathbf{W}z_q$ has a parameter to be estimated in the regression. Here, $\mathbf{W}z_1, \ldots, \mathbf{W}z_q$ denotes the matrix and vector product between $\mathbf{W}$ and a column vector whose entries are the values of $z_1, \ldots, z_q$, respectively. The spatial weights matrix $\mathbf{W}$ comes from the data set that is specified in the WMAT= option in the PROC COUNTREG statement.

The "Parameter Estimates" table in the displayed output shows the estimates for spatially weighted explanatory variables; they are labeled with the prefix "Inf_W_". For example, if you specify z (a variable in your data set) as a spatial effect explanatory variable, then the "Parameter Estimates" table labels the corresponding parameter estimate "Inf_W_z".

You can specify the following *option* after a slash (/):

SELECT=INFO=<(*selection-options***)>**

SELECTVAR=INFO=<(*selection-options***)>**

requests that the variable selection method be based on an information criterion. For a list of *selection-options*, see the section "Options for Variable Selection Based on an Information Criterion" on page 580. For more information about this type of variable selection, see the section "Variable Selection Using an Information Criterion" on page 616.

STORE Statement

STORE <**OUT=**>*item-store-name* **;**

The STORE statement saves the contents of the analysis to an item store in a binary format that cannot be modified. You can restore the stored information by specifying the RESTORE= option in the PROC COUNTREG statement and use it in postprocessing analysis.

TEST Statement

<label:> **TEST** *<'string'> equation1 <, equation2. . . > / test-options* **;**

The TEST statement performs Wald, Lagrange multiplier, and likelihood ratio tests of linear hypotheses about the regression parameters that are specified in the preceding MODEL statement.

Each *test* is written either as a single linear *equation* or as a comma-separated list of two or more linear *equations*. A test *equation* specifies a linear hypothesis to be tested and consists of an *expression*, followed by the equality operator (=), followed by a second expression:

expression = expression

The rules governing valid test expressions are the same as those for restriction expressions. For more information see the section "RESTRICT Statement Expressions" on page 586.

Each *equation* specifies a linear hypothesis to be tested and consists of regression parameter names and relational operators. The regression parameter names are as shown in the Parameter column of the "Parameter Estimates" table. For more information about how parameters are named in the TEST statement, see the section "Parameter Naming Conventions for the RESTRICT, TEST, BOUNDS, and INIT Statements" on page 631. Only linear equality restrictions and tests are permitted in PROC COUNTREG. Test *equations* can consist only of algebraic operations that involve the addition symbol (+), subtraction symbol (-), and multiplication symbol (*).

All hypotheses in one TEST statement are tested jointly.

You can specify the following *test-options* after a slash (/):

ALL

requests Wald, Lagrange multiplier, and likelihood ratio tests.

LM
requests the Lagrange multiplier test.

LR
requests the likelihood ratio test.

WALD
requests the Wald test.

By default, the Wald test is performed.

You can add a label (which is printed in the output) to a TEST statement in two ways: add an unquoted *label* followed by a colon before the TEST keyword, or add a quoted *string* after the TEST keyword. The unquoted *label* cannot contain any spaces. If you include both an unquoted *label* and a quoted *string*, PROC COUNTREG uses the unquoted *label*. If you specify neither an unquoted *label* nor a quoted *string*, PROC COUNTREG automatically labels the tests.

The following statements illustrate the use of the TEST statement:

```
proc countreg;
   model y = x1 x2 x3;
   test x1 = 0, 1.5 * x2 + 2 * x3 = 0;
   test_int: test intercept = 0, x3 = 0.75;
run;
```

In the example, two separate tests are performed. The first test investigates the joint hypothesis that

$$\beta_1 = 0$$

and

$$1.5\beta_2 + 2\beta_3 = 0$$

The second test is labeled “test_int” and investigates the joint hypothesis that

$$\beta_{Intercept} = 0$$

and

$$\beta_3 = 0.75$$

You cannot specify both the TEST statement and the BAYES statement.

WEIGHT Statement

WEIGHT *variable* < / *option* > **;**

The WEIGHT statement specifies a variable to supply weighting values to use for each observation in estimating parameters. The log likelihood for each observation is multiplied by the corresponding weight variable value.

If the weight of an observation is nonpositive, that observation is not used in the estimation.

You can specify the following *option* after a slash (/):

NONORMALIZE
does not normalize the weights. By default, the weights are normalized so that they add up to the actual sample size. Weights w_i are normalized by multiplying them by $\frac{n}{\sum_{i=1}^{n} w_i}$, where n is the sample size. If the weights are required to be used "as is", then specify the NONORMALIZE option.

ZEROMODEL Statement

ZEROMODEL *dependent variable* ~ < *zero-inflated regressors* > < /*options* > **;**

The ZEROMODEL statement is required if you specify either ZIP or ZINB in the DIST= option in the MODEL statement. If ZIP or ZINB is specified, then the ZEROMODEL statement must follow immediately after the MODEL statement. The dependent variable in the ZEROMODEL statement must be the same as the dependent variable in the MODEL statement.

The zero-inflated (ZI) regressors appear in the equation that determines the probability (φ_i) of a zero count. Each of these q variables has a parameter to be estimated in the regression. For example, let $\mathbf{z}_i'$ be the ith observation's $1 \times (q+1)$ vector of values of the q ZI explanatory variables (w_0 is set to 1 for the intercept term). Then φ_i is a function of $\mathbf{z}_i'\boldsymbol{\gamma}$, where $\boldsymbol{\gamma}$ is the $(q+1) \times 1$ vector of parameters to be estimated. (The ZI intercept is γ_0; the coefficients for the q ZI covariates are $\gamma_1, \ldots, \gamma_q$.) If this option is omitted, then only the intercept term γ_0 is estimated. The "Parameter Estimates" table in the displayed output gives the estimates for the ZI intercept and ZI explanatory variables; they are labeled with the prefix "Inf_". For example, the ZI intercept is labeled "Inf_intercept". If you specify Age (a variable in your data set) as a ZI explanatory variable, then the "Parameter Estimates" table labels the corresponding parameter estimate "Inf_Age".

You can specify the following options after a slash (/):

LINK=LOGISTIC | NORMAL
specifies the distribution function to use to compute probability of zeros. The following distribution functions are supported:

LOGISTIC	specifies the logistic distribution.
NORMAL	specifies the standard normal distribution.

If this option is omitted, then the default ZI link function is logistic.

OFFSET=*variable*

specifies a variable in the input data set to be used as a zero-inflated (ZI) offset variable. The ZI offset variable is included as a term, with its coefficient restricted to 1, in the equation that determines the probability (φ_i) of a zero count. The ZI offset variable cannot be the response variable, the offset variable (if any), or one of the explanatory variables. The name of the data set variable that is used as the ZI offset variable is displayed in the "Model Fit Summary" output, where it is labeled as "Inf_offset".

SELECT=INFO<(*option***)>**

SELECTVAR=INFO<(*option***)>**

requests that the variable selection method be based on an information criterion. For a list of *selection-options*, see the section "Options for Variable Selection Based on an Information Criterion" on page 580. For more information about this type of variable selection, see the section "Variable Selection Using an Information Criterion" on page 616.

Details: COUNTREG Procedure

Specification of Regressors

Each term in a model, called a *regressor*, is a variable or combination of variables. Regressors are specified in a special notation that uses variable names and operators. There are two kinds of variables: *classification* (*CLASS*) *variables* and *continuous variables*. There are two primary operators: *crossing* and *nesting*. A third operator, the *bar operator*, is used to simplify effect specification.

In the SAS System, *classification* (*CLASS*) *variables* are declared in the CLASS statement. (They can also be called *categorical*, *qualitative*, *discrete*, or *nominal variables*.) Classification variables can be either *numeric* or *character*. The values of a classification variable are called *levels*. For example, the classification variable Sex has the levels "male" and "female."

In a model, an independent variable that is not declared in the CLASS statement is assumed to be continuous. *Continuous variables*, which must be numeric, are used for covariates. For example, the heights and weights of subjects are continuous variables. A response variable is a *discrete count variable* and must also be numeric.

Types of Regressors

Seven different types of regressors are used in the COUNTREG procedure. In the following list, assume that A, B, C, D, and E are CLASS variables and that X1 and X2 are continuous variables:

- Regressors are specified by writing continuous variables by themselves: X1 X2.
- Polynomial regressors are specified by joining (crossing) two or more continuous variables with asterisks: X1*X1 X1*X2.
- Dummy regressors are specified by writing CLASS variables by themselves: A B C.
- Dummy interactions are specified by joining classification variables with asterisks: A*B B*C A*B*C.

- Nested regressors are specified by following a dummy variable or dummy interaction with a classification variable or list of classification variables enclosed in parentheses. The dummy variable or dummy interaction is nested within the regressor that is listed in parentheses: B(A) C(B*A) D*E(C*B*A). In this example, B(A) is read "B nested within A."
- Continuous-by-class regressors are written by joining continuous variables and classification variables with asterisks: X1*A.
- Continuous-nesting-class regressors consist of continuous variables followed by a classification variable interaction enclosed in parentheses: X1(A) X1*X2(A*B).

One example of the general form of an effect that involves several variables is

```
X1*X2*A*B*C(D*E)
```

This example contains an interaction between continuous terms and classification terms that are nested within more than one classification variable. The continuous list comes first, followed by the dummy list, followed by the nesting list in parentheses. Note that asterisks can appear within the nested list but not immediately before the left parenthesis.

The MODEL statement and several other statements use these effects. Some examples of MODEL statements that use various kinds of effects are shown in Table 11.3, where a, b, and c represent classification variables. The variables x and z are continuous.

Table 11.3 Examples of MODEL Statement and Effects

Specification	Type of Model
`model y=x;`	Simple regression
`model y=x z;`	Multiple regression
`model y=x x*x;`	Polynomial regression
`model y=a;`	Regression with one classification variable
`model y=a b c;`	Regression with multiple classification variables
`model y=a b a*b;`	Regression with classification variables and their interactions
`model y=a b(a) c(b a);`	Regression with classification variables and their interactions
`model y=a x;`	Regression with both continuous and classification variables
`model y=a x(a);`	Separate-slopes regression
`model y=a x x*a;`	Homogeneity-of-slopes regression

The Bar Operator

You can shorten the specification of a large factorial model by using the bar operator. For example, two ways of writing the model for a full three-way factorial model follow:

```
model Y = A B C   A*B A*C B*C   A*B*C;

model Y = A|B|C;
```

When the bar (|) is used, the right and left sides become effects, and the cross of them becomes an effect. Multiple bars are permitted. The expressions are expanded from left to right, using rules 2–4 given in Searle (1971, p. 390).

- Multiple bars are evaluated from left to right. For instance, A | B | C is evaluated as follows:

  A | B | C → { A | B } | C
  → { A B A*B } | C
  → A B A*B C A*C B*C A*B*C

- Crossed and nested groups of variables are combined. For example, A(B) | C(D) generates A*C(B D), among other terms.
- Duplicate variables are removed. For example, A(C) | B(C) generates A*B(C C), among other terms, and the extra C is removed.
- Effects are discarded if a variable occurs on both the crossed and nested parts of an effect. For instance, A(B) | B(D E) generates A*B(B D E), but this effect is discarded immediately.

You can also specify the maximum number of variables involved in any effect that results from bar evaluation by specifying that maximum number, preceded by an @ sign, at the end of the bar effect. For example, the specification A | B | C@2 would result in only those effects that contain two or fewer variables: in this case, A B A*B C A*C and B*C.

More examples of using the | and @ operators follow:

A | C(B)	is equivalent to	A C(B) A*C(B)
A(B) | C(B)	is equivalent to	A(B) C(B) A*C(B)
A(B) | B(D E)	is equivalent to	A(B) B(D E)
A | B(A) | C	is equivalent to	A B(A) C A*C B*C(A)
A | B(A) | C@2	is equivalent to	A B(A) C A*C
A | B | C | D@2	is equivalent to	A B A*B C A*C B*C D A*D B*D C*D
A*B(C*D)	is equivalent to	A*B(C D)

Missing Values

Any observation in the input data set that has a missing value for one or more of the regressors is ignored by PROC COUNTREG and not used in the model fit. PROC COUNTREG rounds any positive noninteger count values to the nearest integer. PROC COUNTREG ignores any observations that have a negative count, a zero or negative weight, or a frequency less than 1.

If there are observations in the input data set that have missing response values but with nonmissing regressors, PROC COUNTREG can compute several statistics and store them in an output data set by using the OUTPUT statement. For example, you can request that the output data set contain the estimates of $\mathbf{x}_i'\boldsymbol{\beta}$, the expected value of the response variable, and the probability that the response variable will take values that you specify. In a zero-inflated model, you can additionally request that the output data set contain the estimates of $\mathbf{z}_i'\boldsymbol{\gamma}$, and the probability that the response is zero as a result of the zero-generating process. The presence of such observations (with missing response values) does not affect the model fit.

Poisson Regression

The most widely used model for count data analysis is Poisson regression. This assumes that y_i, given the vector of covariates $\mathbf{x}_i$, is independently Poisson-distributed with

$$P(Y_i = y_i|\mathbf{x}_i) = \frac{e^{-\mu_i}\mu_i^{y_i}}{y_i!}, \quad y_i = 0, 1, 2, \ldots$$

and the mean parameter (that is, the mean number of events per period) is given by

$$\mu_i = \exp(\mathbf{x}_i'\boldsymbol{\beta})$$

where $\boldsymbol{\beta}$ is a $(k+1) \times 1$ parameter vector. (The intercept is β_0; the coefficients for the k regressors are $\beta_1, \ldots, \beta_k$.) Taking the exponential of $\mathbf{x}_i'\boldsymbol{\beta}$ ensures that the mean parameter μ_i is nonnegative. It can be shown that the conditional mean is given by

$$E(y_i|\mathbf{x}_i) = \mu_i = \exp(\mathbf{x}_i'\boldsymbol{\beta})$$

The name *log-linear model* is also used for the Poisson regression model because the logarithm of the conditional mean is linear in the parameters:

$$\ln[E(y_i|\mathbf{x}_i)] = \ln(\mu_i) = \mathbf{x}_i'\boldsymbol{\beta}$$

Note that the conditional variance of the count random variable is equal to the conditional mean in the Poisson regression model:

$$V(y_i|\mathbf{x}_i) = E(y_i|\mathbf{x}_i) = \mu_i$$

The equality of the conditional mean and variance of y_i is known as *equidispersion*.

The marginal effect of a regressor is given by

$$\frac{\partial E(y_i|\mathbf{x}_i)}{\partial x_{ji}} = \exp(\mathbf{x}_i'\boldsymbol{\beta})\boldsymbol{\beta}_j = E(y_i|\mathbf{x}_i)\beta_j$$

Thus, a one-unit change in the *j*th regressor leads to a *proportional* change in the conditional mean $E(y_i|\mathbf{x}_i)$ of β_j.

The standard estimator for the Poisson model is the maximum likelihood estimator (MLE). Because the observations are independent, the log-likelihood function is written as

$$\mathcal{L} = \sum_{i=1}^{N} w_i(-\mu_i + y_i \ln \mu_i - \ln y_i!) = \sum_{i=1}^{N} w_i(-e^{\mathbf{x}_i'\boldsymbol{\beta}} + y_i \mathbf{x}_i'\boldsymbol{\beta} - \ln y_i!)$$

where w_i is defined as follows:

1	if neither the WEIGHT nor FREQ statement is used.
W_i	where W_i are the nonnormalized values of the variable that are specified in the WEIGHT statement in which the NONORMALIZE option is specified.
$\frac{n}{\sum_{i=1}^{n} W_i} W_i$	where W_i are the nonnormalized values of the variable that is specified in the WEIGHT statement.
F_i	where F_i are the values of the variable that is specified in the FREQ statement.
$W_i F_i$	if both the WEIGHT statement, without the NONORMALIZE option, and the FREQ statement are specified.
$\frac{\sum_{i=1}^{n} F_i}{\sum_{i=1}^{n} F_i W_i} W_i F_i$	if both the FREQ and WEIGHT statements are specified.

The gradient and the Hessian are, respectively,

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} = \sum_{i=1}^{N} w_i(y_i - \mu_i)\mathbf{x}_i = \sum_{i=1}^{N} w_i(y_i - e^{\mathbf{x}_i'\boldsymbol{\beta}})\mathbf{x}_i$$

$$\frac{\partial^2 \mathcal{L}}{\partial \boldsymbol{\beta} \partial \boldsymbol{\beta}'} = -\sum_{i=1}^{N} w_i \mu_i \mathbf{x}_i \mathbf{x}_i{}' = -\sum_{i=1}^{N} w_i e^{\mathbf{x}_i'\boldsymbol{\beta}} \mathbf{x}_i \mathbf{x}_i'$$

The Poisson model has been criticized for its restrictive property that the conditional variance must equal the conditional mean. Real-life data are often characterized by *overdispersion* (that is, the variance exceeds the mean). Allowing for overdispersion can improve model predictions because the Poisson restriction of equal mean and variance results in the underprediction of zeros when overdispersion exists. The most commonly used model that accounts for overdispersion is the negative binomial model. Conway-Maxwell-Poisson regression enables you to model both overdispersion and underdispersion.

Conway-Maxwell-Poisson Regression

The Conway-Maxwell-Poisson (CMP) distribution is a generalization of the Poisson distribution that enables you to model both underdispersed and overdispersed data. It was originally proposed by Conway and Maxwell (1962), but its implementation to model under- and overdispersed count data is attributed to Shmueli et al. (2005).

Recall that y_i, given the vector of covariates $\mathbf{x}_i$, is independently Poisson-distributed as

$$P(Y_i = y_i|\mathbf{x}_i) = \frac{e^{-\lambda_i}\lambda_i^{y_i}}{y_i!}, \quad y_i = 0, 1, 2, \ldots$$

The CMP distribution is defined as

$$P(Y_i = y_i|\mathbf{x}_i, \mathbf{g}_i) = \frac{1}{Z(\lambda_i, \nu_i)}\frac{\lambda_i^{y_i}}{(y_i!)^{\nu_i}}, \quad y_i = 0, 1, 2, \ldots$$

where the normalization factor is

$$Z(\lambda_i, \nu_i) = \sum_{n=0}^{\infty}\frac{\lambda_i^n}{(n!)^{\nu_i}}$$

and

$$\lambda_i = \exp(\mathbf{x}_i'\boldsymbol{\beta})$$

$$\nu_i = \exp(-\mathbf{g}_i'\boldsymbol{\delta})$$

The vector $\boldsymbol{\beta}$ is a $(k + 1) \times 1$ parameter vector. (The intercept is β_0, and the coefficients for the k regressors are $\beta_1, \ldots, \beta_k$.) The vector $\boldsymbol{\delta}$ is an $(m + 1) \times 1$ parameter vector. (The intercept is represented by δ_0, and the coefficients for the m regressors are $\delta_1, \ldots, \delta_k$.) The covariates are represented by the vectors $\mathbf{x}_i$ and $\mathbf{g}_i$.

One of the restrictive properties of the Poisson model is that the conditional mean and variance must be equal:

$$E(y_i|\mathbf{x}_i) = V(y_i|\mathbf{x}_i) = \lambda_i = \exp(\mathbf{x}_i'\boldsymbol{\beta})$$

The CMP distribution overcomes this restriction by defining an additional parameter, ν, which governs the rate of decay of successive ratios of probabilities such that

$$P(Y_i = y_i - 1)/P(Y_i = y_i) = \frac{(y_i)^{\nu_i}}{\lambda_i}$$

The introduction of the additional parameter, ν, allows for flexibility in modeling the tail behavior of the distribution. If $\nu = 1$, the ratio is equal to the rate of decay of the Poisson distribution. If $\nu < 1$, the rate of decay decreases, enabling you to model processes that have longer tails than the Poisson distribution's (overdispersed data). If $\nu > 1$, the rate of decay increases in a nonlinear fashion, thus shortening the tail of the distribution (underdispersed data).

The CMP distribution has several special cases. If $\lambda < 1$ and $\nu \to \infty$, the CMP distribution results in the Bernoulli distribution. In this case, the data can take only the values 0 and 1; this represents an extreme

underdispersion. If $\nu = 1$, the Poisson distribution is recovered along with its equidispersion property. When $\nu = 0$ and $\lambda < 1$, the normalization factor is convergent and forms a geometric series,

$$Z(\lambda_i, 0) = \frac{1}{1 - \lambda_i}$$

and the probability density function becomes

$$P(Y = y_i; \lambda_i, \nu_i = 0) = (1 - \lambda_i)\lambda_i^{y_i}$$

The geometric distribution represents a case of severe overdispersion.

Mean, Variance, and Dispersion for the Conway-Maxwell-Poisson Model

The mean and the variance of the Conway-Maxwell-Poisson distribution are defined as

$$E(Y) = \frac{\partial \ln Z}{\partial \ln \lambda}$$

$$V(Y) = \frac{\partial^2 \ln Z}{\partial^2 \ln \lambda}$$

The CMP distribution does not have closed-form expressions for its moments in terms of its parameters λ and ν. However, the moments can be approximated. Shmueli et al. (2005) use asymptotic expressions for Z to derive $E(Y)$ and $V(Y)$ as

$$E(Y) \approx \lambda^{1/\nu} + \frac{1}{2\nu} - \frac{1}{2}$$

$$V(Y) \approx \frac{1}{\nu}\lambda^{1/\nu}$$

Shmueli et al. (2005) noted that these approximations might not be accurate for underdispersed data ($\nu > 1$) or for values of $\lambda^{1/\nu} < 10$.

In the CMP model, the summation of infinite series is evaluated using a logarithmic expansion. The mean and variance are calculated as follows for the Shmueli et al. (2005) model:

$$E(Y) = \frac{1}{Z(\lambda, \nu)} \sum_{j=0}^{\infty} \frac{j\lambda^j}{(j!)^\nu}$$

$$V(Y) = \frac{1}{Z(\lambda, \nu)} \sum_{j=0}^{\infty} \frac{j^2\lambda^j}{(j!)^\nu} - E(Y)^2$$

The dispersion is defined as

$$D(Y) = \frac{V(Y)}{E(Y)}$$

Log-Likelihood Function for the Conway-Maxwell-Poisson Model

The log-likelihood function for the Conway-Maxwell-Poisson regression model can be written as

$$\begin{aligned}\mathcal{L} &= \sum_{i=1}^{N} \left(y_i \ln(\lambda_i) - \nu_i \ln(y_i!) - \ln[Z(\lambda_i, \nu_i)]\right) \\ &= \sum_{i=1}^{N} \left(y_i \mathbf{x}_i'\boldsymbol{\beta} + \ln(y_i!)\exp(\mathbf{g}_i'\boldsymbol{\delta}) - \ln[Z(\lambda_i, \nu_i)]\right)\end{aligned}$$

The gradients can be written as

$$\begin{aligned}\mathcal{L}_\beta &= \sum_{i=1}^{N} \left(y_i - \frac{Z_\lambda(\lambda_i, \nu_i)}{Z(\lambda_i, \nu_i)}\lambda_i\right)\mathbf{x}_i \\ \mathcal{L}_\delta &= \sum_{i=1}^{N} \left(\ln(y_i!) + \frac{Z_\nu(\lambda_i, \nu_i)}{Z(\lambda_i, \nu_i)}\right)\lambda_i \mathbf{g}_i\end{aligned}$$

where $Z_\lambda(\lambda_i, \nu_i)$ is the derivative of $Z(\lambda, \nu)$ with respect to λ evaluated at $\lambda = \lambda_i$ and $\nu = \nu_i$, and $Z_\nu(\lambda_i, \nu_i)$ is the derivative with respect to ν evaluated at $\lambda = \lambda_i$ and $\nu = \nu_i$.

Conway-Maxwell-Poisson Regression: Guikema and Coffelt (2008) Reparameterization

Guikema and Coffelt (2008) propose a reparameterization of the Shmueli et al. (2005) Conway-Maxwell-Poisson model to provide a measure of central tendency that can be interpreted in the context of the generalized linear model. By substituting $\lambda = \mu^\nu$, you can write the Guikema and Coffelt (2008) formulation as

$$P(Y = y_i; \mu_i, \nu_i) = \frac{1}{S(\mu_i, \nu_i)}\left(\frac{\mu_i^{y_i}}{y_i!}\right)^{\nu_i}$$

where the new normalization factor is defined as

$$S(\mu, \nu) = \sum_{n=0}^{\infty}\left(\frac{\mu^n}{n!}\right)^\nu$$

and

$$\mu_i = \exp(\mathbf{x}_i'\boldsymbol{\beta})$$

$$\nu_i = \exp(-\mathbf{g}_i'\boldsymbol{\delta})$$

In terms of their new formulations, the mean and variance of Y are given as

$$E(Y) = \frac{1}{\nu}\frac{\partial \ln S}{\partial \ln \mu}$$

$$V(Y) = \frac{1}{\nu^2}\frac{\partial^2 \ln S}{\partial^2 \ln \mu}$$

They can be approximated as

$$E(Y) \approx \mu + \frac{1}{2\nu} - \frac{1}{2}$$

$$V(Y) \approx \frac{\mu}{\nu}$$

When you specify the PRED= option in the OUTPUT statement, the COUNTREG procedure calculates the predicted value of the response variable by using the approximation for $E(Y)$ if $\mu > 20$; otherwise the exact formula is used. In PROC COUNTREG, the mean and variance are calculated according to the following formulas for the Guikema and Coffelt (2008) model:

$$E(Y) = \frac{1}{Z(\lambda, \nu)} \sum_{n=0}^{\infty} \frac{n\mu^{\nu n}}{(n!)^{\nu}}$$

$$V(Y) = \frac{1}{Z(\lambda, \nu)} \sum_{n=0}^{\infty} \frac{n^2\mu^{\nu n}}{(n!)^{\nu}} - E(Y)^2$$

In terms of the new parameter μ, the log-likelihood function is specified as

$$\mathcal{L} = \sum_{i=1}^{N} (\nu_i y_i \ln(\mu_i) - \nu_i \ln(y_i!) - \ln[S(\mu_i, \nu_i)])$$

and the gradients are calculated as

$$\mathcal{L}_{\beta} = \sum_{i=1}^{N} \left(\nu_i y_i - \frac{S_{\mu}(\mu_i, \nu_i)}{S(\mu_i, \nu_i)} \mu_i \right) \mathbf{x}_i$$

$$\mathcal{L}_{\delta} = \sum_{i=1}^{N} \left(\ln(y_i!) + \frac{S_{\nu}(\mu_i, \nu_i)}{S(\mu_i, \nu_i)} - y_i \log \mu_i \right) \nu_i \mathbf{g}_i$$

where $S_{\mu}(\mu_i, \nu_i)$ is the derivative of $S(\mu, \nu)$ with respect to μ evaluated at $\mu = \mu_i$ and $\nu = \nu_i$, and $S_{\nu}(\mu_i, \nu_i)$ is the derivative with respect to ν evaluated at $\mu = \mu_i$ and $\nu = \nu_i$. By default, PROC COUNTREG uses the Guikema and Coffelt (2008) specification. You can estimate the Shmueli et al. (2005) model by specifying the PARAMETER=LAMBDA option in the MODEL statement. If you specify DISP=CMPOISSON in the MODEL statement and you omit the DISPMODEL statement, the model is estimated according to the Lord, Guikema, and Geedipally (2008) specification, where ν represents a single parameter that does not depend on any covariates. The Lord, Guikema, and Geedipally (2008) specification makes the model comparable to the negative binomial model because it has only one parameter.

The dispersion is defined as

$$D(Y) = \frac{V(Y)}{E(Y)}$$

Using the Guikema and Coffelt (2008) specification results in the integral part of μ representing the mode, which is a reasonable approximation of the mean. The dispersion can be written as

$$D(Y) = \frac{V(Y)}{E(Y)} \approx \frac{\frac{\mu}{\nu}}{\mu + \frac{1}{2}\nu - \frac{1}{2}} \approx \frac{1}{\upsilon}$$

When $\nu < 1$, the variance can be shown to be greater than the mean and the dispersion can be shown to be greater than 1. This is a result of overdispersed data. When $\nu = 1$ and the mean and variance are equal, the dispersion is equal to 1 (Poisson model). When $\nu > 1$, the variance is smaller than the mean and the dispersion is less than 1. This is a result of underdispersed data.

All Conway-Maxwell-Poisson models in PROC COUNTREG are parameterized in terms of dispersion, where

$$-\ln(\nu) = \delta_0 + \sum_{n=1}^{q} \delta_n g_n$$

Negative values of $\ln(\nu)$ indicate that the data are approximately overdispersed, and positive values of $\ln(\nu)$ indicate that the data are approximately underdispersed.

Negative Binomial Regression

The Poisson regression model can be generalized by introducing an unobserved heterogeneity term for observation i. Thus, the individuals are assumed to differ randomly in a manner that is not fully accounted for by the observed covariates. This is formulated as

$$E(y_i|\mathbf{x}_i, \tau_i) = \mu_i \tau_i = e^{\mathbf{x}_i'\boldsymbol{\beta}+\epsilon_i}$$

where the unobserved heterogeneity term $\tau_i = e^{\epsilon_i}$ is independent of the vector of regressors $\mathbf{x}_i$. Then the distribution of y_i conditional on $\mathbf{x}_i$ and τ_i is Poisson with conditional mean and conditional variance $\mu_i \tau_i$:

$$f(y_i|\mathbf{x}_i, \tau_i) = \frac{\exp(-\mu_i \tau_i)(\mu_i \tau_i)^{y_i}}{y_i!}$$

Let $g(\tau_i)$ be the probability density function of τ_i. Then, the distribution $f(y_i|\mathbf{x}_i)$ (no longer conditional on τ_i) is obtained by integrating $f(y_i|\mathbf{x}_i, \tau_i)$ with respect to τ_i:

$$f(y_i|\mathbf{x}_i) = \int_0^\infty f(y_i|\mathbf{x}_i, \tau_i) g(\tau_i) d\tau_i$$

An analytical solution to this integral exists when τ_i is assumed to follow a gamma distribution. This solution is the negative binomial distribution. When the model contains a constant term, it is necessary to assume that $E(e^{\epsilon_i}) = E(\tau_i) = 1$ in order to identify the mean of the distribution. Thus, it is assumed that τ_i follows a gamma(θ, θ) distribution with $E(\tau_i) = 1$ and $V(\tau_i) = 1/\theta$,

$$g(\tau_i) = \frac{\theta^\theta}{\Gamma(\theta)} \tau_i^{\theta-1} \exp(-\theta \tau_i)$$

where $\Gamma(x) = \int_0^\infty z^{x-1}\exp(-z)dz$ is the gamma function and θ is a positive parameter. Then, the density of y_i given $\mathbf{x}_i$ is derived as

$$\begin{aligned} f(y_i|\mathbf{x}_i) &= \int_0^\infty f(y_i|\mathbf{x}_i,\tau_i)g(\tau_i)d\tau_i \\ &= \frac{\theta^\theta \mu_i^{y_i}}{y_i!\Gamma(\theta)}\int_0^\infty e^{-(\mu_i+\theta)\tau_i}\tau_i^{\theta+y_i-1}d\tau_i \\ &= \frac{\theta^\theta \mu_i^{y_i}\Gamma(y_i+\theta)}{y_i!\Gamma(\theta)(\theta+\mu_i)^{\theta+y_i}} \\ &= \frac{\Gamma(y_i+\theta)}{y_i!\Gamma(\theta)}\left(\frac{\theta}{\theta+\mu_i}\right)^\theta\left(\frac{\mu_i}{\theta+\mu_i}\right)^{y_i} \end{aligned}$$

Making the substitution $\alpha = \frac{1}{\theta}$ ($\alpha > 0$), the negative binomial distribution can then be rewritten as

$$f(y_i|\mathbf{x}_i) = \frac{\Gamma(y_i+\alpha^{-1})}{y_i!\Gamma(\alpha^{-1})}\left(\frac{\alpha^{-1}}{\alpha^{-1}+\mu_i}\right)^{\alpha^{-1}}\left(\frac{\mu_i}{\alpha^{-1}+\mu_i}\right)^{y_i}, \quad y_i = 0,1,2,\ldots$$

Thus, the negative binomial distribution is derived as a gamma mixture of Poisson random variables. It has conditional mean

$$E(y_i|\mathbf{x}_i) = \mu_i = e^{\mathbf{x}_i'\boldsymbol{\beta}}$$

and conditional variance

$$V(y_i|\mathbf{x}_i) = \mu_i[1+\frac{1}{\theta}\mu_i] = \mu_i[1+\alpha\mu_i] > E(y_i|\mathbf{x}_i)$$

The conditional variance of the negative binomial distribution exceeds the conditional mean. Overdispersion results from neglected unobserved heterogeneity. The negative binomial model with variance function $V(y_i|\mathbf{x}_i) = \mu_i + \alpha\mu_i^2$, which is quadratic in the mean, is referred to as the NEGBIN2 model (Cameron and Trivedi 1986). To estimate this model, specify DIST=NEGBIN(p=2) in the MODEL statement. The Poisson distribution is a special case of the negative binomial distribution where $\alpha = 0$. A test of the Poisson distribution can be carried out by testing the hypothesis that $\alpha = \frac{1}{\theta_i} = 0$. A Wald test of this hypothesis is provided (it is the reported t statistic for the estimated α in the negative binomial model).

The log-likelihood function of the negative binomial regression model (NEGBIN2) is given by

$$\begin{aligned} \mathcal{L} &= \sum_{i=1}^N w_i\left\{\sum_{j=0}^{y_i-1}\ln(j+\alpha^{-1}) - \ln(y_i!)\right. \\ &\quad \left. -(y_i+\alpha^{-1})\ln(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta})) + y_i\ln(\alpha) + y_i\mathbf{x}_i'\boldsymbol{\beta}\right\} \end{aligned}$$

$$\Gamma(y+a)/\Gamma(a) = \prod_{j=0}^{y-1}(j+a)$$

if y is an integer. For the definition of w_i, see "Poisson Regression" on page 599.

The gradient is

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} = \sum_{i=1}^{N} w_i \frac{y_i - \mu_i}{1 + \alpha\mu_i}\mathbf{x}_i$$

and

$$\frac{\partial \mathcal{L}}{\partial \alpha} = \sum_{i=1}^{N} w_i \left\{ -\alpha^{-2} \sum_{j=0}^{y_i-1} \frac{1}{(j + \alpha^{-1})} + \alpha^{-2}\ln(1 + \alpha\mu_i) + \frac{y_i - \mu_i}{\alpha(1 + \alpha\mu_i)} \right\}$$

Cameron and Trivedi (1986) consider a general class of negative binomial models with mean μ_i and variance function $\mu_i + \alpha\mu_i^p$. The NEGBIN2 model, with $p = 2$, is the standard formulation of the negative binomial model. Models with other values of p, $-\infty < p < \infty$, have the same density $f(y_i|\mathbf{x}_i)$ except that α^{-1} is replaced everywhere by $\alpha^{-1}\mu^{2-p}$. The negative binomial model NEGBIN1, which sets $p = 1$, has variance function $V(y_i|\mathbf{x}_i) = \mu_i + \alpha\mu_i$, which is linear in the mean. To estimate this model, specify DIST=NEGBIN(p=1) in the MODEL statement.

The log-likelihood function of the NEGBIN1 regression model is given by

$$\begin{aligned}\mathcal{L} \;=\; & \sum_{i=1}^{N} w_i \left\{ \sum_{j=0}^{y_i-1} \ln\left(j + \alpha^{-1}\exp(\mathbf{x}_i'\boldsymbol{\beta})\right) \right. \\ & \left. - \ln(y_i!) - \left(y_i + \alpha^{-1}\exp(\mathbf{x}_i'\boldsymbol{\beta})\right)\ln(1 + \alpha) + y_i \ln(\alpha) \right\}\end{aligned}$$

For the definition of w_i, see the section "Poisson Regression" on page 599.

The gradient is

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} = \sum_{i=1}^{N} w_i \left\{ \left(\sum_{j=0}^{y_i-1} \frac{\mu_i}{(j\alpha + \mu_i)} \right)\mathbf{x}_i - \alpha^{-1}\ln(1 + \alpha)\mu_i\mathbf{x}_i \right\}$$

and

$$\frac{\partial \mathcal{L}}{\partial \alpha} = \sum_{i=1}^{N} w_i \left\{ -\left(\sum_{j=0}^{y_i-1} \frac{\alpha^{-1}\mu_i}{(j\alpha + \mu_i)} \right) + \alpha^{-2}\mu_i \ln(1 + \alpha) - \frac{(y_i + \alpha^{-1}\mu_i)}{1 + \alpha} + \frac{y_i}{\alpha} \right\}$$

Zero-Inflated Count Regression Overview

The main motivation for zero-inflated count models is that real-life data frequently display overdispersion and excess zeros. Zero-inflated count models provide a way of modeling the excess zeros in addition to allowing for overdispersion. In particular, for each observation, there are two possible data generation processes. The result of a Bernoulli trial is used to determine which of the two processes is used. For observation i, Process 1 is chosen with probability φ_i and Process 2 with probability $1 - \varphi_i$. Process 1 generates only zero counts. Process 2 generates counts from either a Poisson or a negative binomial model. In general,

$$y_i \sim \begin{cases} 0 & \text{with probability} \quad \varphi_i \\ g(y_i) & \text{with probability} \quad 1-\varphi_i \end{cases}$$

Therefore, the probability of $\{Y_i = y_i\}$ can be described as

$$\begin{aligned} P(y_i = 0|\mathbf{x}_i) &= \varphi_i + (1-\varphi_i)g(0) \\ P(y_i|\mathbf{x}_i) &= (1-\varphi_i)g(y_i), \quad y_i > 0 \end{aligned}$$

where $g(y_i)$ follows either the Poisson or the negative binomial distribution. You can specify the probability φ by using the PROBZERO= option in the OUTPUT statement.

When the probability φ_i depends on the characteristics of observation i, φ_i is written as a function of $\mathbf{z}_i'\boldsymbol{\gamma}$, where $\mathbf{z}_i'$ is the $1 \times (q+1)$ vector of zero-inflation covariates and $\boldsymbol{\gamma}$ is the $(q+1) \times 1$ vector of zero-inflation coefficients to be estimated. (The zero-inflation intercept is γ_0; the coefficients for the q zero-inflation covariates are $\gamma_1, \ldots, \gamma_q$.) The function F that relates the product $\mathbf{z}_i'\boldsymbol{\gamma}$ (which is a scalar) to the probability φ_i is called the zero-inflation link function,

$$\varphi_i = F_i = F(\mathbf{z}_i'\boldsymbol{\gamma})$$

In the COUNTREG procedure, the zero-inflation covariates are indicated in the ZEROMODEL statement. Furthermore, the zero-inflation link function F can be specified as either the logistic function,

$$F(\mathbf{z}_i'\boldsymbol{\gamma}) = \Lambda(\mathbf{z}_i'\boldsymbol{\gamma}) = \frac{\exp(\mathbf{z}_i'\boldsymbol{\gamma})}{1+\exp(\mathbf{z}_i'\boldsymbol{\gamma})}$$

or the standard normal cumulative distribution function (also called the probit function),

$$F(\mathbf{z}_i'\boldsymbol{\gamma}) = \Phi(\mathbf{z}_i'\boldsymbol{\gamma}) = \int_0^{\mathbf{z}_i'\boldsymbol{\gamma}} \frac{1}{\sqrt{2\pi}} \exp(-u^2/2)du$$

The zero-inflation link function is indicated in the LINK option in ZEROMODEL statement. The default ZI link function is the logistic function.

Zero-Inflated Poisson Regression

In the zero-inflated Poisson (ZIP) regression model, the data generation process that is referred to earlier as Process 2 is

$$g(y_i) = \frac{\exp(-\mu_i)\mu_i^{y_i}}{y_i!}$$

where $\mu_i = e^{\mathbf{x}_i'\boldsymbol{\beta}}$. Thus the ZIP model is defined as

$$\begin{aligned} P(y_i = 0|\mathbf{x}_i, \mathbf{z}_i) &= F_i + (1 - F_i)\exp(-\mu_i) \\ P(y_i|\mathbf{x}_i, \mathbf{z}_i) &= (1 - F_i)\frac{\exp(-\mu_i)\mu_i^{y_i}}{y_i!}, \quad y_i > 0 \end{aligned}$$

The conditional expectation and conditional variance of y_i are given by

$$E(y_i|\mathbf{x}_i, \mathbf{z}_i) = \mu_i(1 - F_i)$$

$$V(y_i|\mathbf{x}_i, \mathbf{z}_i) = E(y_i|\mathbf{x}_i, \mathbf{z}_i)(1 + \mu_i F_i)$$

Note that the ZIP model (as well as the ZINB model) exhibits overdispersion because $V(y_i|\mathbf{x}_i, \mathbf{z}_i) > E(y_i|\mathbf{x}_i, \mathbf{z}_i)$.

In general, the log-likelihood function of the ZIP model is

$$\mathcal{L} = \sum_{i=1}^{N} w_i \ln\left[P(y_i|\mathbf{x}_i, \mathbf{z}_i)\right]$$

After a specific link function (either logistic or standard normal) for the probability φ_i is chosen, it is possible to write the exact expressions for the log-likelihood function and the gradient.

ZIP Model with Logistic Link Function

First, consider the ZIP model in which the probability φ_i is expressed using a logistic link function—namely,

$$\varphi_i = \frac{\exp(\mathbf{z}_i'\boldsymbol{\gamma})}{1 + \exp(\mathbf{z}_i'\boldsymbol{\gamma})}$$

The log-likelihood function is

$$\begin{aligned} \mathcal{L} = & \sum_{\{i:y_i=0\}} w_i \ln\left[\exp(\mathbf{z}_i'\boldsymbol{\gamma}) + \exp(-\exp(\mathbf{x}_i'\boldsymbol{\beta}))\right] \\ & + \sum_{\{i:y_i>0\}} w_i \left[y_i\mathbf{x}_i'\boldsymbol{\beta} - \exp(\mathbf{x}_i'\boldsymbol{\beta}) - \sum_{k=2}^{y_i} \ln(k) \right] \\ & - \sum_{i=1}^{N} w_i \ln\left[1 + \exp(\mathbf{z}_i'\boldsymbol{\gamma})\right] \end{aligned}$$

For the definition of w_i, see the section "Poisson Regression" on page 599.

The gradient for this model is given by

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\gamma}} = \sum_{\{i:y_i=0\}} w_i \left[\frac{\exp(\mathbf{z}_i'\boldsymbol{\gamma})}{\exp(\mathbf{z}_i'\boldsymbol{\gamma}) + \exp(-\exp(\mathbf{x}_i'\boldsymbol{\beta}))} \right] \mathbf{z}_i - \sum_{i=1}^{N} w_i \left[\frac{\exp(\mathbf{z}_i'\boldsymbol{\gamma})}{1 + \exp(\mathbf{z}_i'\boldsymbol{\gamma})} \right] \mathbf{z}_i$$

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} = \sum_{\{i:y_i=0\}} w_i \left[\frac{-\exp(\mathbf{x}_i'\boldsymbol{\beta}) \exp(-\exp(\mathbf{x}_i'\boldsymbol{\beta}))}{\exp(\mathbf{z}_i'\boldsymbol{\gamma}) + \exp(-\exp(\mathbf{x}_i'\boldsymbol{\beta}))} \right] \mathbf{x}_i + \sum_{\{i:y_i>0\}} w_i \left[y_i - \exp(\mathbf{x}_i'\boldsymbol{\beta}) \right] \mathbf{x}_i$$

ZIP Model with Standard Normal Link Function

Next, consider the ZIP model in which the probability φ_i is expressed using a standard normal link function: $\varphi_i = \Phi(\mathbf{z}_i'\boldsymbol{\gamma})$. The log-likelihood function is

$$\begin{aligned} \mathcal{L} &= \sum_{\{i:y_i=0\}} w_i \ln \left\{ \Phi(\mathbf{z}_i'\boldsymbol{\gamma}) + \left[1 - \Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right] \exp(-\exp(\mathbf{x}_i'\boldsymbol{\beta})) \right\} \\ &+ \sum_{\{i:y_i>0\}} w_i \left\{ \ln \left[\left(1 - \Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right) \right] - \exp(\mathbf{x}_i'\boldsymbol{\beta}) + y_i \mathbf{x}_i'\boldsymbol{\beta} - \sum_{k=2}^{y_i} \ln(k) \right\} \end{aligned}$$

For the definition of w_i, see the section "Poisson Regression" on page 599.

The gradient for this model is given by

$$\begin{aligned} \frac{\partial \mathcal{L}}{\partial \boldsymbol{\gamma}} &= \sum_{\{i:y_i=0\}} w_i \frac{\varphi(\mathbf{z}_i'\boldsymbol{\gamma}) \left[1 - \exp(-\exp(\mathbf{x}_i'\boldsymbol{\beta}))\right]}{\Phi(\mathbf{z}_i'\boldsymbol{\gamma}) + \left[1 - \Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right] \exp(-\exp(\mathbf{x}_i'\boldsymbol{\beta}))} \mathbf{z}_i \\ &- \sum_{\{i:y_i>0\}} w_i \frac{\varphi(\mathbf{z}_i'\boldsymbol{\gamma})}{\left[1 - \Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right]} \mathbf{z}_i \end{aligned}$$

$$\begin{aligned} \frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} &= \sum_{\{i:y_i=0\}} w_i \frac{-\left[1 - \Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right] \exp(\mathbf{x}_i'\boldsymbol{\beta}) \exp(-\exp(\mathbf{x}_i'\boldsymbol{\beta}))}{\Phi(\mathbf{z}_i'\boldsymbol{\gamma}) + \left[1 - \Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right] \exp(-\exp(\mathbf{x}_i'\boldsymbol{\beta}))} \mathbf{x}_i \\ &+ \sum_{\{i:y_i>0\}} w_i \left[y_i - \exp(\mathbf{x}_i'\boldsymbol{\beta}) \right] \mathbf{x}_i \end{aligned}$$

Zero-Inflated Conway-Maxwell-Poisson Regression

In the Conway-Maxwell-Poisson regression model, the data generation process is defined as

$$P(Y_i = y_i|\mathbf{x}_i, \mathbf{z}_i) = \frac{1}{Z(\lambda_i, \nu_i)} \frac{\lambda_i^{y_i}}{(y_i!)^{\nu_i}}, \quad y_i = 0, 1, 2, \ldots$$

where the normalization factor is

$$Z(\lambda_i, \nu_i) = \sum_{n=0}^{\infty} \frac{\lambda_i^n}{(n!)^{\nu_i}}$$

and

$$\lambda_i = \exp(\mathbf{x}_i'\boldsymbol{\beta})$$

$$\nu_i = -\exp(\mathbf{g}_i'\delta)$$

The zero-inflated Conway-Maxwell-Poisson model can be written as

$$\begin{aligned} P(y_i = 0|\mathbf{x}_i, \mathbf{z}_i) &= F_i + (1 - F_i) \frac{1}{Z(\lambda_i, \nu_i)} \\ P(y_i|\mathbf{x}_i, \mathbf{z}_i) &= (1 - F_i) \frac{1}{Z(\lambda_i, \nu_i)} \frac{\lambda_i^{y_i}}{(y_i!)^{\nu_i}}, \quad y_i > 0 \end{aligned}$$

The conditional expectation and conditional variance of y_i are given by

$$E(y_i|\mathbf{x}_i, \mathbf{z}_i) = (1 - F_i) \frac{1}{Z(\lambda, \nu)} \sum_{j=0}^{\infty} \frac{j\lambda^j}{(j!)^{\nu}}$$

$$V(y_i|\mathbf{x}_i, \mathbf{z}_i) = (1 - F_i) \frac{1}{Z(\lambda, \nu)} \sum_{j=0}^{\infty} \frac{j^2\lambda^j}{(j!)^{\nu}} - E(y_i|\mathbf{x}_i, \mathbf{z}_i)^2$$

The general form of the log-likelihood function for the Conway-Maxwell-Poisson zero-inflated model is

$$\mathcal{L} = \sum_{i=1}^{N} w_i \ln [P(y_i|\mathbf{x}_i, \mathbf{z}_i)]$$

Zero-Inflated Conway-Maxwell-Poisson Model with Logistic Link Function

In this model the probability φ_i is expressed by using a logistic link function as

$$\varphi_i = \Lambda(\mathbf{z}_i'\boldsymbol{\gamma}) = \frac{\exp(\mathbf{z}_i'\boldsymbol{\gamma})}{1 + \exp(\mathbf{z}_i'\boldsymbol{\gamma})}$$

The log-likelihood function is

$$\begin{aligned}\mathcal{L} &= \sum_{\{i:y_i=0\}} w_i \ln\left\{\Lambda(\mathbf{z}_i'\boldsymbol{\gamma}) + \left[1-\Lambda(\mathbf{z}_i'\boldsymbol{\gamma})\right]\frac{1}{Z(\lambda_i,\nu_i)}\right\} \\ &+ \sum_{\{i:y_i>0\}} w_i \left\{\ln\left[\left(1-\Lambda(\mathbf{z}_i'\boldsymbol{\gamma})\right)\right] - ln(Z(\lambda,\nu)) + (y_i\ln(\lambda) - \nu\ln(y_i!)\right\}\end{aligned}$$

Zero-Inflated Conway-Maxwell-Poisson Model with Normal Link Function

In this model, the probability φ_i is specified by using the standard normal distribution function (probit function): $\varphi_i = \Phi(\mathbf{z}_i'\boldsymbol{\gamma})$.

The log-likelihood function is written as

$$\begin{aligned}\mathcal{L} &= \sum_{\{i:y_i=0\}} w_i \ln\left\{\Phi(\mathbf{z}_i'\boldsymbol{\gamma}) + \left[1-\Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right]\frac{1}{Z(\lambda_i,\nu_i)}\right\} \\ &+ \sum_{\{i:y_i>0\}} w_i \left\{\ln\left[\left(1-\Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right)\right] - ln(Z(\lambda,\nu)) + (y_i\ln(\lambda) - \nu\ln(y_i!)\right\}\end{aligned}$$

Zero-Inflated Negative Binomial Regression

The zero-inflated negative binomial (ZINB) model in PROC COUNTREG is based on the negative binomial model with quadratic variance function ($p = 2$). The ZINB model is obtained by specifying a negative binomial distribution for the data generation process referred to earlier as Process 2:

$$g(y_i) = \frac{\Gamma(y_i+\alpha^{-1})}{y_i!\Gamma(\alpha^{-1})}\left(\frac{\alpha^{-1}}{\alpha^{-1}+\mu_i}\right)^{\alpha^{-1}}\left(\frac{\mu_i}{\alpha^{-1}+\mu_i}\right)^{y_i}$$

Thus the ZINB model is defined to be

$$\begin{aligned}P(y_i=0|\mathbf{x}_i,\mathbf{z}_i) &= F_i + (1-F_i)\left(1+\alpha\mu_i\right)^{-\alpha^{-1}} \\ P(y_i|\mathbf{x}_i,\mathbf{z}_i) &= (1-F_i)\frac{\Gamma(y_i+\alpha^{-1})}{y_i!\Gamma(\alpha^{-1})}\left(\frac{\alpha^{-1}}{\alpha^{-1}+\mu_i}\right)^{\alpha^{-1}} \\ &\times \left(\frac{\mu_i}{\alpha^{-1}+\mu_i}\right)^{y_i}, \quad y_i > 0\end{aligned}$$

In this case, the conditional expectation and conditional variance of y_i are

$$E(y_i|\mathbf{x}_i,\mathbf{z}_i) = \mu_i(1-F_i)$$

$$V(y_i|\mathbf{x}_i,\mathbf{z}_i) = E(y_i|\mathbf{x}_i,\mathbf{z}_i)\left[1+\mu_i(F_i+\alpha)\right]$$

Like the ZIP model, the ZINB model exhibits overdispersion because the conditional variance exceeds the conditional mean.

ZINB Model with Logistic Link Function

In this model, the probability φ_i is given by the logistic function—namely,

$$\varphi_i = \frac{\exp(\mathbf{z}_i'\boldsymbol{\gamma})}{1+\exp(\mathbf{z}_i'\boldsymbol{\gamma})}$$

The log-likelihood function is

$$\begin{aligned}
\mathcal{L} &= \sum_{\{i:y_i=0\}} w_i \ln\left[\exp(\mathbf{z}_i'\boldsymbol{\gamma}) + (1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))^{-\alpha^{-1}}\right] \\
&+ \sum_{\{i:y_i>0\}} w_i \sum_{j=0}^{y_i-1} \ln(j+\alpha^{-1}) \\
&+ \sum_{\{i:y_i>0\}} w_i \left\{-\ln(y_i!) - (y_i+\alpha^{-1})\ln(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta})) + y_i\ln(\alpha) + y_i\mathbf{x}_i'\boldsymbol{\beta}\right\} \\
&- \sum_{i=1}^{N} w_i \ln\left[1+\exp(\mathbf{z}_i'\boldsymbol{\gamma})\right]
\end{aligned}$$

For the definition of w_i, see the section "Poisson Regression" on page 599.

The gradient for this model is given by

$$\begin{aligned}
\frac{\partial\mathcal{L}}{\partial\boldsymbol{\gamma}} &= \sum_{\{i:y_i=0\}} w_i \left[\frac{\exp(\mathbf{z}_i'\boldsymbol{\gamma})}{\exp(\mathbf{z}_i'\boldsymbol{\gamma}) + (1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))^{-\alpha^{-1}}}\right]\mathbf{z}_i \\
&- \sum_{i=1}^{N} w_i \left[\frac{\exp(\mathbf{z}_i'\boldsymbol{\gamma})}{1+\exp(\mathbf{z}_i'\boldsymbol{\gamma})}\right]\mathbf{z}_i
\end{aligned}$$

$$\begin{aligned}
\frac{\partial\mathcal{L}}{\partial\boldsymbol{\beta}} &= \sum_{\{i:y_i=0\}} w_i \left[\frac{-\exp(\mathbf{x}_i'\boldsymbol{\beta})(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))^{-\alpha^{-1}-1}}{\exp(\mathbf{z}_i'\boldsymbol{\gamma}) + (1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))^{-\alpha^{-1}}}\right]\mathbf{x}_i \\
&+ \sum_{\{i:y_i>0\}} w_i \left[\frac{y_i - \exp(\mathbf{x}_i'\boldsymbol{\beta})}{1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta})}\right]\mathbf{x}_i
\end{aligned}$$

$$\frac{\partial\mathcal{L}}{\partial\alpha} = \sum_{\{i:y_i=0\}} w_i \frac{\alpha^{-2}\left[(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))\ln(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta})) - \alpha\exp(\mathbf{x}_i'\boldsymbol{\beta})\right]}{\exp(\mathbf{z}_i'\boldsymbol{\gamma})(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))^{(1+\alpha)/\alpha} + (1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))}$$

$$+ \sum_{\{i:y_i>0\}} w_i \left\{-\alpha^{-2}\sum_{j=0}^{y_i-1}\frac{1}{(j+\alpha^{-1})} + \alpha^{-2}\ln(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta})) + \frac{y_i-\exp(\mathbf{x}_i'\boldsymbol{\beta})}{\alpha(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))}\right\}$$

ZINB Model with Standard Normal Link Function

For this model, the probability φ_i is specified using the standard normal distribution function (probit function): $\varphi_i = \Phi(\mathbf{z}_i'\boldsymbol{\gamma})$. The log-likelihood function is

$$\begin{aligned}
\mathcal{L} &= \sum_{\{i:y_i=0\}} w_i \ln\left\{\Phi(\mathbf{z}_i'\boldsymbol{\gamma}) + \left[1-\Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right](1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))^{-\alpha^{-1}}\right\} \\
&+ \sum_{\{i:y_i>0\}} w_i \ln\left[1-\Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right] \\
&+ \sum_{\{i:y_i>0\}} w_i \sum_{j=0}^{y_i-1}\left\{\ln(j+\alpha^{-1})\right\} \\
&- \sum_{\{i:y_i>0\}} w_i \ln(y_i!) \\
&- \sum_{\{i:y_i>0\}} w_i (y_i+\alpha^{-1})\ln(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta})) \\
&+ \sum_{\{i:y_i>0\}} w_i y_i \ln(\alpha) \\
&+ \sum_{\{i:y_i>0\}} w_i y_i \mathbf{x}_i'\boldsymbol{\beta}
\end{aligned}$$

For the definition of w_i, see the section "Poisson Regression" on page 599.

The gradient for this model is given by

$$\frac{\partial\mathcal{L}}{\partial\boldsymbol{\gamma}} = \sum_{\{i:y_i=0\}} w_i \left[\frac{\varphi(\mathbf{z}_i'\boldsymbol{\gamma})\left[1-(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))^{-\alpha^{-1}}\right]}{\Phi(\mathbf{z}_i'\boldsymbol{\gamma})+\left[1-\Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right](1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))^{-\alpha^{-1}}}\right]\mathbf{z}_i$$

$$- \sum_{\{i:y_i>0\}} w_i \left[\frac{\varphi(\mathbf{z}_i'\boldsymbol{\gamma})}{1-\Phi(\mathbf{z}_i'\boldsymbol{\gamma})}\right]\mathbf{z}_i$$

$$\frac{\partial\mathcal{L}}{\partial\boldsymbol{\beta}} = \sum_{\{i:y_i=0\}} w_i \frac{-\left[1-\Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right]\exp(\mathbf{x}_i'\boldsymbol{\beta})(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))^{-(1+\alpha)/\alpha}}{\Phi(\mathbf{z}_i'\boldsymbol{\gamma})+\left[1-\Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right](1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))^{-\alpha^{-1}}}\mathbf{x}_i$$

$$+ \sum_{\{i:y_i>0\}} w_i \left[\frac{y_i-\exp(\mathbf{x}_i'\boldsymbol{\beta})}{1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta})}\right]\mathbf{x}_i$$

$$\frac{\partial\mathcal{L}}{\partial\alpha} = \sum_{\{i:y_i=0\}} w_i \frac{\left[1-\Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right]\alpha^{-2}\left[(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))\ln(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))-\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta})\right]}{\Phi(\mathbf{z}_i'\boldsymbol{\gamma})(1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))^{(1+\alpha)/\alpha}+\left[1-\Phi(\mathbf{z}_i'\boldsymbol{\gamma})\right](1+\alpha\exp(\mathbf{x}_i'\boldsymbol{\beta}))}$$

$$+ \sum_{\{i:y_i>0\}} w_i \left\{ -\alpha^{-2} \sum_{j=0}^{y_i-1} \frac{1}{(j+\alpha^{-1})} + \alpha^{-2} \ln(1+\alpha \exp(\mathbf{x}_i'\boldsymbol{\beta})) + \frac{y_i - \exp(\mathbf{x}_i'\boldsymbol{\beta})}{\alpha(1+\alpha \exp(\mathbf{x}_i'\boldsymbol{\beta}))} \right\}$$

Spatial Lag of X Model

The spatial lag of X (SLX) model is illustrated by using the general framework for a zero-inflated model. According to the section "Zero-Inflated Count Regression Overview" on page 608, the data model for y_i can be formulated as

$$y_i \sim \begin{cases} 0 & \text{with probability} \quad \varphi_i \\ g(y_i) & \text{with probability} \quad 1-\varphi_i \end{cases}$$

and the general model for parameters can be written in matrix form as

$$\begin{aligned} \boldsymbol{\lambda} &= \exp(\mathbf{X}\boldsymbol{\beta}) \\ \boldsymbol{\varphi} &= F(\mathbf{Z}\boldsymbol{\gamma}) \\ \boldsymbol{\nu} &= -\exp(\mathbf{G}\boldsymbol{\delta}) \end{aligned}$$

where $\boldsymbol{\varphi} = (\varphi_1, \ldots, \varphi_n)'$, $\boldsymbol{\lambda} = (\lambda_1, \ldots, \lambda_n)'$, and $\boldsymbol{\nu} = (\nu_1, \ldots, \nu_n)'$. In addition, $\mathbf{Z}_1$, $\mathbf{X}_1$, and $\mathbf{G}_1$ are design matrices, in which the ith row is $\mathbf{z}_i'$, $\mathbf{x}_i'$, and $\mathbf{g}_i'$ for $i = 1, 2, \ldots, n$, respectively.

In the spatial context, data are often collected over a predetermined set of spatial units, $\mathrm{s}_1, \mathrm{s}_2, \ldots, \mathrm{s}_n$. In this case, both the dependent variable and the explanatory variables are spatially referenced. For example, $y_i = y(\mathrm{s}_i)$ denotes the dependent variable that is observed at location s_i. For the SLX model, the data model for y_i remains the same. However, the parameter model becomes

$$\begin{aligned} \boldsymbol{\lambda} &= \exp(\mathbf{X}_1\boldsymbol{\beta}_1 + \mathbf{W}\mathbf{X}_2\,\boldsymbol{\beta}_2) = \exp(\mathbf{X}\boldsymbol{\beta}) \\ \boldsymbol{\varphi} &= F(\mathbf{Z}_1\boldsymbol{\gamma}_1 + \mathbf{W}\mathbf{Z}_2\,\boldsymbol{\gamma}_2) = F(\mathbf{Z}\boldsymbol{\gamma}) \\ \boldsymbol{\nu} &= -\exp(\mathbf{G}_1\boldsymbol{\delta}_1 + \mathbf{W}\mathbf{G}_2\,\boldsymbol{\delta}_2) = -\exp(\mathbf{G}\boldsymbol{\delta}) \end{aligned}$$

where $\mathbf{W}$ is the spatial weights matrix, $\mathbf{X} = [\mathbf{X}_1\ \mathbf{W}\mathbf{X}_2]$, $\mathbf{Z} = [\mathbf{Z}_1\ \mathbf{W}\mathbf{Z}_2]$, and $\mathbf{G} = [\mathbf{G}_1\ \mathbf{W}\mathbf{G}_2]$. Moreover, $\boldsymbol{\beta}$ becomes a column vector by stacking $\boldsymbol{\beta}_1$ on top of $\boldsymbol{\beta}_2$, and similarly for $\boldsymbol{\gamma}$ and $\boldsymbol{\delta}$. For the sake of flexibility, $\mathbf{X}_2$ does not have to be the same as $\mathbf{X}_1$. Similar arguments apply to the DISPMODEL and ZEROMODEL statements. From the modeling perspective, the SLX model can be useful when spatial effects (as represented by the $\mathbf{W}\mathbf{X}_2$, $\mathbf{W}\mathbf{Z}_2$, and $\mathbf{W}\mathbf{G}_2$ terms) are important. The intercept term is always excluded from the design matrix $\mathbf{X}_2$, $\mathbf{Z}_2$, or $\mathbf{G}_2$.

A spatial weights matrix $\mathbf{W}$ is a square matrix, which often has nonnegative entries and its dimension is the total number of unique spatial units. Moreover, the diagonal elements of $\mathbf{W}$ are zeros because a spatial unit is not considered to be its own neighbor. Furthermore, the spatial weight w_{ij} between locations s_i and s_j describes how much influence the spatial unit s_j has on s_i. In practice, $\mathbf{W}$ is often row-normalized; thus $\mathbf{W}x_1$ can be interpreted as the spatially weighted average of x_1.

In the SLX model, missing spatial weights are not allowed unless the NORMALIZE option is specified, in which case missing spatial weights are replaced by zeros. In addition, missing values are not allowed for the

variables (including both dependent and explanatory variables) in the primary data set (which is specified in the DATA= option in the PROC COUNTREG statement).

The SPATIALEFFECTS, SPATIALZEROEFFECTS, and SPATIALDISPEFFECTS statements are used to include spatial effects in design matrices $\mathbf{X}_2$, $\mathbf{Z}_2$, and $\mathbf{G}_2$, respectively. Observations in the primary data set (specified in the DATA= option in the PROC COUNTREG statement) can be presented in different orders of spatial units than they are presented in the spatial weights data set (specified in the WMAT= option in the PROC COUNTREG statement). In this case, the SPATIALID statement enables you to use a spatial ID variable to associate the observations in the primary data set with those in the spatial weights data set. The SLX model is not supported for a panel data model.

Variable Selection

Variable Selection Methods

Variable Selection Using an Information Criterion

This type of variable selection uses either Akaike's information criterion (AIC) or the Schwartz Bayesian criterion (SBC) and either a forward selection method or a backward elimination method.

Forward selection starts from a small subset of variables. In each step, the variable that gives the largest decrease in the value of the information criterion specified in the CRITER= option (AIC or SBC) is added. The process stops when the next candidate to be added does not reduce the value of the information criterion by more than the amount specified in the LSTOP= option in the MODEL statement.

Backward elimination starts from a larger subset of variables. In each step, one variable is dropped based on the information criterion chosen.

You can force a variable to be retained in the variable selection process by adding a RETAIN list to the SELECT=INFO (or SELECTVAR=INFO) option in your model. For example, suppose you add a RETAIN list to the SELECT=INFO option in your model as follows:

```
MODEL Art = Mar Kid5 Phd  / dist=negbin(p=2) SELECT=INFO(lstop=0.001 RETAIN(Phd));
```

Then this causes the variable selection process to consider only those models that contain Phd as a regressor. As a result, you are guaranteed that Phd will appear as one of the regressor variables in whatever model the variable selection process produces. The model that results is the "best" (relative to your selection criterion) of all the possible models that contain Phd.

When a ZEROMODEL statement is used in conjunction with a MODEL statement, then all the variables that appear in the ZEROMODEL statement are retained by default unless the ZEROMODEL statement itself contains a SELECT=INFO option.

For example, suppose you have the following:

```
MODEL Art = Mar Kid5 Phd  / dist=negbin(p=2) SELECT=INFO(lstop=0.001 RETAIN(Phd));
ZEROMODEL Art ~ Fem Ment / link=normal;
```

Then Phd is retained in the MODEL statement and all the variables in the ZEROMODEL statement (Fem and Ment) are retained as well. You can add an empty SELECT=INFO clause to the ZEROMODEL statement to indicate that all the variables in that statement are eligible for elimination (that is, need not be retained) during variable selection. For example:

```
MODEL Art = Mar Kid5 Phd  / dist=negbin(p=2) SELECT=INFO(lstop=0.001 RETAIN(Phd));
ZEROMODEL Art ~ Fem Ment / link=normal SELECT=INFO();
```

In this example, only Phd from the MODEL statement is guaranteed to be retained. All the other variables in the MODEL statement and all the variables in the ZEROMODEL statement are eligible for elimination.

Similarly, if your ZEROMODEL statement contains a SELECT=INFO option but your MODEL statement does not, then all the variables in the MODEL statement are retained, whereas only those variables listed in the RETAIN() list of the SELECT=INFO option for your ZEROMODEL statement are retained. For example:

```
MODEL Art = Mar Kid5 Phd  / dist=negbin(p=2) ;
ZEROMODEL Art ~ Fem Ment / link=normal SELECT=INFO(RETAIN(Ment));
```

Here, all the variables in the MODEL statement (Mar Kid5 Phd) are retained, but only the Ment variable in the ZEROMODEL statement is retained.

Variable Selection and Class Variables When a model that contains a classification variable is evaluated, the classification variable is effectively replaced by a set of parameters, each of which corresponds to some level of the classification variable. This is known as *levelizing* the classification variable. In the following discussion, the parameters that result from levelizing a classification variable are called *level-qualified parameters*.

By default, as variable selection proceeds, PROC COUNTREG treats each level-qualified parameter as an effect in its own right. This is described as *splitting* the original classification variable effect. Thus, at any particular step during the variable selection process, a candidate model can contain all, none, or only some of the level-qualified parameters that result from levelizing a classification variable.

Variable Selection with Split Effects For example, suppose that Fem and Ment are continuous variables and that Kid5 is a classification variable that has four levels: 0, 1, 2, and 3. Suppose your model is the following:

```
CLASS Kid5;
MODEL Art = Fem Kid5 Ment / dist=poisson SELECT=INFO( lstop=0.001 );
```

Levelizing the Kid5 classification variable produces four level-qualified parameters: Kid5_0, Kid5_1, Kid5_2, and Kid5_3. Because the Intercept is an effect in the model (by default), PROC COUNTREG eliminates the last level-qualified parameter for each levelized class variable in the model. This prevents problems that would otherwise ensue because of collinearity. In this case, PROC COUNTREG eliminates Kid5_3 from the model from the outset. Thus, Kid5_3 will never be included in any candidate model. PROC COUNTREG evaluates the following candidates at Step 1:

{Intercept, Fem}
{Intercept, Kid5_0}
{Intercept, Kid5_1}
{Intercept, Kid5_2}
{Intercept, Ment}

Note how each candidate contains either none or only one of the level-qualified parameters that result from levelizing the Kid5 classification variable. Thus, the classification variable Kid5 has been split: its associated level-qualified parameters are treated as individual effects. Suppose that {Intercept, Ment} is selected from among the candidates. Then PROC COUNTREG evaluates the following candidates at Step 2:

{Intercept, Ment, Fem}
{Intercept, Ment, Kid5_0}
{Intercept, Ment, Kid5_1}
{Intercept, Ment, Kid5_2}

Suppose that {Intercept, Ment, Fem} is selected from among the candidates. Then PROC COUNTREG evaluates the following candidates at Step 3:

{Intercept, Ment, Fem, Kid5_0}
{Intercept, Ment, Fem, Kid5_1}
{Intercept, Ment, Fem, Kid5_2}

Suppose that {Intercept, Ment, Fem, Kid5_0} is selected from among the candidates. Depending on the data, it is entirely possible that none of the Step 4 candidates improves the information criterion that is associated with the model that was selected at Step 3. As a result, the final selected model is:

{Intercept, Ment, Fem, Kid5_0}

As this example shows, when classification effects are split, it is possible for the final selected model to contain some, but not all, of the level-qualified parameters that are associated with the Kid5 classification variable.

Variable Selection without Split Effects If you do not want the variable selection process in PROC COUNTREG to split classification effects as illustrated in the preceding section, then you must specify the NOSPLITEFFECTS option. If you specify the NOSPLITEFFECTS option (which can be abbreviated as NOSPLIT), then as variable selection proceeds, a particular candidate model will contain either all or none of the level-qualified parameters that result from levelizing the classification variable. When the NOSPLIT option is specified, no candidate will ever contain only some but not all of the level-qualified parameters that are associated with a classification variable.

Suppose your model is the following:

```
CLASS Kid5;
MODEL Art = Fem Kid5 Ment / dist=poisson SELECT=INFO( lstop=0.001 NOSPLIT );
```

Because the NOSPLIT option is specified, PROC COUNTREG evaluates the following candidates at Step 1:

{Intercept, Fem}
{Intercept, Kid5_0, Kid5_1, Kid5_2}
{Intercept, Ment}

Note how each candidate contains either all or none of the level-qualified parameters that result from levelizing the Kid5 classification variable. Thus, the classification variable Kid5 is not split: its associated level-qualified parameters are not treated as individual effects. Suppose that {Intercept, Ment} is selected from among the candidates. Then PROC COUNTREG evaluates the following candidates at Step 2:

{Intercept, Ment, Fem}
{Intercept, Ment, Kid5_0, Kid5_1, Kid5_2}

Suppose that {Intercept, Ment, Fem} is selected from among the candidates. Depending on the data, it is entirely possible that none of the Step 3 candidates improves the information criterion that is associated with the model that was selected at Step 2. As a result, the final selected model is:

{Intercept, Ment, Fem}

As this example shows, when the NOSPLIT option is specified, the final selected model contains either all or none of the level-qualified parameters that are associated with the Kid5 classification variable.

Classification Variables and the RETAIN Option As described earlier in this section, if you want to constrain the variable selection process in such a way that it considers only candidates that include a certain variable, then you can use the RETAIN option. However, you cannot refer to a classification variable by name in the RETAIN list. Recall that by default, the variable selection process in PROC COUNTREG splits classification effects into individual effects that correspond to the levels of the classification variable. Thus, if you want to retain the original classification variable Kid5, you must list each of its level-qualified parameters by name. You can also retain some but not all of the level-qualified parameters. For example, to retain the level-qualified parameters Kid5_0 and Kid5_2 of the Kid5 classification variable, you would specify the RETAIN option as follows:

```
MODEL Art = Fem Kid5 Ment / dist=poisson
      SELECT=INFO( lstop=0.001 RETAIN(Kid5_0 Kid5_2) );
```

The RETAIN option can be used to retain effects only when the NOSPLITEFFECTS option is not specified. The RETAIN option is ignored if the NOSPLITEFFECTS option is specified.

Classification Variables and the RETAINEFFECT Option When the NOSPLITEFFECTS option is specified, you must use the RETAINEFFECT option if you want to constrain the variable selection process in such a way that it considers only candidates that include a certain variable. Any effect in your MODEL statement can be added to a RETAINEFFECT list. Thus, if you want to retain the original classification variable Kid5, you can refer to it by name in the RETAINEFFECT option as follows:

```
MODEL Art = Fem Kid5 Ment / dist=poisson
      SELECT=INFO( lstop=0.001  NOSPLIT  RETAINEFFECT(Kid5) );
```

Effects in other modeling statements can be retained in a similar fashion. In the following example, the RETAINEFFECT option in the ZEROMODEL statement causes the zero-inflated Kid5 classification variable to be retained:

```
MODEL Art = Fem Kid5 Ment / dist=ZIP SELECT=INFO( lstop=0.001  NOSPLIT );
ZEROMODEL Art ~ Mar Kid5 / SELECT=INFO( RETAINEFFECT(Kid5) );
```

Individual level-qualified parameters that are associated with a classification variable cannot be retained using the RETAINEFFECT option. The RETAINEFFECT option can be used to retain effects only when the NOSPLITEFFECTS option is specified. The RETAINEFFECT option is ignored if the NOSPLITEFFECTS option is not specified.

Variable Selection Using Penalized Likelihood

Variable selection in the linear regression context can be achieved by adding some form of penalty on the regression coefficients. One particular such form is L_1 norm penalty, which leads to LASSO:

$$\min_{\beta} \|Y - X\beta\|^2 + \lambda \sum_{j=1}^{p} |\beta_j|$$

This penalty method is becoming more popular in linear regression, because of the computational development in the recent years. However, how to generalize the penalty method for variable selection to the more general

statistical models is not trivial. Some work has been done for the generalized linear models, in the sense that the likelihood depends on the data through a linear combination of the parameters and the data:

$$l\left(\beta|x\right) = l\left(x^T\beta\right)$$

In the more general form, the likelihood as a function of the parameters can be denoted by $l(\theta) = \sum_i l_i\left(\theta\right)$, where θ is a vector that can include any parameters and $l(\cdot)$ is the likelihood for each observation. For example, in the Poisson model, $\theta = (\beta_0, \beta_1, \ldots, \beta_p)$, and in the negative binomial model $\theta = (\beta_0, \beta_1, \ldots, \beta_p, \alpha)$. The following discussion introduces the penalty method, using the Poisson model as an example, but it applies similarly to the negative binomial model. The penalized likelihood function takes the form

$$Q\left(\beta\right) = \sum_i l_i\left(\beta\right) - n\sum_{j=1}^{p} p_{\lambda_j}\left(\left|\beta_j\right|\right)$$

The L_1 norm penalty function that is used in the calculation is specified as

$$p_\lambda\left(|\beta|\right) = \lambda$$

The main challenge for this penalized likelihood method is on the computation side. The penalty function is nondifferentiable at zero, posing a computational problem for the optimization. To get around this nondifferentiability problem, Fan and Li (2001) suggested a local quadratic approximation for the penalty function. However, it was later found that the numerical performance is not satisfactory in a few respects. Zou and Li (2008) proposed local linear approximation (LLA) to solve the problem (see page 620) numerically. The algorithm replaces the penalty function with a linear approximation around a fixed point $\beta^{(0)}$:

$$p_\lambda\left(\left|\beta_j\right|\right) \approx p_\lambda\left(\left|\beta_j^{(0)}\right|\right) + p'_\lambda\left(\left|\beta_j^{(0)}\right|\right)\left(\left|\beta_j\right| - \left|\beta_j^{(0)}\right|\right)$$

Then the problem can be solved iteratively. Start from $\beta^{(0)} = \hat{\beta}_M$, which denotes the usual MLE estimate. For iteration k,

$$\beta^{(k+1)} = \arg\max_{\beta}\left\{\sum_i l_i\left(\beta\right) - n\sum_{j=1}^{p} p'_\lambda\left(\left|\beta_j^{(k)}\right|\right)\left|\beta_j\right|\right\}$$

The algorithm stops when $\|\beta^{(k+1)} - \beta^{(k)}\|$ is small. To save computing time, you can also choose a maximum number of iterations. This number can be specified by the LLASTEPS= option.

The objective function is nondifferentiable. The optimization problem can be solved using an optimization methods with constraints, by a variable transformation

$$\beta_j = \beta_j^+ - \beta_j^-, \beta_j^+ \geq 0, \beta_j^- \geq 0$$

For each fixed tuning parameter λ, you can solve the preceding optimization problem to obtain an estimate for β. Because of the property of the L_1 norm penalty, some of the coefficients in β can be exactly zero. The remaining question is to choose the best tuning parameter λ. You can use either of the approaches that are described in the following subsections.

The GCV Approach In the GCV approach, the generalized cross validation criteria (GCV) is computed for each value of λ on a predetermined grid $\{\lambda_1, \ldots, \lambda_L\}$; the value of λ that achieves the minimum of the GCV is the optimal tuning parameter. The maximum value λ_L can be determined by lemma 1 in Park and Hastie (2007) as follows. Suppose β_0 is free of penalty in the objective function. Let $\hat{\beta}_0$ be the MLE of β_0 by forcing the rest of the parameters to be zero. Then the maximum value of λ is

$$\begin{aligned}\lambda_L &= \arg\max_{\lambda} \left\{ \max_{\lambda} : \left| \frac{\partial l}{\partial \beta_j}(\hat{\beta}_0) \right| \leq n P'_\lambda(|\beta_j|), j = 1, \ldots, p \right\} \\ &= \arg\max_{\lambda} \left\{ \left| \frac{1}{n} \frac{\partial l}{\partial \beta_j}(\hat{\beta}_0) \right|, j = 1, \ldots, p \right\}\end{aligned}$$

You can compute the GCV by using the LASSO framework. In the last step of Newton-Raphson approximation, you have

$$\frac{1}{2} \min_{\beta} \left\| (\nabla^2 l(\beta^{(k)}))^{1/2} (\beta - \beta^{(k)}) + (\nabla^2 l(\beta^{(k)}))^{-1/2} \nabla l(\beta^{(k)}) \right\|^2 + n \sum_{j=1}^{p} p'_\lambda(|\beta_j^{(k)}|)|\beta_j|$$

The solution $\hat{\beta}$ satisfies

$$\hat{\beta} - \beta^{(k)} = -(\nabla^2 l(\beta^{(k)}) - 2W^-)^{-1} \left(\nabla l(\beta^{(k)}) - 2\mathbf{b} \right)$$

where

$$\begin{aligned} W^- &= n\text{diag}(W_1^-, \ldots, W_p^-) \\ W_j^- &= \begin{cases} \frac{p'_\lambda(|\beta_j^{(k)}|)}{|\beta_j|}, \text{if} \beta_j \neq 0 \\ 0, \text{if} \beta_j = 0 \end{cases} \\ \mathbf{b} &= n\text{diag}(p'_\lambda(|\beta_1^{(k)}|)\text{sgn}(\beta_1), \ldots, p'_\lambda(|\beta_p^{(k)}|)\text{sgn}(\beta_p)) \end{aligned}$$

Note that the intercept term has no penalty on its absolute value, and therefore the W_j^- term that corresponds to the intercept is 0. More generally, you can make any parameter (such as the α in the negative binomial model) in the likelihood function free of penalty, and you treat them the same as the intercept.

The effective number of parameters is

$$\begin{aligned} e(\lambda) &= \text{tr} \left\{ \left(\nabla^2 l(\beta^{(k)}) \right)^{1/2} \left(\nabla^2 l(\beta^{(k)}) - 2W^- \right)^{-1} \left(\nabla^2 l(\beta^{(k)}) \right)^{1/2} \right\} \\ &= \text{tr} \left\{ \left(\nabla^2 l(\beta^{(k)}) - 2W^- \right)^{-1} \nabla^2 l(\beta^{(k)}) \right\} \end{aligned}$$

and the generalized cross validation error is

$$\text{GCV}(\lambda) = \frac{l(\hat{\beta})}{n[1 - e(\lambda)/n]^2}$$

The GCV1 Approach Another form of GCV uses the number of nonzero coefficients as the degrees of freedom:

$$e_1(\lambda) = \sum_{j=0}^{p} \mathbf{1}_{[\beta_j \neq 0]}$$

$$\mathrm{GCV}_1(\lambda) = \frac{l(\hat{\beta})}{n[1 - e_1(\lambda)/n]^2}$$

The standard errors follow the sandwich formula:

$$\begin{aligned}\mathrm{cov}(\hat{\beta}) &= \left\{\nabla^2 l(\beta^{(k)}) - 2W^-\right\}^{-1} \widehat{\mathrm{cov}}\left(\nabla l(\beta^{(k)}) - 2\mathbf{b}\right) \left\{\nabla^2 l(\beta^{(k)}) - 2W^-\right\}^{-1} \\ &= \left\{\nabla^2 l(\beta^{(k)}) - 2W^-\right\}^{-1} \widehat{\mathrm{cov}}\left(\nabla l(\beta^{(k)})\right) \left\{\nabla^2 l(\beta^{(k)}) - 2W^-\right\}^{-1}\end{aligned}$$

It is common practice to report only the standard errors of the nonzero parameters.

Variable Selection with a NOINT Model

If you specify the NOINT option in your MODEL statement, the model produced by variable selection will always contain at least one effect from the original MODEL statement. If you request forward selection with a NOINT model and you do not retain any main model effect, then the only effects that will be candidates for the single-effect model that is derived in the first step will be the effects that are present in the original MODEL statement. For all subsequent steps, all effects from the MODEL, ZEROMODEL, DISPMODEL, and SPATIALEFFECTS statements will be candidates for inclusion in the model that is derived at that step in the process. Meanwhile, if you request backward selection with a NOINT model, you do not retain a specific main model effect, and a model that contains only one effect from the original MODEL statement is derived at a particular step, then that effect will remain in all the models that are evaluated in all subsequent steps.

Panel Data Analysis

Panel Data Poisson Regression with Fixed Effects

The count regression model for panel data can be derived from the Poisson regression model. Consider the multiplicative one-way panel data model,

$$y_{it} \sim \mathrm{Poisson}(\mu_{it})$$

where

$$\mu_{it} = \alpha_i \lambda_{it} = \alpha_i \exp(\mathbf{x}_{it}'\boldsymbol{\beta}), \quad i = 1, \ldots, N, \quad t = 1, \ldots, T$$

Here, α_i are the individual effects.

In the fixed-effects model, the α_i are unknown parameters. The fixed-effects model can be estimated by eliminating α_i by conditioning on $\sum_t y_{it}$.

In the random-effects model, the α_i are independent and identically distributed (iid) random variables, in contrast to the fixed-effects model. The random-effects model can then be estimated by assuming a distribution for α_i.

In the Poisson fixed-effects model, conditional on λ_{it} and parameter α_i, y_{it} is iid Poisson-distributed with parameter $\mu_{it} = \alpha_i \lambda_{it} = \alpha_i \exp(\mathbf{x}'_{it}\boldsymbol{\beta})$, and x_{it} does not include an intercept. Then, the conditional joint density for the outcomes within the ith panel is

$$\begin{aligned} P[y_{i1}, \ldots, y_{iT_i} | \sum_{t=1}^{T_i} y_{it}] &= P[y_{i1}, \ldots, y_{iT_i}, \sum_{t=1}^{T_i} y_{it}] / P[\sum_{t=1}^{T_i} y_{it}] \\ &= P[y_{i1}, \ldots, y_{iT_i}] / P[\sum_{t=1}^{T_i} y_{it}] \end{aligned}$$

Because y_{it} is iid Poisson(μ_{it}), $P[y_{i1}, \ldots, y_{iT_i}]$ is the product of T_i Poisson densities. Also, $(\sum_{t=1}^{T_i} y_{it})$ is Poisson($\sum_{t=1}^{T_i} \mu_{it}$). Then,

$$\begin{aligned} P[y_{i1}, \ldots, y_{iT_i} | \sum_{t=1}^{T_i} y_{it}] &= \frac{\sum_{t=1}^{T_i} (\exp(-\mu_{it}) \mu_{it}^{y_{it}} / y_{it}!)}{\exp(-\sum_{t=1}^{T_i} \mu_{it}) \left(\sum_{t=1}^{T_i} \mu_{it}\right)^{\sum_{t=1}^{T_i} y_{it}} / \left(\sum_{t=1}^{T_i} y_{it}\right)!} \\ &= \frac{\exp(-\sum_{t=1}^{T_i} \mu_{it}) \left(\prod_{t=1}^{T_i} \mu_{it}^{y_{it}}\right) \left(\prod_{t=1}^{T_i} y_{it}!\right)}{\exp(-\sum_{t=1}^{T_i} \mu_{it}) \prod_{t=1}^{T_i} \left(\sum_{s=1}^{T_i} \mu_{is}\right)^{y_{it}} / \left(\sum_{t=1}^{T_i} y_{it}\right)!} \\ &= \frac{(\sum_{t=1}^{T_i} y_{it})!}{(\prod_{t=1}^{T_i} y_{it}!)} \prod_{t=1}^{T_i} \left(\frac{\mu_{it}}{\sum_{s=1}^{T_i} \mu_{is}}\right)^{y_{it}} \\ &= \frac{(\sum_{t=1}^{T_i} y_{it})!}{(\prod_{t=1}^{T_i} y_{it}!)} \prod_{t=1}^{T_i} \left(\frac{\lambda_{it}}{\sum_{s=1}^{T_i} \lambda_{is}}\right)^{y_{it}} \end{aligned}$$

Thus, the conditional log-likelihood function of the fixed-effects Poisson model is given by

$$\mathcal{L} = \sum_{i=1}^{N} \left[\ln \left((\sum_{t=1}^{T_i} y_{it})! \right) - \sum_{t=1}^{T_i} \ln(y_{it}!) + \sum_{t=1}^{T_i} y_{it} \ln \left(\frac{\lambda_{it}}{\sum_{s=1}^{T_i} \lambda_{is}} \right) \right]$$

The gradient is

$$\begin{aligned} \frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} &= \sum_{i=1}^{N} \sum_{t=1}^{T_i} y_{it} x_{it} - \sum_{i=1}^{N} \sum_{t=1}^{T_i} \left[\frac{y_{it} \sum_{s=1}^{T_i} \left(\exp(\mathbf{x}'_{is}\boldsymbol{\beta}) \mathbf{x}_{is}\right)}{\sum_{s=1}^{T_i} \exp(\mathbf{x}'_{is}\boldsymbol{\beta})} \right] \\ &= \sum_{i=1}^{N} \sum_{t=1}^{T_i} y_{it} (\mathbf{x}_{it} - \bar{\mathbf{x}}_i) \end{aligned}$$

where

$$\bar{\mathbf{x}}_i = \sum_{s=1}^{T_i} \left(\frac{\exp(\mathbf{x}'_{is}\boldsymbol{\beta})}{\sum_{k=1}^{T_i} \exp(\mathbf{x}'_{ik}\boldsymbol{\beta})} \right) \mathbf{x}_{is}$$

Panel Data Poisson Regression with Random Effects

In the Poisson random-effects model, conditional on λ_{it} and parameter α_i, y_{it} is iid Poisson-distributed with parameter $\mu_{it} = \alpha_i \lambda_{it} = \alpha_i \exp(\mathbf{x}'_{it}\boldsymbol{\beta})$, and the individual effects, α_i, are assumed to be iid random variables. The joint density for observations in all time periods for the ith individual, $P[y_{i1}, \ldots, y_{iT}|\lambda_{i1}, \ldots, \lambda_{iT_i}]$, can be obtained after the density $g(\alpha)$ of α_i is specified.

Let

$$\alpha_i \sim \text{iid gamma}(\theta, \theta)$$

so that $E(\alpha_i) = 1$ and $V(\alpha_i) = 1/\theta$:

$$g(\alpha_i) = \frac{\theta^\theta}{\Gamma(\theta)} \alpha_i^{\theta-1} \exp(-\theta\alpha_i)$$

Let $\lambda_i = (\lambda_{i1}, \ldots, \lambda_{iT_i})$. Because y_{it} conditional on λ_{it} and parameter α_i is iid Poisson($\mu_{it} = \alpha_i \lambda_{it}$), the conditional joint probability for observations in all time periods for the ith individual, $P[y_{i1}, \ldots, y_{iT_i}|\lambda_i, \alpha_i]$, is the product of T_i Poisson densities:

$$\begin{aligned}
P[y_{i1}, \ldots, y_{iT_i}|\lambda_i, \alpha_i] &= \prod_{t=1}^{T_i} P[y_{it}|\lambda_i, \alpha_i] \\
&= \prod_{t=1}^{T_i} \left[\frac{\exp(-\mu_{it})\mu_{it}^{y_{it}}}{y_{it}!} \right] \\
&= \left[\prod_{t=1}^{T_i} \frac{e^{-\alpha_i \lambda_{it}} (\alpha_i \lambda_{it})^{y_{it}}}{y_{it}!} \right] \\
&= \left[\prod_{t=1}^{T_i} \lambda_{it}^{y_{it}} / y_{it}! \right] \left(e^{-\alpha_i \sum_t \lambda_{it}} \alpha_i^{\sum_t y_{it}} \right)
\end{aligned}$$

Then, the joint density for the *i*th panel conditional on just the λ can be obtained by integrating out α_i:

$$
\begin{aligned}
P[y_{i1},\ldots,y_{iT_i}|\lambda_i] &= \int_0^\infty P[y_{i1},\ldots,y_{iT}|\lambda_i,\alpha_i]g(\alpha_i)d\alpha_i \\
&= \frac{\theta^\theta}{\Gamma(\theta)}\left[\prod_{t=1}^{T_i}\frac{\lambda_{it}^{y_{it}}}{y_{it}!}\right]\int_0^\infty \exp(-\alpha_i\sum_t\lambda_{it})\alpha_i^{\sum_t y_{it}}\alpha_i^{\theta-1}\exp(-\theta\alpha_i)d\alpha_i \\
&= \frac{\theta^\theta}{\Gamma(\theta)}\left[\prod_{t=1}^{T_i}\frac{\lambda_{it}^{y_{it}}}{y_{it}!}\right]\int_0^\infty \exp\left[-\alpha_i\left(\theta+\sum_t\lambda_{it}\right)\right]\alpha_i^{\theta+\sum_t y_{it}-1}d\alpha_i \\
&= \left[\prod_{t=1}^{T_i}\frac{\lambda_{it}^{y_{it}}}{y_{it}!}\right]\frac{\Gamma(\theta+\sum_t y_{it})}{\Gamma(\theta)} \\
&\quad\times\left(\frac{\theta}{\theta+\sum_t\lambda_{it}}\right)^\theta\left(\theta+\sum_t\lambda_{it}\right)^{-\sum_t y_{it}} \\
&= \left[\prod_{t=1}^{T_i}\frac{\lambda_{it}^{y_{it}}}{y_{it}!}\right]\frac{\Gamma(\alpha^{-1}+\sum_t y_{it})}{\Gamma(\alpha^{-1})} \\
&\quad\times\left(\frac{\alpha^{-1}}{\alpha^{-1}+\sum_t\lambda_{it}}\right)^{\alpha^{-1}}\left(\alpha^{-1}+\sum_t\lambda_{it}\right)^{-\sum_t y_{it}}
\end{aligned}
$$

where $\alpha(=1/\theta)$ is the overdispersion parameter. This is the density of the Poisson random-effects model with gamma-distributed random effects. For this distribution, $E(y_{it})=\lambda_{it}$ and $V(y_{it})=\lambda_{it}+\alpha\lambda_{it}^2$; that is, there is overdispersion.

Then the log-likelihood function is written as

$$
\begin{aligned}
\mathcal{L} &= \sum_{i=1}^N\left\{\sum_{t=1}^{T_i}\ln(\frac{\lambda_{it}^{y_{it}}}{y_{it}!})+\alpha^{-1}\ln(\alpha^{-1})-\alpha^{-1}\ln(\alpha^{-1}+\sum_{t=1}^{T_i}\lambda_{it})\right\} \\
&\quad+\sum_{i=1}^N\left\{-\left(\sum_{t=1}^{T_i}y_{it}\right)\ln\left(\alpha^{-1}+\sum_{t=1}^{T_i}\lambda_{it}\right)\right. \\
&\qquad\left.+\ln\left[\Gamma\left(\alpha^{-1}+\sum_{t=1}^{T_i}y_{it}\right)\right]-\ln(\Gamma(\alpha^{-1}))\right\}
\end{aligned}
$$

The gradient is

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} &= \sum_{i=1}^{N}\left\{\sum_{t=1}^{T_i} y_{it}\mathbf{x}_{it} - \frac{\alpha^{-1}\sum_{t=1}^{T_i}\lambda_{it}\mathbf{x}_{it}}{\alpha^{-1}+\sum_{t=1}^{T_i}\lambda_{it}}\right\} \\
&\quad -\sum_{i=1}^{N}\left\{\left(\sum_{t=1}^{T_i} y_{it}\right)\frac{\sum_{t=1}^{T_i}\lambda_{it}\mathbf{x}_{it}}{\alpha^{-1}+\sum_{t=1}^{T_i}\lambda_{it}}\right\} \\
\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} &= \sum_{i=1}^{N}\left\{\sum_{t=1}^{T_i} y_{it}\mathbf{x}_{it} - \frac{(\alpha^{-1}+\sum_{t=1}^{T_i} y_{it})(\sum_{t=1}^{T_i}\lambda_{it}\mathbf{x}_{it})}{\alpha^{-1}+\sum_{t=1}^{T_i}\lambda_{it}}\right\}
\end{aligned}$$

and

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial \alpha} &= \sum_{i=1}^{N}\left\{-\alpha^{-2}\left[[1+\ln(\alpha^{-1})] - \frac{(\alpha^{-1}+\sum_{t=1}^{T_i} y_{it})}{(\alpha^{-1})+\sum_{t=1}^{T_i}\lambda_{it}} - \ln\left(\alpha^{-1}+\sum_{t=1}^{T_i}\lambda_{it}\right)\right]\right\} \\
&\quad + \sum_{i=1}^{N}\left\{-\alpha^{-2}\left[\frac{\Gamma'(\alpha^{-1}+\sum_{t=1}^{T_i} y_{it})}{\Gamma(\alpha^{-1}+\sum_{t=1}^{T_i} y_{it})} - \frac{\Gamma'(\alpha^{-1})}{\Gamma(\alpha^{-1})}\right]\right\}
\end{aligned}$$

where $\lambda_{it} = \exp(\mathbf{x}'_{it}\boldsymbol{\beta})$, $\Gamma'(\cdot) = d\Gamma(\cdot)/d(\cdot)$ and $\Gamma'(\cdot)/\Gamma(\cdot)$ is the digamma function.

Panel Data Negative Binomial Regression with Fixed Effects

This section shows the derivation of a negative binomial model with fixed effects. Keep the assumptions of the Poisson-distributed dependent variable

$$y_{it} \sim \text{Poisson}\,(\mu_{it})$$

But now let the Poisson parameter be random with gamma distribution and parameters (λ_{it}, τ_i),

$$\mu_{it} \sim \text{gamma}\,(\lambda_{it}, \tau_i)$$

where one of the parameters is the exponentially affine function of independent variables $\lambda_{it} = \exp\left(\mathbf{x}'_{it}\beta\right)$. The τ_i are the individual effects. Use integration by parts to obtain the distribution of y_{it},

$$\begin{aligned}
P\left[y_{it}\right] &= \int_0^{\infty} \frac{e^{-\mu_{it}}\mu_{it}^{y_{it}}}{y_{it}!} f\left(\mu_{it}\right) d\mu_{it} \\
&= \frac{\Gamma\left(\lambda_{it}+y_{it}\right)}{\Gamma\left(\lambda_{it}\right)\Gamma\left(y_{it}+1\right)}\left(\frac{\tau_i}{1+\tau_i}\right)^{\lambda_{it}}\left(\frac{1}{1+\tau_i}\right)^{y_{it}}
\end{aligned}$$

which is a negative binomial distribution with parameters (λ_{it}, τ_i). In the fixed-effects model, the τ_i are unknown parameters, and the model can be estimated by conditioning on $\sum_t y_{it}$. The conditional joint

distribution is given as

$$P[y_{i1},\ldots,y_{iT_i}|\sum_{t=1}^{T_i}y_{it}] = \left(\prod_{t=1}^{T_i}\frac{\Gamma(\lambda_{it}+y_{it})}{\Gamma(\lambda_{it})\Gamma(y_{it}+1)}\right) \times\left(\frac{\Gamma\left(\sum_{t=1}^{T_i}\lambda_{it}\right)\Gamma\left(\sum_{t=1}^{T_i}y_{it}+1\right)}{\Gamma\left(\sum_{t=1}^{T_i}\lambda_{it}+\sum_{t=1}^{T_i}y_{it}\right)}\right)$$

Hence, the conditional fixed-effects negative binomial log-likelihood function is

$$\begin{aligned}\mathcal{L} &= \sum_{i=1}^{N}\left[\log\Gamma\left(\sum_{t=1}^{T_i}\lambda_{it}\right)+\log\Gamma\left(\sum_{t=1}^{T_i}y_{it}+1\right)-\log\Gamma\left(\sum_{t=1}^{T_i}\lambda_{it}+\sum_{t=1}^{T_i}y_{it}\right)\right]\\ &\quad+\sum_{i=1}^{N}\sum_{t=1}^{T_i}\left[\log\Gamma(\lambda_{it}+y_{it})-\log\Gamma(\lambda_{it})-\log\Gamma(y_{it}+1)\right]\end{aligned}$$

The gradient is

$$\begin{aligned}\frac{\partial\mathcal{L}}{\partial\beta} &= \sum_{i=1}^{N}\left[\left(\frac{\Gamma'\left(\sum_{t=1}^{T_i}\lambda_{it}\right)}{\Gamma\left(\sum_{t=1}^{T_i}\lambda_{it}\right)}-\frac{\Gamma'\left(\sum_{t=1}^{T_i}\lambda_{it}+\sum_{t=1}^{T_i}y_{it}\right)}{\Gamma\left(\sum_{t=1}^{T_i}\lambda_{it}+\sum_{t=1}^{T_i}y_{it}\right)}\right)\sum_{t=1}^{T_i}\lambda_{it}\mathbf{x}_{it}\right]\\ &\quad+\sum_{i=1}^{N}\sum_{t=1}^{T_i}\left[\left(\frac{\Gamma'(\lambda_{it}+y_{it})}{\Gamma(\lambda_{it}+y_{it})}-\frac{\Gamma'(\lambda_{it})}{\Gamma(\lambda_{it})}\right)\lambda_{it}\mathbf{x}_{it}\right]\end{aligned}$$

Panel Data Negative Binomial Regression with Random Effects

This section describes the derivation of a negative binomial model with random effects. The setup begins in the same way as the negative binomial model with fixed effects. Suppose that

$$y_{it}\sim\text{Poisson}(\mu_{it})$$

with the Poisson parameter distributed as gamma,

$$\mu_{it}\sim\text{gamma}(\lambda_{it},\tau_i)$$

where τ_i is the individual effect and

$$\lambda_{it}=\exp\left(\mathbf{x}_{it}'\beta\right)$$

Define the variable

$$z_i=\frac{\tau_i}{1+\tau_i}$$

and assume that it is beta-distributed with parameters (a,b):

$$z_i\sim\text{Beta}(a,b)$$

Explicitly, the beta density with [0, 1] domain is

$$f\left(z\right) = \left[B\left(a,b\right)\right]^{-1} z^{a-1}\left(1-z\right)^{b-1}$$

where $B\left(a,b\right)$ is the beta function. Then, the conditional joint distribution of dependent variables is

$$P[y_{i1},\ldots,y_{iT_i}|\mathbf{x}_{i1},\ldots,\mathbf{x}_{iT_i},\tau_i] = \prod_{t=1}^{T_i}\frac{\Gamma\left(\lambda_{it}+y_{it}\right)}{\Gamma\left(\lambda_{it}\right)\Gamma\left(y_{it}+1\right)}\left(\frac{\tau_i}{1+\tau_i}\right)^{\lambda_{it}}\left(\frac{1}{1+\tau_i}\right)^{y_{it}}$$

Integrating out the individual effects, the τ_is, yields the following conditional distribution function:

$$\begin{aligned}
P[y_{i1},\ldots,y_{iT_i}|\mathbf{x}_{i1},\ldots,\mathbf{x}_{iT_i}] &= \int_0^1\left[\prod_{t=1}^{T_i}\frac{\Gamma\left(\lambda_{it}+y_{it}\right)}{\Gamma\left(\lambda_{it}\right)\Gamma\left(y_{it}+1\right)}z_i^{\lambda_{it}}\left(1-z_i\right)^{y_{it}}\right]f\left(z_i\right)dz_i \\
&= \frac{\Gamma\left(a+b\right)\Gamma\left(a+\sum_{t=1}^{T_i}\lambda_{it}\right)\Gamma\left(b+\sum_{t=1}^{T_i}y_{it}\right)}{\Gamma\left(a\right)\Gamma\left(b\right)\Gamma\left(a+b+\sum_{t=1}^{T_i}\lambda_{it}+\sum_{t=1}^{T_i}y_{it}\right)} \\
&\quad\times\prod_{t=1}^{T_i}\frac{\Gamma\left(\lambda_{it}+y_{it}\right)}{\Gamma\left(\lambda_{it}\right)\Gamma\left(y_{it}+1\right)}
\end{aligned}$$

Consequently, the conditional log-likelihood function for a negative binomial model with random effects is

$$\begin{aligned}
\mathcal{L} &= \sum_{i=1}^{N}\left[\log\Gamma\left(a+b\right)+\log\Gamma\left(a+\sum_{t=1}^{T_i}\lambda_{it}\right)+\log\Gamma\left(b+\sum_{t=1}^{T_i}y_{it}\right)\right] \\
&\quad-\sum_{i=1}^{N}\left[\log\Gamma\left(a\right)+\log\Gamma\left(b\right)+\log\Gamma\left(a+b+\sum_{t=1}^{T_i}\lambda_{it}+\sum_{t=1}^{T_i}y_{it}\right)\right] \\
&\quad+\sum_{i=1}^{N}\sum_{t=1}^{T_i}\left[\log\Gamma\left(\lambda_{it}+y_{it}\right)-\log\Gamma\left(\lambda_{it}\right)-\log\Gamma\left(y_{it}+1\right)\right]
\end{aligned}$$

The gradient is

$$\begin{aligned}
\frac{\partial\mathcal{L}}{\partial\beta} &= \sum_{i=1}^{N}\left[\frac{\Gamma'\left(a+\sum_{t=1}^{T_i}\lambda_{it}\right)}{\Gamma\left(a+\sum_{t=1}^{T_i}\lambda_{it}\right)}\sum_{t=1}^{T_i}\lambda_{it}\mathbf{x}_{it}\right] \\
&\quad-\sum_{i=1}^{N}\left[\frac{\Gamma'\left(a+b+\sum_{t=1}^{T_i}\lambda_{it}+\sum_{t=1}^{T_i}y_{it}\right)}{\Gamma\left(a+b+\sum_{t=1}^{T_i}\lambda_{it}+\sum_{t=1}^{T_i}y_{it}\right)}\sum_{t=1}^{T_i}\lambda_{it}\mathbf{x}_{it}\right] \\
&\quad+\sum_{i=1}^{N}\sum_{t=1}^{T_i}\left[\left(\frac{\Gamma'\left(\lambda_{it}+y_{it}\right)}{\Gamma\left(\lambda_{it}+y_{it}\right)}-\frac{\Gamma'\left(\lambda_{it}\right)}{\Gamma\left(\lambda_{it}\right)}\right)\lambda_{it}\mathbf{x}_{it}\right]
\end{aligned}$$

and

$$\frac{\partial \mathcal{L}}{\partial a} = \sum_{i=1}^{N}\left[\frac{\Gamma'(a+b)}{\Gamma(a+b)} + \frac{\Gamma'\left(a+\sum_{t=1}^{T_i}\lambda_{it}\right)}{\Gamma\left(a+\sum_{t=1}^{T_i}\lambda_{it}\right)}\right] - \sum_{i=1}^{N}\left[\frac{\Gamma'(a)}{\Gamma(a)} + \frac{\Gamma'\left(a+b+\sum_{t=1}^{T_i}\lambda_{it}+\sum_{t=1}^{T_i}y_{it}\right)}{\Gamma\left(a+b+\sum_{t=1}^{T_i}\lambda_{it}+\sum_{t=1}^{T_i}y_{it}\right)}\right]$$

and

$$\frac{\partial \mathcal{L}}{\partial b} = \sum_{i=1}^{N}\left[\frac{\Gamma'(a+b)}{\Gamma(a+b)} + \frac{\Gamma'\left(b+\sum_{t=1}^{T_i}y_{it}\right)}{\Gamma\left(b+\sum_{t=1}^{T_i}y_{it}\right)}\right] - \sum_{i=1}^{N}\left[\frac{\Gamma'(b)}{\Gamma(b)} + \frac{\Gamma'\left(a+b+\sum_{t=1}^{T_i}\lambda_{it}+\sum_{t=1}^{T_i}y_{it}\right)}{\Gamma\left(a+b+\sum_{t=1}^{T_i}\lambda_{it}+\sum_{t=1}^{T_i}y_{it}\right)}\right]$$

BY Groups and Scoring with an Item Store

If you use the BY statement in conjunction with the ITEMSTORE statement when you fit your model, then the parameter estimates for each BY group are preserved in your item store.

You must use a BY statement if you want to score a data set by using an item store that was created when a BY statement was provided. The names of the BY variables in the data set to be scored (hereafter referred to as the *scored* data set) must match the names of the BY variables in the data set that is used to produce the item store (hereafter referred to as the *fitted* data set). The order of the names of the BY variables in your BY statement must match their order in the BY statement that was used when the item store was created.

The order in which the values of the BY variables appear in the scored data set does not have to match their order in the fitted data set. Furthermore, not all the values of the BY variables that are present in the fitted data set need to be present in the scored data set.

For example, suppose you have a data set named DocVisit that you use to fit a model by using a BY statement. Your BY variable is named AgeGroup, and there are four values for the AgeGroup variable (0, 1, 2, and 3) in the DocVisit data set.

In the first step, you use the following statements to fit your model by using the BY statement and generate an item store named DocVisitByAgeGroup:

```
PROC COUNTREG data=DocVisit;
model doctorvisits = sex illness income / dist=poisson;
store DocVisitByAgeGroup;
by AgeGroup;
run;
```

Now suppose you want to score a second data set named AdditionalPatients by using the DocVisitByAgeGroup item store. Then the AdditionalPatients data set must contain a variable named AgeGroup, and the values

of this variable must be a subset of 0, 1, 2, and 3. Suppose that the values of the AgeGroup variable in the AdditionalPatients data set are 1 and 3.

In that case, you can score the data set by using this second step:

```
PROC COUNTREG data=AdditionalPatients restore=DocVisitByAgeGroup;
score out=OutScores mean=meanPoisson probability=prob;
by AgeGroup;
run;
```

Because the AdditionalPatients data set contains two BY groups, PROC COUNTREG first extracts the parameter estimates that are associated with the AgeGroup=1 BY group from the DocVisitByAgeGroup item store and uses them to score the first BY group in the AdditionalPatients data set. Then, PROC COUNTREG extracts the parameter estimates that are associated with the AgeGroup=3 BY group from the DocVisitByAgeGroup item store and uses them to score the second BY group in the AdditionalPatients data set.

What happens if your scored data set contains a value of the BY variable that is not present in the fitted data set? Modifying the preceding example slightly, suppose the values of the AgeGroup variable in the AdditionalPatients data set are 1, 2, 3, and 6. In that case, when the second step is submitted, PROC COUNTREG scores the BY groups in which AgeGroup equals 1, 2, or 3, but it does not attempt to score the BY group in which AgeGroup=6.

If you want to use the parameter estimates that are associated with a particular BY group in an item store to score a data set that contains no BY variable, it is fairly easy to do so. First, you create a new data set based on your original data set that includes an additional single-valued BY variable (whose value corresponds to the BY group in the item store in which you are interested). Second, you use the new data set and the BY statement to retrieve the parameter estimates of interest, which are then used to score the entire data set.

For example, suppose that the AdditionalPatients data set does not contain the AgeGroup variable. But suppose you happen to know that all the observations in the AdditionalPatients data set fall within the age group in which AgeGroup=2, as defined in the DocVisit data set. Then you could score the AdditionalPatients data set by using the following steps.

First, you would create a new data set named AdditionalPatientsWithByVar, which essentially adds a variable named AgeGroup, with its value set to 2, to each observation in the AdditionalPatients data set:

```
data AdditionalPatientsWithByVar;
set AdditionalPatients;
agegroup=2;
run;
```

Then, you would score the AdditionalPatientsWithByVar data set by using the DocVisitByAgeGroup item store along with the BY statement, as follows:

```
PROC COUNTREG data=AdditionalPatientsWithByVar restore=DocVisitByAgeGroup;
score out=OutScores mean=meanPoisson probability=prob;
by AgeGroup;
run;

Parameter Naming Conventions for the RESTRICT, TEST, BOUNDS, and INIT Statements

This section describes how you can refer to the parameters that are defined in the MODEL, ZEROMODEL, DISPMODEL, SPATIALEFFECTS, SPATIALDISPEFFECTS, and SPATIALZEROEFFECTS statements when you use the RESTRICT, TEST, BOUNDS, or INIT statement. The following examples use the RESTRICT statement, but the same remarks apply to naming parameters when you use the TEST, BOUNDS, or INIT statement. The names of the parameters are written to the OUTEST= data set.

To impose a restriction on a parameter that is related to a regressor in the MODEL statement, you simply use the name of the regressor itself to refer to its associated parameter. Suppose your model is defined in the following statement, where x1 through x5 are continuous variables:

```
model y = x1 x2 x5;
```

If you want to restrict the parameter that is associated with the regressor x5 to be greater than 1.7, then you use the following statement:

```
RESTRICT x5 > 1.7;
```

To impose a restriction on a parameter associated with a regressor in the ZEROMODEL statement, you can form the name of the parameter by prefixing Inf_ to the name of the regressor. Suppose your MODEL and ZEROMODEL statements are as follows:

```
model y = x1 x2 x5;
zeromodel y ~ x3 x5;
```

If you want to restrict the parameter related to the x5 regressor in the ZEROMODEL statement to be less than 1.0, then you refer to the parameter as Inf_x5 and provide the following statement:

```
RESTRICT Inf_x5 < 1.0;
```

Even though the regressor x5 appears in both the MODEL and ZEROMODEL statements, the parameter associated with x5 in the MODEL statement is, of course, different from the parameter associated with x5 in the ZEROMODEL statement. Thus, the name of a regressor that appears in a RESTRICT statement without any prefix refers to the parameter associated with that regressor in the MODEL statement, and the name of a regressor that appears in a RESTRICT statement with the prefix Inf_ refers to the parameter associated with that regressor in the ZEROMODEL statement. The parameter that is associated with the intercept in the ZEROMODEL is named Inf_Intercept.

In a similar way, you can form the name of a parameter associated with a regressor in the DISPMODEL statement by prefixing Dsp_ to the name of the regressor. The parameter associated with the intercept in the DISPMODEL is named Dsp_Intercept.

And you can form the name of a parameter associated with a regressor in the SPATIALEFFECTS statement by prefixing W_ to the name of the regressor. The parameter associated with the intercept in the SPATIALEFFECTS is named W_Intercept.

Referring to Class-Level Parameters

When your MODEL statement includes a classification variable, you can impose restrictions on the parameters associated with each of the levels that are related to the classification variable as follows.

Suppose your classification variable is named C and it has three levels: 0, 1, 2. Suppose your model is the following:

```
class C;
model y = x1 x2 C;
```

Adding a classification variable as a regressor to your model introduces additional parameters into your model, each of which is associated with one of the levels of the classification variable. You can form the name of the parameter associated with a particular level of your class variable by inserting the underscore character between the name of the classification variable and the value of the level. Thus, to restrict the parameter associated with level 0 of the classification variable C to always be greater than 0.7, you refer to the parameter as C_0 and provide the following statement:

```
RESTRICT C_0 > 0.7;
```

Referring to Parameters Associated with Interactions between Regressors

When a regressor in your model involves an interaction between other regressors, you can impose restrictions on the parameters associated with the interaction.

Suppose you have the following model:

```
model y = x1 x2 x3*x4;
```

You can form the name of the parameter associated with the interaction regressor x3*x4 by replacing the multiplication sign with an underscore. Thus, x3_x4 refers to the parameter that is associated with the interaction regressor x3*x4.

Referring to interactions between regressors and classification variables is handled in the same way. Suppose you have a classification variable that is named C and has three levels: 0, 1, 2. Suppose that your model is the following:

```
class C;
model y = x1 x2 C*x3;
```

The interaction between the continuous variable x3 and the classification variable C introduces three additional parameters, which are named x3_C_0, x3_C_1, and x3_C_2. Although the order of the terms in the interaction is C followed by x3, note how the name of the parameter associated with the interaction is formed by placing the name of the continuous variable x3 first, followed by an underscore, followed by the name of the classification variable C, followed by an underscore, and then followed by the level value. Depending on the parameterization you specify in your CLASS statement, for each interaction in your model that involves a classification variable, one of the parameters associated with that interaction might be dropped from your model prior to optimization.

The name of a parameter associated with a nested interaction is formed in a slightly different way. Suppose you have a classification variable that is named C and has three levels: 0, 1, 2. Suppose that your model is the following:

```
class C;
model y = x1 x2 x3(C);
```

The nested interaction between the continuous variable x3 and the classification variable C introduces three additional parameters, which are named x3_C__0, x3_C__1, and x3_C__2. Note how the name in each case is formed from the name of the regressor by replacing the left and right parentheses with underscores and then appending another underscore followed by the level value.

Referring to Class Level Parameters with Negative Values

When the value of a level is a negative number, you must replace the minus sign with an underscore when you form the name of the parameter that is associated with that particular level of the classification variable. For example, suppose your classification variable is named D and has four levels: –1, 0, 1, 2. Suppose your model is the following:

```
class D;
model y = x1 x2 D;
```

To restrict the parameter that is associated with level –1 of the classification variable D to always be less than 0.4, you refer to the parameter as D__1 (note that there are two underscores in this parameter name: one to connect the name of the classification variable to its value and the other to replace the minus sign in the value itself) and provide the following statement:

```
RESTRICT D__1 < 0.4;
```

Dropping a Class Level Parameter to Avoid Collinearity

Depending on the parameterization you impose on your classification variable, one of the parameters associated with its levels might be dropped from your model prior to optimization in order to avoid collinearity. For example, when the default parameterization GLM is imposed, the parameter that is associated with the last level of your classification variable is dropped prior to optimization. If you attempt to impose a restriction on a dropped parameter by using the RESTRICT statement, PROC COUNTREG issues an error message in the log.

For example, suppose that your classification variable is named C and that it has three levels: 0, 1, 2. Suppose your model is the following:

```
class C;
model y = x1 x2 C;
```

Because no additional options are specified in the CLASS statement, GLM parameterization is assumed. This means that the parameter named C_2 (which is the parameter associated with the last level of your classification variable) is dropped from your model before the optimizer is invoked. Therefore, an error is issued if you attempt to restrict the C_2 parameter in any way by referring to it in a RESTRICT statement. For example, the following RESTRICT statement generates an error:

```
RESTRICT C_2 < 0.3;
```

Referring to Implicit Parameters

For certain model types, one or more implicit parameters are added to your model prior to optimization. You can impose restrictions on these implicit parameters.

For the Poisson model for which ERRORCOMP=RANDOM is specified, PROC COUNTREG automatically adds the _Alpha parameter to your model.

If no ERRORCOMP= option is specified for zero-inflated binomial and negative binomial models, then PROC COUNTREG adds the _Alpha parameter to the model. If ERRORCOMP=RANDOM is specified for the zero-inflated binomial and negative binomial models, then PROC COUNTREG adds two implicit parameters to the model: _Alpha and _Beta.

For Conway-Maxwell Poisson models that do not include a DISPMODEL statement, the _lnNu parameter is added to the model.

Whenever your model type dictates the addition of one or more of these implicit parameters, you can impose restrictions on the implicit parameters by referring to them by name in a RESTRICT statement. For example, if your model type implies the existence of the _Alpha parameter, you can restrict _Alpha to be greater than 0.2 as follows:

```
RESTRICT _Alpha > 0.2;
```

Computational Resources

The time and memory that PROC COUNTREG requires are proportional to the number of parameters in the model and the number of observations in the data set being analyzed. Less time and memory are required for smaller models and fewer observations. Also affecting these resources are the method that is chosen to calculate the variance-covariance matrix and the optimization method. All optimization methods available through the METHOD= option have similar memory use requirements.

The processing time might differ for each method, depending on the number of iterations and functional calls needed. The data set is read into memory to save processing time. If not enough memory is available to hold the data, the COUNTREG procedure stores the data in a utility file on disk and rereads the data as needed from this file. When this occurs, the execution time of the procedure increases substantially. The gradient and the variance-covariance matrix must be held in memory. If the model has p parameters including the intercept, then at least $8 * (p + p * (p + 1)/2)$ bytes are needed. If the quasi-maximum likelihood method is used to estimate the variance-covariance matrix (COVEST=QML), an additional $8 * p * (p + 1)/2$ bytes of memory are needed.

Time is also a function of the number of iterations needed to converge to a solution for the model parameters. The number of iterations that are needed cannot be known in advance. The MAXITER= option can be used to limit the number of iterations that PROC COUNTREG does. The convergence criteria can be altered by nonlinear optimization options available in the PROC COUNTREG statement. For a list of all the nonlinear optimization options, see Chapter 6, “Nonlinear Optimization Methods.”

Nonlinear Optimization Options

PROC COUNTREG uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. In the PROC COUNTREG statement, you can specify nonlinear optimization options that are then passed to the NLO subsystem. For a list of all the nonlinear optimization options, see Chapter 6, "Nonlinear Optimization Methods."

Covariance Matrix Types

The COUNTREG procedure enables you to specify the estimation method for the covariance matrix. The COVEST=HESSIAN option estimates the covariance matrix based on the inverse of the Hessian matrix, COVEST=OP uses the outer product of gradients, and COVEST=QML produces the covariance matrix based on both the Hessian and outer product matrices. The default is COVEST=HESSIAN.

Although all three methods produce asymptotically equivalent results, they differ in computational intensity and produce results that might differ in finite samples. The COVEST=OP option provides the covariance matrix that is typically the easiest to compute. In some cases, the OP approximation is considered more efficient than the Hessian or QML approximation because it contains fewer random elements. The QML approximation is computationally the most complex because both the outer product of gradients and the Hessian matrix are required. In most cases, OP or Hessian approximation is preferred to QML. The need to use QML approximation arises in some cases when the model is misspecified and the information matrix equality does not hold.

Displayed Output

PROC COUNTREG produces the following displayed output.

Class Level Information

If you specify the CLASS statement, the COUNTREG procedure displays a table that contains the following information:

- classification variable name
- number of levels of the classification variable
- list of values of the classification variable

Iteration History for Parameter Estimates

If you specify the ITPRINT or PRINTALL option in the PROC COUNTREG statement, PROC COUNTREG displays a table that contains the following information for each iteration. Some information is specific to the model-fitting procedure that you choose (for example, Newton-Raphson, trust region, quasi-Newton).

- iteration number

- number of restarts since the fitting began
- number of function calls
- number of active constraints at the current solution
- value of the objective function (–1 times the log-likelihood value) at the current solution
- change in the objective function from previous iteration
- value of the maximum absolute gradient element
- step size (for Newton-Raphson and quasi-Newton methods)
- slope of the current search direction (for Newton-Raphson and quasi-Newton methods)
- lambda (for trust region method)
- radius value at current iteration (for trust region method)

Model Fit Summary

The "Model Fit Summary" table contains the following information:

- dependent (count) variable name
- number of observations used
- number of missing values in data set, if any
- data set name
- type of model that was fit
- parameterization for the Conway-Maxwell-Poisson model
- offset variable name, if any
- zero-inflated link function, if any
- zero-inflated offset variable name, if any
- log-likelihood value at solution
- maximum absolute gradient at solution
- number of iterations
- AIC value at solution (a smaller value indicates better fit)
- SBC value at solution (a smaller value indicates better fit)

Under the "Model Fit Summary" is a statement about whether the algorithm successfully converged.

Parameter Estimates

The "Parameter Estimates" table gives the estimates of the model parameters. In zero-inflated (ZI) models, estimates are also given for the ZI intercept and ZI regressor parameters labeled with the prefix "Inf_". For example, the ZI intercept is labeled "Inf_intercept". If you specify "Age" as a ZI regressor, then the "Parameter Estimates" table labels the corresponding parameter estimate "Inf_Age". If you do not list any ZI regressors, then only the ZI intercept term is estimated.

If the DISPMODEL statement is specified for the Conway-Maxwell-Poisson model, the estimates are given for the dispersion intercept, and parameters are labeled with the prefix "Dsp_". For example, the dispersion model intercept is labeled "Dsp_Intercept". If you specify "Education" as a dispersion model regressor, then the "Parameter Estimates" table labels the corresponding parameter estimate "Dsp_Education". If you do not list any dispersion regressors, then only the dispersion intercept is estimated.

"_Alpha" is the negative binomial dispersion parameter. The t statistic given for "_Alpha" is a test of overdispersion.

Last Evaluation of the Gradient

If you specify the model option ITPRINT, the COUNTREG procedure displays the last evaluation of the gradient vector.

Covariance of Parameter Estimates

If you specify the COVB option in the MODEL statement or in the PROC COUNTREG statement, the COUNTREG procedure displays the estimated covariance matrix, defined as the inverse of the information matrix at the final iteration.

Correlation of Parameter Estimates

If you specify the CORRB option in the MODEL statement or in the PROC COUNTREG statement, PROC COUNTREG displays the estimated correlation matrix. It is based on the Hessian matrix that is used in the final iteration.

Bayesian Analysis

To perform Bayesian analysis, you must specify a BAYES statement. Unless otherwise stated, all options in this section are options in the BAYES statement.

By default, PROC COUNTREG uses the random walk Metropolis algorithm to obtain posterior samples. For information about implementing the Metropolis algorithm in PROC COUNTREG, such as blocking the parameters and tuning the covariance matrices, see the sections "Blocking of Parameters" on page 638 and "Tuning the Proposal Distribution" on page 638.

The Bayes theorem states that

$$p(\theta|\mathbf{y}) \propto \pi(\theta)L(y|\theta)$$

where θ is a parameter or a vector of parameters and $\pi(\theta)$ is the product of the prior densities that are specified in the PRIOR statement. The term $L(y|\theta)$ is the likelihood that is associated with the MODEL statement.

Blocking of Parameters

In a multivariate parameter model, all the parameters are updated in one single block (by default or when you specify the SAMPLING=MULTIMETROPOLIS option). This could be inefficient, especially when parameters have vastly different scales. As an alternative, you could update the parameters one at a time (by specifying SAMPLING=UNIMETROPOLIS).

Tuning the Proposal Distribution

One key factor in achieving high efficiency of a Metropolis-based Markov chain is finding a good proposal distribution for each block of parameters. This process is called *tuning*. The tuning phase consists of a number of loops that are controlled by the options MINTUNE= and MAXTUNE=. The MINTUNE= option controls the minimum number of tuning loops and has a default value of 2. The MAXTUNE= option controls the maximum number of tuning loops and has a default value of 24. Each loop iterates the number of times that are specified by the NTU= option, which has a default of 500. At the end of every loop, PROC COUNTREG examines the acceptance probability for each block. The acceptance probability is the percentage of samples, specified by the NTU= option, that have been accepted. If this probability does not fall within the acceptable tolerance range (see the following section), the proposal distribution is modified before the next tuning loop begins.

A good proposal distribution should resemble the actual posterior distribution of the parameters. Large sample theory states that the posterior distribution of the parameters approaches a multivariate normal distribution (see Gelman et al. 2004, Appendix B; Schervish 1995, Section 7.4). That is why a normal proposal distribution often works well in practice. The default proposal distribution in PROC COUNTREG is the normal distribution.

Scale Tuning

The acceptance rate is closely related to the sampling efficiency of a Metropolis chain. For a random walk Metropolis, a high acceptance rate means that most new samples occur right around the current data point. Their frequent acceptance means that the Markov chain is moving rather slowly and not exploring the parameter space fully. A low acceptance rate means that the proposed samples are often rejected; hence the chain is not moving much. An efficient Metropolis sampler has an acceptance rate that is neither too high nor too low. The scale c in the proposal distribution $q(\cdot|\cdot)$ effectively controls this acceptance probability. Roberts, Gelman, and Gilks (1997) show that if both the target and proposal densities are normal, the optimal acceptance probability (TargetAcceptance) for the Markov chain should be around 0.45 in a one-dimensional problem and should asymptotically approach 0.234 in higher-dimensional problems. The corresponding optimal scale is 2.38, which is the initial scale that is set for each block.

Because of the nature of stochastic simulations, it is impossible to fine-tune a set of variables so that the Metropolis chain has exactly the desired acceptance rate that you want. In addition, Roberts and Rosenthal (2001) empirically demonstrate that an acceptance rate between 0.15 and 0.5 is at least 80% efficient, so there is really no need to fine-tune the algorithms to reach an acceptance probability that is within a small tolerance of the optimal values. PROC COUNTREG works with a probability range, determined by TargetAcceptance $\pm$ 0.075. If the observed acceptance rate in a given tuning loop is less than the lower bound of the range, the scale is reduced; if the observed acceptance rate is greater than the upper bound of the range, the scale is increased. During the tuning phase, a scale parameter in the normal distribution is adjusted as a function of the observed acceptance rate and the target acceptance rate. PROC COUNTREG

uses the updating scheme[1]

$$c_{\text{new}} = \frac{c_{\text{cur}} \cdot \Phi^{-1}(p_{\text{opt}}/2)}{\Phi^{-1}(p_{\text{cur}}/2)}$$

where c_{cur} is the current scale, p_{cur} is the current acceptance rate, and p_{opt} is the optimal acceptance probability.

Covariance Tuning

To tune a covariance matrix, PROC COUNTREG takes a weighted average of the old proposal covariance matrix and the recent observed covariance matrix, based on the number of samples (as specified by the NTU= option) in the current loop. The formula to update the covariance matrix is

$$\text{COV}_{\text{new}} = 0.75\ \text{COV}_{\text{cur}} + 0.25\ \text{COV}_{\text{old}}$$

There are two ways to initialize the covariance matrix:

- The default is an identity matrix that is multiplied by the initial scale of 2.38 and divided by the square root of the number of estimated parameters in the model. A number of tuning phases might be required before the proposal distribution is tuned to its optimal stage, because the Markov chain needs to spend time learning about the posterior covariance structure. If the posterior variances of your parameters vary by more than a few orders of magnitude, if the variances of your parameters are much different from 1, or if the posterior correlations are high, then the proposal tuning algorithm might have difficulty forming an acceptable proposal distribution.
- Alternatively, you can use a numerical optimization routine, such as the quasi-Newton method, to find a starting covariance matrix. The optimization is performed on the joint posterior distribution, and the covariance matrix is a quadratic approximation at the posterior mode. In some cases this is a better and more efficient way of initializing the covariance matrix. However, there are cases, such as when the number of parameters is large, in which the optimization could fail to find a matrix that is positive definite. In those cases, the tuning covariance matrix is reset to the identity matrix.

A by-product of the optimization routine is that it also finds the maximum a posteriori (MAP) estimates with respect to the posterior distribution. The MAP estimates are used as the initial values of the Markov chain.

For more information, see the section "INIT Statement" on page 579.

[1] Roberts, Gelman, and Gilks (1997) and Roberts and Rosenthal (2001) demonstrate that the relationship between acceptance probability and scale in a random walk Metropolis scheme is $p = 2\Phi\left(-\sqrt{I}c/2\right)$, where c is the scale, p is the acceptance rate, Φ is the CDF of a standard normal, and $I \equiv E_f[(f'(x)/f(x))^2]$, $f(x)$ is the density function of samples (Roberts, Gelman, and Gilks 1997; Roberts and Rosenthal 2001). This relationship determines the updating scheme, with I replaced by the identity matrix to simplify calculation.

Initial Values of the Markov Chains

You can assign initial values to any parameters. (For more information, see the section "INIT Statement" on page 579) If you use the optimization option PROPCOV=, then PROC COUNTREG starts the tuning at the optimized values. This option overwrites the provided initial values. If you specify the RANDINIT option, the information that the INIT statement provides is overwritten.

Aggregation of Multiple Chains

When you want to exploit the possibility of running several MCMC instances at the same time (that is, the value of the NTRDS= option is greater than 1), you face the problem of aggregating the chains. In ordinary applications, each MCMC instance can easily obtain stationary samples from the entire posterior distribution. In these applications, you can use the option AGGREGATION=NOWEIGHTED. This option piles one chain on top of another and makes no particular adjustment. However, when the posterior distribution is characterized by multiple distinct posterior modes, some of the MCMC instances fail to obtain stationary samples from the entire posterior distribution. You can use the option AGGREGATION=WEIGHTED when the posterior samples from each MCMC instance approximate well only a part of the posterior distribution.

The main idea behind the option AGGREGATION=WEIGHTED is to consider the entire posterior distribution to be similar to a mixture distribution. When you are sampling with multiple threads, each MCMC instance samples from one of the mixture components. Then the samples from each mixture component are aggregated together using a resampling scheme in which weights are proportional to the nonnormalized posterior distribution.

Description of the Algorithm

The preliminary step of the aggregation that is implied by the option AGGREGATION=WEIGHTED is to run several (K) independent instances of the MCMC algorithm. Each instance searches for a set of stationary samples. Notice that the concept of stationarity is weaker: each instance might be able to explore not the entire posterior but only portions of it. In the following, each column represents the output from one MCMC instance:

$$\begin{pmatrix} x_{11} \\ x_{21} \\ \cdots \\ x_{n1} \end{pmatrix} \begin{pmatrix} x_{12} \\ x_{22} \\ \cdots \\ x_{n2} \end{pmatrix} \cdots \begin{pmatrix} x_{1K} \\ x_{2K} \\ \cdots \\ x_{nK} \end{pmatrix} \sim \text{globally or locally sampled from the posterior}$$

If the length of each chain is less than n, you can augment the corresponding chain by subsampling the chain itself. Each chain is then sorted with respect to the nonnormalized posterior density: $\pi(x_{[1].}) \leq \pi(x_{[2].}) \leq \cdots \pi(x_{[n].})$. Therefore,

$$\begin{pmatrix} x_{11} \\ x_{21} \\ \cdots \\ x_{n1} \end{pmatrix} \begin{pmatrix} x_{12} \\ x_{22} \\ \cdots \\ x_{n2} \end{pmatrix} \cdots \begin{pmatrix} x_{1K} \\ x_{2K} \\ \cdots \\ x_{nK} \end{pmatrix} \rightarrow \begin{pmatrix} x_{[1]1} \\ x_{[2]1} \\ \cdots \\ x_{[n]1} \end{pmatrix} \begin{pmatrix} x_{[1]2} \\ x_{[2]2} \\ \cdots \\ x_{[n]2} \end{pmatrix} \cdots \begin{pmatrix} x_{[1]K} \\ x_{[2]K} \\ \cdots \\ x_{[n]K} \end{pmatrix}$$

The final step is to use a multinomial sampler to resample each row i with weights proportional to the nonnormalized posterior densities:

$$\widetilde{x}_{(i-1)K+1}, \widetilde{x}_{(i-1)K+2}, \ldots, \widetilde{x}_{(i-1)K+K} \sim \text{Multinom}\left[x_{[i]1}, x_{[i]2}, \ldots, x_{[i]K}; \pi(x_{[i]1}), \pi(x_{[i]2}), \ldots, \pi(x_{[i]K})\right]$$

The resulting posterior sample,

$$\widetilde{x}_1, \widetilde{x}_2, \ldots, \widetilde{x}_K, \ldots, \widetilde{x}_{(i-1)K+1}, \widetilde{x}_{(i-1)K+2}, \ldots, \widetilde{x}_{(i-1)K+K}, \ldots, \widetilde{x}_{(n-1)K+1}, \widetilde{x}_{(n-1)K+2}, \ldots, \widetilde{x}_{nK}$$

is a good approximation of the posterior distribution that is characterized by multiple modes.

Automated Initialization of MCMC

The MCMC methods can generate samples from the posterior distribution. The correct implementation of these methods often requires the stationarity analysis, convergence analysis, and accuracy analysis of the posterior samples. These analyses usually imply the following:

- initialization of the proposal distribution
- initialization of the chains (starting values)
- determination of the burn-in
- determination of the length of the chains

In more general terms, this determination is equivalent to deciding whether the samples are drawn from the posterior distribution (stationarity analysis) and whether the number of samples is large enough to accurately approximate the posterior distribution (accuracy analysis). You can use the AUTOMCMC option to automate and facilitate the stationary analysis and the accuracy analysis.

Description of the Algorithm

The algorithm has two phases. In the first phase, the stationarity phase, the algorithm tries to generate stationary samples from the posterior distribution. In the second phase, the accuracy phase, the algorithm searches for an accurate representation of the posterior distribution. The algorithm implements the following tools:

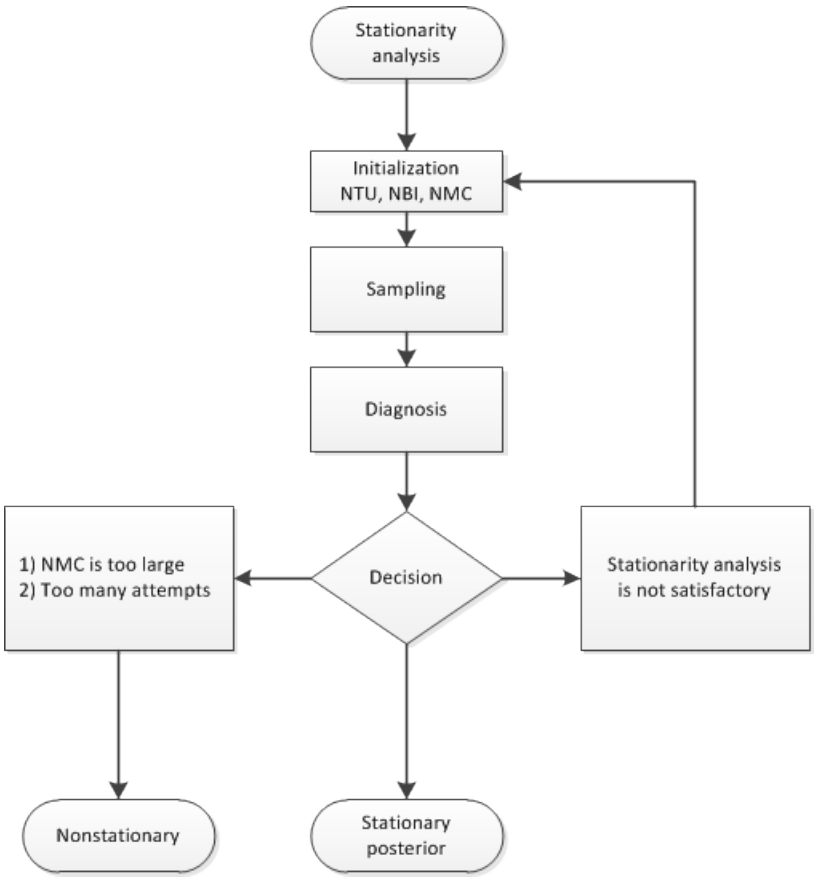
- Geweke test to check stationarity
- Heidelberger-Welch test to check stationarity and provide a proxy for the burn-in
- Heidelberger-Welch halfwidth test to check the accuracy of the posterior mean
- Raftery-Lewis test to check the accuracy of a specified percentile (indirectly providing a proxy for the number of required samples)
- effective sample size analysis to determine a proxy for the number of required samples

During the stationarity phase, the algorithm searches for stationarity. The number of attempts that the algorithm makes is determined by the ATTEMPTS= option. During each attempt, a preliminary tuning stage chooses a proposal distribution for the MCMC sampler. At the end of the preliminary tuning phase, the algorithm analyzes tests for the stationarity of the samples. If the percentage of successful stationary tests is greater than or equal to the percentage that is indicated by the TOL= option, then the posterior sample is considered to be stationary. If the sample cannot be considered stationary, then the algorithm attempts to achieve stationarity by changing some of the initialization parameters as follows:

- increasing the number of tuning samples (NTU= option)
- increasing the number of posterior samples (NMC= option)
- increasing the burn-in (NBI= option)

Figure 11.6 shows a flowchart of the AUTOMCMC algorithm as it searches for stationarity.

Figure 11.6 Flowchart of the AUTOMCMC Algorithm: Stationarity Analysis



You can initialize NMC=M, NBI=B, and NTU=T during the stationarity phase by specifying the NMC=, NBI=, and NTU= options in the BAYES statement. You can also change the minimum stationarity acceptance ratio of successful stationarity tests that are needed to exit the stationarity phase. By default, TOL=0.95. For example:

```
proc countreg data=dataset;
   ...;
   bayes nmc=M nbi=B ntu=T automcmc=( stationarity=(tol=0.95) );
   ...;
run;
```

During the accuracy phase, the algorithm attempts to determine how many posterior samples are needed. The number of attempts is determined by the ATTEMPTS= option. You can choose between two different approaches to study the accuracy:

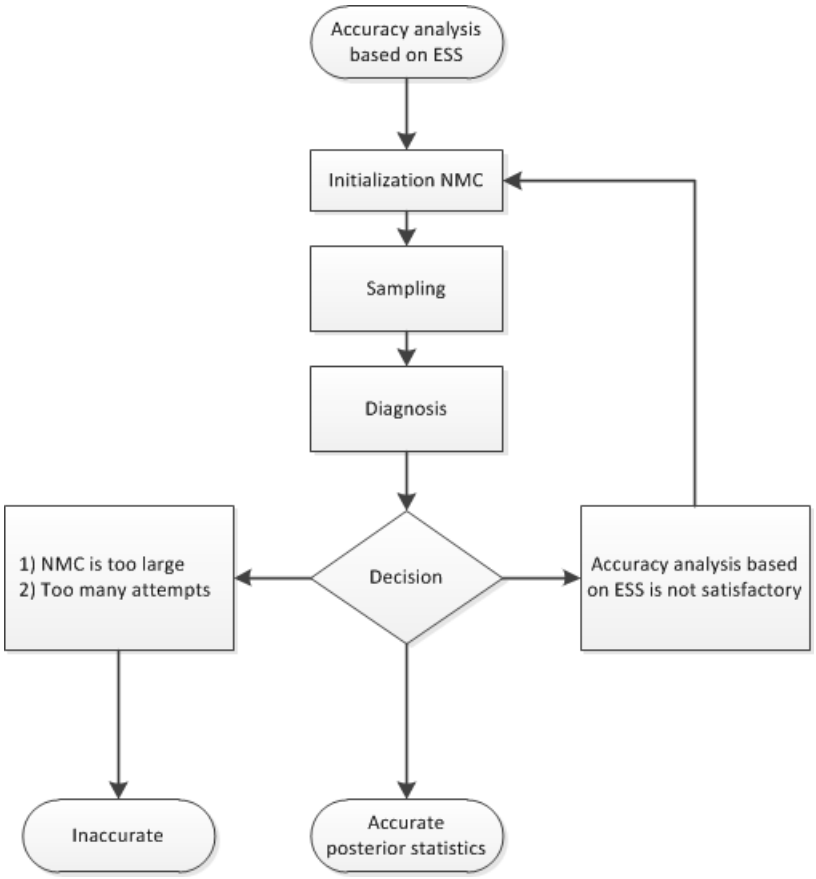
- accuracy analysis based on the effective sample size (ESS)
- accuracy analysis based on the Heidelberger-Welch halfwidth test and the Raftery-Lewis test

If you choose the effective sample size approach, you must provide the minimum number of effective samples that are needed. You can also change the tolerance for the ESS accuracy analysis (by default, TOL=0.95). For example:

```
proc countreg data=dataset;
   ...;
   bayes automcmc=(targetess=N accuracy=(tol=0.95));
   ...;
run;
```

Figure 11.7 shows a flowchart of the AUTOMCMC algorithm based on the effective sample size approach to determine whether the samples provide an accurate representation of the posterior distribution.

Figure 11.7 Flowchart of the AUTOMCMC Algorithm: Accuracy Analysis Based on the ESS



If you choose the accuracy analysis based on the Heidelberger-Welch halfwidth test and the Raftery-Lewis test (the default option), then you might want to choose a posterior quantile of interest for the Raftery-Lewis test (by default, 0.025). You can also change the tolerance for the accuracy analysis (by default, TOL=0.95). Notice that the Raftery-Lewis test produces a proxy for the number of posterior samples that are required. In each attempt, the current number of posterior samples is compared to this proxy. If the proxy is greater

than the current NMC, then the algorithm reinitializes itself. To control this reinitialization, you can use the option RLLIMITS=(LB=*lb* UB=*ub*). In particular, there are three cases

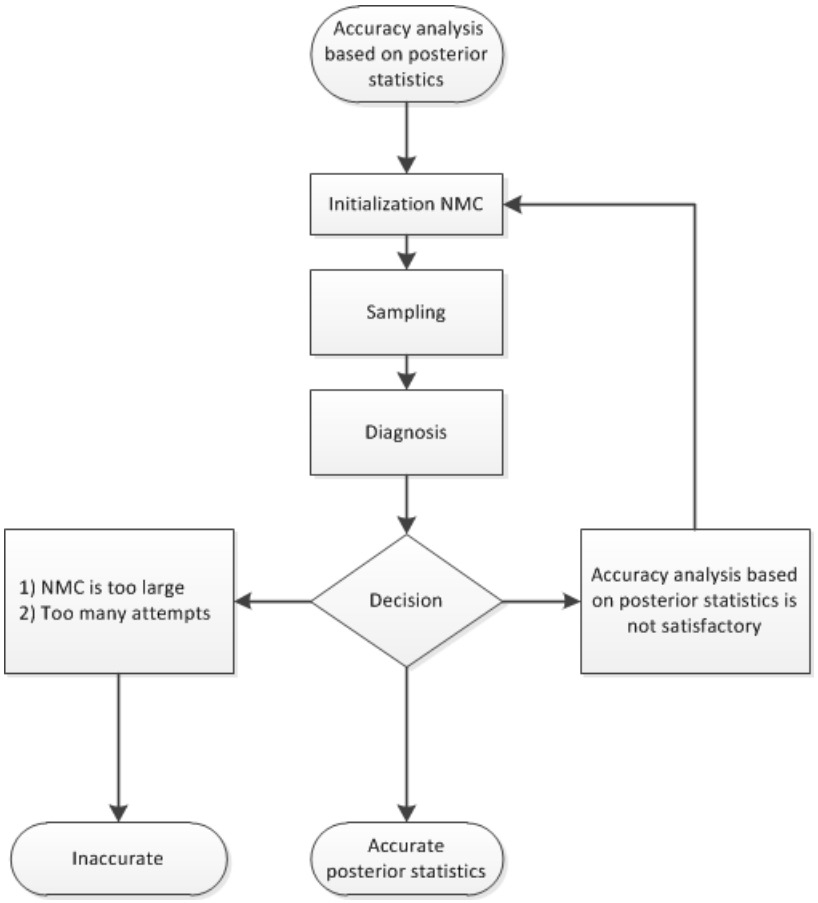
- If the proxy is greater than *ub*, then NMC is set equal to *ub*.
- If the proxy is less than *lb*, then NMC is set equal to *lb*.
- If *lb* is less than the proxy, which is less than *ub*, then NMC is set equal to the proxy.

For example:

```
proc countreg data=dataset;
   ...;
   bayes automcmc=( accuracy=(tol=0.95 targetstats=(rllimits=(lb=k1 ub=k2))) )
        raftery(q=0.025);
   ...;
run;
```

Figure 11.8 shows a flowchart of the AUTOMCMC algorithm based on the Heidelberger-Welch halfwidth test and the Raftery-Lewis test approach to determine whether the posterior samples provide an accurate representation of the posterior distribution.

Figure 11.8 Flowchart of the AUTOMCMC Algorithm: Accuracy Analysis Based on the Heidelberger-Welch Halfwidth Test and the Raftery-Lewis Test



Prior Distributions

The PRIOR statement is used to specify the prior distribution of the model parameters. You must specify a list of parameters, a tilde (∼), and then a distribution and its parameters. You can specify multiple PRIOR statements to define independent priors. Parameters that are associated with a regressor variable are referred to by the name of the corresponding regressor variable.

You can specify the special keyword _REGRESSORS to consider all the regressors of a model. If multiple prior statements affect the same parameter, the prior that is specified is used. For example, in a regression that uses three regressors (X1, X2, X3), the following statements imply that the prior on X1 is NORMAL(MEAN=0, VAR=1), the prior on X2 is GAMMA(SHAPE=3, SCALE=4), and the prior on X3 is UNIFORM(MIN=0, MAX=1):

```
...
prior _Regressors ~ uniform(min=0, max=1);
prior X1 X2 ~ gamma(shape=3, scale=4);
prior X1 ~ normal(mean=0, var=1);
...
```

If a parameter is not associated with a PRIOR statement or if some of the prior hyperparameters are missing, then the default choices shown in Table 11.4 are considered.

Table 11.4 Default Values for Prior Distributions

PRIOR *distribution*	**Hyperparameter**$_1$	**Hyperparameter**$_2$	**Min**	**Max**	**Parameters Default Choice**
NORMAL	MEAN=0	VAR=1E6	$-\infty$	∞	Regression-Location-Threshold
IGAMMA	SHAPE=2.000001	SCALE=1	> 0	∞	Scale
GAMMA	SHAPE=1	SCALE=1	0	∞	
UNIFORM			$-\infty$	∞	
BETA	SHAPE1=1	SHAPE2=1	$-\infty$	∞	
T	LOCATION=0	DF=3	$-\infty$	∞	

For density specifications, see the section "Standard Distributions" on page 649.

Automated MCMC

The main purpose is to provide the user with the opportunity of obtaining a good approximation of the posterior distribution without initializing the MCMC algorithm: initial values, proposal distributions, burn-in and number of samples.

The automated algorithm is composed of two phases: tuning and sampling. In the tuning phase, there are two main concerns: the choice of a good proposal distribution and the search for the stationary region of the posterior distribution. In the sampling phase, the algorithm will decide how many samples are necessary to obtain good approximations of the posterior mean and some quantiles of interest.

Stationarity Phase

During the stationarity phase, the algorithm tries to search for a good proposal distribution and, at the same time, to reach the stationary region of the posterior. The choice of the proposal distribution is based on the analysis of the acceptance rates. This is similar to what is done in PROC MCMC; for more information, see Chapter 80.10, "Tuning the Proposal Distribution" (*SAS/STAT User's Guide*). For the stationarity analysis, the main idea is to run two tests, Geweke (Ge) and Heidleberger-Welch (HW), on the posterior chains at the end of each attempt. For more information, see Chapter 8.4, "Geweke Diagnostics" (*SAS/STAT User's Guide*), and Chapter 8.4, "Heidelberger and Welch Diagnostics" (*SAS/STAT User's Guide*). If the stationarity hypothesis is rejected, then the tuning samples are increased and the tests repeated in the next attempt. After 10 attempts, the stationarity phase will be ended regardless of the results. The tuning parameters for the first attempt are fixed:

1000	burn-in (nbi),
500	tuning samples (ntu),
1000	MCMC samples (nmc).

For the remaining attempts, the tuning parameters will be adjusted dynamically. More specifically, each parameter will be assigned an acceptance ratio (AR) of the stationarity hypothesis,

$AR_i = 0$	if	both tests reject the stationarity hypothesis,
$AR_i = 0.5$	if	one tests rejects and the other does not,
$AR_i = 1$	if	both tests do not reject the stationarity hypothesis,

for $i = 1, \ldots, k$. For the Geweke test, the implemented significance level is 0.05. Then, an overall stationarity average (SA) for all parameters ratios is evaluated,

$$SA = \sum_{i=1}^{k} \frac{AR_i}{k}$$

and the number of tuning samples is updated accordingly:

$\text{ntu} = \text{ntu} + 2000$	if	$SA < 70\%$,
$\text{ntu} = \text{ntu} + 1000$	if	$70\% \leq SA < 100\%$,
$\text{ntu} = \text{ntu}$	if	$SA = 100\%$.

The burn-in is also updated whenever stationarity is not achieved:

$$\text{nbi} = \text{nbi} + 1000$$

Moreover, the Heidelberger-Welch test also provides an indications of how much burn-in should be used. The algorithm requires this burn-in to be: $\text{nbi(HW)} = 0$. If that is not the case, the burn-in will updated accordingly,

$$\text{nbi} = \max[\text{nbi}, \text{nbi(HW)}]$$

and a new attempt searching for stationarity will be implemented. This choice is motivated by the fact that the burn-in must be discarded in order to reach the stationary region of the posterior distribution.

The number of samples is updated at each attempt. However, in order to exit the stationarity phase, it will not be required nmc(RL) = 0. The default update is nmc = nmc + 1000. Depending on the outcome of the Raftery-Lewis diagnostics, if nmc $< \min\{\text{LB}[\text{nmc(RL)}], \text{nmc(RL)}\}$, the number of sampling is further updated to nmc = LB [nmc(RL)]. By default, LB [nmc(RL)] = 10000. Finally, if the number of projected samples is not sufficient to perform a stable evaluation of the Raftery-Lewis test, the number of samples is updated to nmc = $\min$ [nmc(RL)]. For more information, see "AUTOMCMC<=(*automcmc-options*)>" on page 569 and Chapter 8.4, "Raftery and Lewis Diagnostics" (*SAS/STAT User's Guide*).

Accuracy Phase

The main idea of the accuracy phase is to make sure that the mean and a quantile of interest are evaluated accurately. This can be tested by implementing the half-width test by Heidelberger-Welch and by analyzing the Raftery-Lewis diagnostic tool. In addition, the requirements defined in the stationarity phase will also be checked: the Geweke and the Heidelberger-Welch tests must not reject the stationary hypothesis and the burn-in predicted by the Heidelberger-Welch test must be zero.

The accuracy phase is characterized by a maximum of 10 attempts. If the algorithm exceeds this limit, the accuracy phase will end and indications on how to improve sampling will be given. The search of accuracy can be performed using two different method. The first method (the default) is triggered by the option TARGETSTATS and it is based on the accuracy analysis of the mean and a percentile of interest. The second method is triggered by the option TARGETESS and it targets a minimum number of effective samples. The accuracy phase will first update the burn-in with the information provided by the HW test: nbi = nbi + nbi(HW). Then, it determines the difference between the actual number of samples and the number of samples predicted by either the RL test or the ESS: Δ[nmc] = nmc(RL) − nmc, or Δ[nmc] = nmc(ESS) − nmc. The new number of samples will be updated accordingly:

$$\begin{aligned}
&\text{nmc} = \text{nmc} + \text{LB}[\text{nmc(RL)}] && \text{if} && 0 < \Delta[\text{nmc}] \leq \text{LB}[\text{nmc(RL)}],\\
&\text{nmc} = \text{nmc} + \Delta[\text{nmc}] && \text{if} && \text{LB}[\text{nmc(RL)}] < \Delta[\text{nmc}] \leq \text{UB}[\text{nmc(RL)}],\\
&\text{nmc} = \text{nmc} + \text{UB}[\text{nmc(RL)}] && \text{if} && \text{UB}[\text{nmc(RL)}] < \Delta[\text{nmc}].
\end{aligned}$$

By default, LB [nmc(RL)] = 10000 and UB [nmc(RL)] = 300000.

In addition, the accuracy search triggered by the option TARGETSTATS also implements the HW half-width test to checks whether the sample mean is accurate. If the mean of any parameters is not considered to be accurate and the number of samples has not been updated based on Δ[nmc], then the number of samples is increased:

$$\text{nmc} = \text{nmc} + 5000 \quad \text{if} \quad \Delta[\text{nmc}] \leq 0,$$

Marginal Likelihood

The Bayes theorem states that

$$p(\theta|\mathbf{y}) \propto \pi(\theta)L(y|\theta)$$

where θ is a vector of parameters and $\pi(\theta)$ is the product of the prior densities, which are specified in the PRIOR statement. The term $L(y|\theta)$ is the likelihood associated with the MODEL statement. The function $\pi(\theta)L(y|\theta)$ is the nonnormalized posterior distribution over the parameter vector θ. The normalized posterior distribution, or simply the posterior distribution, is

$$p(\theta|\mathbf{y}) = \frac{\pi(\theta)L(y|\theta)}{\int_\theta \pi(\theta)L(y|\theta)d\theta}$$

The denominator $m(y) = \int_\theta \pi(\theta)L(y|\theta)d\theta$, also called the "marginal likelihood," is a quantity of interest because it represents the probability of the data after the effect of the parameter vector has been averaged out. Due to its interpretation, the marginal likelihood can be used in various applications, including model averaging and variable or model selection.

A natural estimate of the marginal likelihood is provided by the harmonic mean,

$$m(y) = \left\{ \frac{1}{n} \sum_{i=1}^{n} \frac{1}{L(y|\theta_i)} \right\}^{-1}$$

where θ_i is a sample draw from the posterior distribution. This estimator has proven to be unstable in practical applications.

An alternative and more stable estimator can be obtained by using an importance sampling scheme. The auxiliary distribution for the importance sampler can be chosen through the cross-entropy theory (Chan and Eisenstat 2015). In particular, given a parametric family of distributions, the auxiliary density function is chosen to be the one closest, in terms of the Kullback-Leibler divergence, to the probability density that would give a zero variance estimate of the marginal likelihood. In practical terms, this is equivalent to the following algorithm:

1. Choose a parametric family, $f(., \beta)$, for the parameters of the model: $f(\theta|\beta)$
2. Evaluate the maximum likelihood estimator of β by using the posterior samples $\theta_1, \ldots, \theta_n$ as data
3. Use $f(\theta^*|\hat{\beta}_{mle})$ to generate the importance samples: $\theta_1^*, \ldots, \theta_{n^*}^*$
4. Estimate the marginal likelihood:

$$m(y) = \frac{1}{n^*} \sum_{j=1}^{n^*} \frac{L(y|\theta_j^*)\pi(\theta_j^*)}{f(\theta_j^*|\hat{\beta}_{mle})}$$

The parametric family for the auxiliary distribution is chosen to be Gaussian. The parameters that are subject to bounds are transformed accordingly

- If $-\infty < \theta < \infty$, then $p = \theta$.

- If $m \leq \theta < \infty$, then $q = \log(\theta - m)$.
- If $-\infty < \theta \leq M$, then $r = \log(M - \theta)$.
- If $m \leq \theta \leq M$, then $s = \log(\theta - m) - \log(M - \theta)$.

Assuming independence for the parameters that are subject to bounds, the auxiliary distribution to generate importance samples is

$$\begin{pmatrix} \mathbf{p} \\ \mathbf{q} \\ \mathbf{r} \\ \mathbf{s} \end{pmatrix} \sim \mathbf{N}\left[\begin{pmatrix} \mu_p \\ \mu_q \\ \mu_r \\ \mu_s \end{pmatrix}, \begin{pmatrix} \Sigma_p & 0 & 0 & 0 \\ 0 & \Sigma_q & 0 & 0 \\ 0 & 0 & \Sigma_r & 0 \\ 0 & 0 & 0 & \Sigma_r \end{pmatrix} \right]$$

where $\mathbf{p}$, $\mathbf{q}$, $\mathbf{r}$ and $\mathbf{s}$ are vectors containing the transformations of the unbounded, bounded-below, bounded-above and bounded-above-and-below parameters. Also, given the imposed independence structure, Σ_p can be a non-diagonal matrix while Σ_q, Σ_r and Σ_s are imposed to be diagonal matrices.

Standard Distributions

Table 11.5 through Table 11.10 show all the distribution density functions that PROC COUNTREG recognizes. You specify these distribution densities in the PRIOR statement.

Table 11.5 Beta Distribution

PRIOR statement	BETA(SHAPE1=a, SHAPE2=b, MIN=m, MAX=M)
	Note: Commonly $m = 0$ and $M = 1$.
Density	$\frac{(\theta-m)^{a-1}(M-\theta)^{b-1}}{B(a,b)(M-m)^{a+b-1}}$
Parameter restriction	$a > 0, \quad b > 0, \quad -\infty < m < M < \infty$
Range	$\begin{cases} [m, M] & \text{when } a = 1, b = 1 \\ [m, M) & \text{when } a = 1, b \neq 1 \\ (m, M] & \text{when } a \neq 1, b = 1 \\ (m, M) & \text{otherwise} \end{cases}$
Mean	$\frac{a}{a+b} \times (M - m) + m$
Variance	$\frac{ab}{(a+b)^2(a+b+1)} \times (M - m)^2$
Mode	$\begin{cases} \frac{a-1}{a+b-2} \times M + \frac{b-1}{a+b-2} \times m & a > 1, b > 1 \\ m \text{ and } M & a < 1, b < 1 \\ m & \begin{cases} a < 1, b \geq 1 \\ a = 1, b > 1 \end{cases} \\ M & \begin{cases} a \geq 1, b < 1 \\ a > 1, b = 1 \end{cases} \\ \text{not unique} & a = b = 1 \end{cases}$
Defaults	SHAPE1=SHAPE2=1, MIN $\rightarrow -\infty$, MAX $\rightarrow \infty$

Table 11.6 Gamma Distribution

PRIOR statement	GAMMA(SHAPE=a, SCALE=b)
Density	$\frac{1}{b^a\Gamma(a)}\theta^{a-1}e^{-\theta/b}$
Parameter restriction	$a > 0, b > 0$
Range	$[0, \infty)$
Mean	ab
Variance	ab^2
Mode	$(a-1)b$
Defaults	SHAPE=SCALE=1

Table 11.7 Inverse Gamma Distribution

PRIOR statement	IGAMMA(SHAPE=a, SCALE=b)
Density	$\frac{b^a}{\Gamma(a)}\theta^{-(a+1)}e^{-b/\theta}$
Parameter restriction	$a > 0, b > 0$
Range	$0 < \theta < \infty$
Mean	$\frac{b}{a-1}, \quad a > 1$
Variance	$\frac{b^2}{(a-1)^2(a-2)}, \quad a > 2$
Mode	$\frac{b}{a+1}$
Defaults	SHAPE=2.000001, SCALE=1

Table 11.8 Normal Distribution

PRIOR statement	NORMAL(MEAN=μ, VAR=σ^2)
Density	$\frac{1}{\sigma\sqrt{2\pi}}\exp\left(-\frac{(\theta-\mu)^2}{2\sigma^2}\right)$
Parameter restriction	$\sigma^2 > 0$
Range	$-\infty < \theta < \infty$
Mean	μ
Variance	σ^2
Mode	μ
Defaults	MEAN=0, VAR=1000000

Table 11.9 *t* **Distribution**

PRIOR statement	T(LOCATION=μ, DF=ν)
Density	$\frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)\sqrt{\pi\nu}}\left[1+\frac{(\theta-\mu)^2}{\nu}\right]^{-\frac{\nu+1}{2}}$
Parameter restriction	$\nu > 0$
Range	$-\infty < \theta < \infty$
Mean	μ, for $\nu > 1$
Variance	$\frac{\nu}{\nu-2}$, for $\nu > 2$
Mode	μ
Defaults	LOCATION=0, DF=3

Table 11.10 **Uniform Distribution**

PRIOR statement	UNIFORM(MIN=m, MAX=M)
Density	$\frac{1}{M-m}$
Parameter restriction	$-\infty < m < M < \infty$
Range	$\theta \in [m, M]$
Mean	$\frac{m+M}{2}$
Variance	$\frac{(M-m)^2}{12}$
Mode	Not unique
Defaults	MIN$\rightarrow -\infty$, MAX$\rightarrow \infty$

OUTPUT OUT= Data Set

The OUTPUT statement creates a new SAS data set that contains all the variables in the input data set and, optionally, the estimates of $\mathbf{x}_i'\boldsymbol{\beta}$, the expected value of the response variable, and the probability that the response variable will take the current value or other values that you specify. In a zero-inflated model, you can also request that the output data set contain the estimates of $\mathbf{z}_i'\boldsymbol{\gamma}$, and the probability that the response is zero as a result of the zero-generating process. In a Conway-Maxwell-Poisson model, you can also request that the output data set contains estimates of $\mathbf{g}_i'\boldsymbol{\delta}$, λ, ν, μ, mode, variance and dispersion.

Except for the probability of the current value, these statistics can be computed for all observations in which the regressors are not missing, even if the response is missing. By adding observations that have missing response values to the input data set, you can compute these statistics for new observations or for settings of the regressors that are not present in the data without affecting the model fit.

OUTEST= Data Set

The OUTEST= data set is has two rows: the first row (with _TYPE_='PARM') contains each of the parameter estimates in the model, and the second row (with _TYPE_='STD') contains the standard errors for the parameter estimates in the model.

If you specify the COVOUT option in the PROC COUNTREG statement, the OUTEST= data set also contains the covariance matrix for the parameter estimates. The covariance matrix appears in the observations for which _TYPE_='COV', and the _NAME_ variable labels the rows with the parameter names.

The names of the parameters are used as variable names. These are the same names that are used in the INIT, BOUNDS, and RESTRICT statements.

ODS Table Names

PROC COUNTREG assigns a name to each table that it creates. You can use these names to denote the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 11.11.

Table 11.11 ODS Tables Produced in PROC COUNTREG

ODS Table Name	Description	Option
ODS Tables Created by the MODEL Statement		
ClassLevels	Class levels	Default
FitSummary	Summary of nonlinear estimation	Default
ConvergenceStatus	Convergence status	Default
ParameterEstimates	Parameter estimates	Default
CovB	Covariance of parameter estimates	COVB
CorrB	Correlation of parameter estimates	CORRB
InputOptions	Input options	ITPRINT
IterStart	Optimization start	ITPRINT
IterHist	Iteration history	ITPRINT
IterStop	Optimization results	ITPRINT
ParameterEstimatesResults	Parameter estimates	ITPRINT
ParameterEstimatesStart	Parameter estimates	ITPRINT

ODS Tables Created by the TEST Statement		
TestResults	Test results	Default
ODS Tables Created by the BAYES Statement		
AutoCorr	Autocorrelation statistics for each parameter	Default
AutoMcmcSummary	Automatic MCMC summary	DIAGNOSTICS=AUTOSUM
Corr	Correlation matrix of the posterior samples	STATS=COR

Table 11.11 *continued*

ODS Table Name	Description	Option
Cov	Covariance matrix of the posterior samples	STATS=COV
ESS	Effective sample size for each parameter	Default
MCSE	Monte Carlo standard error for each parameter	Default
Geweke	Geweke diagnostics for each parameter	Default
Heidelberger	Heidelberger-Welch diagnostics for each parameter	DIAGNOSTICS=HEIDEL
LogMarginLike	Marginal likelihood	MARGINLIKE
PostIntervals	Equal-tail and HPD intervals for each parameter	Default
PosteriorSample	Posterior samples	(ODS output data set only)
PostSummaries	Posterior summaries	Default
PriorSummaries	Prior summaries	STATS=PRIOR
Raftery	Raftery-Lewis diagnostics for each parameter	DIAGNOSTICS=RAFTERY

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

This section describes the use of ODS Graphics to create graphics by using the COUNTREG procedure.

To request these graphs, you must specify the ODS GRAPHICS ON statement. There is no default plot for the COUNTREG procedure. If, in addition to the ODS GRAPHICS statement, you specify the ALL option in the PROC COUNTREG statement, then all applicable plots are created.

ODS Graph Names

PROC COUNTREG assigns a name to each graph that it creates using ODS. You can use these names to refer to the graphs when using ODS. The names are listed in Table 11.12.

Table 11.12 ODS Graphics Produced in PROC COUNTREG

ODS Table Name	Description	PLOTS= Option
PredProbPlot	Predictive probability plot	PLOTS(COUNTS)=PREDPROB
ProfileLikPlot	Profile likelihood functions	PLOTS(UNPACK)=PROFILELIKE or PROLIK
OverDispersion	Overdispersion diagnostic plot	PLOTS=DISPERSION
ZpProfilePlot	Zero-probability and zero-inflation profile plot	PLOTS(UNPACK)=ZEROPROFILE or ZPPRO
PredProfilePlot	Predictive probability profile plot	PLOTS(UNPACK COUNTS)=PREDPRO or PREDPROFILE

Table 11.13 Graphs Produced by PROC COUNTREG When a BAYES Statement Is Included

Examples: COUNTREG Procedure

Example 11.1: Basic Models

Data Description and Objective

The data set DocVisit contains information for approximately 5,000 Australian individuals about the number and possible determinants of doctor visits that were made during a two-week interval. This data set contains a subset of variables that are taken from the Racd3 data set used by Cameron and Trivedi (1998). The DocVisit data set can be found in the SAS/ETS Sample Library.

The variable Doctorco represents doctor visits. Additional variables in the data set that you want to evaluate as determinants of doctor visits include Sex (coded 0=male, 1=female), Age (age in years divided by 100), Illness (number of illnesses during the two-week interval, with five or more coded as five), Income (annual income in Australian dollars divided by 1,000), and Hscore (a score on a general health questionnaire, in which a high score indicates bad health). Summary statistics for these variables are computed in the following statements and presented in Output 11.1.1:

```
proc means data=docvisit;
   var doctorco sex age illness income hscore;
run;
```

Output 11.1.1 Summary Statistics

The MEANS Procedure

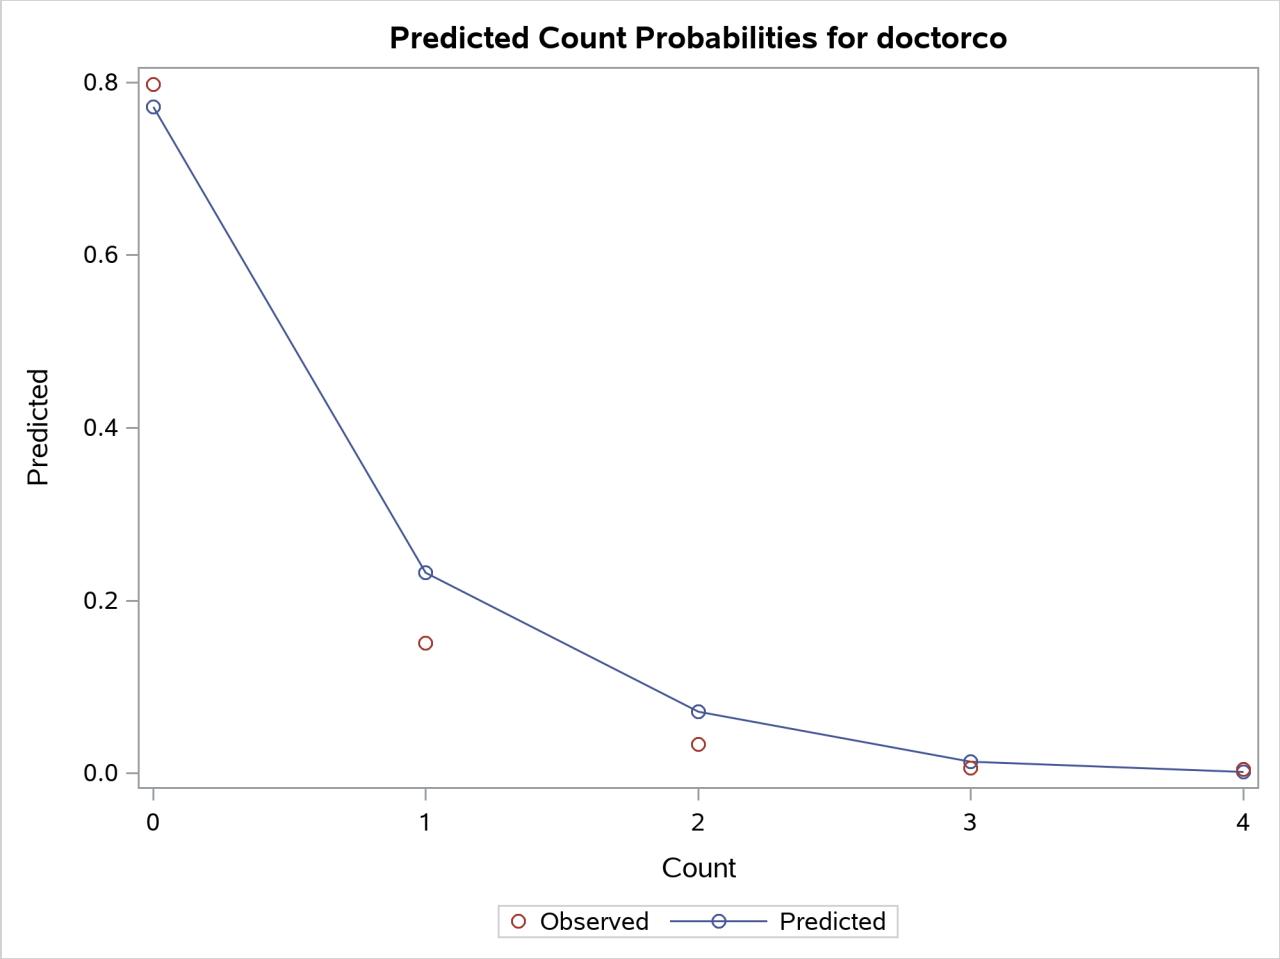
Variable	N	Mean	Std Dev	Minimum	Maximum
doctorco	5190	0.3017341	0.7981338	0	9.0000000
sex	5190	0.5206166	0.4996229	0	1.0000000
age	5190	0.4063854	0.2047818	0.1900000	0.7200000
illness	5190	1.4319846	1.3841524	0	5.0000000
income	5190	0.5831599	0.3689067	0	1.5000000
hscore	5190	1.2175337	2.1242665	0	12.0000000

Poisson Model

The following statements fit a Poisson model to the data by using the covariates Sex, Illness, Income, and Hscore:

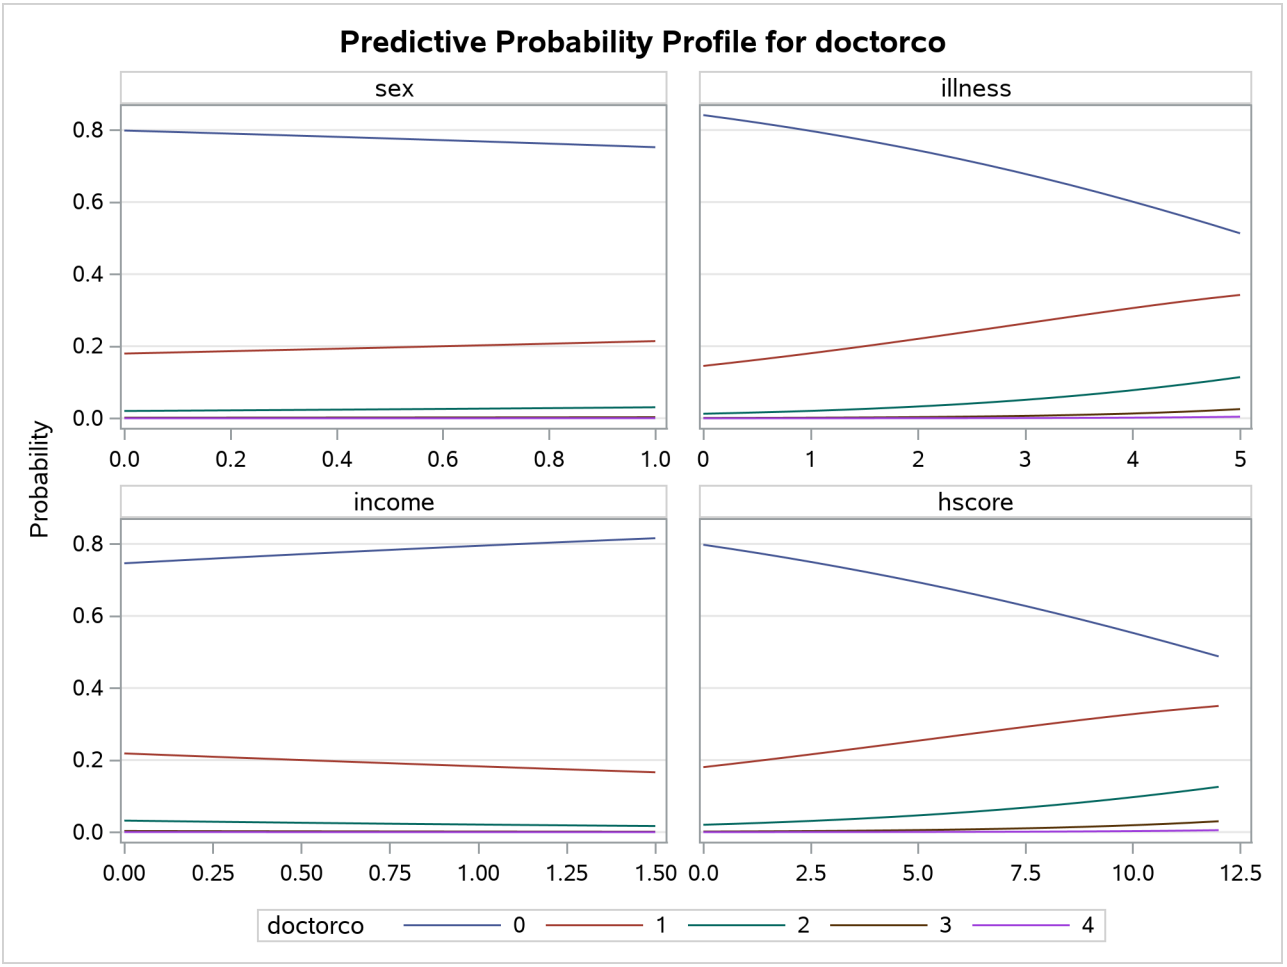
```
proc countreg data=docvisit plots(only counts(0 to 4 by 1))=(predprob predpro);
   model doctorco=sex illness income hscore / dist=poisson printall;
run;
```

Output 11.1.2 Mean Predicted Count Probabilities



Output 11.1.2 shows the predicted probabilities of count levels 0 to 4 from the Poisson model. Most of the observed counts are in the range 0 to 4 and account for more than 99% of the entire data set. One factor that would be interesting to explore is how the model-predicted probabilities of those count levels react to different regressor values. Output 11.1.3 shows the predictive profiles of the count levels in question against the first three regressors in the model. In each panel, the regressor in question is varied while all other regressors are fixed at their observed mean and the model parameters are fixed at their MLE.

Output 11.1.3 Profile Function of Predictive Probabilities



In this example, the DIST= option in the MODEL statement specifies the Poisson distribution. In addition, the PRINTALL option displays the correlation and covariance matrices for the parameters, log-likelihood values, and convergence information in addition to the parameter estimates. The parameter estimates for this model are shown in Output 11.1.4.

Output 11.1.4 Parameter Estimates of Poisson Model

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	-1.855552	0.074545	-24.89	<.0001
sex	1	0.235583	0.054362	4.33	<.0001
illness	1	0.270326	0.017080	15.83	<.0001
income	1	-0.242095	0.077829	-3.11	0.0019
hscore	1	0.096313	0.009089	10.60	<.0001

Using the CLASS Statement

If some regressors are categorical in nature (meaning that these variables can take only a few discrete qualitative values), specify them in the CLASS statement. In this example, Sex is categorical because it takes only two values. A CLASS variable can be numeric or character.

Consider the following extension:

```
proc countreg data=docvisit;
   class sex;
   model doctorco=sex illness income hscore / dist=poisson;
run;
```

The partial output is given in Output 11.1.5.

Output 11.1.5 Parameter Estimates of Poisson Model with CLASS statement

The COUNTREG Procedure

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	-1.619969	0.063985	-25.32	<.0001
sex 0	1	-0.235583	0.054362	-4.33	<.0001
sex 1	0	0	.	.	.
illness	1	0.270326	0.017080	15.83	<.0001
income	1	-0.242095	0.077829	-3.11	0.0019
hscore	1	0.096313	0.009089	10.60	<.0001

If the CLASS statement is present, the COUNTREG procedure creates as many indicator or dummy variables as there are categories in a CLASS variable and uses them as independent variables. In order to avoid collinearity with the intercept, the last-created dummy variable is assigned a zero coefficient by default. This means that only the dummy variable that is associated with the first level of Sex (male=0) is used as a regressor. Consequently, the estimated coefficient for this dummy variable is the negative of the one for the original Sex variable in Output 11.1.4, because the reference level has switched from male to female.

Now consider a more practical task. The previous example implicitly assumes that each additional illness during the two-week interval has the same effect. In other words, this variable is thought of as a continuous variable. But this variable has only six values, and it is quite possible that the number of illnesses has a nonlinear effect on doctor visits. In order to check this conjecture, the following statements specify the Illness variable in the CLASS statement so that it is represented in the model by a set of six dummy variables that can account for any type of nonlinearity:

```
proc countreg data=docvisit;
   class sex illness;
   model doctorco=sex illness income hscore / dist=poisson;
run;
```

The parameter estimates are displayed in Output 11.1.6.

Output 11.1.6 Parameter Estimates of Poisson Model with CLASS statement

The COUNTREG Procedure

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	-0.385930	0.088062	-4.38	<.0001
sex 0	1	-0.219118	0.054190	-4.04	<.0001
sex 1	0	0	.	.	.
illness 0	1	-1.934983	0.121267	-15.96	<.0001
illness 1	1	-0.698307	0.089732	-7.78	<.0001
illness 2	1	-0.471100	0.090742	-5.19	<.0001
illness 3	1	-0.488481	0.099127	-4.93	<.0001
illness 4	1	-0.272372	0.107593	-2.53	0.0114
illness 5	0	0	.	.	.
income	1	-0.253583	0.077441	-3.27	0.0011
hscore	1	0.094590	0.009025	10.48	<.0001

The Estimate column shows the difference between each ILLNESS parameter and ILLNESS=5. Note that these estimates for different Illness categories do not increase linearly but instead show a relatively large jump from zero illnesses to one illness, followed by relatively smaller increases.

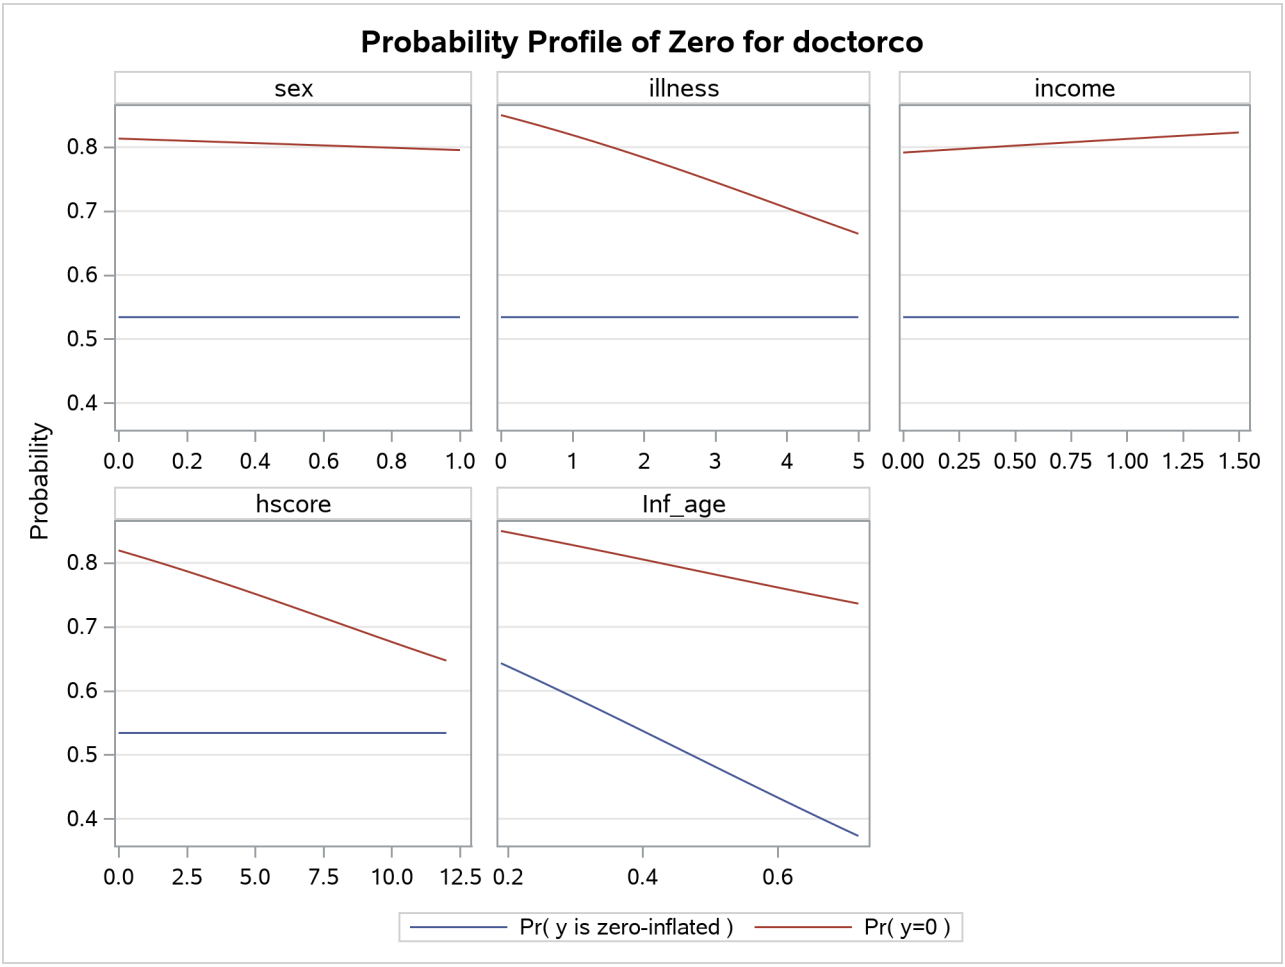
Zero-Inflated Poisson (ZIP) Model

Suppose you suspect that the population of individuals can be viewed as two distinct groups: a low-risk group, consisting of individuals who never go to the doctor, and a high-risk group, consisting of individuals who do go to the doctor. You might suspect that the data have this structure both because the sample variance of Doctorco (0.64) exceeds its sample mean (0.30), which suggests overdispersion, and because a large fraction of the Doctorco observations (80%) have the value zero. Estimating a zero-inflated model is one way to deal with overdispersion that results from excess zeros.

Suppose also that you suspect that the covariate Age has an impact on whether an individual belongs to the low-risk group. For example, younger individuals might have illnesses of much lower severity when they do get sick and be less likely to visit a doctor, all other factors being equal. The following statements estimate a zero-inflated Poisson regression, with Age as a covariate in the zero-generation process:

```
proc countreg data=docvisit plots(only)=(dispersion zeroprofile);
   model doctorco=sex illness income hscore / dist=zip;
   zeromodel doctorco ~ age;
run;
```

Output 11.1.7 Profile Function of Zero Process Selection and Zero Prediction



You might be interested in exploring how the zero process selection probability reacts to different regressor values. Output 11.1.7 displays this information in much the same fashion as Output 11.1.3. Because Sex, Illness, Income, and Hscore do not appear in the ZEROMODEL statement, the zero-inflation selection probability does not change for different values of those regressors. However, the plot shows that Age positively affects the zero process selection probability in a linear fashion.

In this case, the ZEROMODEL statement that follows the MODEL statement specifies that both an intercept and the variable Age be used to estimate the likelihood of zero doctor visits. Output 11.1.8 shows the resulting parameter estimates.

Output 11.1.8 Parameter Estimates for ZIP Model

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	-1.033387	0.096973	-10.66	<.0001
sex	1	0.122511	0.062566	1.96	0.0502
illness	1	0.237478	0.019997	11.88	<.0001
income	1	-0.143945	0.087810	-1.64	0.1012
hscore	1	0.088386	0.010043	8.80	<.0001
Inf_Intercept	1	0.986557	0.131339	7.51	<.0001
Inf_age	1	-2.090924	0.270580	-7.73	<.0001

The estimates of the zero-inflated intercept (Inf_Intercept) and the zero-inflated regression coefficient for Age (Inf_age) are approximately 0.99 and –2.09, respectively. Because the zero-inflation model uses a logistic link by default, you can estimate the probabilities for individuals of ages 20, 50, and 70 as follows:

$$\text{20 years: } \frac{e^{(0.99-2.09*.20)}}{1+e^{(0.99-2.09*.20)}} = 0.64$$

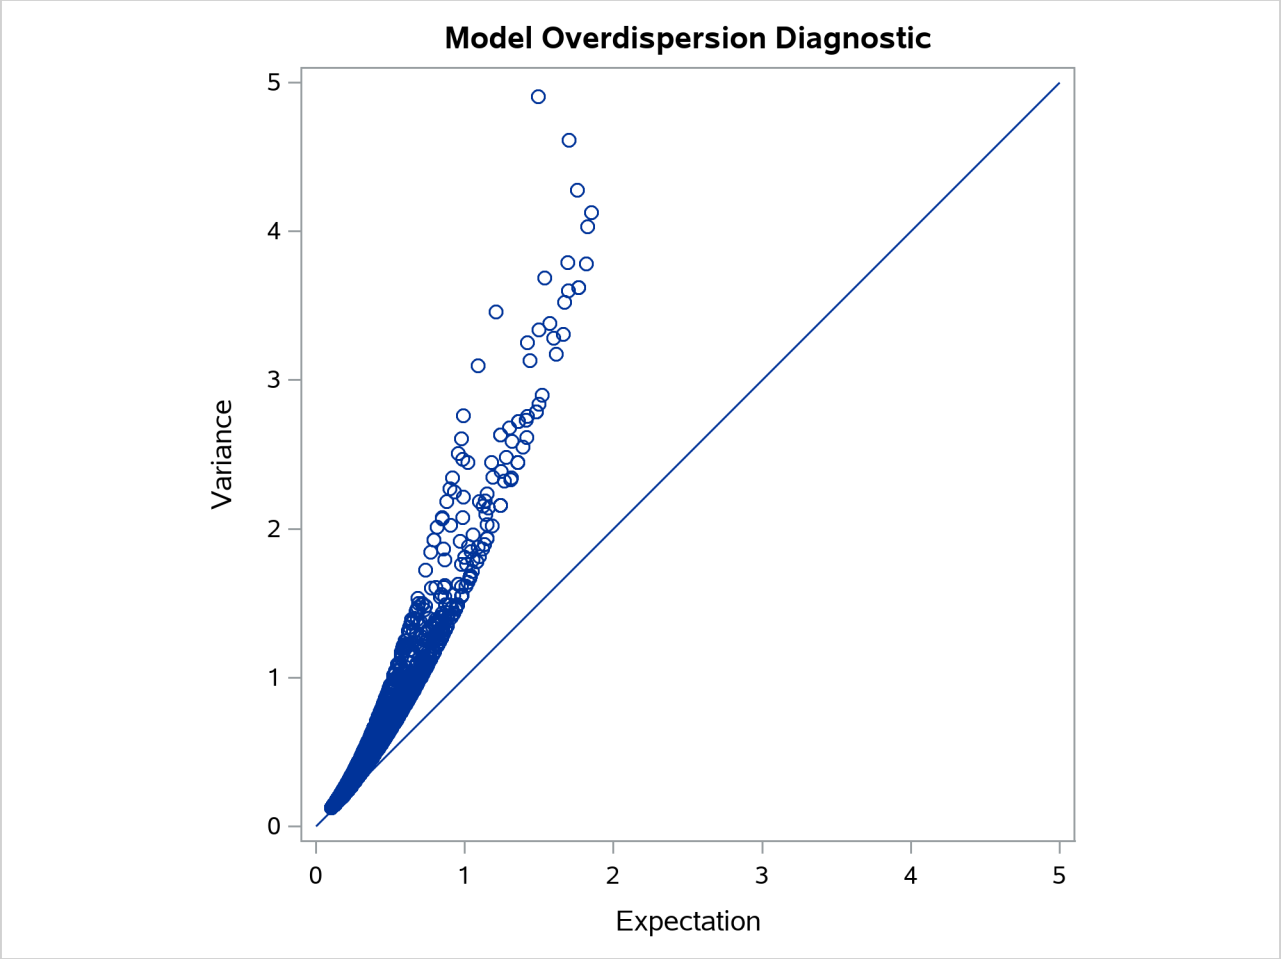
$$\text{50 years: } \frac{e^{(0.99-2.09*.50)}}{1+e^{(0.99-2.09*.50)}} = 0.49$$

$$\text{70 years: } \frac{e^{(0.99-2.09*.70)}}{1+e^{(0.99-2.09*.70)}} = 0.38$$

That is, the estimated probability of belonging to the low-risk group is about 0.64 for a 20-year-old individual, 0.49 for a 50-year-old individual, and only 0.38 for a 70-year-old individual. This supports the suspicion that older individuals are more likely to have a positive number of doctor visits.

Alternative models to account for the overdispersion are the negative binomial and the zero-inflated negative binomial models, which can be fit using the DIST=NEGBIN and DIST=ZINB options, respectively.

Output 11.1.9 Overdispersion Diagnostic Plot



Output 11.1.9 plots the conditional variance against the conditional mean and can be used as a diagnostic tool to check the level of overdispersion in a model.

Example 11.2: ZIP and ZINB Models for Data That Exhibit Extra Zeros

In the study by Long (1997) of the number of published articles by scientists (see the section "Getting Started: COUNTREG Procedure" on page 558), the observed proportion of scientists who publish no articles is 0.3005. The following statements use PROC FREQ to compute the proportion of scientists who publish each observed number of articles. Output 11.2.1 shows the results.

```
proc freq data=long97data;
   table art / out=obs;
run;
```

Output 11.2.1 Proportion of Scientists Who Publish a Certain Number of Articles

The FREQ Procedure

art	Frequency	Percent	Cumulative Frequency	Cumulative Percent
0	275	30.05	275	30.05
1	246	26.89	521	56.94
2	178	19.45	699	76.39
3	84	9.18	783	85.57
4	67	7.32	850	92.90
5	27	2.95	877	95.85
6	17	1.86	894	97.70
7	12	1.31	906	99.02
8	1	0.11	907	99.13
9	2	0.22	909	99.34
10	1	0.11	910	99.45
11	1	0.11	911	99.56
12	2	0.22	913	99.78
16	1	0.11	914	99.89
19	1	0.11	915	100.00

PROC COUNTREG is then used to fit Poisson and negative binomial models to the data. For each model, the PROBCOUNT option computes the probability that the number of published articles is m, for $m = 0$ to 10. The following statements compute the estimates for Poisson and negative binomial models. The MEAN procedure is then used to compute the average probability of a zero response.

```
proc countreg data=long97data;
   model art=fem mar kid5 phd ment / dist=poisson;
   output out=predpoi probcount(0 to 10);
run;

proc means mean data=predpoi;
   var p_0;
run;
```

The output from the Poisson model for the COUNTREG and MEAN procedures is shown in Output 11.2.2.

Mean
0.3035957

For each model, the predicted proportion of zero articles can be calculated as the average predicted probability of zero articles across all scientists. Under the Poisson model, the predicted proportion of zero articles is 0.2092, which considerably underestimates the observed proportion. The negative binomial more closely estimates the proportion of zeros (0.3036). Also, the test of the dispersion parameter, _Alpha, in the negative binomial model indicates significant overdispersion ($p < 0.0001$). As a result, the negative binomial model is preferred to the Poisson model.

Another way to account for the large number of zeros in this data set is to fit a zero-inflated Poisson (ZIP) or a zero-inflated negative binomial (ZINB) model. In the following statements, DIST=ZIP requests the ZIP model. In the ZEROMODEL statement, you can specify the predictors, $\mathbf{z}$, for the process that generates the additional zeros. The ZEROMODEL statement also specifies the model for the probability φ. By default, a logistic model is used for φ. You can change the default by using the LINK= option. In this particular ZIP model, all variables that are used to model the article counts are also used to model φ.

```
proc countreg data=long97data;
   model art = fem mar kid5 phd ment / dist=zip;
   zeromodel art ~ fem mar kid5 phd ment;
   output out=predzip probcount(0 to 10);
run;

proc means data=predzip mean;
   var p_0;
run;
```

The parameters of the ZIP model are displayed in Output 11.2.5. The first set of parameters gives the estimates of $\boldsymbol{\beta}$ in the model for the Poisson process mean. Parameters that have the prefix "Inf_" are the estimates of $\boldsymbol{\gamma}$ in the logistic model for φ.

Output 11.2.5 ZIP Model Estimation

Output 11.2.5 *continued*

The MEANS Procedure

Analysis Variable : P_0 Probability of art taking level=0
Mean
0.2985679

The proportion of zeros that are predicted by the ZIP model is 0.2986, which is much closer to the observed proportion than the Poisson model. But Output 11.2.7 shows that both models deviate from the observed proportions at one, two, and three articles.

The ZINB model is specified by the DIST=ZINB option. All variables are again used to model both the number of articles and φ. The METHOD=QN option specifies that the quasi-Newton method be used to fit the model rather than the default Newton-Raphson method. These options are implemented in the following statements:

```
proc countreg data=long97data;
   model art=fem mar kid5 phd ment / dist=zinb method=qn;
   zeromodel art ~ fem mar kid5 phd ment;
   output out=predzinb probcount(0 to 10);
run;

proc means data=predzinb mean;
   var p_0;
run;
```

The estimated parameters of the ZINB model are shown in Output 11.2.6. The test for overdispersion again indicates a preference for the negative binomial version of the zero-inflated model ($p < 0.0001$). The ZINB model also does a good job of estimating the proportion of zeros (0.3119), and it follows the observed proportions well, though possibly not as well as the negative binomial model.

Output 11.2.6 ZINB Model Estimation

   output out=mnnb mean(p_0-p_10)=mn0-mn10;
run;
proc summary data=predzip;
   var p_0-p_10;
   output out=mnzip mean(p_0-p_10)=mn0-mn10;
run;
proc summary data=predzinb;
   var p_0-p_10;
   output out=mnzinb mean(p_0-p_10)=mn0-mn10;
run;

data means;
   set mnpoi mnnb mnzip mnzinb;
```

```
   drop _type_ _freq_;
run;

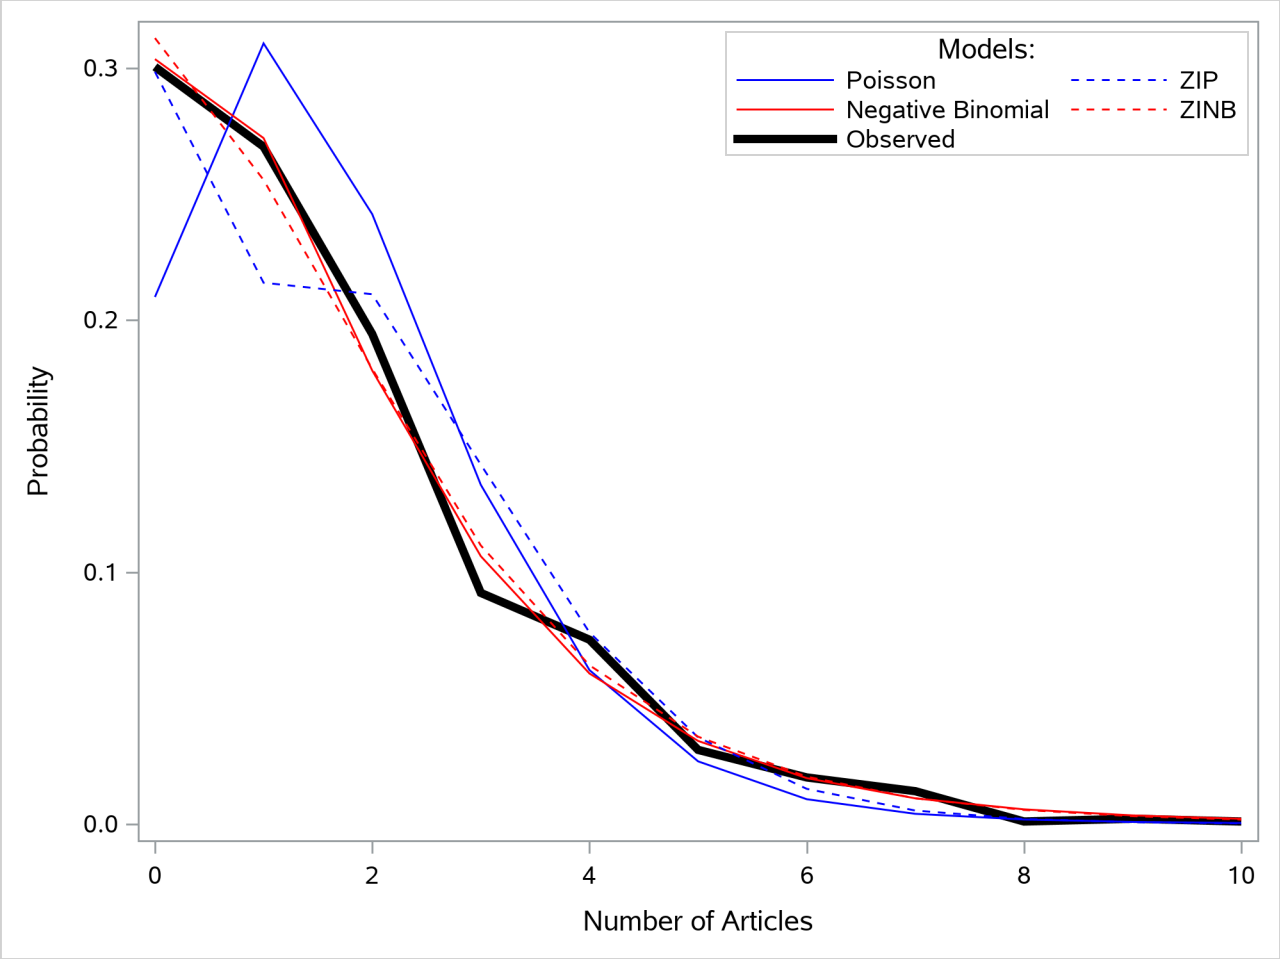
proc transpose data=means out=tmeans;
run;

data allpred;
   merge obs(where=(art<=10)) tmeans;
   obs=percent/100;
run;

proc sgplot;
   yaxis label='Probability';
   xaxis label='Number of Articles';
   series y=obs  x=art / name='obs' legendlabel='Observed'
      lineattrs=(color=black thickness=4px);
   series y=col1 x=art / name='poi' legendlabel='Poisson'
      lineattrs=(color=blue);
   series y=col2 x=art/ name='nb' legendlabel='Negative Binomial'
      lineattrs=(color=red);
   series y=col3 x=art/ name='zip' legendlabel='ZIP'
      lineattrs=(color=blue pattern=2);
   series y=col4 x=art/ name='zinb' legendlabel='ZINB'
      lineattrs=(color=red pattern=2);
   discretelegend 'poi' 'zip' 'nb' 'zinb' 'obs' / title='Models:'
      location=inside position=ne across=2 down=3;
run;
```

For each of the four fitted models, Output 11.2.7 shows the average predicted count probability for each article count across all scientists. The Poisson model clearly underestimates the proportion of zero articles published, whereas the other three models are quite accurate at zero. All the models do well at the larger numbers of articles.

Output 11.2.7 Average Predicted Count Probability



Example 11.3: Variable Selection

This example demonstrates two algorithms of automatic variable selection in the COUNTREG procedure. Automatic variable selection is most effective when the number of possible candidates for explaining the variation of some variable is large. For clarity of exposition, this example uses only a small number of variables. The data set Article published by Long (1997) contains six variables. (This data set is also used in "Example 11.2: ZIP and ZINB Models for Data That Exhibit Extra Zeros" on page 662.) The dependent variable Art records the number of articles that were published by a doctoral student in the last three years of his or her program. Explanatory variables include sex of the student (Fem), marital status (Mar), number of children (Kid5), prestige of the program (Phd), and publishing activity of the academic adviser (Ment). All these variables intuitively suggest their effect on the students' primary academic output.

First, for comparison purposes, estimate the simple Poisson model. The choice of model is specified by DIST= option in the MODEL statement, as follows:

```
proc countreg data = long97data;
   model art = fem mar kid5 phd ment / dist = poisson;
run;
```

The output of these statements is shown in Figure 11.3.1.

Output 11.3.1 Poisson Model for the Number of Published Articles

The COUNTREG Procedure

Model Fit Summary	
Dependent Variable	art
Number of Observations	915
Data Set	WORK.LONG97DATA
Model	Poisson
Log Likelihood	-1651
Maximum Absolute Gradient	3.57426E-9
Number of Iterations	5
Optimization Method	Newton-Raphson
AIC	3314
SBC	3343

Algorithm converged.

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	0.304617	0.102982	2.96	0.0031
fem	1	-0.224594	0.054614	-4.11	<.0001
mar	1	0.155243	0.061375	2.53	0.0114
kid5	1	-0.184883	0.040127	-4.61	<.0001
phd	1	0.012823	0.026397	0.49	0.6271
ment	1	0.025543	0.002006	12.73	<.0001

Note that the Newton-Raphson optimization algorithm took five steps to converge. All parameters, except for one, are significant at a 1% or 5% level, whereas Phd is not significant even at the 10% level.

In this case, it might be easy to identify the variables that have limited explanatory power. However, if the number of variables were large, the manual selection could be time-consuming and inaccurate. For a large number of variables, you would be better off in applying one of the automatic algorithms of variable selection. The following statements use the penalized likelihood method, which is indicated by SELECT=PEN option in the MODEL statement:

```
proc countreg data = long97data method = qn;
   model art = fem mar kid5 phd ment / dist   = poisson
                                       select = PEN;
run;
```

The output of these statements is shown in Output 11.3.2.

Output 11.3.2 Poisson Model for the Number of Published Articles with Penalized Likelihood Method

The COUNTREG Procedure

Model Fit Summary	
Dependent Variable	art
Number of Observations	915
Data Set	WORK.LONG97DATA
Model	Poisson

Algorithm converged.

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	0.345174	0.060125	5.74	<.0001
fem	1	-0.225303	0.054615	-4.13	<.0001
mar	1	0.152175	0.061067	2.49	0.0127
kid5	1	-0.184993	0.040139	-4.61	<.0001
ment	1	0.025761	0.001950	13.21	<.0001

The "Parameter Estimates" table shows that the variable Phd was dropped from the model.

The next statements use the information criterion by specifying the SELECT=INFO option. The direction of the search is chosen to be forward, and the information criterion is AIC. In order to achieve the same selection of variables as for the penalized likelihood method, 0.001 is specified for the percentage of decrease in the information criterion necessary for the algorithm to stop.

```
proc countreg data = long97data;
   model art = fem mar kid5 phd ment / dist      = poisson
                                       select    = INFO
                                     ( direction = forward
                                       criter    = AIC
                                       lstop     = 0.001 );
run;
```

The output of these statements is shown in Figure 11.3.3.

Output 11.3.3 Poisson Model for the Number of Published Articles with Search Method Using Information Criterion

The COUNTREG Procedure

Variable Selection Information

ment	1	0.025761	0.001950	13.21	<.0001

From the output, it is clear that the same set of variables was chosen as the result of information criterion algorithm. Note that the forward optimization algorithm starts with the constant as the only explanatory variable.

Example 11.4: Spatial Effects

This example demonstrates how to use the COUNTREG procedure to model count data with spatial effects. The data set Shigdata contains county-level data related to shigellosis, an infectious bacterial disease. The dependent variable Shigellosis records the number of shigellosis cases reported in each California county in 2011. The data are from the California Department of Public Health. Additional variables include PopDensity (population in thousands per square mile), Hispanic (percentage of Hispanic population), and BigHousehold (percentage of households with six or more persons); these data are from the 2010 United States Census. The following statements compute summary statistics for these variables and the frequency of each observed shigellosis count:

```
proc means data=Shigdata;
   var Shigellosis PopDensity Hispanic BigHousehold;
run;
proc freq data=Shigdata;
   table Shigellosis;
run;
```

The results are presented in Output 11.4.1.

Output 11.4.1 Summary Statistics and Frequency of Counts

The MEANS Procedure

Variable	N	Mean	Std Dev	Minimum	Maximum
Shigellosis	58	16.3620690	40.6692687	0	284.0000000
PopDensity	58	0.6632695	2.3148907	0.0015900	17.1801800
Hispanic	58	28.4724138	17.3124947	6.9600000	80.3700000
Bighousehold	58	6.3818966	3.4006318	1.7500000	13.1500000

Output 11.4.1 *continued*

The FREQ Procedure

Shigellosis	Frequency	Percent	Cumulative Frequency	Cumulative Percent
0	18	31.03	18	31.03
1	5	8.62	23	39.66
2	1	1.72	24	41.38
3	4	6.90	28	48.28
4	5	8.62	33	56.90
5	1	1.72	34	58.62
6	1	1.72	35	60.34
8	2	3.45	37	63.79
9	2	3.45	39	67.24
12	1	1.72	40	68.97
13	1	1.72	41	70.69
15	1	1.72	42	72.41
16	2	3.45	44	75.86
17	1	1.72	45	77.59
18	1	1.72	46	79.31
21	2	3.45	48	82.76
25	1	1.72	49	84.48
26	1	1.72	50	86.21
34	1	1.72	51	87.93
37	1	1.72	52	89.66
39	1	1.72	53	91.38
48	1	1.72	54	93.10
50	1	1.72	55	94.83
64	1	1.72	56	96.55
109	1	1.72	57	98.28
284	1	1.72	58	100.00

The number of observations is 58, which is the number of California counties. The variance of Shigellosis (1653.99) is much larger than its mean (16.36), suggesting overdispersion. Moreover, the fact that 18 counties (31.03%) have counts of 0 indicates zero-inflation in the data.

A map of California counties that shows their shigellosis counts would help visualize any spatial effects. You can generate such a map by using the following statements:

```
ods graphics on;
goptions reset=all border;
data ca;
   set maps.counties;
   where state = 6;
run;

proc sort data=ca out=ca;
   by county;
run;

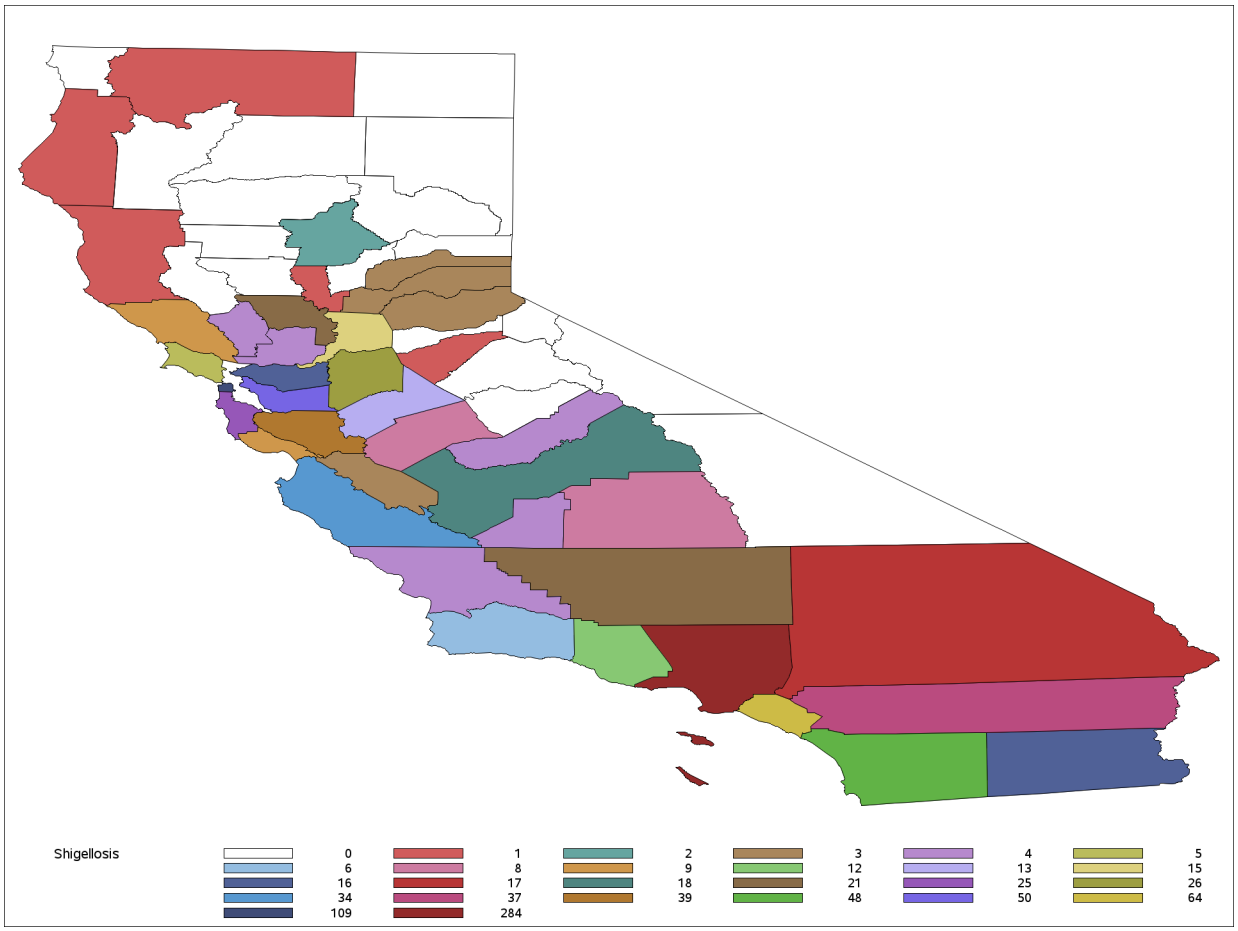
pattern value=mempty color=blue;
```

```
/* The COUNTY and COUNTIES data sets are unprojected */
/* Without the gproject procedure, you would get an inverse map */
proc gproject data=ca out=caproj;
   id state county;
run;

proc gmap map=caproj data=Shigdata all;
   id county;
   choro Shigellosis/discrete coutline=black;
run;
```

The map is shown in Output 11.4.2.

Output 11.4.2 California Map Showing Shigellosis Counts



The following statements fit a Poisson model with spatially weighted regressors:

```
proc countreg data=Shigdata Wmat=W;
   model Shigellosis = PopDensity BigHousehold / dist=poisson;
   spatialeffects PopDensity BigHousehold;
run;
```

The SPATIALEFFECTS statement accounts for spatial effects on regressors in the MODEL statement. Because there might be local spillovers in the two explanatory variables, PopDensity and BigHousehold, both

variables are included in the SPATIALEFFECTS statement. The data set W contains the spatial weights matrix. The model fit summary, convergence status, and parameter estimation results are shown in Output 11.4.3.

Output 11.4.3 Poisson Model with Spatially Weighted Regressors

The COUNTREG Procedure

Model Fit Summary	
Dependent Variable	Shigellosis
Number of Observations	58
Data Set	WORK.SHIGDATA
Model	Poisson
Log Likelihood	-450.76547
Maximum Absolute Gradient	3.81352E-8
Number of Iterations	5
Optimization Method	Newton-Raphson
AIC	911.53094
SBC	921.83315

Algorithm converged.

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	-3.801313	0.291041	-13.06	<.0001
PopDensity	1	0.257388	0.008752	29.41	<.0001
Bighousehold	1	0.147668	0.014902	9.91	<.0001
W_PopDensity	1	0.566756	0.032005	17.71	<.0001
W_Bighousehold	1	0.567433	0.026606	21.33	<.0001

As shown in the "Parameter Estimates" table, all estimates are significant at the 5% level. The spatially weighted regressors are labeled with the prefix "W_". Because of the likely overdispersion in the data, you might consider using a negative binomial model. The following statements fit a negative binomial model with spatially weighted regressors:

```
proc countreg data=Shigdata Wmat=W;
   model Shigellosis = PopDensity BigHousehold / dist=negbin;
   spatialeffects PopDensity BigHousehold;
run;
```

The model fit summary, convergence status, and parameter estimation results are listed in Output 11.4.4.

Output 11.4.4 Negative Binomial Model with Spatially Weighted Regressors

The COUNTREG Procedure

Model Fit Summary	
Dependent Variable	Shigellosis
Number of Observations	58
Data Set	WORK.SHIGDATA
Model	NegBin(p=2)
Log Likelihood	-165.09815
Maximum Absolute Gradient	3.89549E-8
Number of Iterations	6
Optimization Method	Newton-Raphson
AIC	342.19629
SBC	354.55895

Algorithm converged.

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	-2.296188	0.541472	-4.24	<.0001
PopDensity	1	0.293422	0.103991	2.82	0.0048
Bighousehold	1	0.200243	0.063505	3.15	0.0016
W_PopDensity	1	0.542599	0.178125	3.05	0.0023
W_Bighousehold	1	0.329966	0.089232	3.70	0.0002
_Alpha	1	1.029608	0.259475	3.97	<.0001

The AIC and SBC values in the "Model Fit Summary" table in Output 11.4.4 are both smaller than those in Output 11.4.3, indicating that the negative binomial model provides a better fit than the Poisson model. The parameter estimate for _Alpha is an estimate of the dispersion parameter in the negative binomial distribution. The null hypothesis that _Alpha is 0 can be tested against the alternative hypothesis that _Alpha is positive, by using the likelihood ratio test. The likelihood ratio test statistic is $-2(\mathcal{L}_P - \mathcal{L}_{NB}) = -2(-450.77 + 165.10) = 571.34$, where $\mathcal{L}_P$ and $\mathcal{L}_{NB}$ are the log likelihoods for the Poisson (null) and negative binomial (alternative) models, respectively. The likelihood ratio test is highly significant at the 5% level, providing strong evidence of overdispersion.

An alternative model to account for overdispersion is the Conway-Maxwell-Poisson (CMP) model, which uses dispersion regressors to model the parameter ν that controls the degree of dispersion. The following statements fit a CMP model that accounts for local spillovers in both model regressors and includes a DISPMODEL statement for the dispersion model:

```
proc countreg data=Shigdata Wmat=W;
   model Shigellosis =  PopDensity / dist=compoisson;
   spatialeffects PopDensity;
   dispmodel Shigellosis ~ Hispanic;
   spatialdispeffects Hispanic;
run;
```

The model fit summary, convergence status, and parameter estimation results are provided in Output 11.4.5.

Output 11.4.5 CMP Model with Spatially Weighted Regressors

The COUNTREG Procedure

Model Fit Summary	
Dependent Variable	Shigellosis
Number of Observations	58
Data Set	WORK.SHIGDATA
Model	CMPoisson
Parameterization	Mu
Log Likelihood	-175.88177
Maximum Absolute Gradient	6.7876E-10
Number of Iterations	21
Optimization Method	Newton-Raphson
AIC	363.76354
SBC	376.12620

Algorithm converged.

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	-16.687824	26.882100	-0.62	0.5347
PopDensity	1	0.965827	1.192338	0.81	0.4179
W_PopDensity	1	3.309434	4.352853	0.76	0.4471
Dsp_Intercept	1	1.715179	1.717222	1.00	0.3179
Dsp_Hispanic	1	0.036919	0.015175	2.43	0.0150
Dsp_W_Hispanic	1	0.068771	0.018894	3.64	0.0003

The regression coefficients in the DISPMODEL statement are labeled with the prefix "Dsp_", and their spatially weighted counterparts in the DISPSPATIALEFFECTS statement are labeled with the prefix "Dsp_W". Both coefficients—Dsp_Hispanic and Dsp_W_Hispanic—are significant at the 5% level. The AIC and SBC values in Output 11.4.5 are both slightly higher than those from the previous negative binomial model. Therefore, the negative binomial model with spatially weighted regressors provides the best fit thus far.

Because 31% of observations have counts of 0, you might consider a zero-inflated negative binomial (ZINB) model. The following statements fit a ZINB model with local spillovers in the model regressors, with a ZEROMODEL statement to model zero inflation:

```
proc countreg data=Shigdata Wmat=W;
   model Shigellosis = PopDensity BigHousehold / dist=ZINB;
   zeromodel Shigellosis ~  Hispanic;
   spatialeffects PopDensity BigHousehold;
   spatialzeroeffects Hispanic;
run;
```

The model fit summary, convergence status, and parameter estimation results are shown in Output 11.4.6.

Output 11.4.6 ZINB Model with Spatially Weighted Regressors

The COUNTREG Procedure

Model Fit Summary	
Dependent Variable	Shigellosis
Number of Observations	58

Overview: DATASOURCE Procedure

The DATASOURCE procedure extracts time series and event data from many different kinds of data files distributed by various data vendors and stores them in a SAS data set. Once stored in a SAS data set, the time series and event variables can be processed by other SAS procedures.

The DATASOURCE procedure has statements and options to extract only a subset of time series data from an input data file. It gives you control over the frequency of data to be extracted, time series variables to be selected, cross sections to be included, and time range of data to be output.

The DATASOURCE procedure can create auxiliary data sets containing descriptive information on the time series variables and cross sections. More specifically, the OUTCONT= option names a data set containing information on time series variables, the OUTBY= option names a data set that reports information on cross-sectional variables, and the OUTALL= option names a data set that combines both time series variables and cross-sectional information.

In addition to the auxiliary data sets, two types of primary output data sets are the OUT= and OUTEVENT= data sets. The OUTEVENT= data set contains event variables but excludes periodic time series data. The OUT= data set contains periodic time series data and any event variables referenced in the KEEP statement.

The output variables in the output and auxiliary data sets can be assigned various attributes by the DATASOURCE procedure. These attributes are labels, formats, new names, and lengths. While the first three attributes in this list are used to enhance the output, the length attribute is used to control the memory and disk-space usage of the DATASOURCE procedure.

Data files currently supported by the DATASOURCE procedure include the following:

- U.S. Bureau of Economic Analysis data files
  - National Income and Product Accounts
  - National Income and Product Accounts PC format
  - S-pages
- U.S. Bureau of Labor Statistics data files
  - Consumer Price Index Surveys

  - Producer Price Index Survey
  - National Employment, Hours, and Earnings Survey
  - State and Area Employment, Hours, and Earnings Survey

- Standard & Poor's Compustat Services Financial Database Files
  - COMPUSTAT Annual
  - COMPUSTAT 48 Quarter
  - COMPUSTAT Full Coverage Annual
  - COMPUSTAT Full Coverage 48 Quarter

- Center for Research in Security Prices (CRSP) data files
  - Daily Binary Format Files
  - Monthly Binary Format Files
  - Daily Character Format Files
  - Monthly Character Format Files

- Global Insight, formerly DRI/McGraw-Hill data files
  - Basic Economics Data (formerly CITIBASE)

  - Balance of Payment Statistics
  - Government Finance Statistics

- Organization for Economic Cooperation and Development
  - Annual National Accounts
  - Quarterly National Accounts
  - Main Economic Indicators

Getting Started: DATASOURCE Procedure

Structure of a SAS Data Set Containing Time Series Data

SAS procedures require time series data to be in a specific form recognizable by the SAS System. This form is a two-dimensional array, called a SAS data set, whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain time periods.

The time periods at which observations are recorded can be included in the data set as a time ID variable. The DATASOURCE procedure does include a time ID variable by the name of DATE.

For example, the data set in Table 12.1, extracted from a DRIBASIC data file, gives the foreign exchange rates for Japan, Switzerland, and the United Kingdom, respectively.

Table 12.1 The Form of SAS Data Sets Required by Most SAS/ETS Procedures

Time ID Variable	**Time Series Variables**		
DATE	EXRJAN	EXRSW	EXRUK
SEP1987	143.290	1.50290	164.460
OCT1987	143.320	1.49400	166.200
NOV1987	135.400	1.38250	177.540
DEC1987	128.240	1.33040	182.880
JAN1988	127.690	1.34660	180.090
FEB1988	129.170	1.39160	175.820

Reading Data Files

The DATASOURCE procedure is designed to read data from many different files and to place them in a SAS data set. For example, if you have a DRI Basic Economics data file you want to read, use the following statements:

```
proc datasource filetype=dribasic infile=citifile out=dataset;
run;
```

Here, the FILETYPE= option indicates that you want to read DRI's Basic Economics data file, the INFILE= option specifies the fileref CITIFILE of the external file you want to read, and the OUT= option names the SAS data set to contain the time series data.

Subsetting Input Data Files

When only a subset of a data file is needed, it is inefficient to extract all the data and then subset it in a subsequent DATA step. Instead, you can use the DATASOURCE procedure options and statements to extract only needed information from the data file.

The DATASOURCE procedure offers the following subsetting capabilities:

- the INTERVAL= option controls the frequency of data output
- the KEEP or DROP statement selects a subset of time series variables
- the RANGE statement restricts the time range of data
- the WHERE statement selects a subset of cross sections

Controlling the Frequency of Data: The INTERVAL= Option

The OUT= data set contains only data with the same frequency. If the data file you want to read contains time series data with several frequencies, you can indicate the frequency of data you want to extract with the INTERVAL= option. For example, the following statements extract all monthly time series from the DRIBASIC file CITIFILE:

```
proc datasource filetype=dribasic infile=citifile
                interval=month  out=dataset;
run;
```

When the INTERVAL= option is not given, the default frequency defined for the FILETYPE= type file is used. For example, the statements in the previous section extract yearly series since INTERVAL=YEAR is the default frequency for DRI's Basic Economic Data files.

To extract data for several frequencies, you need to execute the DATASOURCE procedure once for each frequency.

Selecting Time Series Variables: The KEEP and DROP Statements

If you want to include specific series in the OUT= data set, list them in a KEEP statement. If, on the other hand, you want to exclude some variables from the OUT= data set, list them in a DROP statement. For example, the following statements extract monthly foreign exchange rates for Japan (EXRJAN), Switzerland (EXRSW), and the United Kingdom (EXRUK) from a DRIBASIC file CITIFILE:

```
proc datasource filetype=dribasic infile=citifile
                interval=month  out=dataset;
   keep  exrjan exrsw exruk;
run;
```

The KEEP statement also allows input names to be quoted strings. If the name of a series in the input file contains blanks or special characters that are not valid SAS name syntax, put the series name in quotes to select it. Another way to allow the use of special characters in your SAS variable names is to use the SAS options statement to designate VALIDVARNAME=ANY. This option will allow PROC DATASOURCE to include special characters in your SAS variable names. The following is an example of extracting series from a FAME database by using the DATASOURCE procedure:

```
proc datasource filetype=fame dbname='fame_nys /disk1/prc/prc'
                interval=weekday out=outds outcont=attrds;
   range '1jan90'd to '1feb90'd;
   keep cci.close
        '{ibm.high,ibm.low,ibm.close}'
        'mave(ibm.close,30)'
        'crosslist({gm,f,c},{volume})'
        'cci.close+ibm.close';
   rename 'mave(ibm.close,30)' = ibm30day
          'cci.close+ibm.close' = cci_ibm;
run;
```

The resulting output data set OUTDS contains the following series: DATE, CCI_CLOS, IBM_HIGH, IBM_LOW, IBM_CLOS, IBM30DAY, GM_VOLUM, F_VOLUME, C_VOLUME, CCI_IBM.

Obviously, to be able to use KEEP and DROP statements, you need to know the name of time series variables available in the data file. The OUTCONT= option gives you this information. More specifically, the OUTCONT= option creates a data set containing descriptive information on the same frequency time series. This descriptive information includes series names, a flag indicating if the series is selected for output, series variable types, lengths, position of series in the OUT= data set, labels, format names, format lengths, format decimals, and a set of FILETYPE= specific descriptor variables.

For example, the following statements list some of the monthly series available in the CITIFILE and are shown in Figure 12.1:

```
/*-- Selecting Time Series Variables -- The KEEP and DROP Statements --*/

Controlling the Time Range of Data: The RANGE Statement

The RANGE statement is used to control the time range of observations included in the output data set. Figure 12.2 shows an example extracting the foreign exchange rates from September 1985 to February 1987. You can use the following statements:

```
/*-- Controlling the Time Range of Data - The RANGE Statement --*/
filename citifile "%sysget(DATASRC_DATA)citiaf.dat" RECFM=F LRECL=80;
proc datasource filetype=dribasic infile=citifile
                interval=month  out=dataset;
   keep  exrjan exrsw exruk;
   range from 1985:9 to 1987:2;
run;

title1 'Printout of the OUT= Data Set';
proc print data=dataset;
run;
```

Reading in Data Files Containing Cross Sections

Some data files group time series data with respect to cross-section identifiers; for example, International Financial Statistics files, distributed by IMF, group data with respect to countries (COUNTRY). Within each country, data are further grouped by Control Source Code (CSC), Partner Country Code (PARTNER), and Version Code (VERSION).

If a data file contains cross-section identifiers, the DATASOURCE procedure adds them to the output data set as BY variables. For example, the data set in Table 12.2 contains three cross sections:

- Cross-section one is identified by (COUNTRY='112' CSC='F' PARTNER=' ' VERSION='Z').
- Cross-section two is identified by (COUNTRY='146' CSC='F' PARTNER=' ' VERSION='Z').
- Cross-section three is identified by (COUNTRY='158' CSC='F' PARTNER=' ' VERSION='Z').

Table 12.2 The Form of a SAS Data Set Containing BY Variables

BY Variables				**Time ID Variable**	**Time Series Variables**	
COUNTRY	CSC	PARTNER	VERSION	DATE	EFFEXR	EXRINDEX
112	F		Z	SEP1987	9326	12685
112	F		Z	OCT1987	9393	12813
112	F		Z	NOV1987	9626	13694
112	F		Z	DEC1987	9675	14099
112	F		Z	JAN1988	9581	13910
112	F		Z	FEB1988	9493	13549
146	F		Z	SEP1987	12046	16192
146	F		Z	OCT1987	12067	16266
146	F		Z	NOV1987	12558	17596
146	F		Z	DEC1987	12759	18301
146	F		Z	JAN1988	12642	18082
146	F		Z	FEB1988	12409	17470
158	F		Z	SEP1987	13841	16558
158	F		Z	OCT1987	13754	16499
158	F		Z	NOV1987	14222	17505
158	F		Z	DEC1987	14768	18423
158	F		Z	JAN1988	14933	18565
158	F		Z	FEB1988	14915	18331

Note that the data sets in Table 12.1 and Table 12.2 use two different ways of representing time series data for three different countries: the United Kingdom (COUNTRY='112'), Switzerland (COUNTRY='146'), and Japan (COUNTRY='158'). The first representation (Table 12.1) incorporates each country's name into the series names, while the second representation (Table 12.2) represents countries as different cross sections

by using the BY variable named COUNTRY. See the section "Time Series and SAS Data Sets" in Chapter 3, "Working with Time Series Data."

Obtaining Descriptive Information on Cross Sections

If you want to know the unique set of values BY variables assume for each cross section in the data file, use the OUTBY= option. For example, the following statements list some of the cross sections available for an IFS file, and are shown in Figure 12.3:

```
filename ifsfile "%sysget(DATASRC_DATA)imfifs1.dat" RECFM=F LRECL=88;
proc datasource
   filetype=imfifsp infile=ifsfile
   outselect=on ebcdic
   interval=month
   outby=xsection;
run;

title1 'Some Cross Sections Available in IFSFILE';
proc print data=xsection;
run;
```

Figure 12.3 Listing of the OUTBY= Data Set

Some Cross Sections Available in IFSFILE

Obs	COUNTRY	CSC	PARTNER	VERSION	ST_DATE	END_DATE	NTIME	NOBS	NSERIES	NSELECT	CNTYNAME
1	111	F		Z	JAN1957	SEP1986	357	357	6	3	UNITED STATES
2	112	F		Z	JAN1957	SEP1986	357	357	6	3	UNITED KINGDOM
3	146	F		Z	JAN1957	SEP1986	357	357	6	3	SWITZERLAND
4	158	F		Z	JAN1957	SEP1986	357	357	6	3	JAPAN
5	186	F		Z	JAN1957	SEP1986	357	357	6	3	TURKEY

The OUTBY= data set reports the total number of series, NSERIES, defined in each cross section, NSELECT of which represent the selected variables. If you want to see the descriptive information on each of these NSELECT variables for each cross section, specify the OUTALL= option. For example, the following statements print descriptive information on all monthly series defined for all cross sections (COUNTRY='111', COUNTRY='112', COUNTRY='146', COUNTRY='158', and COUNTRY='186'), which are shown in Figure 12.4:

```
filename datafile "%sysget(DATASRC_DATA)imfifs1.dat" RECFM=F LRECL=88;

title3 'Time Series Defined in Cross Section';
proc datasource filetype=imfifsp
   outselect=on ebcdic
   interval=month
   outall=ifsall;
run;

title4 'Cross Sections Available in OUTALL=IFSALL Data Set';
proc print
   data=ifsall;
run;
```

The OUTCONT= data set contains one observation for each time series variable with the descriptive information summarized over BY groups. When the data file contains no cross sections, the OUTCONT= and OUTALL= data sets are equivalent, except that the OUTALL= data set also reports time ranges of available

data. The OUTBY= data set in this case contains a single observation reporting the number of series and time ranges for the whole data file.

Subsetting a Data File Containing Cross Sections

Data files containing cross sections can be subsetted by controlling which cross sections to include in the output data set. Selecting a subset of cross sections is accomplished using the WHERE statement. The WHERE statement gives a condition that the BY variables must satisfy for a cross section to be selected. For example, the following statements extract the monthly market rate conversion factors for the United Kingdom (COUNTRY='112') and Switzerland (COUNTRY='146') for the period from September 1985 to February 1986:

```
filename datafile "%sysget(DATASRC_DATA)imfifs1.dat" RECFM=F LRECL=88;

title3 'Time Series Defined in Selected Cross Sections';
proc datasource filetype=imfifsp
   outselect=on ebcdic
   interval=month
   out=ifs;

   where country in ('146', '112') and partner=' ';
   keep F___AA F___AC;
   range from '01sep85'd to '01feb86'd;
run;

title4 'OUTALL=IFS Data Set';
proc print
   data=ifs;
run;
```

Renaming Time Series Variables

Sometimes the time series variable names as given by data vendors are not descriptive enough, or you might prefer a different naming convention. In such cases, you can use the RENAME statement to assign more meaningful names to time series variables. You can also use LABEL statements to associate descriptive labels with your series variables.

For example, the series names for market rate conversion factor (F___AA) and market rate conversion factor (F___AC) used by IMF can be given more descriptive names and labels by the following statements and are shown in Figure 12.5 and Figure 12.6.

```
filename ifsfile "%sysget(DATASRC_DATA)imfifs1.dat" RECFM=F LRECL=88;

proc datasource filetype=imfifsp infile=ifsfile
                interval=month
                out=market outcont=mrktvars;
   where country in ('112','146','158') and partner=' ';
   keep  f___aa f___ac;
   range from '01jun85'd to '01feb86'd;
```

```
   rename  f___aa=alphmkt  f___ac=charmkt;
   label   f___aa='F___AA: Market Rate Conversion Factor Used in Alpha Test'
           f___ac='F___AC: Market Rate Conversion Used in Charlie Test';
run;

title1 'Printout of OUTCONT= Showing New NAMEs and LABELs';
proc print data=mrktvars ;
   var  name label length;
run;

title1 'Contents of OUT= Showing New NAMEs and LABELs';
proc contents data=market;
run;
```

The RENAME statement allows input names to be quoted strings. If the name of a series in the input file contains blanks or special characters that are not in valid SAS name syntax, use the SAS option VALIDVARNAME=ANY or put the series name in quotes to rename it. See the FAME example using the RENAME statement in the section "Selecting Time Series Variables: The KEEP and DROP Statements" on page 690.

Figure 12.5 Renaming and Labeling Variables

Printout of OUTCONT= Showing New NAMEs and LABELs

Obs	NAME	LABEL	LENGTH
1	alphmkt	F___AA: Market Rate Conversion Factor Used in Alpha Test	5
2	charmkt	F___AC: Market Rate Conversion Used in Charlie Test	5

Figure 12.6 Renaming and Labeling Variables

Alphabetic List of Variables and Attributes

#	Variable	Type	Len	Format	Label
1	COUNTRY	Char	3		COUNTRY CODE
2	CSC	Char	1		CONTROL SOURCE CODE
5	DATE	Num	4	MONYY7.	Date of Observation
3	PARTNER	Char	3		PARTNER COUNTRY CODE
4	VERSION	Char	1		VERSION CODE
6	alphmkt	Num	5		F___AA: Market Rate Conversion Factor Used in Alpha Test
7	charmkt	Num	5		F___AC: Market Rate Conversion Used in Charlie Test

Notice that even though you changed the names of F___AA and F___AC to alphmkt and charmkt, respectively, you still use their old names in the KEEP and LABEL statements because renaming takes place at the output stage.

Changing the Lengths of Numeric Variables

The length attribute indicates the number of bytes the SAS System uses for storing the values of variables in output data sets. Therefore, the shorter the variable lengths, the more efficient the disk-space usage. However, there is a trade-off. The lengths of numeric variables are closely tied to their precision, and reducing their lengths arbitrarily can cause precision loss.

The DATASOURCE procedure uses default lengths for series variables appropriate to each file type. For example, the default lengths for numeric variables are 5 for IMFIFSP type files. In some cases, however, you might want to assign different lengths. Assigning lengths less than the defaults reduces memory and disk-space usage at the expense of precision. Specifying lengths longer than the defaults increases the precision but causes the DATASOURCE procedure to use more memory and disk space. The following statements define a default length of 4 for all numeric variables in the IFSFILE and then assign a length of 6 to the exchange rate index. Output is shown in Figure 12.7 and Figure 12.8.

```
filename ifsfile "%sysget(DATASRC_DATA)imfifs1.dat" RECFM=F LRECL=88;

proc datasource filetype=imfifsp infile=ifsfile
                interval=month
                out=market outcont=mrktvars;
   where country in ('112','146','158') and partner=' ';
   keep  f___aa f___ac;
   range from '01jun85'd to '01feb86'd;
   rename  f___aa=alphmkt  f___ac=charmkt;
   label   f___aa='F___AA: Market Rate Conversion Factor Used in Alpha Test'
           f___ac='F___AC: Market Rate Conversion Used in Charlie Test';
   length _numeric_ 4;
   length f___aa 6;
run;

title1 'Printout of OUTCONT= Showing New NAMEs and LABELs';
proc print data=mrktvars ;
   var  name label length;
run;

title1 'Contents of OUT= Showing New NAMEs and LABELs';
proc contents data=market;
run;
```

Figure 12.7 Changing the Lengths of Numeric Variables

Printout of OUTCONT= Showing New NAMEs and LABELs

Obs	NAME	LABEL	LENGTH
1	alphmkt	F___AA: Market Rate Conversion Factor Used in Alpha Test	6
2	charmkt	F___AC: Market Rate Conversion Used in Charlie Test	4

Figure 12.8 Changing the Lengths of Numeric Variables

Alphabetic List of Variables and Attributes					
#	Variable	Type	Len	Format	Label
1	COUNTRY	Char	3		COUNTRY CODE
2	CSC	Char	1		CONTROL SOURCE CODE
5	DATE	Num	4	MONYY7.	Date of Observation

6	alphmkt	Num	6		F___AA: Market Rate Conversion Factor Used in Alpha Test
7	charmkt	Num	4		F___AC: Market Rate Conversion Used in Charlie Test

The default lengths of the character variables are set to the minimum number of characters that can hold the longest possible value.

Syntax: DATASOURCE Procedure

The following statements are available in the DATASOURCE procedure:

PROC DATASOURCE *options* ;
  KEEP *variable-list* ;
  DROP *variable-list* ;
  KEEPEVENT *variable-list* ;
  DROPEVENT *variable-list* ;
  WHERE *where-expression* ;
  RANGE FROM *from* **TO** *to* ;
  ATTRIBUTE *variable-list attribute-list . . .* ;
  FORMAT *variable-list format . . .* ;
  LABEL *variable="label" . . .* ;
  LENGTH *variable-list length . . .* ;
  RENAME *old-name=new-name . . .* ;

The PROC DATASOURCE statement is required. All the rest of the statements are optional.

The DATASOURCE procedure uses two kinds of statements, subsetting statements and attribute statements. Subsetting statements provide selection of time series data over selected time periods and cross sections from the input data file. Attribute statements control the attributes of the variables in the output SAS data set.

The subsetting statements are the KEEP, DROP, KEEPEVENT, and DROPEVENT statements (which select output variables); the RANGE statement (which selects time ranges); and the WHERE statement (which selects cross sections). The attribute statements are the ATTRIBUTE, FORMAT, LABEL, LENGTH, and RENAME statements.

The statements and options used by PROC DATASOURCE are summarized in Table 12.3. The rest of this section provides detailed syntax information about each of these statements, beginning with the PROC DATASOURCE statement. The remaining statements are described in alphabetical order.

Table 12.3 Functional Summary

Option	Description
Input Data File Options	
FILETYPE=	Type of input data file to read
INFILE=	Filerefs of the input data
LRECL=	LRECLs of the input data
RECFM=	RECFMs of the input data
ASCII	Character set of the incoming data
EBCDIC	Character set of the incoming data
Output Data Set Options	
OUT=	Write the extracted time series data
OUTALL=	Information on time series and cross sections
OUTBY=	Information on only cross sections
OUTCONT=	Information on only time series variables
OUTEVENT=	Write event-oriented data
OUTSELECT=	Control reporting of all or only selected series and cross sections
INDEX	Create single indexes from BY variables for the OUT= data set
ALIGN=	Control the alignment of SAS date values
Subsetting Option and Statements	
INTERVAL=	Select periodicity of series to extract
KEEP	Time series to include in the OUT= data set
DROP	Time series to exclude from the OUT= data set
KEEPEVENT	Events to include in the OUTEVENT= data set
DROPEVENT	Events to exclude from the OUTEVENT= data set
WHERE	Select cross sections for output
RANGE	Time range of observations to be output
Assigning Attributes Options and Statements	
FORMAT	Assign formats to variables in the output data sets
ATTRIBUTE FORMAT=	Assign formats to variables in the output data sets
LABEL	Assign labels to variables in the output data sets
ATTRIBUTE LABEL=	Assign labels to variables in the output data sets
LENGTH	Control the lengths of variables in the output data sets
ATTRIBUTE LENGTH=	Control the lengths of variables in the output data sets
RENAME	Assign new names to variables in the output data sets

PROC DATASOURCE Statement

PROC DATASOURCE *options* **;**

The PROC DATASOURCE statement invokes the DOCSAMPLE procedure. You can specify the following *options*:

ALIGN=*option*
controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. BEGINNING is the default.

ASCII
specifies the incoming data is ASCII. This option is used when the native character set of your host machine is EBCDIC.

DBNAME='*database name***'**
specifies the FAME database to access. Only use this option with the FILETYPE=FAME option. The character string you specify in the DBNAME= option is passed through to FAME. Specify the value of this option as you would in accessing the database from within FAME software.

EBCDIC
specifies the incoming data is ebcdic. This option is needed when the native character set of your host machine is ASCII.

FAMEPRINT
prints the FAME command file generated by PROC DATASOURCE and the log file produced by the FAME component of the interface system. Only use this option with the FILETYPE=FAME option.

FILETYPE=*entry*

DBTYPE=*dbtype*
specifies the kind of input data file to process. For a list of supported file types, see the section "Data Elements Reference: DATASOURCE Procedure" on page 717. The FILETYPE= option is required.

INDEX
creates a set of single indexes from BY variables for the OUT= data set. Under some circumstances, creating indexes for a SAS data set might increase the efficiency in locating observations when BY or WHERE statements are used in subsequent steps. For more information about SAS indexes, see *SAS Programmers Guide: Essentials*. The INDEX option is ignored when no OUT= data set is created or when the data file does not contain any BY variables. The INDEX= data set option can be used to override the index variable definitions.

INFILE=*fileref*

INFILE=*(fileref1 fileref2 . . . filerefn)*
specifies the fileref assigned to the input data file. The default value is DATAFILE. The *fileref* (or if no INFILE= option is specified, the fileref DATAFILE) must be associated with the physical data file in a FILENAME statement. (On some operating systems, the fileref assignment can be made with the system's control language, and a FILENAME statement might not be needed. For more information about the FILENAME statement, see *SAS Global Statements: Reference*. Physical data files can reside on DVD, CD-ROM, or other media.

For some file types, the data are distributed over several files. In this case, the INFILE= option is required, and it lists in parentheses the *filerefs* for each of the files that make up the database. The order in which these *filerefs* are listed is important and must conform to the specifics of each file type as explained in the section "Data Elements Reference: DATASOURCE Procedure" on page 717.

LRECL=*lrecl*

LRECL=*(lrecl1 lrecl2 . . . lrecln)*

specifies the logical record length in bytes of the infile. Use this option only if you need to override the default LRECL of the file. For some file types, the data are distributed over several files. In this case, the LRECL= option lists in parentheses the *lrecls* for each of the files that make up the database. The order in which these *lrecls* are listed is important and must conform to the specifics of each file type as explained in the section "Data Elements Reference: DATASOURCE Procedure" on page 717.

RECFM=*recfm*

RECFM=*(recfm1 recfm2 . . . recfmn)*

specifies the record format of the infile. Use this option only if you need to override the default record format of the file. For some file types, the data are distributed over several files. In this case, the RECFM= option lists in parentheses the *recfms* for each of the files making up the database. The order in which these *recfms* are listed is important and must conform to the specifics of each file type as explained in the section "Data Elements Reference: DATASOURCE Procedure" on page 717. The possible values of RECFM are as follows:

- F or FIXED for fixed length records
- N or BIN for binary records
- D or VAR for varying length records
- U or DEF for host default record format
- DOM_V or DOMAIN_VAR or BIN_V or BIN_VAR for UNIX binary record format

INTERVAL=*interval*

FREQUENCY=*interval*

TYPE=*interval*

specifies the periodicity of series selected for output to the OUT= data set. The OUT= data set created by PROC DATASOURCE can contain only time series with the same periodicity. Some data files contain time series with different periodicities; for example, a file can contain both monthly series and quarterly series. Use the INTERVAL= option to indicate which periodicity you want. If you want to extract series with different periodicities, use different PROC DATASOURCE invocations with the desired INTERVAL= options.

Common values for INTERVAL= are YEAR, QUARTER, MONTH, WEEK, and DAY. The values allowed, as well as the default value of the INTERVAL= option, depend on the file type. For the INTERVAL= values appropriate to the data file type you are reading, see the section "Data Elements Reference: DATASOURCE Procedure" on page 717.

OUT=*SAS-data-set*
names the output data set for the time series extracted from the data file. If none of the output data set options are specified, including the OUT= data set itself, an OUT= data set is created and named according to the DATA*n* convention. However, when you create any of the other output data sets, such as OUTCONT=, OUTBY=, OUTALL=, or OUTEVENT=, you must explicitly specify the OUT= data set; otherwise, it will not be created. For more information, see the section "OUT= Data Set" on page 712.

OUTALL=*SAS-data-set*
writes information on the contents of the input data file to an output data set. The OUTALL= data set includes descriptive information, time ranges, and observation counts for all the time series within each BY group. By default, no OUTALL= data set is created.

The OUTALL= data set contains the Cartesian product of the information output by the OUTCONT= and OUTBY= options. In data files for which there are no cross sections, the OUTALL= and OUTCONT= data sets are almost equivalent, except that OUTALL= data set also reports time ranges and observation counts of series. For more information, see the section "OUTALL= Data Set" on page 715.

OUTBY=*SAS-data-set*
writes information on the BY variables to an output data set. The OUTBY= data set contains the list of cross sections in the database delimited by the unique set of values that the BY variables assume. Unless the OUTSELECT=OFF option is present, only the selected BY groups are written to the OUTBY= data set. If you omit the OUTBY= option, no OUTBY= data set is created. For more information, see the section "OUTBY= Data Set" on page 714.

OUTCONT=*SAS-data-set*
writes information on the contents of the input data file to an output data set. By default, the OUTCONT= data set includes descriptive information on all of the unique series of the selected periodicity in the data file. When the OUTSELECT=OFF option is omitted, the OUTCONT= data set includes observations only for the series selected for output to the OUT= data set. By default, no OUTCONT= data set is created. For more information, see the section "OUTCONT= Data Set" on page 713.

OUTEVENT=*SAS-data-set*
names the output data set to output event-oriented time series data. This option can only be used when CRSP stock files are being processed. For all other file types, it will be ignored. For more information, see the section "OUTEVENT= Data Set" on page 716.

OUTSELECT=ON | OFF
determines whether to output all observations (OUTSELECT=OFF) or only those corresponding to the selected time series and selected BY groups (OUTSELECT=ON) to OUTCONT=, OUTBY=, and OUTALL= data sets. The default is OUTSELECT=ON. The OUTSELECT= option is only relevant when any one of the auxiliary data sets is specified. The option writes observations to OUTCONT=, OUTBY=, and OUTALL= data sets for only the selected time series and selected BY groups if it is set ON. The OUTSELECT= option is only relevant when any one of the OUTCONT=, OUTBY=, and OUTALL= options is specified. The default is OUTSELECT=ON.

ATTRIBUTE Statement

ATTRIBUTE *variable-list attribute-list . . .* **;**

The ATTRIBUTE statement assigns formats, labels, and lengths to variables in the output data sets.

The *variable-list* can contain variable names and variable name range specifications. For more information, see the section "Variable Lists" on page 711. The attributes specified in the following attribute list apply to all variables in the variable list.

An *attribute-list* consists of one or more of the following options:

FORMAT=*format*
: associates a format with variables in *variable-list*. The *format* can be either a standard SAS format or a format defined with the FORMAT procedure. The default formats for variables depend on the file type.

LABEL=*"label"*
: assigns a label to the variables in the variable list. The default labels for variables depend on the file type. Labels can be up to 256 bytes in length.

LENGTH=*length*
: specifies the number of bytes used to store the values of variables in the variable list. The default lengths for numeric variables depend on the file type. Usually default lengths are set to 5 bytes.

  The length specification also controls the amount of memory that PROC DATASOURCE uses to hold variable values while processing the input data file. Thus, specifying a LENGTH= value smaller than the default will reduce both the disk space taken up by the output data sets and the amount of memory used by the PROC DATASOURCE step, at the cost of precision of output data values.

DROP Statement

DROP *variable-list* **;**

The DROP statement specifies that some variables be excluded from the OUT= data set. Only the time series and event variables can be specified in a DROP statement. None of the BY variables or the time ID variable DATE can be excluded from the OUT= data set. If they are referenced in a DROP statement, a warning message is given and the reference is ignored. Use the WHERE statement for selection based on BY variables, and use the RANGE statement for date selections.

The variable list can contain variable names or name range specifications. For more information, see the section "Variable Lists" on page 711.

Only one DROP or one KEEP statement can be used. KEEP and DROP are mutually exclusive.

There is a default DROP or KEEP list for each file type. Usually, descriptor type variables, like footnotes, are not included in the default KEEP list. If you specify a DROP statement, the default list becomes undefined.

You can also use the DROP= data set option to control which variables to exclude from the OUT= data set. However, the DROP statement differs from the DROP= data set option in several aspects:

- The DROP statement selection is applied before variables are read from the data file, while the DROP= data set option selection is applied after variables are read and as they are written to the OUT= data set. Therefore, using the DROP statement instead of the DROP= data set option is much more efficient.
- If the DROP statement causes all series variables to be excluded, then no observations are output to the OUT= data set.
- The DROP statement variable specifications are applied to each cross section independently. This behavior might produce variables different from those produced by the DROP= data set option when order-range variable list specifications are used.

DROPEVENT Statement

DROPEVENT *variable-list* **;**

The DROPEVENT statement specifies that some event variables be excluded from the OUTEVENT= data set. As a result, the DROPEVENT statement is valid only for data files containing event-oriented time series data. All the BY variables, the time ID variable DATE, and the event-grouping variable EVENT are always included in the OUTEVENT= data set. These variables cannot be referenced in the DROPEVENT statement. If any of these variables are referenced, a warning message is given and the reference is ignored.

The *variable-list* can contain variable names or name range specifications. For more information, see the section "Variable Lists" on page 711.

Only one DROPEVENT or one KEEPEVENT statement can be used. DROPEVENT and KEEPEVENT are mutually exclusive.

You can also use the DROP= data set option to control which event variables to exclude from the OUTEVENT= data set. However, the DROPEVENT statement differs from the DROP= data set option in several respects:

- The DROPEVENT statement selection is applied before variables are read from the data file, while the DROP= data set option selection is applied after variables are read and as they are written to the OUTEVENT= data set. Therefore, using the DROPEVENT statement instead of the DROP= data set option is much more efficient.
- If the DROPEVENT statement causes all series variables to be excluded, then no observations are output to the OUTEVENT= data set.

FORMAT Statement

FORMAT *variable-list format . . .* **;**

The FORMAT statement assigns formats to variables in output data sets. The *variable-list* can contain variable names and variable name range specifications. For more information, see the section "Variable Lists" on page 711. The format specified applies to all variables in the variable list.

A single FORMAT statement can assign the same format to several variables or different formats to different variables. The FORMAT statement can use standard SAS formats or formats defined using the FORMAT procedure.

Any later format specification for a variable, using either the FORMAT statement or the FORMAT= option in the ATTRIBUTE statement, always overrides the previous one.

KEEP Statement

KEEP *variable-list* **;**

The KEEP statement specifies which variables in the data file are to be included in the OUT= data set. Only the time series and event variables can be specified in a KEEP statement. All the BY variables and the time ID variable DATE are always included in the OUT= data set; they cannot be referenced in a KEEP statement. If they are referenced, a warning message is given and the reference is ignored.

The *variable-list* can contain variable names or name range specifications. For more information, see the section "Variable Lists" on page 711.

There is a default KEEP list for each file type. Usually, descriptor type variables, like footnotes, are not included in the default KEEP list. If you give a KEEP statement, the default list becomes undefined.

Only one KEEP or one DROP statement can be used. KEEP and DROP are mutually exclusive.

You can also use the KEEP= data set option to control which variables to include in the OUT= data set. However, the KEEP statement differs from the KEEP= data set option in several respects:

- The KEEP statement selection is applied before variables are read from the data file, while the KEEP= data set option selection is applied after variables are read and as they are written to the OUT= data set. Therefore, using the KEEP statement instead of the KEEP= data set option is much more efficient.
- If the KEEP statement causes no series variables to be selected, then no observations are output to the OUT= data set.
- The KEEP statement variable specifications are applied to each cross section independently. This behavior might produce variables different from those produced by the KEEP= data set option when order-range variable list specifications are used.

KEEPEVENT Statement

KEEPEVENT *variable-list* **;**

The KEEPEVENT statement specifies which event variables in the data file are to be included in the OUTEVENT= data set. As a result, the KEEPEVENT statement is valid only for data files containing event-oriented time series data. All the BY variables, the time ID variable DATE, and the event-grouping variable EVENT are always included in the OUTEVENT= data set. These variables cannot be referenced in the KEEPEVENT statement. If any of these variables are referenced, a warning message is given and the reference is ignored.

The *variable-list* can contain variable names or name range specifications. For more information, see the section "Variable Lists" on page 711.

Only one KEEPEVENT or one DROPEVENT statement can be used. KEEPEVENT and DROPEVENT are mutually exclusive.

You can also use the KEEP= data set option to control which event variables to include in the OUTEVENT= data set. However, the KEEPEVENT statement differs from the KEEP= data set option in several respects:

- The KEEPEVENT statement selection is applied before variables are read from the data file, while the KEEP= data set option selection is applied after variables are read and as they are written to the OUTEVENT= data set. Therefore, using the KEEPEVENT statement instead of the KEEP= data set option is much more efficient.
- If the KEEPEVENT statement causes no event variables to be selected, then no observations are output to the OUTEVENT= data set.

LABEL Statement

LABEL *variable = "label" . . .* **;**

The LABEL statement assigns SAS variable labels to variables in the output data sets. You can give labels for any number of variables in a single LABEL statement. The default labels for variables depend on the file type. Extra-long labels (> 256 bytes) reside in the OUTCONT= data set as the DESCRIPT variable.

Any later label specification for a variable, using either the LABEL statement or the LABEL= option in the ATTRIBUTE statement, always overrides the previous one.

LENGTH Statement

LENGTH *variable-list length . . .* **;**

The LENGTH statement, like the LENGTH= option in the ATTRIBUTE statement, specifies the number of bytes used to store values of variables in output data sets. The default lengths for numeric variables depend on the file type. Usually default lengths are set to 5 bytes.

The default lengths of character variables are defined as the minimum number of characters that can hold the longest possible value.

For some file types, the LENGTH statement also controls the amount of memory used to store values of numeric variables while processing the input data file. Thus, specifying LENGTH values smaller than the default will reduce both the disk space taken up by the output data sets and the amount of memory used by the PROC DATASOURCE step, at the cost of precision of output data values.

Any later length specification for a variable, using either the LENGTH statement or the LENGTH= option in the ATTRIBUTE statement, always overrides the previous one.

RANGE Statement

RANGE FROM *from* **TO** *to* **;**

The RANGE statement selects the time range of observations written to the OUT= and OUTEVENT= data sets. The *from* and *to* values can be SAS date, time, or datetime constants, or they can be specified as *year* or *year* **:** *period*, where *year* is a two-digit or four-digit year, and *period* (when specified) is a period within the year corresponding to the INTERVAL= option. (For example, if INTERVAL=QTR, then *period* refers to quarters.) When *period* is omitted, the beginning of the year is assumed for the *from* value, and the end of the year is assumed for the *to* value.

If a two-digit year is specified, PROC DATASOURCE uses the current value of the YEARCUTOFF option to determine the century of your data. Warnings are issued in the SAS log whenever DATASOURCE needs to determine the century from a two-digit year specification.

The default YEARCUTOFF value is 1926. To use a different YEARCUTOFF value, specify

```
options yearcutoff=yyyy;
```

where YYYY is the YEARCUTOFF value you want to use. For more information about the YEARCUTOFF option, see *SAS System Options: Reference*.

Both the FROM and TO specifications are optional, and both the FROM and TO keywords are optional. If the FROM limit is omitted, the output observations start with the minimum date for which data are available for any selected series. Similarly, if the TO limit is omitted, the output observations end with the maximum date for which data are available.

The following are some examples of RANGE statements:

```
range from 1980 to 1990;
range 1980 - 1990;
range from 1980;
range 1980;
```

```
range to 1990;
range to 1990:2;
range from '31aug89'd to '28feb1990'd;
```

The RANGE statement applies to each BY group independently. If all the selected series contain no data in the specified range for a given BY group, then there will be no observations for that BY group in the OUT= and OUTEVENT= data sets.

If you want to know the time ranges for which periodic time series data are available, you can first run PROC DATASOURCE with the OUTBY= or OUTALL= option. The OUTBY= data set reports the union of the time ranges over all the series within each BY group, while the OUTALL= data set gives time ranges for each series separately in each BY group.

RENAME Statement

RENAME *old-name = new-name . . .* **;**

The RENAME statement is used to change the names of variables in the output data sets. Any number of variables can be renamed in a single RENAME statement. The most recent RENAME specification overrides any previous ones for a given variable. The *new-name* is limited to 32 characters.

Renaming of variables is done at the output stage. Therefore, you need to use the old variable names in all other PROC DATASOURCE statements. For example, the series variable names DATA1–DATA350 used with annual COMPUSTAT files are not very descriptive, so you can choose to rename them to reflect the financial aspect they represent. You can rename "DATA51" as "INVESTTAX" with the RENAME statement

```
rename data51=investtax;
```

since it contains investment tax credit data. However, in all other DATASOURCE statements, you must use the old name, DATA51.

WHERE Statement

WHERE *where-expression* **;**

The WHERE statement specifies conditions that BY variables must satisfy in order for a cross section to be included in the OUT= and OUTEVENT= data sets. By default, all BY groups are selected.

The *where-expression* must refer only to BY variables defined for the file type you are reading. The section "Data Elements Reference: DATASOURCE Procedure" on page 717 lists the names of the BY variables for each file type.

For example, DOTS (Direction of Trade Statistics) files, distributed by the International Monetary Fund, have four BY variables: COUNTRY, CSC, PARTNER, and VERSION. Both COUNTRY and PARTNER are three-digit country codes. To select the direction of trade statistics of the United States (COUNTRY='111') with Turkey (COUNTRY='186'), Japan (COUNTRY='158'), and the oil exporting countries group (COUNTRY='985'), you should specify

```
where country='111' and partner in ('186','158','985');
```

You can use any SAS language operators and special WHERE expression operators in the WHERE statement condition. For more information about WHERE expressions, see *SAS Programmers Guide: Essentials*.

If you want to see the names of the BY variables and the values they assume for each cross section, you can first run PROC DATASOURCE with only the OUTBY= option. The information contained in the OUTBY= data set will aid you in selecting the appropriate BY groups for subsequent PROC DATASOURCE steps.

Details: DATASOURCE Procedure

Variable Lists

Variable lists used in PROC DATASOURCE statements can consist of any combination of variable names and name range specifications. Items in variable lists can have the following forms:

- a name, such as PZU.
- an alphabetic range *name1-name2*. For example, A-DZZZZZZZ specifies all variables with names starting with A, B, C, or D.
- a prefix range *prefix* :. For example, IP: selects all variables with names starting with the letters IP.
- an order range *name1–name2*. For example, GLR72–GLRD72 specifies all variables in the input data file between GLR72 and GRLD72 inclusive.
- a numeric order range *name1*-NUMERIC-*name2*. For example, GLR72-NUMERIC-GLRD72 specifies all numeric variables between GLR72 and GRLD72 inclusive.
- a character order range *name1*-CHARACTER-*name2*. For example, GLR72-CHARACTER-GLRD72 specifies all character variables between GLR72 and GRLD72 inclusive.
- one of the keywords _NUMERIC_, _CHARACTER_, or _ALL_. The keyword _NUMERIC_ specifies all numeric variables, _CHARACTER_ specifies all character variables, and _ALL_ specifies all variables.

To determine the order of series in a data file, run PROC DATASOURCE with the OUTCONT= option, and print the output data set. Note that order and alphabetic range specifications are inclusive, meaning that the beginning and ending names of the range are also included in the variable list.

For order ranges, the names used to define the range must actually name variables in the input data file. For alphabetic ranges, however, the names used to define the range need not be present in the data file.

Note that variable specifications are applied to each cross section independently. This might cause the order-range variable list specification to behave differently than its DATA step and data set option counterparts. This is because PROC DATASOURCE knows which variables are defined for which cross sections, while the DATA step applies order range specification to the whole collection of time series variables.

If the ending variable name in an order range specification is not in the current cross section, all variables starting from the beginning variable to the last variable defined in that cross section get selected. If the first variable is not in the current cross section, then order range specification has no effect for that cross section.

The variable names used in variable list specifications can refer either to series names appearing in the input data file or to the SAS names assigned to series data fields internally if the series names are not recorded to the INFILE= file. When the latter is the case, internally defined variable names are listed in the section "Data Elements Reference: DATASOURCE Procedure" on page 717.

The following are examples of the use of variable lists:

```
keep  ip: pw112-pw117 pzu;
drop  data1-data99  data151-data350;
length data1-numeric-aftnt350  ucode 4;
```

The first statement keeps all the variables starting with IP:, all the variables between PW112 and PW117 including PW112 and PW117 themselves, and a single variable PZU. The second statement drops all the variables that fall alphabetically between DATA1 and DATA99, and between DATA151 and DATA350. Finally, the third statement assigns a length of 4 bytes to all the numeric variables defined between DATA1 and AFTNT350, and UCODE. Variable lists can not exceed 200 characters in length.

OUT= Data Set

The OUT= data set can contain the following variables:

- the BY variables, which identify cross-sectional dimensions when the input data file contains time series replicated for different values of the BY variables. Use the BY variables in a WHERE statement to process the OUT= data set by cross sections. The order in which BY variables are defined in the OUT= data set corresponds to the order in which the data file is sorted.
- DATE, a SAS date-, time-, or datetime-valued variable that reports the time period of each observation. The values of the DATE variable can span different time ranges for different BY groups. The format of the DATE variable depends on the INTERVAL= option.
- the periodic time series variables, which are included in the OUT= data set only if they have data in at least one selected BY group and they are not discarded by a KEEP or DROP statement
- the event variables, which are included in the OUT= data set if they are not discarded by a KEEP or DROP statement. By default, these variables are not output to the OUT= data set.

The values of BY variables remain constant in each cross section. Observations within each BY group correspond to the sampling of the series variables at the time periods indicated by the DATE variable.

You can create a set of single indexes for the OUT= data set by using the INDEX option, provided there are BY variables. Under some circumstances, this might increase the efficiency of subsequent PROC and DATA steps that use BY and WHERE statements. However, there is a cost associated with creation and maintenance of indexes. The *SAS Programmers Guide: Essentials* lists the conditions under which the benefits of indexes outweigh the cost.

With data files containing cross sections, there can be various degrees of overlap among the series variables. One extreme is when all the series variables contain data for all the cross sections. In this case, the output

data set is very compact. In the other extreme case, however, the set of time series variables are unique for each cross section, making the output data set very sparse, as depicted in Table 12.4.

Table 12.4 The OUT= Data Set Containing Unique Series for Each BY Group

BY Variables BY1 . . . BY*P*	Series in first BY group F1 F2 F3 . . . FN	Series in second BY group S1 S2 S3 . . . SM	. . . . . .	Series in last BY group T1 T2 T3 . . . TK
BY group 1	DATA is here			
BY group 2		DATA is here	Data is missing everywhere except on diagonal	
⋮			DATA is here	
BY group N				DATA is here

The data in Table 12.4 can be represented more compactly if cross-sectional information is incorporated into series variable names.

OUTCONT= Data Set

The OUTCONT= data set contains descriptive information for the time series variables. This descriptive information includes various attributes of the time series variables. The OUTCONT= data set contains the following variables:

- NAME, a character variable that contains the series name
- KEPT, a numeric variable that indicates whether the series was selected for output by the DROP or KEEP statements. KEPT is usually the same as SELECTED, but can differ if a WHERE statement is used.
- SELECTED, a numeric variable that indicates whether the series is selected for output to the OUT= data set. The series is included in the OUT= data set (SELECTED=1) if it is kept (KEPT=1) and it has data for at least one selected BY group.
- TYPE, a numeric variable that indicates the type of the time series variable. TYPE=1 for numeric series; TYPE=2 for character series.
- LENGTH, a numeric variable that gives the number of bytes allocated for the series variable in the OUT= data set

- VARNUM, a numeric variable that gives the variable number of the series in the OUT= data set. If the series variable is not selected for output (SELECTED=0), then VARNUM has a missing value. Likewise, if no OUT= option is given, VARNUM has all missing values.
- LABEL, a character variable that contains the label of the series variable. LABEL contains only the first 256 characters of the labels. If they are longer than 256 characters, then the variable DESCRIPT is defined to hold the whole length of series labels. Note that if a data file assigns different labels to the same series variable within different cross sections, only the first occurrence of labels will be transferred to the LABEL column.
- the variables FORMAT, FORMATL, and FORMATD, which give the format name, length, and number of format decimals, respectively
- the GENERIC variables, whose values can vary from one series to another, but whose values remain constant across BY groups for the same series

By default, the OUTCONT= data set contains observations for only the selected series where SELECTED=1. If the OUTSELECT=OFF option is specified, the OUTCONT= data set contains one observation for each unique series of the specified periodicity contained in the input data file.

If you do not know what series are in the data file, you can run PROC DATASOURCE with the OUTCONT= option and OUTSELECT=OFF. The information contained in the OUTCONT= data set can then help you to determine which time series data you want to extract.

OUTBY= Data Set

The OUTBY= data set contains information on the cross sections contained in the input data file. These cross sections are represented as BY groups in the OUT= data set. The OUTBY= data set contains the following variables:

- the BY variables, whose values identify the different cross sections in the data file. The BY variables depend on the file type.
- BYSELECT, a numeric variable that reports the outcome of the WHERE statement condition for the BY variable values for this observation. The value of BYSELECT is 1 for BY groups selected by the WHERE statement for output to the OUT= data set and is 0 for BY groups that are excluded by the WHERE statement. BYSELECT is added to the data set only if a WHERE statement is given. When there is no WHERE statement, then all the BY groups are selected.
- ST_DATE, a numeric variable that gives the starting date for the BY group. The starting date is the earliest of the starting dates of all the series that have data for the current BY group.
- END_DATE, a numeric variable that gives the ending date for the BY group. The ending date is the latest of the ending dates of all the series that have data for the BY group.
- NTIME, a numeric variable that gives the number of time periods between ST_DATE and END_DATE, inclusive. Usually, this is the same as NOBS, but they differ when time periods are not equally spaced and when the OUT= data set is not specified. NTIME is a maximum limit on NOBS.

- NOBS, a numeric variable that gives the number of time series observations in the OUT= data set between ST_DATE and END_DATE inclusive. When a given BY group is discarded by a WHERE statement, the NOBS variable corresponding to this BY group becomes 0, since the OUT= data set does not contain any observations for this BY group. Note that BYSELECT=0 for every discarded BY group.
- NINRANGE, a numeric variable that gives the number of observations in the range (*from,to*) defined by the RANGE statement. This variable is only added to the OUTBY= data set when the RANGE statement is specified.
- NSERIES, a numeric variable that gives the total number of unique time series variables having data for the BY group
- NSELECT, a numeric variable that gives the total number of selected time series variables having data for the BY group
- the generic variables, whose values remain constant for all the series in the current BY group

In this list, you can only control the attributes of the BY and GENERIC variables.

The variables NOBS, NTIME, and NINRANGE give observation counts, while the variables NSERIES and NSELECT give series counts.

By default, observations for only the selected BY groups (where BYSELECT=1) are output to the OUTBY= data set, and the date and time range variables are computed over only the selected time series variables. If the OUTSELECT=OFF option is specified, the OUTBY= data set contains an observation for each BY group, and the date and time range variables are computed over all the time series variables.

For file types that have no BY variables, the OUTBY= data set contains one observation giving ST_DATE, END_DATE, NTIME, NOBS, NINRANGE, NSERIES, and NSELECT for all the series in the file.

If you do not know the BY variable names or their possible values, you can do an initial run of PROC DATASOURCE with the OUTBY= option. The information contained in the OUTBY= data set can help you design your WHERE expression and RANGE statement for the subsequent executions of PROC DATASOURCE to obtain different subsets of the same data file.

OUTALL= Data Set

The OUTALL= data set combines and expands the information provided by the OUTCONT= and OUTBY= data sets. That is, the OUTALL= data set not only reports the OUTCONT= information separately for each BY group, but also reports the OUTBY= information separately for each series. Each observation in the OUTBY= data set gets expanded to NSERIES or NSELECT observations in the OUTALL= data set, depending on whether the OUTSELECT=OFF option is specified.

By default, only the selected BY groups and series are included in the OUTALL= data set. If the OUTSELECT=OFF option is specified, then all the series within all the BY groups are reported.

The OUTALL= data set contains all the variables defined in the OUTBY= and OUTCONT= data sets and also contains the GENERIC variables (whose values can vary from one series to another and from one BY group to another). Another additional variable is BLKNUM, which gives the data block number in the data file containing the series variable.

The OUTALL= data set is useful when BY groups do not contain the same time series variables or when the time ranges for series change across BY groups.

You should be careful in using the OUTALL= option, since the OUTALL= data set can get very large for many file types. Some file types have the same series and time ranges for each BY group; the OUTALL= option should not be used with these file types. For example, you should not specify the OUTALL= option with COMPUSTAT files, since all the BY groups contain the same series variables.

The OUTALL= and OUTCONT= data sets are equivalent when there are no BY variables, except that the OUTALL= data set contains extra information about the time ranges and observation counts of the series variables.

OUTEVENT= Data Set

The OUTEVENT= data set is used to output event-oriented time series data. Events occurring at discrete points in time are recorded along with the date they occurred. Only CRSP stock files contain event-oriented time series data. For all other types of files, the OUTEVENT= option is ignored.

The OUTEVENT= data set contains the following variables:

- the BY variables, which identify cross-sectional dimensions when the input data file contains time series replicated for different values of the BY variables. Use the BY variables in a WHERE statement to process the OUTEVENT= data set by cross sections. The order in which BY variables are defined in the OUTEVENT= data set corresponds to the order in which the data file is sorted.
- DATE, a SAS date-, time- or datetime-valued variable that reports the discrete time periods at which events occurred. The format of the DATE variable depends on the INTERVAL= option, and should accurately report the date based on the SAS YEARCUTOFF option. The default value for YEARCUTOFF is 1920. The dates used can span up to 250 years.
- EVENT, a character variable that contains the event group name. The EVENT variable is another cross-sectional variable.
- the event variables, which are included in the OUTEVENT= data set only if they have data in at least one selected BY group, and are not discarded by a KEEPEVENT or DROPEVENT statement

Note that each event group contains a nonoverlapping set of event variables; therefore, the OUTEVENT= data set is very sparse. You should exercise care when selecting event variables to be included in the OUTEVENT= data set.

Also note that even though the OUTEVENT= data set cannot contain any periodic time series variables, the OUT= data set can contain event variables if they are explicitly specified in a KEEP statement. In summary, you can specify event variables in a KEEP statement, but you cannot specify periodic time series variables in a KEEPEVENT statement.

While variable selection for OUT= and OUTEVENT= data sets are controlled by a different set of statements (KEEP versus KEEPEVENT or DROP versus DROPEVENT), cross-section and range selections are controlled by the same statements, so in summary, the WHERE and the RANGE statements are effective for both output data sets.

Data Elements Reference: DATASOURCE Procedure

PROC DATASOURCE can process only certain kinds of data files. For certain time series databases, the DATASOURCE procedure has built-in information on the layout of files composing the database. PROC DATASOURCE knows how to read only these kinds of data files. To access these databases, you must indicate the data file type in the FILETYPE= option. For more detailed information, see the corresponding document for each filetype. (See "References.") The currently supported file types are summarized in Table 12.5.

Data supplier abbreviations used in Table 12.5 are summarized in Table 12.6.

Table 12.6 Data Supplier Abbreviations

Abbreviation	Supplier
BEA	Bureau of Economic Analysis, U.S. Department of Commerce
BLS	Bureau of Labor Statistics, U.S. Department of Labor
CRSP	Center for Research in Security Prices
DRI	Global Insight (formerly DRI/McGraw-Hill)
FAME	FAME Information Services, Inc.
GLOBAL INSIGHT	Global Insight, Inc.
HAVER	Haver Analytics Inc.
IMF	International Monetary Fund
OECD	Organization for Economic Cooperation and Development
S&P	Standard & Poor's Compustat Services Inc.

BEA Data Files

The Bureau of Economic Analysis, U.S. Department of Commerce, supplies national income, product accounting, and various other macroeconomic data at the regional, national, and international levels in the form of data files with various formats and on various media.

The following BEA data file types are supported.

FILETYPE=BEANIPA–National Income and Product Accounts Format

Table 12.7 FILETYPE=BEANIPA–National Income and Product Accounts Format

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY Variables	PARTNO	Part Number of Publication, Integer Portion of the Table Number, 1–9 (character)

Table 12.7 *continued*

Metadata Field Types	Metadata Fields	Metadata Labels
	TABNUM	Table Number Within Part, Decimal Portion of the Table Number, 1–24 (character)
Series Variables	Series variable names are constructed by concatenating table number suffix, line and column numbers within each table. An underscore (_) prefix is also added for readability.	

FILETYPE=BEANIPAD–National Income and Product Accounts PC Format

The PC format National Income and Product Accounts files contain the same information as the BEANIPA files described previously.

Table 12.8 FILETYPE=BEANIPAD–National Income and Product Accounts PC Format

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY Variables	PARTNO	Part Number of Publication, Integer Portion of the Table Number, 1–9 (character)
	TABNUM	Table Number Within Part, Decimal Portion of the Table Number, 1–24 (character)
Series Variables	Series variable names are constructed by concatenating table number suffix, line and column numbers within each table. An underscore (_) prefix is also added for readability.	

BLS Data Files

The Bureau of Labor Statistics, U.S. Department of Labor, compiles and distributes data on employment, expenditures, prices, productivity, injuries and illnesses, and wages.

The following BLS file types are supported.

FILETYPE=BLSCPI–Consumer Price Index Surveys (=CU,CW)

Table 12.9 FILETYPE=BLSCPI–Consumer Price Index Surveys (=CU,CW)

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR, SEMIYEAR1.6, MONTH (default)	
BY Variables	SURVEY	Survey type: CU=All Urban Consumers, CW=Urban Wage Earners and Clerical Workers (character)
	SEASON	Seasonality: S=Seasonally adjusted, U=Unadjusted (character)
	AREA	Geographic Area (character)
	BASPTYPE	Index Base Period Type, S=Standard, A=Alternate Reference (character)
	BASEPER	Index Base Period (character)
Series Variables	Series variable names are the same as consumer item codes listed in the Series Directory shipped with the data.	
Missing Codes	A data value of 0 is interpreted as MISSING.

	EE62	Index of Diffusion; 3-month Span; Base 1977
	EE63	Index of Diffusion; 6-month Span; Base 1977
	EE64	Index of Diffusion; 12-month Span; Base 1977
Missing Codes	Series data values are set to MISSING when their status codes are 1.	

FILETYPE=BLSEESA–State and Area Employment, Hours, and Earnings Survey

Table 12.12 FILETYPE=BLSEESA–State and Area Employment, Hours, and Earnings Survey

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR, MONTH (default)	
BY Variables	STATE	State FIPS codes (numeric)
	AREA	Area codes (character)
	DIVISION	Major industrial division (character)
	INDUSTRY	Industry code (character)
	DETAIL	Private/Government detail
Sorting Order	BY STATE AREA DIVISION INDUSTRY DETAIL	
Series Variables	Series variable names are the same as data type codes prefixed by SA.	
	SA1	All employees
	SA2	Women workers
	SA3	Production workers
	SA4	Average weekly earnings
	SA5	Average weekly hours
Missing Codes	Series data values are set to MISSING when their status codes are 1.	

Global Insight DRI Data Files

The DRIBASIC (formerly CITIBASE) database contains economic and financial indicators of the U.S. and international economies gathered from various government and private sources by DRI/McGraw-Hill, Inc. There are over 8000 yearly, quarterly, monthly, weekly, and daily time series.

Global Insight, formerly DRI/McGraw-Hill, distributes Basic Economic data files on various media. Old DRIDDS data files can be read by DATASOURCE using the DRIDDS filetype.

The following DRI file types are supported.

FILETYPE=DRIBASIC–Global Insight DRI Basic Economic Data Files

Table 12.13 FILETYPE=DRIBASIC–Global Insight DRI Basic Economic Data Files

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH, WEEK, WEEK1.1, WEEK1.2, WEEK1.3, WEEK1.4, WEEK1.5, WEEK1.6, WEEK1.7, WEEKDAY	
BY Variables	None	
Series Variables	Variable names are taken from the series descriptor records in the data file. Note that series codes can be 20 bytes.	
Missing Codes	MISSING=('1.000000E9'=. 'NA'-'ND'=.)	

Note that when you specify the INTERVAL=WEEK option, all the weekly series will be aggregated, and the DATE variable in the OUT= data set will be set to the date of Sundays. The date of first observation for each series is the Sunday marking the beginning of the week that contains the starting date of that variable.

FILETYPE=DRIDDS–Global Insight DRI Data Delivery Service Data Files

Table 12.14 FILETYPE=DRIDDS–Global Insight DRI Data Delivery Service Data Files

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), SEMIYEAR, QUARTER, MONTH, SEMIMONTH, TENDAY, WEEK, WEEK1.1, WEEK1.2, WEEK1.3, WEEK1.4, WEEK1.5, WEEK1.6, WEEK1.7, WEEKDAY, DAY	
BY Variables	None	
Series Variables	Variable names are taken from the series descriptor records in the data file. Note that series names can be 24 bytes.	
Missing Codes	MISSING=('NA'-'ND'=.)	

FILETYPE=CITIOLD–Old Format CITIBASE Data Files

This file type is used for CITIBASE data distributed prior to May 1987.

Table 12.15 FILETYPE=CITIOLD–Old Format CITIBASE Data Files

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in a single file.	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY Variables	None	
Series Variables	Variable names are taken from the series descriptor records in the data file and are the same as the series codes reported in the *CITIBASE Directory*.	
Missing Codes	1.0E9=.	

FILETYPE=CITIDISK–PC Format CITIBASE Databases

Table 12.16 FILETYPE=CITIDISK–PC Format CITIBASE Databases

Metadata Field Types	Metadata Fields	Metadata Labels
Data Files	Database is stored in groups of three associated files having the same file name but different extensions: KEY, IND, or DB. The INFILE= option should contain three filerefs in the following order: INFILE=(*keyfile indfile dbfile*).	
INTERVAL=	YEAR (default), QUARTER, MONTH	
BY Variables	None	
Series Variables	Series variable names are the same as series codes reported in the *CITIBASE Directory*.	
Missing Codes	1.0E9=.	

COMPUSTAT Data Files

COMPUSTAT data files, distributed by Standard & Poor's Compustat Services, Inc., consist of a collection of financial, statistical, and market information covering several thousand industrial and nonindustrial companies. Data are available in both an IBM 360/370 format and a "Universal Character" format, both of which further subdivide into annual and quarterly formats.

The BY variables are used to select individual companies or a group of companies. Individual companies can be selected by their unique six-digit CUSIP issuer code (CNUM). A number of specific groups of companies can be extracted by the following key fields:

FILE	specifies the file identification code used to group companies by files.
ZLIST	specifies the exchange listing code that can be used to group companies by exchange.
DNUM	is used to extract companies in a specific SIC industry group.

Series names are internally constructed from the data array names documented in the COMPUSTAT manual. Each column of data array is treated as a SAS variable. The names of these variables are generated by concatenating the corresponding column numbers to the array name.

Missing values use four codes. Missing code '.C' represents a combined figure where the data item has been combined into another data item, '.I' reports an insignificant figure, '.S' represents a semi-annual figure in the second and fourth quarters, '.A' represents an annual figure in the fourth quarter, and '.' indicates that the data item is not available. The missing codes '.C' and '.I' are not used for Aggregate or Prices, Dividends, and Earnings (PDE) files. The missing codes '.S' and '.A' are used only on the Industrial Quarterly File and not on the Aggregate Quarterly, Business Information, or PDE files.

CRSP Stock Files

The Center for Research in Security Prices provides comprehensive security price data through two primary stock files, the NYSE/AMEX file and the NASDAQ file. These files contain master and return components, available separately or combined. CRSP stock files are further differentiated by the frequency at which prices and returns are reported, daily or monthly. Both daily and monthly files contain annual data fields.

CRSP data files are distributed in CRSPAccess format. For more information about accessing your CRSPAccess database, see Chapter 46, "The SASECRSP Interface Engine." You can convert your CRSPAccess data to binary format (SFA format) by using the CRSP-supplied utility (STK_DUMP_BIN). Use the DATASOURCE procedure for SFA format access and use SASECRSP Interface for CRSPAccess.

CRSP stock data (in SFA format) are provided in two files, a main data file containing security information and a calendar/indices file containing a list of trading dates and market information associated with those trading dates.

The file types for CRSP stock files are constructed by concatenating CRSP with a D or M to indicate the frequency of data, followed by B, C, or I to indicate file formats. B is for host binary, C is for character, and I is for IBM binary formats. The last character in the file type indicates if you are reading the Calendar/Indices file (I), or if you are extracting the security (S) or annual data (A). For example, the file type for the daily NYSE/AMEX combined data in IBM binary format is CRSPDIS. Its calendar/indices file can be read by CRSPDII, and its annual data can be extracted by CRSPDIA.

Starting in 1995, binary data used split records (RICFAC=2), so the 1995 filetypes (CR95*) should be used for 1995 and 1996 binary data. If you use utility routines supplied by CRSP to convert a character format file to a binary format file on a given host, then you need to use host binary file types (RIDFAC=1) to read those files in. Note that you cannot do the conversion on one host and transfer and read the file on another host.

If you are using the CRSPAccess Database, you will need to use the utility routine (stk_dump_bin) supplied by CRSP to generate the UNIX binary format of the data. You can access the UNIX (or SUN) binary data by using PROC DATASOURCE with the CRSPDUS for daily or CRSPMUS for monthly stock data.

For the four-digit year data, use the Y2K-compliant filetypes for that data type.

For CRSP file types, the INFILE= option must be of the form

```
INFILE=( calfile security1 < security2 \ldots > )
```

where *calfile* is the fileref assigned to the calendar/indices file, and *security1* < *security2* . . . > are the filerefs given to the security files, in the order in which they should be read.

FAME Information Services Databases

The DATASOURCE procedure provides access to FAME Information Services databases for UNIX-based systems only. For information about a more flexible FAME database access, see the section "The SASEFAME Interface Engine" in Chapter 47, "The SASEFAME Interface Engine."

The DATASOURCE interface to FAME requires a component supplied by FAME Information Services, Inc. Once this FAME component is installed on your system, you can use the DATASOURCE procedure to extract data from your FAME databases by giving the following specifications.

Specify FILETYPE=FAME in the PROC DATASOURCE statement and give the FAME database name to access with a DBNAME='*fame-database* ' option. The character string you specify in the DBNAME= option

is passed through to FAME; specify the value of this option as you would in accessing the database from within FAME software.

Specify the output SAS data set to be created, the frequency of the series to be extracted, and other usual DATASOURCE procedure options as appropriate.

Specify the time range to extract with a RANGE statement. The RANGE statement is required when extracting series from FAME databases.

Name the FAME series to be extracted with a KEEP statement. The items in the KEEP statement are passed through to FAME software; therefore, you can use any valid FAME expression to specify the series to be extracted. Enclose in quotes any FAME series name or expression that is not a valid SAS name.

Name the SAS variable names you want to use for the extracted series in a RENAME statement. Give the FAME series name or expression (in quotes if needed) followed by an equal sign and the SAS name. The RENAME statement is not required; however, if the FAME series name is not a valid SAS variable name, the DATASOURCE procedure will construct a SAS name by translating and truncating the FAME series name. This process might not produce the desired name for the variable in the output SAS data set, so a rename statement could be used to produce a more appropriate variable name. The VALIDVARNAME=ANY option in your SAS options statement can be used to allow special characters in the SAS variable name.

For an alternative solution to PROC DATASOURCE's access to FAME, see the section "The SASEFAME Interface Engine" in Chapter 47, "The SASEFAME Interface Engine."

Haver Analytics Data Files

Haver Analytics offers a broad range of economic, financial, and industrial data for the United States and other countries. For information about accessing your HAVER DLX database, see the section "The SASEHAVR Interface Engine" in Chapter 49, "The SASEHAVR Interface Engine." SASEHAVR is supported on most Windows environments. Use the DATASOURCE procedure for serial access of your data. The format of Haver Analytics data files is similar to the CITIBASE/DRIBASIC formats.

IMF Data Files

The International Monetary Fund's Economic Information System (EIS) offers subscriptions for their International Financial Statistics (IFS), Direction of Trade Statistics (DOTS), Balance of Payment Statistics (BOPS), and Government Finance Statistics (GFS) databases. The first three contain annual, quarterly, and monthly data, while the GFS file has only annual data.

PROC DATASOURCE supports only the packed format IMF data.

FILETYPE=IMFIFSP–International Financial Statistics, Packed Format

The IFS data files contain over 23,000 time series including interest and exchange rates, national income and product accounts, price and production indexes, money and banking, export commodity prices, and balance of payments for nearly 200 countries and regional aggregates.

Table 12.27 FILETYPE=IMFIFSP–International Financial Statistics Format

Examples: DATASOURCE Procedure

Example 12.1: BEA National Income and Product Accounts

In this example, exports and imports of goods and services are extracted to demonstrate how to work with a National Income and Product Accounts (NIPA) file.

From the "Statistical Tables" published by the United States Department of Commerce, Bureau of Economic Analysis, the relation of foreign transactions in the Balance of Payments Accounts (BPA) are given in the fifth table (TABNUM='05') of the "Foreign Transactions" section (PARTNO='4'). Moreover, the first line in the table gives BPAs, while the eighth gives exports of goods and services. The series names __00100 and __00800 are constructed by two underscores followed by three digits as the line numbers, and then two digits as the column numbers.

The following statements put this information together to extract quarterly BPAs and exports from a BEANIPA type file:

```
/*- assign fileref to the external file to be processed --------*/

filename ascifile "%sysget(DATASRC_DATA)beanipa.data" recfm=v lrecl=108;

title1 'Relation of Foreign Transactions to Balance of Payment Accounts';
title2 'Range from 1984 to 1989';

title3 'Annual';
proc datasource filetype=beanipa infile=ascifile
                interval=year
                outselect=off
                outkey=byfor4;

   range from 1984 to 1989;
   keep __00100 __00800;

   label __00100='Balance of Payment Accounts';
   label __00800='Exports of Goods and Services';

   rename __00100=BPAs __00800=exports;
run;

proc print data=byfor4;
run;

 /*- assign fileref to the external file to be processed --------*/

filename ascifile "%sysget(DATASRC_DATA)beanipa.data" recfm=v lrecl=108;

title1 'Relation of Foreign Transactions to Balance of Payment Accounts';
title2 'Range from 1984 to 1989';

title3 'Annual';
proc datasource filetype=beanipa infile=ascifile
                interval=year
                outselect=off
                outkey=byfor4
                out=foreign4;

   range from 1984 to 1989;
   keep __00100 __00800;

   label __00100='Balance of Payment Accounts';
   label __00800='Exports of Goods and Services';

   rename __00100=BPAs __00800=exports;

run;

proc contents data=foreign4;
run;
proc print data=foreign4;
run;
```

The results are shown in Output 12.1.1, Output 12.1.2, and Output 12.1.3.

Output 12.1.1 Listing of OUTBY=byfor4 of the BEANIPA Data

Relation of Foreign Transactions to Balance of Payment Accounts

This example illustrates the following features:

- You need to know the series variables names used by a particular vendor in order to construct the KEEP statement.
- You need to know the BY-variable names and their values for the required cross sections.
- You can use RENAME and LABEL statements to associate more meaningful names and labels with your selected series variables.

Example 12.2: BLS Consumer Price Index Surveys

This example compares changes of the prices in medical care services with respect to different regions for all urban consumers (SURVEY='CU') since May 1975. The source of the data is the Consumer Price Index Surveys distributed by the U.S. Department of Labor, Bureau of Labor Statistics.

An initial run of PROC DATASOURCE gives the descriptive information on different regions available (the OUTBY= data set), as well as the series variable name corresponding to medical care services (the OUTCONT= data set).

```
options yearcutoff = 1900;

filename datafile "%sysget(DATASRC_DATA)blscpi1.data" recfm=v lrecl=152;
proc datasource filetype=blscpi
   interval=mon
   outselect=off
   outby=cpikey(where=( upcase(areaname)
                  in ('NORTHEAST','NORTH CENTRAL','SOUTH','WEST')) )
   outcont=cpicont(where= ( index( upcase(label), 'MEDICAL CARE' )) );
   where survey='CU';
run;

title1 'OUTBY= Data Set, By AREANAME Selection';
proc print
   data=cpikey;
run;

title1 'OUTCONT= Data Set, By LABEL Selection';
proc print
   data=cpicont;
run;
```

The OUTBY= data set in Output 12.2.1 lists all cross sections available for the four geographical regions: Northeast (AREA='0100'), North Central (AREA='0200'), Southern (AREA='0300'), and Western (AREA='0400'). The OUTCONT= data set in Output 12.2.2 gives the variable names for medical care related series.

Output 12.2.1 Partial Listings of the OUTBY= Data Set

OUTBY= Data Set, By AREANAME Selection

23	CU	U	North Central Region	S	1982-84=100	JUL1990	1573

The OUTALL= data set in Output 12.2.3 indicates that data values are stored with one decimal place (see the NDEC variable). Therefore, they need to be rescaled, as follows:

```
data medical;
   set medical;
   medcare = medcare * 0.1;
run;
```

This example illustrates the following features:

- Descriptive information needed to write KEEP and WHERE statements can be obtained with an initial run of the DATASOURCE procedure.
- The OUTCONT= and OUTALL= data sets contain information on how data values are stored, such as the precision, the units, and so on.
- The OUTCONT= and OUTALL= data sets report the new series names assigned by the RENAME statement, not the old names (see the NAME variable in Output 12.2.3).
- You can use PROC FORMAT to define formats for series or BY variables to enhance your output. Note that PROC DATASOURCE associates a permanent format, $AREAFMT., with the BY variable

AREA. As a result, the formatted values are displayed in the printout of the OUTALL=MEDINFO data set (see Output 12.2.3).

Example 12.3: BLS State and Area Employment, Hours, and Earnings Surveys

This example illustrates how to extract specific series from a State and Area Employment, Hours, and Earnings Survey. The series to be extracted is total employment in real estate and construction industries with respect to states from March 1989 to March 1990.

The State and Area, Employment, Hours and Earnings survey designates the totals for statewide figures by AREA='0000'.

The data type code for total employment is reported to be 1. Therefore, the series name for this variable is SA1, since series names are constructed by adding an SA prefix to the data type codes given by BLS.

Output 12.3.1 and Output 12.3.2 show statewide figures for total employment (SA1) in many industries from March 1989 through March 1990.

```
filename ascifile "%sysget(DATASRC_DATA)blseesa.dat" RECFM=F LRECL=152;
proc datasource  filetype=blseesa
                 infile=ascifile
                 outall=totkey
                 out=totemp;
   keep sa1;
   range from 1989:3 to 1990:3;
   rename sa1=totemp;
run;

title1 'Information on Total Employment, OUTALL= Data Set';
proc print data=totkey;
run;

Note the following for this example:

- When the INFILE= option is omitted, the fileref assigned to the BLSEESA file is the default value DATAFILE.
- The FROM and TO values in the RANGE statement correspond to monthly data points since the INTERVAL= option defaults to MONTH for the BLSEESA filetype.

Example 12.4: DRI/McGraw-Hill Format CITIBASE Files

Output 12.4.1 and Output 12.4.2 illustrate how to extract weekly series from a sample CITIBASE file. They also demonstrate how the OUTSELECT= option affects the contents of the auxiliary data sets.

The weekly series contained in the sample data file CITIDEMO are listed by the following statements:

```
options yearcutoff=1920;

filename datafile "%sysget(DATASRC_DATA)citidem.dat" RECFM=D LRECL=80;

proc datasource filetype=citibase interval=week
                outall=citiall outby=citikey;
run;

title1 'Summary Information on Weekly Data for CITIDEMO File';
proc print data=citikey;
run;
```

```
title1 'Weekly Series Available in CITIDEMO File';
proc print data=citiall( drop=label );
run;
```

Output 12.4.1 Listing of the OUTBY= CITIKEY Data Set

Note the following from Output 12.4.2:

- The OUTALL= data set reports the time ranges of variables.
- There are six observations in the OUTALL= data set, the same number as reported by NSERIES and NSELECT variables in the OUTBY= data set.
- The VARNUM variable contains all MISSING values, since no OUT= data set is created.

Output 12.4.3 and Output 12.4.4 demonstrate how the OUTSELECT= option affects the contents of the OUTBY= and OUTALL= data sets when a KEEP statement is present. First, set the OUTSELECT= option to OFF.

```
filename citidemo "%sysget(DATASRC_DATA)citidem.dat" RECFM=D LRECL=80;

proc datasource filetype=citibase infile=citidemo interval=week
                outall=alloff outby=keyoff outselect=off;

3	WSPIA	1	1	Sun, 29 Dec 1985	Sun, 3 Mar 1991	271	271
4	WSPGLT	1	1	Sun, 29 Dec 1985	Sun, 3 Mar 1991	271	271

Comparison of Output 12.4.4 and Output 12.4.6 reveals the following:

- The OUTALL= data set contains six (NSERIES) observations when OUTSELECT=OFF, and four (NSELECT) observations when OUTSELECT=ON.
- The observations in OUTALL=ALLON are those for which SELECTED=1 in OUTALL=ALLOFF.
- The time ranges in the OUTBY= data set are computed over all the variables (selected or not) for OUTSELECT=OFF, but only computed over the selected variables for OUTSELECT=ON. This corresponds to computing time ranges over all the series reported in the OUTALL= data set.
- The variable NTIME is the number of time periods between ST_DATE and END_DATE, while NOBS is the number of observations the OUT= data set is to contain. Thus, NTIME is different depending on whether the OUTSELECT= option is set to ON or OFF, while NOBS stays the same.

The KEEP statement in the last two examples illustrates the use of an additional variable, KEPT, in the OUTALL= data sets of Output 12.4.4 and Output 12.4.6. KEPT, which reports the outcome of the KEEP statement, is only added to the OUTALL= data set when there is KEEP statement.

Adding the RANGE statement to the last example generates the data sets in Output 12.4.7 and Output 12.4.8:

```
filename citidemo "%sysget(DATASRC_DATA)citidem.dat" RECFM=D LRECL=80;
proc datasource filetype=citibase infile=citidemo interval=week
                outby=keyrange out=citiout outselect=on;
   keep WSP:;
   range from '01dec1990'd;
run;

title1 'Summary Information on Weekly Data for CITIDEMO File';
proc print data=keyrange;
run;

title1 'Weekly Data in CITIDEMO File';
proc print data=citiout;
```

```
run;
```

14	Sun, 24 Feb 1991	9.61000	9.53000	9.68000	8.50000
15	Sun, 3 Mar 1991	9.61000	9.53000	9.68000	8.50000

The OUTBY= data set in this last example contains an additional variable NINRANGE. This variable is added since there is a RANGE statement. Its value, 15, is the number of observations in the OUT= data set. In this case, NOBS gives the number of observations the OUT= data set would contain if there were not a RANGE statement.

Example 12.5: DRI Data Delivery Service Database

This example demonstrates the DRIDDS filetype for the daily Federal Reserve Series fxrates_dds. Use VALIDVARNAME=ANY in your SAS options statement to allow special characters such as @, $, and % to be in the series name. Note the use of long variable names in the OUT= data set in Output 12.5.2 and long labels in the OUTCONT= data set in Output 12.5.1.

The following statements extract daily series starting in January 1, 1997:

```
options validvarname=any;
filename datafile "%sysget(DATASRC_DATA)drifxrat.dat" RECFM=F LRECL=80;
proc format;
   value distekfm 0 = 'Unspecified'
                  2 = 'Linear'
```

```
                    4 = 'Triag'
                    6 = 'Polynomial'
                    8 = 'Even'
                   10 = 'Step'
                   12 = 'Stocklast'
                   14 = 'LinearUnadjusted'
                   16 = 'PolyUnadjusted'
                   18 = 'StockWithNAS'
                   99 = 'None'
                  255 = 'None';

   value convtkfm 0 = 'Unspecified'
                  1 = 'Average'
                  3 = 'AverageX'
                  5 = 'Sum'
                  7 = 'SumAnn'
                  9 = 'StockEnd'
                 11 = 'StockBegin'
                 13 = 'AvgNP'
                 15 = 'MaxNP'
                 17 = 'MinNP'
                 19 = 'StockEndNP'
                 21 = 'StockBeginNP'
                 23 = 'Max'
                 25 = 'Min'

Example 12.6: PC Format CITIBASE Database

This example uses a PC format CITIBASE database (FILETYPE=CITIDISK) to extract annual population estimates for females and males with respect to various age groups.

Population estimate series for all ages of females including those in the armed forces overseas are given by PANF, while PANM gives the population estimate for all ages of males including those in armed forces overseas. More population estimate time series are described in Output 12.6.1 and are output in Output 12.6.2.

The following statements extract the required population estimates series:

```
filename keyfile "%sysget(DATASRC_DATA)basekey.dat" RECFM=V LRECL=22;
filename indfile "%sysget(DATASRC_DATA)baseind.dat" RECFM=F LRECL=84;
filename dbfile "%sysget(DATASRC_DATA)basedb.dat" RECFM=F LRECL=4;

proc datasource filetype=citidisk  infile=( keyfile indfile dbfile )
                out=popest outall=popinfo;

run;

proc print data=popinfo;
run;
proc print data=popest;
run;
```

Output 12.6.1 Listing of the OUTALL=POPINFO Data Set for FILETYPE=CITIDISK

9	1988	246307	189867	152113	126118	120189
10	1989	248762	191570	153695	127317	121445

This example demonstrates the following:

- The INFILE= options lists the filerefs of the key, index, and database files, in that order.
- The INTERVAL= option is omitted since the default interval for CITIDISK type files is YEAR.

Example 12.7: Quarterly COMPUSTAT Data Files

This example shows how to extract data from a 48-quarter Compustat Database File. For COMPUSTAT data files, the series variable names are constructed by concatenating the name of the data array DATA and the column number containing the required information. For example, for quarterly files the common stock data is in column 56. Therefore, the variable name for this series is DATA56. Similarly, the series variable names for quarterly footnotes are constructed by adding the column number to the array name, QFTNT. For example, the variable name for common stock footnotes is QFTNT14 since the 14th column of the QFTNT array contains this information.

The following example extracts common stock series (DATA56) and its footnote (QFTNT14) for companies whose stocks are traded over-the-counter and not in the S&P 500 Index (ZLIST=06) and whose data reside in the over-the-counter file (FILE=06):

```
filename compstat "%sysget(DATASRC_DATA)csqibm.dat" recfm=s370v
   lrecl=4820 blksize=14476;
proc datasource filetype=cs48qibm  infile=compstat
                out=stocks outby=company;
   keep data56 qftnt14;
   rename data56=comstock  qftnt14=ftcomstk;
   label  data56='Common Stock'
          qftnt14='Footnote for Common Stock';
   range  from 1990:4;

run;

/*- add company name to the out= data set    */
data stocks;
   merge stocks company( keep=dnum cnum cic coname );
   by dnum cnum cic;
run;

title1 'Common Stocks for Last Quarter of 1990';
proc print data=stocks ;
run;
```

Output 12.7.1 contains a listing of the STOCKS data set.

Output 12.7.1 Listing of the OUT=STOCKS Data Set

Common Stocks for Last Quarter of 1990

Note that quarterly Compustat data are also available in Universal Character format. If you have this type of file instead of IBM 360/370 General format, use the FILETYPE=CS48QUC option instead.

Example 12.8: Annual COMPUSTAT Data Files, V9.2 New Filetype CSAUC3

Annual COMPUSTAT data in Universal Character format are read for PRICES since the year 2002, so that the desired output show the PRICE (HIGH), PRICE (LOW), and PRICE (CLOSE) for each company.

```
filename datafile "%sysget(DATASRC_DATA)csaucy3.dat" RECFM=F LRECL=13612;
/*-------------------------------------------------------------*

Note that annual COMPUSTAT data are available in either IBM 360/370 General format or Universal Character format. The first example expects an IBM 360/370 General format file since the FILETYPE= is set

to CSAIBM, while the second example uses a Universal Character format file (FILETYPE=CSAUC).

Example 12.9: CRSP Daily NYSE/AMEX Combined Stocks

This sample code reads all the data in a three-volume daily NYSE/AMEX combined character data set. Assume that the following filerefs are assigned to the calendar/indices file and security files that this database comprises:

Fileref	VOLSER	File Type
calfile	DXAA1	Calendar/indices file on volume 1
secfile1	DXAA1	Security file on volume 1
secfile2	DXAA2	Security file on volume 2
secfile3	DXAA3	Security file on volume 3

The data set CALDATA is created by the following statements to contain the calendar/indices file:

```
proc datasource filetype=crspdci infile=calfile out=caldata;
run;
```

Here the FILETYPE=CRSPDCI indicates that you are reading a character format (indicated by a C in the 6th position) daily (indicated by a D in the 5th position) calendar/indices file (indicated by an I in the 7th position).

The annual data in security files can be obtained by the following statements:

```
proc datasource filetype=crspdca
                infile=( secfile1 secfile2 secfile3 )
                out=annual;
run;
```

Similarly, the data sets to contain the daily security data (the OUT= data set) and the event data (the OUTEVENT= data set) are obtained by the following statements:

```
proc datasource filetype=crspdcs
                infile=( calfile secfile1 secfile2 secfile3 )
                out=periodic index outevent=events;
run;
```

Note that the FILETYPE= has an S in the 7th position, since you are reading the security files. Also, the INFILE= option first expects the fileref of the calendar/indices file since the dating variable (CALDT) is contained in that file. Following the fileref of calendar/indices file, you give the list of security files in the order in which you want to read them. When data span more than one physical volume, the filerefs of the security files residing on each volume must be given following the fileref of the calendar/indices file. The DATASOURCE procedure reads each of these files in the order in which they are specified. Therefore, you can request that all three volumes be mounted to the same drive, if you choose to do so.

This sample code illustrates the following points:

- The INDEX option in the second PROC DATASOURCE run creates an index file for the OUT=PERIODIC data set. This index file provides random access to the OUT= data set and might

increase the efficiency of the subsequent PROC and DATA steps that use BY and WHERE statements. The index variables are CUSIP, CRSP permanent number (PERMNO), NASDAQ company number (COMPNO), NASDAQ issue number (ISSUNO), header exchange code (HEXCD), and header SIC code (HSICCD). Each one of these variables forms a different key which is a single index. If you want to form keys from a combination of variables (composite indexes) or use some other variables as indexes, you should use the INDEX= data set option for the OUT= data set.

- The OUTEVENT=EVENTS data set is sparse. In fact, for each EVENT type, a unique set of event variables are defined. For example, for EVENT='SHARES', only the variables SHROUT and SHRFLG are defined, and they have missing values for all other EVENT types. Pictorially, this structure is similar to the data set shown in Figure 12.4. Because of this sparse representation, you should create the OUTEVENT= data set only when you need a subset of securities and events.

By default, the OUT= data set contains only the periodic data. However, you might also want to include the event-oriented data in the OUT= data set. This is accomplished by listing the event variables together with periodic variables in a KEEP statement. For example, if you want to extract the historical CUSIP (NCUSIP), number of shares outstanding (SHROUT), and dividend cash amount (DIVAMT) together with all the periodic series, use the following statements:

```
proc datasource filetype=crspdcs
                infile=( calfile secfile1 secfile2 secfile3 )
                out=both outevent=events;
   where cusip='09523220';
   keep  bidlo askhi prc vol ret sxret bxret ncusip shrout divamt;
run;
```

The KEEP statement has no effect on the event variables output to the OUTEVENT= data set. If you want to extract only a subset of event variables, you need to use the KEEPEVENT statement. For example, the following sample code outputs only NCUSIP and SHROUT to the OUTEVENT= data set for CUSIP='09523220':

```
proc datasource filetype=crspdxc
                infile=( calfile secfile)
                outevent=subevts;
   where cusip='09523220';
   keepevent  ncusip shrout;
run;
```

Output 12.9.1, Output 12.9.2, Output 12.9.3, and Output 12.9.4 show how to read the CRSP Daily NYSE/AMEX Combined ASCII Character Files.

```
filename dxci "%sysget(DATASRC_DATA)dxccal95.dat" RECFM=F LRECL=130;
filename dxc "%sysget(DATASRC_DATA)dxcsub95.dat" RECFM=F LRECL=400;

Overview: ENTROPY Procedure

The ENTROPY procedure implements a parametric method of linear estimation based on generalized maximum entropy. The ENTROPY procedure is suitable when there are outliers in the data and robustness is required, when the model is ill-posed or under-determined for the observed data, or for regressions that involve small data sets.

The main features of the ENTROPY procedure are as follows:

- estimation of simultaneous systems of linear regression models
- estimation of Markov models
- estimation of seemingly unrelated regression (SUR) models
- estimation of unordered multinomial discrete choice models
- solution of pure inverse problems
- allowance of bounds and restrictions on parameters
- performance of tests on parameters
- allowance of data and moment constrained generalized cross entropy

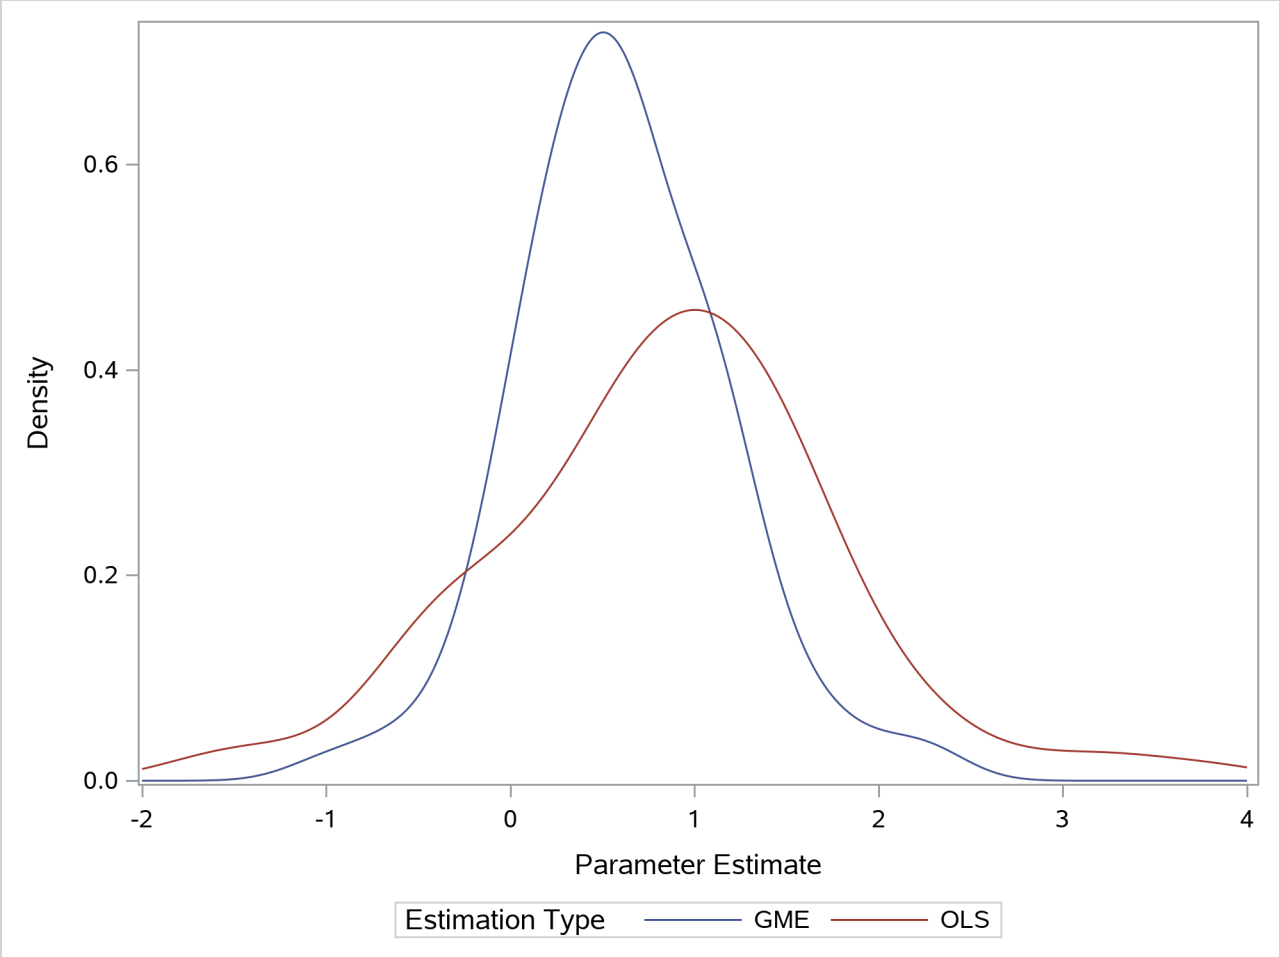
It is often the case that the statistical/economic model of interest is ill-posed or under-determined for the observed data. For the general linear model, this can imply that high degrees of collinearity exist among explanatory variables or that there are more parameters to estimate than observations available to estimate them. These conditions lead to high variances or non-estimability for traditional generalized least squares (GLS) estimates.

Under these situations it might be in the researcher's or practitioner's best interest to consider a nontraditional technique for model fitting. The principle of maximum entropy is the foundation for an estimation methodology that is characterized by its robustness to ill-conditioned designs and its ability to fit over-parameterized models. For a discussion of Shannon's maximum entropy measure and the related Kullback-Leibler information, see Mittelhammer, Judge, and Miller (2000) and Golan, Judge, and Miller (1996).

Generalized maximum entropy (GME) is a means of selecting among probability distributions to choose the distribution that maximizes uncertainty or uniformity remaining in the distribution, subject to information already known about the distribution. Information takes the form of data or moment constraints in the estimation procedure. PROC ENTROPY creates a GME distribution for each parameter in the linear model, based upon support points supplied by the user. The mean of each distribution is used as the estimate of the

parameter. Estimates tend to be biased, as they are a type of shrinkage estimate, but typically portray smaller variances than ordinary least squares (OLS) counterparts, making them more desirable from a mean squared error viewpoint (see Figure 13.1).

Figure 13.1 Distribution of Maximum Entropy Estimates versus OLS



Maximum entropy techniques are most widely used in the econometric and time series fields. Some important uses of maximum entropy include the following:

- size distribution of firms
- stationary Markov process
- social accounting matrix (SAM)
- consumer brand preference
- exchange rate regimes
- wage-dependent firm relocation
- oil market dynamics

Getting Started: ENTROPY Procedure

This section introduces the ENTROPY procedure and shows how to use PROC ENTROPY for several kinds of statistical analyses.

Simple Regression Analysis

The ENTROPY procedure is similar in syntax to the other regression procedures in SAS. To demonstrate the similarity, suppose the endogenous/dependent variable is y, and x1 and x2 are two exogenous/independent variables of interest. To estimate the parameters in this single equation model using PROC ENTROPY, use the following SAS statements:

```
proc entropy;
   model y = x1 x2;
run;
```

Test Scores Data Set

Consider the following test score data compiled by Coleman et al. (1966):

```
title "Test Scores Compiled by Coleman et al. (1966)";
data coleman;
   input test_score 6.2 teach_sal 6.2 prcnt_prof 8.2
            socio_stat 9.2 teach_score 8.2 mom_ed 7.2;
   label test_score="Average sixth grade test scores in observed district";
   label teach_sal="Average teacher salaries per student (1000s of dollars)";
   label prcnt_prof="Percent of students' fathers with professional employment";
   label socio_stat="Composite measure of socio-economic status in the district";
   label teach_score="Average verbal score for teachers";
   label mom_ed="Average level of education (years) of the students' mothers";
datalines;
37.01   3.83   28.87     7.20   26.60   6.19

   ... more lines ...
```

This data set contains outliers, and the condition number of the matrix of regressors, $\mathbf{X}$, is large, which indicates collinearity among the regressors. Since the maximum entropy estimates are both robust with respect to the outliers and also less sensitive to a high condition number of the $\mathbf{X}$ matrix, maximum entropy estimation is a good choice for this problem.

To fit a simple linear model to these data by using PROC ENTROPY, use the following statements:

```
proc entropy data=coleman;
   model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
run;
```

This requests the estimation of a linear model for TEST_SCORE with the following form:

$$\begin{aligned} test\_score &= intercept + a * teach\_sal + b * prcnt\_prof + c * socio\_stat \\ &\quad + d * teach\_score + e * mom\_ed + \epsilon; \end{aligned}$$

This estimation produces the "Model Summary" table in Figure 13.2, which shows the equation variables used in the estimation.

Figure 13.2 Model Summary Table

Test Scores Compiled by Coleman et al. (1966)

The ENTROPY Procedure

Variables(Supports(Weights))	teach_sal prcnt_prof socio_stat teach_score mom_ed Intercept
Equations(Supports(Weights))	test_score

Since support points and prior weights are not specified in this example, they are not shown in the "Model Summary" table. The next four pieces of information displayed in Figure 13.3 are the "Data Set Options," the "Minimization Summary," the "Final Information Measures," and the "Observations Processed."

Figure 13.3 Estimation Summary Tables

Test Scores Compiled by Coleman et al. (1966)

The ENTROPY Procedure
GME Estimation Summary

Data Set Options	
DATA=	WORK.COLEMAN

Minimization Summary	
Parameters Estimated	6
Covariance Estimator	GME
Entropy Type	Shannon
Entropy Form	Dual
Numerical Optimizer	Quasi Newton

Final Information Measures	
Objective Function Value	9.553699
Signal Entropy	9.569484
Noise Entropy	-0.01578
Normed Entropy (Signal)	0.990976
Normed Entropy (Noise)	0.999786
Parameter Information Index	0.009024
Error Information Index	0.000214

Observations Processed	
Read	20
Used	20

The item labeled "Objective Function Value" is the value of the entropy estimation criterion for this estimation problem. This measure is analogous to the log-likelihood value in a maximum likelihood estimation. The "Parameter Information Index" and the "Error Information Index" are normalized entropy values that measure the proximity of the solution to the prior or target distributions.

The next table displayed is the ANOVA table, shown in Figure 13.4. This is in the same form as the ANOVA table for the MODEL procedure, since this is also a multivariate procedure.

Figure 13.4 Summary of Residual Errors

GME Summary of Residual Errors

Equation	DF Model	DF Error	SSE	MSE	Root MSE	R-Square	Adj RSq
test_score	6	14	175.8	8.7881	2.9645	0.7266	0.6290

The last table displayed is the "Parameter Estimates" table, shown in Figure 13.5. The difference between this parameter estimates table and the parameter estimates table produced by other regression procedures is that the standard error and the probabilities are labeled as approximate.

Figure 13.5 Parameter Estimates

GME Variable Estimates

Variable	Estimate	Approx Std Err	t Value	Approx Pr > |t|
teach_sal	0.287979	0.00551	52.26	<.0001
prcnt_prof	0.02266	0.00323	7.01	<.0001
socio_stat	0.199777	0.0308	6.48	<.0001
teach_score	0.497137	0.0180	27.61	<.0001
mom_ed	1.644472	0.0921	17.85	<.0001
Intercept	10.5021	0.3958	26.53	<.0001

The parameter estimates produced by the REG procedure for this same model are shown in Figure 13.6. Note that the parameters and standard errors from PROC REG are much different than estimates produced by PROC ENTROPY.

```
proc reg data=coleman plots=residualchart(unpack);
   model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
run;
```

Figure 13.6 REG Procedure Parameter Estimates

Test Scores Compiled by Coleman et al. (1966)

mom_ed	1	-1.81092	2.02739	-0.89	0.3868

This data set contains two outliers, observations 3 and 18. These can be seen in a plot of the residuals shown in Figure 13.7: the studentized residuals of observations 3 and 18 are outside $[-1.771, 1.771]$, the 90% confidence interval for a Student's t distribution with 13 degrees of freedom.

Figure 13.7 PROC REG Residuals with Outliers

Studentized Residuals for test_score

Obs	Residual	Std Err Residual	Studentized Residuals
1	0.3488	1.4922	0.234
2	-0.3499	1.4868	-0.235
3	-3.9497	1.9313	-2.045
4	-0.4736	1.8884	-0.251
5	0.7809	1.8805	0.415
6	-0.0857	1.4669	-0.058
7	0.7188	1.8094	0.397
8	-0.4343	1.9596	-0.222

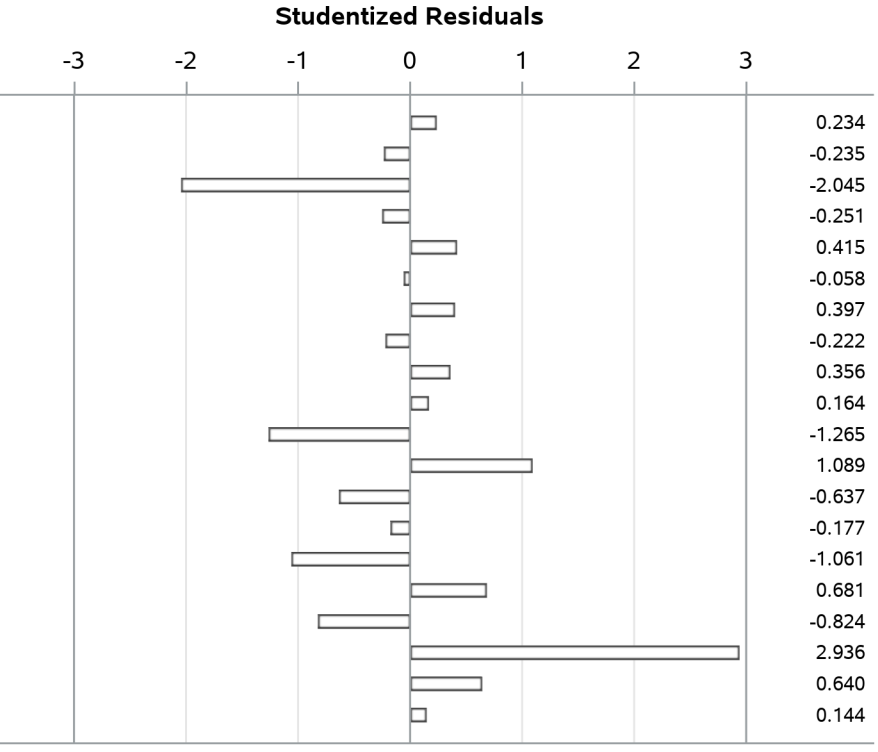
10	0.2104	1.2820	0.164
11	-2.2080	1.7461	-1.265
12	1.7465	1.6031	1.089
13	-1.0487	1.6473	-0.637
14	-0.3457	1.9582	-0.177
15	-1.7789	1.6769	-1.061
16	1.2974	1.9046	0.681
17	-1.4398	1.7471	-0.824
18	5.0018	1.7035	2.936
19	1.1226	1.7545	0.640
20	0.2628	1.8288	0.144



The presence of outliers suggests that a robust estimator such as *M*-estimator in the ROBUSTREG procedure should be used. The following statements use the ROBUSTREG procedure to estimate the model:

```
proc robustreg data=coleman;
   model test_score = teach_sal prcnt_prof
                      socio_stat teach_score mom_ed;
run;
```

The results of the estimation are shown in Figure 13.8.

Figure 13.8 *M*-Estimation Results

Test Scores Compiled by Coleman et al. (1966)

The ROBUSTREG Procedure

Parameter Estimates

Parameter	DF	Estimate	Standard Error	95% Confidence Limits		Chi-Square	Pr > ChiSq
Intercept	1	29.3416	6.0381	17.5072	41.1761	23.61	<.0001
teach_sal	1	-1.6329	0.5465	-2.7040	-0.5618	8.93	0.0028
prcnt_prof	1	0.0823	0.0236	0.0361	0.1286	12.17	0.0005
socio_stat	1	0.6653	0.0412	0.5846	0.7461	260.95	<.0001
teach_score	1	1.1744	0.1922	0.7977	1.5510	37.34	<.0001
mom_ed	1	-3.9706	0.8983	-5.7312	-2.2100	19.54	<.0001
Scale	1	0.6966					

Note that TEACH_SAL(VAR1) and MOM_ED(VAR5) change greatly when the robust estimation is used. Unfortunately, these two coefficients are negative, which implies that the test scores increase with decreasing teacher salaries and decreasing levels of the mother's education. Since ROBUSTREG is robust to outliers, they are not causing the counterintuitive parameter estimates.

The condition number of the regressor matrix **X** also plays a important role in parameter estimation. The condition number of the matrix can be obtained by specifying the COLLIN option in the PROC ENTROPY statement.

```
proc entropy data=coleman collin;
   model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
run;
```

The output produced by the COLLIN option is shown in Figure 13.9.

Figure 13.9 Collinearity Diagnostics

Test Scores Compiled by Coleman et al. (1966)

The ENTROPY Procedure

Collinearity Diagnostics

			Proportion of Variation					
Number	Eigenvalue	Condition Number	teach_sal	prcnt_prof	socio_stat	teach_score	mom_ed	Intercept
1	4.978128	1.0000	0.0007	0.0012	0.0026	0.0001	0.0001	0.0000
2	0.937758	2.3040	0.0006	0.0028	0.2131	0.0001	0.0000	0.0001
3	0.066023	8.6833	0.0202	0.3529	0.6159	0.0011	0.0000	0.0003
4	0.016036	17.6191	0.7961	0.0317	0.0534	0.0059	0.0083	0.0099
5	0.001364	60.4112	0.1619	0.3242	0.0053	0.7987	0.3309	0.0282
6	0.000691	84.8501	0.0205	0.2874	0.1096	0.1942	0.6607	0.9614

The condition number of the $\mathbf{X}$ matrix is reported to be 84.85. This means that the condition number of $\mathbf{X}'\mathbf{X}$ is $84.85^2 = 7199.5$, which is very large.

Ridge regression can be used to offset some of the problems associated with ill-conditioned $\mathbf{X}$ matrices. Using the formula for the ridge value as

$$\lambda_R = \frac{kS^2}{\hat{\beta}'\hat{\beta}} \approx 0.9$$

where $\hat{\beta}$ and S^2 are the least squares estimators of β and σ^2 and $k = 6$. A ridge regression of the test score model was performed by using the data set with the outliers removed. The following PROC REG code performs the ridge regression:

```
data coleman;
   set coleman;
   if _n_ = 3 or _n_ = 18 then delete;
run;

proc reg data=coleman ridge=0.9 outest=t noprint;
   model test_score = teach_sal prcnt_prof socio_stat teach_score mom_ed;
run;

proc print data=t;
run;
```

The results of the estimation are shown in Figure 13.10.

Figure 13.10 Ridge Regression Estimates

Test Scores Compiled by Coleman et al. (1966)

Obs	_MODEL_	_TYPE_	_DEPVAR_	_RIDGE_	_PCOMIT_	_RMSE_	Intercept	teach_sal
1	MODEL1	PARMS	test_score	.	.	0.78236	29.7577	-1.69854
2	MODEL1	RIDGE	test_score	0.9	.	3.19679	9.6698	-0.08892

Obs	prcnt_prof	socio_stat	teach_score	mom_ed	test_score
1	0.085118	0.66617	1.18400	-4.06675	-1
2	0.041889	0.23223	0.60041	1.32168	-1

Note that the ridge regression estimates are much closer to the estimates produced by the ENTROPY procedure that uses the original data set. Ridge regressions are not robust to outliers as maximum entropy estimates are. This might explain why the estimates still differ for TEACH_SAL.

Using Prior Information

You can use prior information about the parameters or the residuals to improve the efficiency of the estimates. Some authors prefer the term *pre-sample* or *pre-data* over the term *prior* when used with maximum entropy to avoid confusion with Bayesian methods. The maximum entropy method described here does not use Bayes' rule when including prior information in the estimation.

To perform regression, the ENTROPY procedure uses a generalization of maximum entropy called *generalized maximum entropy*. In maximum entropy estimation, the unknowns are probabilities. Generalized maximum entropy expands the set of problems that can be solved by introducing the concept of *support points*. Generalized maximum entropy still estimates probabilities, but these are the probabilities of a support point. Support points are used to map the (0, 1) domain of the maximum entropy to any finite range of values.

Prior information, such as expected ranges for the parameters or the residuals, is added by specifying support points for the parameters or the residuals. Support points are points in one dimension that specify the expected domain of the parameter or the residual. The wider the domain specified, the less efficient your parameter estimates are (the more variance they have). Specifying more support points in the same width interval also improves the efficiency of the parameter estimates at the cost of more computation. Golan, Judge, and Miller (1996) show that the gains in efficiency fall off for adding more than five support points. You can specify between 2 and 256 support points in the ENTROPY procedure.

If you have only a small amount of data, the estimates are very sensitive to your selection of support points and weights. For larger data sets, incorrect priors are discounted if they are not supported by the data.

Consider the data set generated by the following SAS statements:

```
title "Prior Distribution of Parameter T";

data prior;
   do by = 1 to 100;
      do t = 1 to 10;
         y = 2*t + 5 * rannor(4);
         output;
      end;
```

```
    end;
run;
```

The PRIOR data set contains 100 samples of 10 observations each from the population

$$\begin{aligned} y &= 2 * t + \epsilon \\ \epsilon &\sim N(0, 5) \end{aligned}$$

You can estimate these samples using PROC ENTROPY as follows:

```
proc entropy data=prior outest=parm1 noprint;
   model y = t ;
   by by;
run;
```

The 100 estimates are summarized by using the following SAS statements:

```
proc univariate data=parm1;
   var t;
run;
```

The summary statistics from PROC UNIVARIATE are shown in Output 13.11. The true value of the coefficient T is 2.0, demonstrating that maximum entropy estimates tend to be biased.

Figure 13.11 No Prior Information Monte Carlo Summary

Prior Distribution of Parameter T

The UNIVARIATE Procedure
Variable: t

Basic Statistical Measures			
Location		**Variability**	
Mean	1.693608	**Std Deviation**	0.30199
Median	1.707653	**Variance**	0.09120
Mode	.	**Range**	1.46194
		Interquartile Range	0.32329

Now assume that you have prior information about the slope and the intercept for this model. You are reasonably confident that the slope is 2 and you are less confident that intercept is zero. To specify prior information about the parameters, use the PRIORS statement.

There are two parts to the prior information specified in the PRIORS statement. The first part is the support points for a parameter. The support points specify the domain of the parameter. For example, the following statement sets the support points –1000 and 1000 for the parameter associated with variable T:

```
priors t -1000 1000;
```

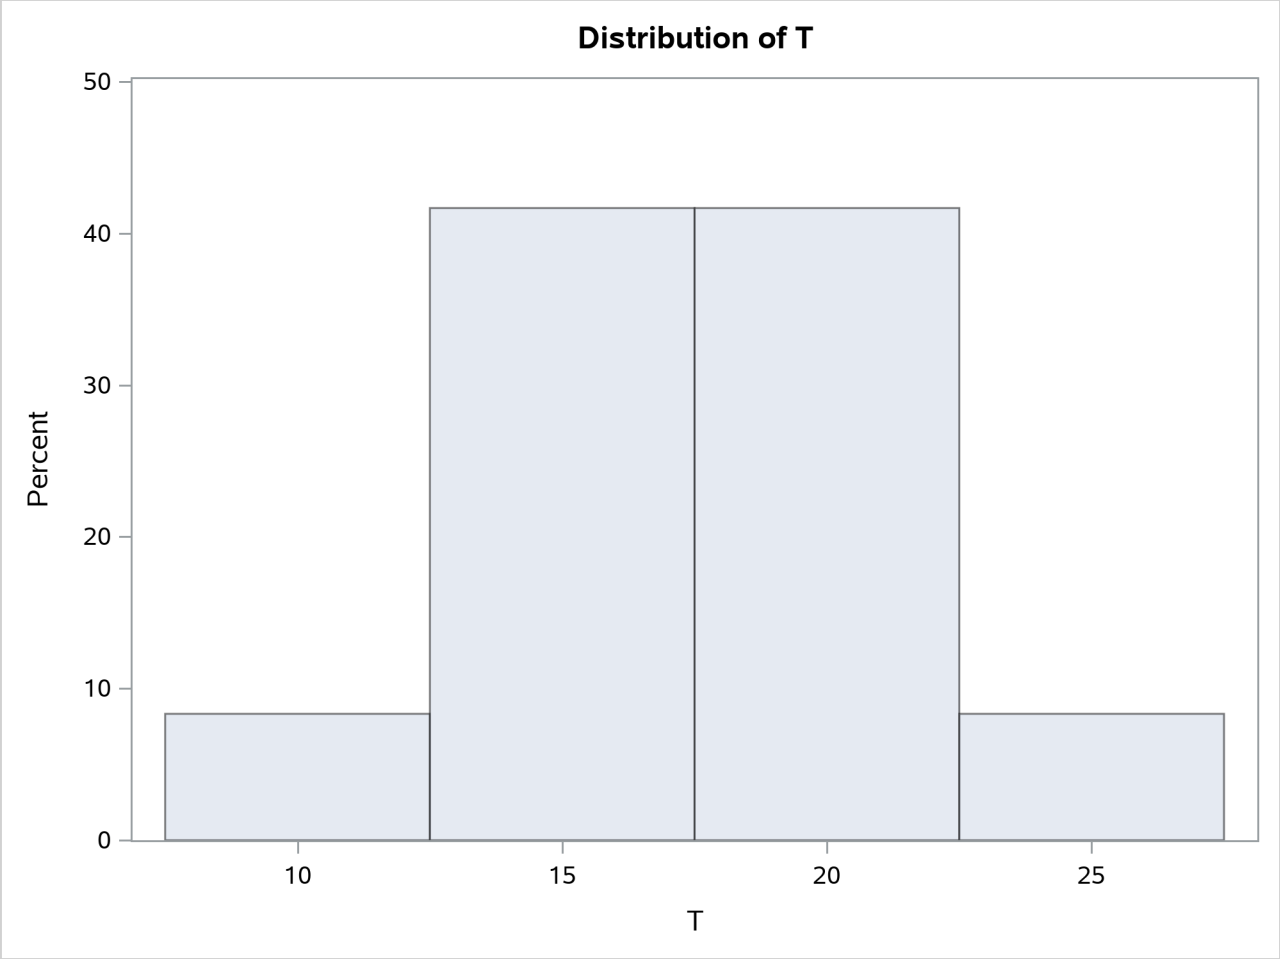
This means that the coefficient lies in the interval $[-1000, 1000]$. If the estimated value of the coefficient is actually outside of this interval, the estimation will not converge. In the previous PRIORS statement, no weights were specified for the support points, so uniform weights are assumed. This implies that the coefficient has a uniform probability of being in the interval $[-1000, 1000]$.

The second part of the prior information is the weights on the support points. For example, the following statements sets the support points 10, 15, 20, and 25 with weights 1, 5, 5, and 1, respectively, for the coefficient of T:

```
priors t 10(1) 15(5) 20(5) 25(1);
```

This creates the prior distribution on the coefficient shown in Figure 13.12. The weights are automatically normalized so that they sum to one.

Figure 13.12 Prior Distribution of Parameter T



For the PRIOR data set created previously, the expected value of the coefficient of T is 2. The following SAS statements reestimate the parameters with a prior weight specified for each one:

```
proc entropy data=prior outest=parm2 noprint;
   priors t 0(1) 2(3) 4(1)
          intercept -100(.5) -10(1.5) 0(2) 10(1.5) 100(0.5);
   model y = t;
   by by;
run;
```

The priors on the coefficient of T express a confident view of the value of the coefficient. The priors on INTERCEPT express a more diffuse view on the value of the intercept. The following PROC UNIVARIATE

statement computes summary statistics from the estimations:

```
proc univariate data=parm2;
   var t;
run;
```

The summary statistics for the distribution of the estimates of T are shown in Figure 13.13.

Mode	.	**Range**	0.08525
		Interquartile Range	0.01855

The prior information improves the estimation of the coefficient of T dramatically. The downside of specifying priors comes when they are incorrect. For example, say the priors for this model were specified as

```
priors t -2(1) 0(3) 2(1);
```

to indicate a prior centered on zero instead of two.

The resulting summary statistics shown in Figure 13.14 indicate how the estimation is biased away from the solution.

Figure 13.14 Incorrect Prior Information Monte Carlo Summary

Prior Distribution of Parameter T

The UNIVARIATE Procedure
Variable: t

Basic Statistical Measures			
Location		**Variability**	
Mean	0.062550	**Std Deviation**	0.00920
Median	0.062527	**Variance**	0.0000847
Mode	.	**Range**	0.05442
		Interquartile Range	0.01112

The more data available for estimation, the less sensitive the parameters are to the priors. If the number of observations in each sample is 50 instead of 10, then the summary statistics shown in Figure 13.15 are produced. The prior information is not supported by the data, so it is discounted.

		Interquartile Range	0.01498

Pure Inverse Problems

A special case of systems of equations estimation is the pure inverse problem. A pure problem is one that contains an exact relationship between the dependent variable and the independent variables and does not have an error component. A pure inverse problem can be written as

$$\mathbf{y} = X\beta$$

where $\mathbf{y}$ is a n-dimensional vector of observations, $\mathbf{X}$ is a $n \times k$ matrix of regressors, and β is a k-dimensional vector of unknowns. Notice that there is no error term.

A classic example is a dice problem (Jaynes 1963). Given a six-sided die that can take on the values $x = 1, 2, 3, 4, 5, 6$ and the average outcome of the die $y = A$, compute the probabilities $\beta = (p_1, p_2, \ldots, p_6)'$ of rolling each number. This infers six values from two pieces of information. The data points are the expected value of y, and the sum of the probabilities is one. Given $E(y) = 4.0$, this problem is solved by using the following SAS code:

```
title "Pure Inverse Problems";

data one;
   array x[6] ( 1 2 3 4 5 6 );
   y=4.0;
run;

proc entropy data=one pure;
   priors x1 0 1 x2 0 1 x3 0 1 x4 0 1 x5 0 1 x6 0 1;
   model y = x1-x6/ noint;
   restrict x1 + x2 +x3 +x4 + x5 + x6 =1;
run;
```

The probabilities are given in Figure 13.16.

Figure 13.16 Jaynes' Dice Pure Inverse Problem

Pure Inverse Problems

The ENTROPY Procedure

GME Variable Estimates

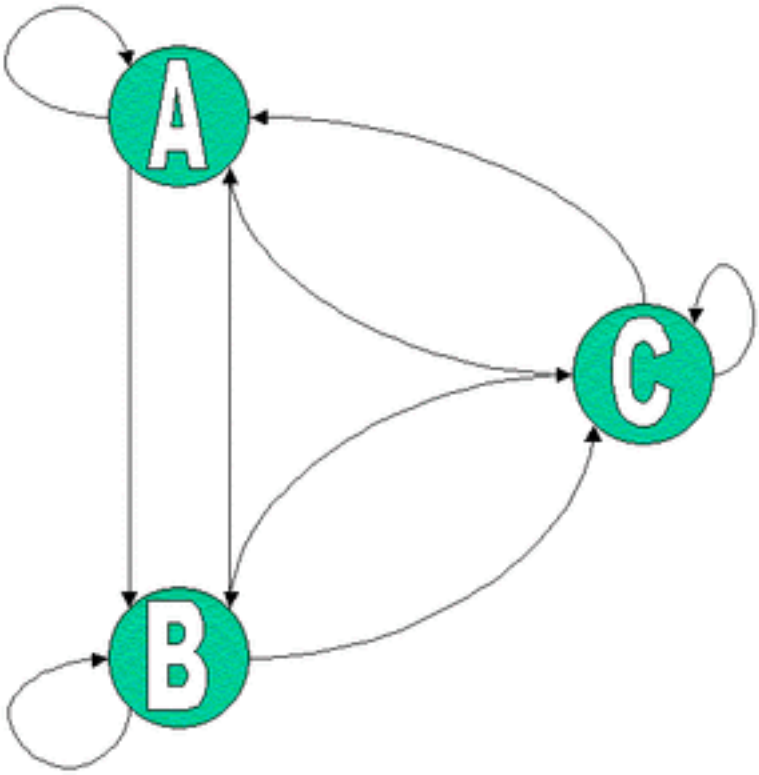
Variable	Estimate	Information Index	Label
x1	0.101763	0.5254	
x2	0.122658	0.4630	
x3	0.147141	0.3974	
x4	0.175533	0.3298	
x5	0.208066	0.2622	
x6	0.244839	0.1970	
Restrict943	2.388082	.	x1 + x2 + x3 + x4 + x5 + x6 = 1

Note how the probabilities are skewed to the higher values because of the high average roll provided in the input data.

First-Order Markov Process Estimation

A more useful inverse problem is the first-order markov process. Companies have a share of the marketplace where they do business. Generally, customers for a specific market space can move from company to company. The movement of customers can be visualized graphically as a flow diagram, as in Figure 13.17. The arrows represent movements of customers from one company to another.

Figure 13.17 Markov Transition Diagram



You can model the probability that a customer moves from one company to another using a first-order Markov model. Mathematically the model is

$$y_t = P y_{t-1}$$

where y_t is a vector of k market shares at time t and P is a $k \times k$ matrix of unknown transition probabilities. The value p_{ij} represents the probability that a customer who is currently using company j at time $t-1$ moves to company i at time t. The diagonal elements then represent the probability that a customer stays with the current company. The columns in P sum to one.

Given market share information over time, you can estimate the transition probabilities P. In order to estimate P using traditional methods, you need at least k observations. If you have fewer than k transitions, you can use the ENTROPY procedure to estimate the probabilities.

Suppose you are studying the market share for four companies. If you want to estimate the transition probabilities for these four companies, you need a time series with four observations of the shares. Assume the current transition probability matrix is as follows:

$$\begin{bmatrix} 0.7 & 0.4 & 0.0 & 0.1 \\ 0.1 & 0.5 & 0.4 & 0.0 \\ 0.0 & 0.1 & 0.6 & 0.0 \\ 0.2 & 0.0 & 0.0 & 0.9 \end{bmatrix}$$

The following SAS DATA step statements generate a series of market shares from this probability matrix. A transition is represented as the current period shares, `y`, and the previous period shares, `x`.

```
data m;
            /* Known Transition matrix */
   array p[4,4] (0.7 .4 .0 .1
                 0.1 .5 .4 .0
                 0.0 .1 .6 .0
                 0.2 .0 .0 .9 ) ;
            /* Initial Market shares */
   array y[4] y1-y4 ( .4 .3 .2 .1 );
   array x[4] x1-x4;
   drop p1-p16 i;
   do i = 1 to 3;
       x[1] = y[1]; x[2] = y[2];
       x[3] = y[3]; x[4] = y[4];
       y[1] = p[1,1] * x1 + p[1,2] * x2 + p[1,3] * x3 + p[1,4] * x4;
       y[2] = p[2,1] * x1 + p[2,2] * x2 + p[2,3] * x3 + p[2,4] * x4;
       y[3] = p[3,1] * x1 + p[3,2] * x2 + p[3,3] * x3 + p[3,4] * x4;
       y[4] = p[4,1] * x1 + p[4,2] * x2 + p[4,3] * x3 + p[4,4] * x4;
       output;
   end;
run;
```

The following SAS statements estimate the transition matrix by using only the first transition:

```
proc entropy markov pure data=m(obs=1);
   model y1-y4 = x1-x4;
run;
```

The MARKOV option implies NOINT for each model, that the sum of the parameters in each column is one, and chooses support points of 0 and 1. This model can be expressed equivalently as follows:

```
proc entropy pure data=m(obs=1) ;
   priors y1.x1 0 1 y1.x2 0 1 y1.x3 0 1 y1.x4 0 1;
   priors y2.x1 0 1 y2.x2 0 1 y2.x3 0 1 y2.x4 0 1;
   priors y3.x1 0 1 y3.x2 0 1 y3.x3 0 1 y3.x4 0 1;
   priors y4.x1 0 1 y4.x2 0 1 y4.x3 0 1 y4.x4 0 1;

   model y1 = x1-x4 / noint;
   model y2 = x1-x4 / noint;
   model y3 = x1-x4 / noint;
   model y4 = x1-x4 / noint;

   restrict y1.x1 + y2.x1 + y3.x1 + y4.x1 = 1;
   restrict y1.x2 + y2.x2 + y3.x2 + y4.x2 = 1;
   restrict y1.x3 + y2.x3 + y3.x3 + y4.x3 = 1;
   restrict y1.x4 + y2.x4 + y3.x4 + y4.x4 = 1;
run;
```

The transition matrix is given in Figure 13.18.

Figure 13.18 Estimate of *P* by Using One Transition

Pure Inverse Problems

The ENTROPY Procedure

GME Variable Estimates

Variable	Estimate	Information Index
y1.x1	0.463407	0.0039
y1.x2	0.41055	0.0232
y1.x3	0.356272	0.0605
y1.x4	0.302163	0.1161
y2.x1	0.272755	0.1546
y2.x2	0.271459	0.1564
y2.x3	0.267252	0.1625
y2.x4	0.260084	0.1731
y3.x1	0.119926	0.4709
y3.x2	0.148481	0.3940
y3.x3	0.180224	0.3194
y3.x4	0.214394	0.2502
y4.x1	0.143903	0.4056
y4.x2	0.169504	0.3434
y4.x3	0.196252	0.2856
y4.x4	0.223364	0.2337

Note that *P* varies greatly from the true solution.

If two transitions are used instead (OBS=2), the resulting transition matrix is shown in Figure 13.19.

```
proc entropy markov pure data=m(obs=2);
   model y1-y4 = x1-x4;
run;
```

Figure 13.19 Estimate of *P* by Using Two Transitions

Pure Inverse Problems

The ENTROPY Procedure

GME Variable Estimates

Variable	Estimate	Information Index
y1.x1	0.721012	0.1459
y1.x2	0.355703	0.0609
y1.x3	0.026095	0.8256
y1.x4	0.096654	0.5417
y2.x1	0.083987	0.5839
y2.x2	0.53886	0.0044
y2.x3	0.373668	0.0466
y2.x4	0.000133	0.9981
y3.x1	0.000062	0.9990
y3.x2	0.099848	0.5315
y3.x3	0.600104	0.0291
y3.x4	7.871E-8	1.0000
y4.x1	0.194938	0.2883
y4.x2	0.00559	0.9501
y4.x3	0.000133	0.9981
y4.x4	0.903214	0.5413

This transition matrix is much closer to the actual transition matrix.

If, in addition to the transitions, you had other information about the transition matrix, such as your own company's transition values, that information can be added as restrictions to the parameter estimates. For noisy data, the PURE option should be dropped. Note that this example has six zero probabilities in the transition matrix; the accurate estimation of transition matrices with fewer zero probabilities generally requires more transition observations.

Analyzing Multinomial Response Data

Multinomial discrete choice models suffer the same problems with collinearity of the regressors and small sample sizes as linear models. Unordered multinomial discrete choice models can be estimated using a variant of GME for discrete models called GME-D.

Consider the model shown in Golan, Judge, and Perloff (1996). In this model, there are five occupational categories, and the categories are considered a function of four individual characteristics. The sample contains 337 individuals.

```
title "Analyzing Multinomial Response Data";

data kpdata;
   input job x1 x2 x3 x4;
datalines;
   0 1 3 11 1
```

```
   ... more lines ...
```

The dependent variable in these data, job, takes on values 0 through 4. Support points are used only for the error terms; so error supports are specified in the MODEL statement.

```
proc entropy data=kpdata gmed tech=nra;
   model job = x1 x2 x3 x4 / noint
         esupports=( -.1 -0.0666 -0.0333 0 0.0333 0.0666 .1 );
run;
```

Figure 13.20 Estimate of Jobs Model by Using GME-D

Analyzing Multinomial Response Data

The ENTROPY Procedure

GME-D Variable Estimates

Variable	Estimate	Approx Std Err	t Value	Approx Pr > |t|
x1_1	1.802572	1.3610	1.32	0.1863
x2_1	-0.00251	0.0154	-0.16	0.8705
x3_1	-0.17282	0.0885	-1.95	0.0517
x4_1	1.054659	0.6986	1.51	0.1321
x1_2	0.089156	1.2764	0.07	0.9444
x2_2	0.019947	0.0146	1.37	0.1718
x3_2	0.010716	0.0830	0.13	0.8974
x4_2	0.288629	0.5775	0.50	0.6176
x1_3	-4.62047	1.6476	-2.80	0.0053
x2_3	0.026175	0.0166	1.58	0.1157
x3_3	0.245198	0.0986	2.49	0.0134
x4_3	1.285466	0.8367	1.54	0.1254
x1_4	-9.72734	1.5813	-6.15	<.0001
x2_4	0.027382	0.0156	1.75	0.0805
x3_4	0.660836	0.0947	6.98	<.0001
x4_4	1.47479	0.6970	2.12	0.0351

Note there are five estimates of the parameters produced for each regressor, one for each choice. The first choice is restricted to zero for normalization purposes. PROC ENTROPY drops the zeroed regressors. PROC ENTROPY also generates tables of marginal effects for each regressor. The following statements generate the marginal effects table for the previous analysis at the means of the variables:

```
proc entropy data=kpdata gmed tech=nra;
   model job = x1 x2 x3 x4 / noint
         esupports=( -.1 -0.0666 -0.0333 0 0.0333 0.0666 .1 )
         marginals;
run;
```

Figure 13.21 Estimate of Jobs Model by Using GME-D (Marginals)

Analyzing Multinomial Response Data

The ENTROPY Procedure

GME-D Variable Marginal Effects Table

Variable	Marginal Effect	Mean
x1_0	0.338758	1
x2_0	-0.0019	20.50148
x3_0	-0.02129	13.09496
x4_0	-0.09917	0.916914
x1_1	0.859883	1
x2_1	-0.00345	20.50148
x3_1	-0.0648	13.09496
x4_1	0.034396	0.916914
x1_2	0.86101	1
x2_2	0.000963	20.50148
x3_2	-0.04948	13.09496
x4_2	-0.16297	0.916914
x1_3	-0.25969	1
x2_3	0.0015	20.50148
x3_3	0.009289	13.09496
x4_3	0.065569	0.916914
x1_4	-1.79996	1
x2_4	0.00288	20.50148
x3_4	0.126283	13.09496
x4_4	0.162172	0.916914

The marginals are derivatives of the probabilities with respect to each variable and so summarize how a small change in each variable affects the overall probability.

PROC ENTROPY also enables the user to specify where the derivative is evaluated, as follows:

```
proc entropy data=kpdata gmed tech=nra;
   model job = x1 x2 x3 x4 / noint
         esupports=( -.1 -0.0666 -0.0333 0 0.0333 0.0666 .1 )
         marginals=( x2=.4 x3=10 x4=0);
run;
```

Figure 13.22 Estimate of Jobs Model by Using GME-D (Marginals)

Analyzing Multinomial Response Data

The ENTROPY Procedure

GME-D Variable Marginal Effects Table

Variable	Marginal Effect	Mean	Marginal Effect at User Supplied Values	User Supplied Values
x1_0	0.338758	1	-0.0901	1
x2_0	-0.0019	20.50148	-0.00217	0.4
x3_0	-0.02129	13.09496	0.009586	10
x4_0	-0.09917	0.916914	-0.14204	0
x1_1	0.859883	1	0.463181	1
x2_1	-0.00345	20.50148	-0.00311	0.4
x3_1	-0.0648	13.09496	-0.04339	10
x4_1	0.034396	0.916914	0.174876	0
x1_2	0.86101	1	-0.07894	1
x2_2	0.000963	20.50148	0.004405	0.4
x3_2	-0.04948	13.09496	0.015555	10
x4_2	-0.16297	0.916914	-0.072	0
x1_3	-0.25969	1	-0.16459	1
x2_3	0.0015	20.50148	0.000623	0.4
x3_3	0.009289	13.09496	0.00929	10
x4_3	0.065569	0.916914	0.02648	0
x1_4	-1.79996	1	-0.12955	1
x2_4	0.00288	20.50148	0.000256	0.4
x3_4	0.126283	13.09496	0.008956	10
x4_4	0.162172	0.916914	0.012684	0

In this example, you evaluate the derivative when x1=1, x2=0.4, x3=10, and x4=0. If the user neglects a variable, PROC ENTROPY uses its mean value.

Syntax: ENTROPY Procedure

The following statements are available in the ENTROPY procedure:

PROC ENTROPY *options* **;**

Specify that a Lagrange multiplier test be computed	TEST	LM
Specify that a likelihood ratio test be computed	TEST	LR
Request all three types of tests	TEST	ALL

The following sections describe the PROC ENTROPY statement and then describe the other statements in alphabetical order.

PROC ENTROPY Statement

PROC ENTROPY *options* **;**

The following options can be specified in the PROC ENTROPY statement.

General Options

COLLIN

requests that the collinearity diagnostics of the $X'X$ matrix be printed.

COVBEST=CROSS | GME | GMEM
specifies the method for producing the covariance matrix of parameters for output and for standard error calculations. GMEM and GME are aliases and are the default.

GME | GCE
requests generalized maximum entropy or generalized cross entropy. This is the default estimation method.

GMEM | GCEM
requests moment maximum entropy or the moment cross entropy.

GMED
requests a variant of GME suitable for multinomial discrete choice models.

MARKOV
specifies that the model is a first-order Markov model.

PURE
specifies a regression without an error term.

SUR | ITSUR
specifies seemingly unrelated regression or iterated seemingly unrelated regression.

VARDEF=N | WGT | DF | WDF
specifies the denominator to be used in computing variances and covariances. You can specify the following values:

N	uses the number of nonmissing observations.
WGT	uses the sum of the weights.
DF	uses the number of nonmissing observations minus the model degrees of freedom (number of parameters).
WDF	uses the sum of the weights minus the model degrees of freedom.

By default, VARDEF=DF.

Data Set Options

DATA=*SAS-data-set*
specifies the input data set. Values for the variables in the model are read from this data set.

PDATA=*SAS-data-set*
names the SAS data set that contains the data about priors and supports.

OUT=*SAS-data-set*
names the SAS data set to contain the residuals from each estimation.

OUTCOV

COVOUT

writes the covariance matrix of the estimates to the OUTEST= data set in addition to the parameter estimates. The OUTCOV option is applicable only if the OUTEST= option is also specified.

OUTEST=*SAS-data-set*

names the SAS data set to contain the parameter estimates and optionally the covariance of the estimates.

OUTL=*SAS-data-set*

names the SAS data set to contain the estimated Lagrange multipliers for the models.

OUTP=*SAS-data-set*

names the SAS data set to contain the support points and estimated probabilities.

OUTS=*SAS-data-set*

names the SAS data set to contain the estimated covariance matrix of the equation errors. This is the covariance of the residuals computed from the parameter estimates.

OUTSUSED=*SAS-data-set*

names the SAS data set to contain the **S** matrix used in the objective function definition. The OUTSUSED= data set is the same as the OUTS= data set for the methods that iterate the **S** matrix.

SDATA=*SAS-data-set*

specifies a data set that provides the covariance matrix of the equation errors. The matrix read from the SDATA= data set is used for the equation error covariance matrix (**S** matrix) in the estimation. The SDATA= matrix is used to provide only the initial estimate of **S** for the methods that iterate the **S** matrix.

Printing Options

ITPRINT

prints the parameter estimates, objective function value, and convergence criteria at each iteration.

NOPRINT

suppresses the normal printed output but does not suppress error listings. Using any other print option turns the NOPRINT option off.

PLOTS=*global-plot-options* | *plot-request*

controls the plots that the ENTROPY procedure produces. (For general information about ODS Graphics, see Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).) The *global-plot-options* apply to all relevant plots generated by the ENTROPY procedure.

The *global-plot-options* supported by the ENTROPY procedure are as follows:

ONLY suppresses the default plots. Only the plots specifically requested are produced.

UNPACKPANEL displays each graph separately. (By default, some graphs can appear together in a single panel.)

The specific *plot-request* values supported by the ENTROPY procedure are as follows:

ALL	requests that all plots appropriate for the particular analysis be produced. ALL is equivalent to specifying FITPLOT, COOKSD, QQ, RESIDUALHISTOGRAM, and STUDENTRESIDUAL.
FITPLOT	plots the predicted and actual values.
COOKSD	produces the Cook's *D* plot.
QQ	produces a Q-Q plot of residuals.
RESIDUALHISTOGRAM	plots the histogram of residuals.
STUDENTRESIDUAL	plots the studentized residuals.
NONE	suppresses all plots.

The default behavior is to plot all plots appropriate for the particular analysis (ALL) in a panel.

Options to Control the Minimization Process

The following options can be helpful if a convergence problem occurs for a given model and set of data. The ENTROPY procedure uses the nonlinear optimization subsystem (NLO) to perform the model optimizations. In addition to the options listed below, all options supported in the NLO subsystem can be specified on the ENTROPY procedure statement. For more information, see Chapter 6, "Nonlinear Optimization Methods."

CONVERGE=*value*

GCONV=*value*

specifies the convergence criteria for *S*-iterated methods. The convergence measure computed during model estimation must be less than *value* before convergence is assumed. By default, CONVERGE=0.001.

DUAL | PRIMAL

specifies whether the optimization problem is solved using the dual or primal form. The dual form is the default.

MAXITER=*n*

specifies the maximum number of iterations allowed. By default, MAXITER=100.

MAXSUBITER=*n*

specifies the maximum number of subiterations allowed for an iteration. The MAXSUBITER= option limits the number of step halvings. By default, MAXSUBITER=30.

METHOD=CONGR | DBLDOG | LEVMAR | NEWRAP | NRR | NSIMP | QN | TR

TECHNIQUE=TR | NEWRAP | NRR | QN | CONGR | NSIMP | DBLDOG | LEVMAR

TECH=TR | NEWRAP | NRR | QN | CONGR | NSIMP | DBLDOG | LEVMAR

specifies the iterative minimization method to use. You can specify the following values:

CONGR	specifies the conjugate-gradient optimization method.
DBLDOG	specifies the double-dogleg optimization method.
LEVMAR	specifies the Levenberg-Marquardt method.
NEWRAP	specifies the Newton-Raphson method.
NRR	specifies the Newton-Raphson ridge method.

NSIMP	specifies the Nelder-Mead simplex optimization method.
QN	specifies the quasi-Newton method.
TR	specifies the trust region method.

For more information about optimization methods, see Chapter 6, "Nonlinear Optimization Methods." By default, METHOD=QN for the dual form and METHOD=NEWRAP for the primal form.

BOUNDS Statement

BOUNDS *bound1* < , *bound2* . . . > **;**

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. BOUNDS statement constraints refer to the parameters estimated by the ENTROPY procedure. You can specify any number of BOUNDS statements.

Each *boundary constraint* is composed of variables, constants, and inequality operators in the following form:

```
item operator item <,operator item <,operator item ...> >
```

Each *item* is a constant, the name of a regressor variable, or a list of regressor names. Each *operator* is <, >, <=, or >=.

You can use either the BOUNDS statement or the RESTRICT statement to impose boundary constraints; the BOUNDS statement provides a simpler syntax for specifying inequality constraints. For more information about the computational details of estimation with inequality restrictions, see the section "RESTRICT Statement" on page 806.

Lagrange multipliers are reported for all the active boundary constraints. In the printed output and in the OUTEST= data set, the Lagrange multiplier estimates are identified with the names BOUND1, BOUND2, and so forth. The probability of the Lagrange multipliers are computed using a beta distribution (LaMotte 1994). Nonactive or nonbinding bounds have no effect on the estimation results and are not noted in the output. To give the constraints more descriptive names, use the RESTRICT statement instead of the BOUNDS statement.

The following BOUNDS statement constrains the estimates of the coefficients of WAGE and TARGET and the 10 coefficients of x1 through x10 to be between zero and one. This example illustrates the use of parameter lists to specify boundary constraints.

```
bounds 0 < wage target x1-x10 < 1;
```

The following is an example of the use of the BOUNDS statement to impose boundary constraints on the variables X1, X2, and X3:

```
title "BOUNDS Statement";

proc entropy data=zero;
   bounds .1 <= x1 <= 100,
           0 <= x2 <=  25.6,
           0 <= x3 <=   5;
```

```
   model y = x1 x2 x3;
run;
```

The parameter estimates from this run are shown in Figure 13.23.

BY Statement

BY *variables* **;**

A BY statement is used to obtain separate estimates for observations in groups defined by the BY variables. To save parameter estimates for each BY group, use the OUTEST= option.

ID Statement

ID *variables* **;**

The ID statement specifies variables to identify observations in error messages or other listings and in the OUT= data set. The ID variables are normally SAS date or datetime variables. If more than one ID variable is used, the first variable is used to identify the observations and the remaining variables are added to the OUT= data set.

MODEL Statement

MODEL *dependent* = *regressors* < / *options* > **;**

The MODEL statement specifies the dependent variable and independent regressor variables for the regression model. If no independent variables are specified in the MODEL statement, only the mean (intercept) is estimated. To model a system of equations, specify more than one MODEL statement.

The following options can be used in the MODEL statement after a slash (/):

ESUPPORTS=(*support (prior) . . .* **)**

specifies the support points and prior weights on the residuals for the specified equation. The default is the following five support values:

$$-10 * value, -value, 0, value, 10 * value$$

where *value* is computed as

$$value = (max(y) - \bar{y}) * multiplier$$

for GME, where y is the dependent variable, and

$$value = (max(y) - \bar{y}) * multiplier * nobs * max(X) * 0.1$$

for generalized maximum entropy—moments (GME-M), where **X** is the information matrix, and *nobs* is the number of observations. The *multiplier* depends on the MULTIPLIER= option. The MULTIPLIER= option defaults to 2 for unrestricted models and to 4 for restricted models. The prior probabilities default to the following:

$$0.0005, 0.333, 0.333, 0.333, 0.0005$$

The support points and prior weights are selected so that hypothesis tests can be performed without adding significant bias to the estimation. These prior probability values are ad hoc.

NOINT
suppresses the intercept parameter.

MARGINALS = *(variable = value, . . . , variable = value)*
requests that the marginal effects of each variable be calculated for GME-D. Specifying the MARGINALS option with an optional list of values calculates the marginals at that vector of values. For example, if x1–x4 are explanatory variables, then including

MARGINALS = (x1 = 2, x2 = 4, x3 = –1, x4 = 5)

calculates the marginal effects at that vector. A skipped variable implies that its mean value is to be used.

CENSORED *((UB | LB) = (variable | value)*, **ESUPPORTS** *=(support (prior) . . .))*
specifies that the dependent variable be observed with censoring and specifies the censoring thresholds and the supports of the censored observations.

CATEGORY= *variable*
specifies the variable that keeps track of the categories the dependent variable is in when there is range censoring. When the actual value is observed, this variable should be set to MISSING.

RANGE (ID = (QS | INT) L = (*number* **) R = (** *number* **) , ESUPPORTS=(** *support < (prior) > . . .* **))**
specifies that the dependent variable be range bound. The RANGE option defines the range and the key (RANGE) that is used to identify the observation as being range bound. The RANGE = value should be some value in the CATEGORY= variable. The L and R define, respectively, the left endpoint of the range and the right endpoint of the range. ESUPPORTS sets the error supports on the variable.

PRIORS Statement

PRIORS *variable < support points < (priors) > > variable < support points < (priors) > > . . .* **;**

The PRIORS statement specifies the support points and prior weights for the coefficients on the variables.

Support points for coefficients default to five points, determined as follows:

$$-2 * value, -value, 0, value, 2 * value$$

where *value* is computed as

$$value = (\|mean\| + 3 * stderr) * multiplier$$

where the *mean* and the *stderr* are obtained from OLS and the *multiplier* depends on the MULTIPLIER= option. The MULTIPLIER= option defaults to 2 for unrestricted models and to 4 for restricted models. The prior probabilities for each support point default to the uniform distribution.

The number of support points must be at least two. If priors are specified, they must be positive and there must be the same number of priors as there are support points. Priors and support points can also be specified through the PDATA= data set.

RESTRICT Statement

RESTRICT *restriction1* < *, restriction2 . . .* > **;**

The RESTRICT statement is used to impose linear restrictions on the parameter estimates. You can specify any number of RESTRICT statements.

Each *restriction* is written as an optional name, followed by an expression, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

```
<"name" > expression operator expression
```

The optional *"name"* is a string used to identify the restriction in the printed output and in the OUTEST= data set. The *operator* can be =, <, >, <= , or >=. The operator and second expression are optional, as in the TEST statement, where they default to = 0.

Restriction expressions can be composed of variable names, multiplication (∗), and addition (+) operators, and constants. Variable names in restriction expressions must be among the variables whose coefficients are estimated by the model. The restriction expressions must be a linear function of the variables.

The following is an example of the use of the RESTRICT statement:

```
proc entropy data=one;
   restrict y1.x1*2 <= x2 + y2.x1;
   model y1 = x1 x2;
   model y2 = x1 x3;
run;
```

This example illustrates the use of compound names, `y1.x1`, to specify coefficients of specific equations.

TEST Statement

TEST < *"name"*> *test1* < *, test2 . . .* > < *,/ options* > **;**

The TEST statement performs tests of linear hypotheses on the model parameters.

The TEST statement applies only to parameters estimated in the model. You can specify any number of TEST statements.

Each *test* is written as an expression optionally followed by an equal sign (=) and a second expression:

```
expression <= expression>
```

Test expressions can be composed of variable names, multiplication (∗), addition (+), and subtraction (−) operators, and constants. Variables named in test expressions must be among the variables estimated by the model.

If you specify only one expression in a TEST statement, that expression is tested against zero. For example, the following two TEST statements are equivalent:

```
test a + b;

test a + b = 0;
```

When you specify multiple tests in the same TEST statement, a joint test is performed. For example, the following TEST statement tests the joint hypothesis that both of the coefficients on a and b are equal to zero:

```
test a, b;
```

To perform separate tests rather than a joint test, use separate TEST statements. For example, the following TEST statements test the two separate hypotheses that a is equal to zero and that b is equal to zero:

```
test a;
test b;
```

You can use the following options in the TEST statement:

WALD
specifies that a Wald test be computed. WALD is the default.

LM

RAO

LAGRANGE
specifies that a Lagrange multiplier test be computed.

LR

LIKE
specifies that a pseudo-likelihood ratio test be computed.

ALL
requests all three types of tests.

OUT=
specifies the name of an output SAS data set that contains the test results. The format of the OUT= data set produced by the TEST statement is similar to that of the OUTEST= data set.

WEIGHT Statement

WEIGHT *variable* **;**

The WEIGHT statement specifies a variable to supply weighting values to use for each observation in estimating parameters.

If the weight of an observation is nonpositive, that observation is not used for the estimation. *Variable* must be a numeric variable in the input data set. The regressors and the dependent variables are multiplied by the square root of the weight variable to form the weighted **X** matrix and the weighted dependent variable. The same weight is used for all MODEL statements.

Details: ENTROPY Procedure

Shannon's measure of entropy for a distribution is given by

$$\begin{aligned} &\text{maximize} && -\sum_{i=1}^{n} p_i \ln(p_i) \\ &\text{subject to} && \sum_{i=1}^{n} p_i = 1 \end{aligned}$$

where p_i is the probability associated with the ith support point. Properties that characterize the entropy measure are set forth by Kapur and Kesavan (1992).

The objective is to maximize the entropy of the distribution with respect to the probabilities p_i and subject to constraints that reflect any other known information about the distribution (Jaynes 1957). This measure, in the absence of additional information, reaches a maximum when the probabilities are uniform. A distribution other than the uniform distribution arises from information already known.

Generalized Maximum Entropy

Reparameterization of the errors in a regression equation is the process of specifying a support for the errors, observation by observation. If a two-point support is used, the error for the tth observation is reparameterized by setting $e_t = w_{t1} v_{t1} + w_{t2} v_{t2}$, where v_{t1} and v_{t2} are the upper and lower bounds for the tth error e_t, and w_{t1} and w_{t2} represent the weight associated with the point v_{t1} and v_{t2}. The error distribution is usually chosen to be symmetric, centered around zero, and the same across observations so that $v_{t1} = -v_{t2} = R$, where R is the support value chosen for the problem (Golan, Judge, and Miller 1996).

The generalized maximum entropy (GME) formulation was proposed for the ill-posed or underdetermined case where there is insufficient data to estimate the model with traditional methods. β is reparameterized by defining a support for β (and a set of weights in the cross entropy case), which defines a prior distribution for β.

In the simplest case, each β_k is reparameterized as $\beta_k = p_{k1} z_{k1} + p_{k2} z_{k2}$, where p_{k1} and p_{k2} represent the probabilities ranging from [0,1] for each β, and z_{k1} and z_{k2} represent the lower and upper bounds placed on β_k. The support points, z_{k1} and z_{k2}, are usually distributed symmetrically around the most likely value for β_k based on some prior knowledge.

With these reparameterizations, the GME estimation problem is

$$\begin{aligned} &\text{maximize} && H(p,w) = -p' \ln(p) - w' \ln(w) \\ &\text{subject to} && y = X Z p + V w \\ & && 1_K = (I_K \otimes 1_L') p \\ & && 1_T = (I_T \otimes 1_L') w \end{aligned}$$

where y denotes the column vector of length T of the dependent variable; $\mathbf{X}$ denotes the $(T \times K)$ matrix of observations of the independent variables; p denotes the LK column vector of weights associated with

the points in Z; w denotes the LT column vector of weights associated with the points in V; 1_K, 1_L, and 1_T are K-, L-, and T-dimensional column vectors, respectively, of ones; and I_K and I_T are $(K \times K)$- and $(T \times T)$-dimensional identity matrices.

These equations can be rewritten using set notation as follows:

$$\text{maximize} \quad H(p,w) = -\sum_{l=1}^{L}\sum_{k=1}^{K} p_{kl}\,\ln(p_{kl}) - \sum_{l=1}^{L}\sum_{t=1}^{T} w_{tl}\,\ln(w_{tl})$$

$$\text{subject to} \quad y_t = \sum_{l=1}^{L}\left[\sum_{k=1}^{K}(X_{kt}\,Z_{kl}\,p_{kl}) + V_{tl}\,w_{tl}\right]$$

$$\sum_{l=1}^{L} p_{kl} = 1 \quad \text{and} \quad \sum_{l=1}^{L} w_{tl} = 1$$

The subscript l denotes the support point (l=1, 2, ..., L), k denotes the parameter (k=1, 2, ..., K), and t denotes the observation (t=1, 2, ..., T).

The GME objective is strictly concave; therefore, a unique solution exists. The optimal estimated probabilities, p and w, and the prior supports, Z and V, can be used to form the point estimates of the unknown parameters, β, and the unknown errors, e.

Generalized Cross Entropy

Kullback and Leibler (1951) cross entropy measures the "discrepancy" between one distribution and another. Cross entropy is called a measure of discrepancy rather than distance because it does not satisfy some of the properties one would expect of a distance measure. (For a discussion of cross entropy as a measure of discrepancy, see Kapur and Kesavan (1992).) Mathematically, cross entropy is written as

$$\text{minimize} \quad \sum_{i=1}^{n} p_i \ln(p_i / q_i)$$

$$\text{subject to} \quad \sum_{i=1}^{n} p_i = 1$$

where q_i is the probability associated with the ith point in the distribution from which the discrepancy is measured. The q_i (in conjunction with the support) are often referred to as the prior distribution. The measure is nonnegative and is equal to zero when p_i equals q_i. The properties of the cross entropy measure are examined by Kapur and Kesavan (1992).

The principle of minimum cross entropy (Kullback 1959; Good 1963) states that one should choose probabilities that are as close as possible to the prior probabilities. That is, out of all probability distributions that satisfy a given set of constraints which reflect known information about the distribution, choose the distribution that is closest (as measured by $p(\ln(p) - \ln(q))$) to the prior distribution. When the prior distribution is uniform, maximum entropy and minimum cross entropy produce the same results (Kapur

and Kesavan 1992), where the higher values for entropy correspond exactly with the lower values for cross entropy.

If the prior distributions are nonuniform, the problem can be stated as a generalized cross entropy (GCE) formulation. The cross entropy terminology specifies weights, q_i and u_i, for the points Z and V, respectively. Given informative prior distributions on Z and V, the GCE problem is

$$\begin{aligned} \text{minimize} \quad & I(p,q,w,u) = p' \ln(p/q) + w' \ln(w/u) \\ \text{subject to} \quad & y = X\,Z\,p + V\,w \\ & 1_K = (I_K \otimes 1_L')\,p \\ & 1_T = (I_T \otimes 1_L')\,w \end{aligned}$$

where y denotes the T column vector of observations of the dependent variables; $\mathbf{X}$ denotes the $(T \times K)$ matrix of observations of the independent variables; q and p denote LK column vectors of prior and posterior weights, respectively, associated with the points in Z; u and w denote the LT column vectors of prior and posterior weights, respectively, associated with the points in V; 1_K, 1_L, and 1_T are K-, L-, and T-dimensional column vectors, respectively, of ones; and $\mathbf{I_K}$ and $\mathbf{I_T}$ are $(K \times K)$- and $(T \times T)$-dimensional identity matrices.

The optimization problem can be rewritten using set notation as follows:

$$\text{minimize} \quad I(p,q,w,u) = \sum_{l=1}^{L}\sum_{k=1}^{K} p_{kl} \ln(p_{kl}/q_{kl}) + \sum_{l=1}^{L}\sum_{t=1}^{T} w_{tl} \ln(w_{tl}/u_{tl})$$

$$\text{subject to} \quad y_t = \sum_{l=1}^{L}\left[\sum_{k=1}^{K} (X_{kt}\,Z_{kl}\,p_{kl}) + V_{tl}\,w_{tl}\right]$$

$$\sum_{l=1}^{L} p_{kl} = 1 \quad \text{and} \quad \sum_{l=1}^{L} w_{tl} = 1$$

The subscript l denotes the support point (l=1, 2, . . . , L), k denotes the parameter (k=1, 2, . . . , K), and t denotes the observation (t=1, 2, . . . , T).

The objective function is strictly convex; therefore, there is a unique global minimum for the problem (Golan, Judge, and Miller 1996). The optimal estimated weights, p and w, and the prior supports, Z and V, can be used to form the point estimates of the unknown parameters, β, and the unknown errors, e, by using

$$\beta = Z\,p = \begin{bmatrix} z_{11} & \cdots & z_{L1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & z_{12} & \cdots & z_{L2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & z_{1K} & \cdots & z_{LK} \end{bmatrix} \begin{bmatrix} p_{11} \\ \vdots \\ p_{L1} \\ p_{12} \\ \vdots \\ p_{L2} \\ \vdots \\ p_{1K} \\ \vdots \\ p_{LK} \end{bmatrix}$$

$$e = V w = \begin{bmatrix} v_{11} & \cdots & v_{L1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & v_{12} & \cdots & v_{L2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & v_{1T} & \cdots & v_{LT} \end{bmatrix} \begin{bmatrix} w_{11} \\ \vdots \\ w_{L1} \\ w_{12} \\ \vdots \\ w_{L2} \\ \vdots \\ w_{1T} \\ \vdots \\ w_{LT} \end{bmatrix}$$

Computational Details

This constrained estimation problem can be solved either directly (primal) or by using the dual form. Either way, it is prudent to factor out one probability for each parameter and each observation as the sum of the other probabilities. This factoring reduces the computational complexity significantly. If the primal formalization is used and two support points are used for the parameters and the errors, the resulting GME problem is $\mathrm{O}((nparms + nobs)^3)$. For the dual form, the problem is $\mathrm{O}((nobs)^3)$. Therefore for large data sets, GME-M should be used instead of GME.

Moment Generalized Maximum Entropy

The default estimation technique is moment generalized maximum entropy (GME-M). This is simply GME with the data constraints modified by multiplying both sides by X'. GME-M then becomes

$$\begin{aligned} \text{maximize} \quad & H(p, w) = -p' \ln(p) - w' \ln(w) \\ \text{subject to} \quad & X'y = X'X\,Z\,p + X'V\,w \\ & 1_K = (I_K \otimes 1_L')\,p \\ & 1_T = (I_T \otimes 1_L')\,w \end{aligned}$$

There is also the cross entropy version of GME-M, which has the same form as GCE but with the moment constraints.

GME versus GME-M

GME-M is more computationally attractive than GME for large data sets because the computational complexity of the estimation problem depends primarily on the number of parameters and not on the number of observations. GME-M is based on the first moment of the data, whereas GME is based on the data itself. If the distribution of the residuals is well defined by its first moment, then GME-M is a good choice. So if the residuals are normally distributed or exponentially distributed, then GME-M should be used. On the other hand if the distribution is Cauchy, lognormal, or some other distribution where the first moment does not describe the distribution, then use GME. For an illustration of this point, see Example 13.1.

Maximum Entropy-Based Seemingly Unrelated Regression

In a multivariate regression model, the errors in different equations might be correlated. In this case, the efficiency of the estimation can be improved by taking these cross-equation correlations into account. Seemingly unrelated regression (SUR), also called joint generalized least squares (JGLS) or Zellner estimation, is a generalization of OLS for multi-equation systems.

Like SUR in the least squares setting, the generalized maximum entropy SUR (GME-SUR) method assumes that all the regressors are independent variables and uses the correlations among the errors in different equations to improve the regression estimates. The GME-SUR method requires an initial entropy regression to compute residuals. The entropy residuals are used to estimate the cross-equation covariance matrix.

In the iterative GME-SUR (ITGME-SUR) case, the preceding process is repeated by using the residuals from the GME-SUR estimation to estimate a new cross-equation covariance matrix. ITGME-SUR method alternates between estimating the system coefficients and estimating the cross-equation covariance matrix until the estimated coefficients and covariance matrix converge.

The estimation problem becomes the generalized maximum entropy system adapted for multi-equations,

$$
\begin{aligned}
\text{maximize} \quad & H(p,w) = -p' \ln(p) - w' \ln(w) \\
\text{subject to} \quad & y = X Z p + V w \\
& 1_{KM} = (I_{KM} \otimes 1_L') p \\
& 1_{MT} = (I_{MT} \otimes 1_L') w
\end{aligned}
$$

where

$$\beta = Z p$$

$$
Z = \begin{bmatrix}
z^1_{11} & \cdots & z^1_{L1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & z^K_{11} & \cdots & z^K_{L1} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & z^1_{1M} & \cdots & z^1_{LM} & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & z^K_{1M} & \cdots & z^K_{LM}
\end{bmatrix}
$$

$$p = \begin{bmatrix} p^1_{11} & \cdot & p^1_{L1} & \cdot & p^K_{11} & \cdot & p^K_{L1} & \cdot & p^1_{1M} & \cdot & p^1_{LM} & \cdot & p^K_{1M} & \cdot & p^K_{LM} \end{bmatrix}'$$

$$e = V w$$

$$V = \begin{bmatrix} v_{11}^1 & \cdots & v_{11}^L & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & v_{1T}^1 & \cdots & v_{1T}^L & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & v_{M1}^1 & \cdots & v_{M1}^L & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \ddots & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & v_{MT}^1 & \cdots & v_{MT}^L \end{bmatrix}$$

$$w = \begin{bmatrix} w_{11}^1 & \cdot & w_{11}^L & \cdot & w_{1T}^1 & \cdot & w_{1T}^L & \cdot & w_{M1}^1 & \cdot & w_{M1}^L & \cdot & w_{MT}^1 & \cdot & w_{MT}^L \end{bmatrix}'$$

y denotes the MT column vector of observations of the dependent variables; $\mathbf{X}$ denotes the $(MT \times KM)$ matrix of observations for the independent variables; p denotes the LKM column vector of weights associated with the points in Z; w denotes the LMT column vector of weights associated with the points in V; 1_L, 1_{KM}, and 1_{MT} are L-, KM-, and MT-dimensional column vectors, respectively, of ones; and $\mathbf{I_{KM}}$ and $\mathbf{I_{MT}}$ are $(KM \times KM)$- and $(MT \times MT)$-dimensional identity matrices. The subscript l denotes the support point $(l = 1, 2, \ldots, L)$, k denotes the parameter $(k = 1, 2, \ldots, K)$, m denotes the equation $(m = 1, 2, \ldots, M)$, and t denotes the observation $(t = 1, 2, \ldots, T)$.

Using this notation, the maximum entropy problem that is analogous to the OLS problem used as the initial step of the traditional SUR approach is

$$\begin{aligned} \text{maximize} \quad & H(p, w) = -p' \ln(p) - w' \ln(w) \\ \text{subject to} \quad & (y - X Z p) = \sqrt{\Sigma}\, V w \\ & 1_{KM} = (I_{KM} \otimes 1_L')\, p \\ & 1_{MT} = (I_{MT} \otimes 1_L')\, w \end{aligned}$$

The results are GME-SUR estimates with independent errors, the analog of OLS. The covariance matrix $\hat{\Sigma}$ is computed based on the residual of the equations, $Vw = e$. An $L'L$ factorization of the $\hat{\Sigma}$ is used to compute the square root of the matrix.

After solving this problem, these entropy-based estimates are analogous to the Aitken two-step estimator. For iterative GME-SUR, the covariance matrix of the errors is recomputed, and a new $\hat{\Sigma}$ is computed and factored. As in traditional ITSUR, this process repeats until the covariance matrix and the parameter estimates converge.

The estimation of the parameters for the normed-moment version of SUR (GME-SUR-NM) uses an identical process. The constraints for GME-SUR-NM is defined as

$$X'y = X'(\mathbf{S}^{-1} \otimes \mathbf{I}) X Z p + X'(\mathbf{S}^{-1} \otimes \mathbf{I}) V w$$

The estimation of the parameters for GME-SUR-NM uses an identical process as outlined previously for GME-SUR.

Generalized Maximum Entropy for Multinomial Discrete Choice Models

Multinomial discrete choice models take the form of an experiment that consists of n trials. On each trial, one of k alternatives is observed. If y_{ij} is the random variable that takes on the value 1 when alternative j is selected for the ith trial and 0 otherwise, then the probability that y_{ij} is 1, conditional on a vector of regressors X_i and unknown parameter vector β_j, is

$$\Pr(y_{ij} = 1|X_i, \beta_j) = G(X_i'\beta_j)$$

where $G()$ is a link function. For noisy data the model becomes

$$y_{ij} = G(X_i'\beta_j) + \epsilon_{ij} = p_{ij} + \epsilon_{ij}$$

The standard maximum likelihood approach for multinomial logit is equivalent to the maximum entropy solution for discrete choice models. The generalized maximum entropy approach avoids an assumption of the form of the link function $G()$.

The generalized maximum entropy for discrete choice models (GME-D) is written in primal form as

$$\begin{array}{lrl} \text{maximize} & H(p,w) & = -p'\ln(p) - w'\ln(w) \\ \text{subject to} & (I_j \otimes X'y) & = (I_j \otimes X')p + (I_j \otimes X')V\,w \\ & \sum_j^k p_{ij} & = 1 \quad \text{for } i = 1 \text{ to } N \\ & \sum_m^L w_{ijm} & = 1 \quad \text{for } i = 1 \text{ to } N \text{ and } j = 1 \text{ to } k \end{array}$$

Golan, Judge, and Miller (1996) have shown that the dual unconstrained formulation of the GME-D can be viewed as a general class of logit models. Additionally, as the sample size increases, the solution of the dual problem approaches the maximum likelihood solution. Because of these characteristics, only the dual approach is available for the GME-D estimation method.

The parameters β_j are the Lagrange multipliers of the constraints. The covariance matrix of the parameter estimates is computed as the inverse of the Hessian of the dual form of the objective function.

Censored or Truncated Dependent Variables

In practice, you might find that variables are not always measured throughout their natural ranges. A given variable might be recorded continuously in a range, but, outside of that range, only the endpoint is denoted. In other words, say that the data generating process is

$$y_i = \mathbf{x}_{i\bullet} + \epsilon$$

However, you observe the following:

$$y_i^\star = \begin{cases} ub & : \quad y_i \geq ub \\ \mathbf{x}_{i\bullet} + \epsilon & : \quad lb < y_i < ub \\ lb & : \quad y_i \leq lb \end{cases}$$

The primal problem is simply a slight modification of the primal formulation for GME-GCE. You specify different supports for the errors in the truncated or censored region, perhaps reflecting some nonsample information. Then the data constraints are modified. The constraints that arise in the censored areas are changed to inequality constraints (Golan, Judge, and Perloff 1997). Let the variable $\mathbf{X}^u$ denote the observations of the explanatory variable where censoring occurs from the top, $\mathbf{X}^l$ from the bottom, and $\mathbf{X}^a$ in the middle region (no censoring). Let $\mathbf{V}^u$ be the supports for the observations at the upper bound, $\mathbf{V}^l$ lower bound, and $\mathbf{V}^a$ in the middle.

You have

$$\begin{bmatrix} \mathbf{y}^u \geq ub \\ \mathbf{y}^a \\ \mathbf{y}^l \leq lb \end{bmatrix} = \begin{bmatrix} \mathbf{X}^u \\ \mathbf{X}^a \\ \mathbf{X}^l \end{bmatrix} \mathbf{Zp} + \begin{bmatrix} \mathbf{V}^u \mathbf{w}^u \\ \mathbf{V}^a \mathbf{w}^a \\ \mathbf{V}^l \mathbf{w}^l \end{bmatrix}$$

The primal problem then becomes

$$\begin{aligned} \text{maximize} \quad & H(p, w) = -p' \ln(p) - w' \ln(w) \\ \text{subject to} \quad & \mathbf{y}^a = \mathbf{X}^a \mathbf{V}^a p + \mathbf{V}^a \mathbf{w}^a \\ & \mathbf{y}^u \geq \mathbf{X}^u \mathbf{V}^u p + \mathbf{V}^u \mathbf{w}^u \\ & \mathbf{y}^l \leq \mathbf{X}^l \mathbf{V}^l p + \mathbf{V}^l \mathbf{w}^l \\ & 1_K = (I_K \otimes 1'_L) p \\ & 1_T = (I_T \otimes 1'_L) w \end{aligned}$$

PROC ENTROPY requires that the number of supports be identical for all three regions.

Alternatively, you can think of cases where the dependent variable is observed continuously for most of its range. However, the variable's range is reported for some observations. Such data are often found in highly disaggregated state level employment measures.

$$y_i^\star = \begin{cases} \textit{missing} & : & l_1 \leq y \leq r_1 \\ \vdots & : & \vdots \\ \textit{missing} & : & l_k \leq y \leq r_k \\ \mathbf{x}_{i\epsilon} + \epsilon & : & \text{otherwise} \end{cases}$$

Just as in the censored case, each range yields two inequality constraints for each observation in that range.

Information Measures

PROC ENTROPY returns several measures of fit. First, the value of the objective function is returned. Next, the signal entropy is provided followed by the noise entropy. The sum of the noise and signal entropies should equal the value of the objective function. The next two metrics that follow are the normed entropies of both the signal and the noise.

Normalized entropy (NE) measures the relative informational content of both the signal and noise components through p and w, respectively (Golan, Judge, and Miller 1996). Let S denote the normalized entropy of the signal, $X\beta$, defined as

$$S(\tilde{p}) = \frac{-\tilde{p}' \ln(\tilde{p})}{-q' \ln(q)}$$

where $S(\tilde{p}) \epsilon [0, 1]$. In the case of GME, where uniform priors are assumed, S can be written as

$$S(\tilde{p}) = \frac{-\tilde{p}' \ln(\tilde{p})}{\sum_i \ln(M_i)}$$

where M_i is the number of support points for parameter i. A value of 0 for S implies that there is no uncertainty regarding the parameters; hence, it is a degenerate situation. However, a value of 1 implies that the posterior distributions equal the priors, which indicates total uncertainty if the priors are uniform.

Because NE is relative, it can be used for comparing various situations. Consider adding a data point to the model. If $S_{T+1} = S_T$, then there is no additional information contained within that data constraint. However, if $S_{T+1} < S_T$, then the data point gives a more informed set of parameter estimates.

NE can be used for determining the importance of particular variables with regard to the reduction of the uncertainty they bring to the model. Each of the k parameters that is estimated has an associated NE defined as

$$S(\tilde{p_k}) = \frac{-\tilde{p}_k' \ln(\tilde{p}_k)}{-\ln(q_k)}$$

or, in the GME case,

$$S(\tilde{p_k}) = \frac{-\tilde{p}_k' \ln(\tilde{p}_k)}{\ln(M)}$$

where $\tilde{p_k}$ is the vector of supports for parameter β_k and M is the corresponding number of support points. Since a value of 1 implies no relative information for that particular sample, Golan, Judge, and Miller (1996) suggest an exclusion criteria of $S(\tilde{p_k}) > 0.99$ as an acceptable means of selecting noninformative variables. For some simulation results, see Golan, Judge, and Miller (1996).

The final set of measures of fit are the parameter information index and error information index. These measures can be best summarized as 1 – the appropriate normed entropy.

Parameter Covariance for GCE

For the cross-entropy problem, the estimate of the asymptotic variance of the signal parameter is given by

$$\hat{\text{Var}}(\hat{\beta}) = \frac{\hat{\sigma_\gamma^2}(\hat{\beta})}{\hat{\psi}^2(\hat{\beta})}(X'X)^{-1}$$

where

$$\hat{\sigma_\gamma^2}(\hat{\beta}) = \frac{1}{N}\sum_{i=1}^{N}\gamma_i^2$$

and γ_i is the Lagrange multiplier associated with the ith row of the Vw constraint matrix. Also,

$$\hat{\psi}^2(\hat{\beta}) = \left[\frac{1}{N}\sum_{i=1}^{N}\left(\sum_{j=1}^{J} v_{ij}^2 w_{ij} - (\sum_{j=1}^{J} v_{ij} w_{ij})^2\right)^{-1}\right]^2$$

Parameter Covariance for GCE-M

Golan, Judge, and Miller (1996) give the finite approximation to the asymptotic variance matrix of the moment formulation as

$$\hat{\text{Var}}(\hat{\beta}) = \Sigma_z X'XC^{-1}DC^{-1}X'X\Sigma_z$$

where

$$C = X'X\Sigma_z X'X + \Sigma_v$$

and

$$D = X'\Sigma_e X$$

Recall that in the moment formulation, V is the support of $\frac{X'e}{T}$, which implies that Σ_v is a k-dimensional variance matrix. Σ_z and Σ_v are both diagonal matrices with the form

$$\Sigma_z = \begin{bmatrix} \sum_{l=1}^{L} z_{1l}^2 p_{1l} - (\sum_{l=1}^{L} z_{1l} p_{1l})^2 & 0 & 0 \\ 0 & \ddots & 0 \\ 0 & 0 & \sum_{l=1}^{L} z_{Kl}^2 p_{Kl} - (\sum_{l=1}^{L} z_{Kl} p_{Kl})^2 \end{bmatrix}$$

and

$$\Sigma_v = \begin{bmatrix} \sum_{j=1}^{J} v_{1j}^2 w_{jl} - (\sum_{j=1}^{J} v_{1j} w_{1j})^2 & 0 & 0 \\ 0 & \ddots & 0 \\ 0 & 0 & \sum_{j=1}^{J} v_{Kl}^2 w_{Kl} - (\sum_{j=1}^{J} v_{Kl} w_{Kl})^2 \end{bmatrix}$$

Statistical Tests

Since the GME estimates have been shown to be asymptotically normally distributed, the classical Wald, Lagrange multiplier, and likelihood ratio statistics can be used for testing linear restrictions on the parameters.

Wald Tests

Let $H_0 : L\beta = m$, where L is a set of linearly independent combinations of the elements of β. Then under the null hypothesis, the Wald test statistic,

$$T_W = (L\beta - m)' \left(L(\hat{\mathrm{Var}}(\hat{\beta}))L' \right)^{-1} (L\beta - m)$$

has a central χ^2 limiting distribution with degrees of freedom equal to the rank of L.

Pseudo-Likelihood Ratio Tests

Using the conditionally maximized entropy function as a pseudo-likelihood, F, Mittelhammer and Cardell (2000) state that

$$\frac{2\hat{\psi}(\hat{\beta})}{\hat{\sigma}_\gamma^2(\hat{\beta})} \left(F(\hat{\beta}) - F(\tilde{\beta}) \right)$$

has the limiting distribution of the Wald statistic when testing the same hypothesis. Note that $F(\hat{\beta})$ and $F(\tilde{\beta})$ are the maximum values of the entropy objective function over the full and restricted parameter spaces, respectively.

Lagrange Multiplier Tests

Again using the GME function as a pseudo-likelihood, Mittelhammer and Cardell (2000) define the Lagrange multiplier statistic as

$$\frac{1}{\hat{\sigma}_\gamma^2(\tilde{\beta})} G(\tilde{\beta})'(X'X)^{-1} G(\tilde{\beta})$$

where G is the gradient of F, which is being evaluated at the optimum point for the restricted parameters. This test statistic shares the same limiting distribution as the Wald and pseudo-likelihood ratio tests.

Missing Values

If an observation in the input data set contains a missing value for any of the regressors or dependent values, that observation is dropped from the analysis.

Input Data Sets

DATA= Data Set

The DATA= data set specified in the PROC ENTROPY statement is the data set that contains the data to be analyzed.

PDATA= Data Set

The PDATA= data set specified in the PROC ENTROPY statement specifies the support points and prior probabilities to be used in the estimation. The PDATA= can be used in lieu of a PRIORS statement, but is intended for use in conjunction with the OUTP= option. Once priors are entered through a PRIORS statement, they can be reused in subsequent estimations by specifying the PDATA= option.

The variables in the data set are as follows:

- BY variables (if any)
- _TYPE_, a character variable of length 8 that identifies the estimation method: GME or GMEM. This is an optional column.
- variable, a character variable of length 32 that indicates the name of the regressor. The regressor name and the equation name identify a unique coefficient. This is required.
- _OBS_, a numeric variable that is either missing when the probabilities are for coefficients or the observation number when the probabilities are for the residual terms. The _OBS_ and the equation name identify which residual the probability is associated with. This an optional column.
- equation, a character variable of length 32 indicating the name of the dependent variable. This is a required column.
- NSupport, a numeric variable that indicates the number of support points for each basis. This variable is required.
- support, a numeric variable that is the support value the probability is associated with. This is a required column.
- prior, a numeric variable that is the prior probability associated with the probability. This is a required column.
- Prb, a numeric variable that is the estimated probability. This is optional.

SDATA= Data Set

The SDATA= data set specifies a data set that provides the covariance matrix of the equation errors. The matrix read from the SDATA= data set is used for the equation covariance matrix (**S** matrix) in the estimation. (The SDATA= **S** matrix is used to provide only the initial estimate of **S** for the methods that iterate the **S** matrix.)

Output Data Sets

OUT= Data Set

The OUT= data set specified in the PROC ENTROPY statement contains residuals of the dependent variables computed from the parameter estimates. The ID and BY variables are also added to this data set.

OUTEST= Data Set

The OUTEST= data set contains parameter estimates and, if requested via the COVOUT option, estimates of the covariance of the parameter estimates.

The variables in the data set are as follows:

- BY variables
- _NAME_, a character variable of length 32, blank for observations that contain parameter estimates or a parameter name for observations that contain covariances
- _TYPE_, a character variable of length 8 that identifies the estimation method: GME or GMEM
- the parameters estimated

If the COVOUT option is specified, an additional observation is written for each row of the estimate of the covariance matrix of parameter estimates, with the _NAME_ values containing the parameter names for the rows.

OUTP= Data Set

The OUTP= data set specified in the PROC ENTROPY statement contains the probabilities estimated for each support point, as well as the support points and prior probabilities used in the estimation.

The variables in the data set are as follows:

- BY variables (if any)
- _TYPE_, a character variable of length 8 that identifies the estimation method: GME or GMEM.
- variable, a character variable of length 32 that indicates the name of the regressor. The regressor name and the equation name identify a unique coefficient.
- _OBS_, a numeric variable that is either missing when the probabilities are for coefficients or the observation number when the probabilities are for the residual terms. The _OBS_ and the equation name identify which residual the probability is associated with.

- equation, a character variable of length 32 that indicates the name of the dependent variable
- NSupport, a numeric variable that indicates the number of support points for each basis
- support, a numeric variable that is the support value the probability is associated with
- prior, a numeric variable that is the prior probability associated with the probability
- Prb, a numeric variable that is the estimated probability

OUTL= Data Set

The OUTL= data set specified in the PROC ENTROPY statement contains the Lagrange multiplier values for the underlying maximum entropy problem.

The variables in the data set are as follows:

- BY variables
- equation, a character variable of length 32 that indicates the name of the dependent variable
- variable, a character variable of length 32 that indicates the name of the regressor. The regressor name and the equation name identify a unique coefficient.
- _OBS_, a numeric variable that is either missing when the probabilities are for coefficients or the observation number when the probabilities are for the residual terms. The _OBS_ and the equation name identify which residual the Lagrange multiplier is associated with.
- LagrangeMult, a numeric variable that contains the Lagrange multipliers

ODS Table Names

PROC ENTROPY assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 13.2.

Table 13.2 ODS Tables Produced in PROC ENTROPY

ODS Table Name	Description	Option
ConvCrit	Convergence criteria for estimation	Default
ConvergenceStatus	Convergence status	Default
DatasetOptions	Data sets used	Default
MinSummary	Number of parameters, estimation kind	Default
ObsUsed	Observations read, used, and missing	Default
ParameterEstimates	Parameter estimates	Default
ResidSummary	Summary of the SSE, MSE for the equations	Default
TestResults	Test statement table	TEST statement

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

This section describes the use of ODS for creating graphics with the ENTROPY procedure.

ODS Graph Names

PROC ENTROPY assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 13.3.

To request these graphs, you must specify the ODS GRAPHICS statement.

Table 13.3 ODS Graphics Produced by PROC ENTROPY

ODS Graph Name	Plot Description
DiagnosticsPanel	Includes all the plots listed below
FitPlot	Predicted versus actual plot
CooksD	Cook's *D* plot
QQPlot	Q-Q plot of residuals
StudentResidualPlot	Studentized residual plot
ResidualHistogram	Histogram of the residuals

Examples: ENTROPY Procedure

Example 13.1: Nonnormal Error Estimation

This example illustrates the difference between GME-M and GME. One of the basic assumptions of OLS estimation is that the errors in the estimation are normally distributed. If this assumption is violated, the estimated parameters are biased. For GME-M, the story is similar. If the first moment of the distribution of the errors and a scale factor cannot be used to describe the distribution, then the parameter estimates from GME-MN are more biased. GME is much less sensitive to the underlying distribution of the errors than GME-M.

To illustrate this, data for the following model are simulated with three different error distributions:

$$y = a * x_1 + b * x_2 + \epsilon$$

For the first simulation, ϵ is distributed normally, then a chi-squared distribution with six degrees of freedom is assumed for the second simulation, and finally ϵ is assumed to have a Cauchy distribution in the third simulation.

In each of the three simulations, 100 samples of 10 observations each were simulated. The data for the model with the Cauchy error distribution are generated using the following DATA step code:

```
data one;
   call streaminit(156789);
   do by = 1 to 100;
      do x2 = 1 to 10;
         x1 = 10 * ranuni( 512);
         y = x1 + 2*x2 + rand('cauchy');
         output;
      end;
   end;
run;
```

The statements for the other distributions are identical except for the argument to the RAND() function.

The parameters to the model were estimated by using maximum entropy with the following programming statements:

```
title "Nonnormal Error Estimation";
proc entropy data=one gme outest=parm1;
   model y = x1 x2;
   by by;
run;
```

The estimation by using moment-constrained maximum entropy was performed by changing the GME option to GMEM. For comparison, the same model was estimated by using OLS with the following PROC REG statements:

```
proc reg data=one outest=parm3;
   model y = x1 x2;
   by by;
run;
```

The 100 estimations of the coefficient on variable x1 are then summarized for each of the three error distributions by using PROC UNIVARIATE, as follows:

```
proc univariate data=parm1;
   var x1;
run;
```

The following table summarizes the results from the estimations. The true value for the coefficient on x1 is 1.0.

Estimation Method	Normal		Chi-Squared		Cauchy	
	Mean	Std Deviation	Mean	Std Deviation	Mean	Std Deviation
GME	0.418	0.117	0.626	.330	0.818	3.36
GME-M	0.878	0.116	0.948	0.427	3.03	13.62
OLS	0.973	0.142	1.023	0.467	5.54	26.83

For normally distributed or nearly normally distributed data, moment-constrained maximum entropy is a good choice. For distributions not well described by a normal distribution, data-constrained maximum entropy is a good choice.

Example 13.2: Unreplicated Factorial Experiments

Factorial experiments are useful for studying the effects of various factors on a response. For the practitioner constrained to the use of OLS regression, there must be replication to estimate all of the possible main and interaction effects in a factorial experiment. Using OLS regression to analyze unreplicated experimental data results in zero degrees of freedom for error in the ANOVA table, since there are as many parameters as observations. This situation leaves the experimenter unable to compute confidence intervals or perform hypothesis testing on the parameter estimates.

Several options are available when replication is impossible. The higher-order interactions can be assumed to have negligible effects, and their degrees of freedom can be pooled to create the error degrees of freedom used to perform inference on the lower-order estimates. Or, if a preliminary experiment is being run, a normal probability plot of all effects can provide insight as to which effects are significant, and therefore focused, in a later, more complete experiment.

The following example illustrates the probability plot methodology and the alternative by using PROC ENTROPY. Consider a 2^4 factorial model with no replication. The data are taken from Myers and Montgomery (1995).

```
data rate;
   do a=-1,1; do b=-1,1; do c=-1,1; do d=-1,1;
      input y @@;
      ab=a*b; ac=a*c; ad=a*d; bc=b*c; bd=b*d; cd=c*d;
      abc=a*b*c; abd=a*b*d; acd=a*c*d; bcd=b*c*d;
      abcd=a*b*c*d;
```

```
      output;
   end; end; end; end;
   datalines;
   45 71 48 65 68 60 80 65 43 100 45 104 75 86 70 96
   ;
run;
```

Analyze the data by using PROC REG, then output the resulting estimates.

```
proc reg data=rate outest=regout;
   model y=a b c d ab ac ad bc bd cd abc abd acd bcd abcd;
run;

proc transpose data=regout out=ploteff name=effect prefix=est;
   var a b c d ab ac ad bc bd cd abc abd acd bcd abcd;
run;
```

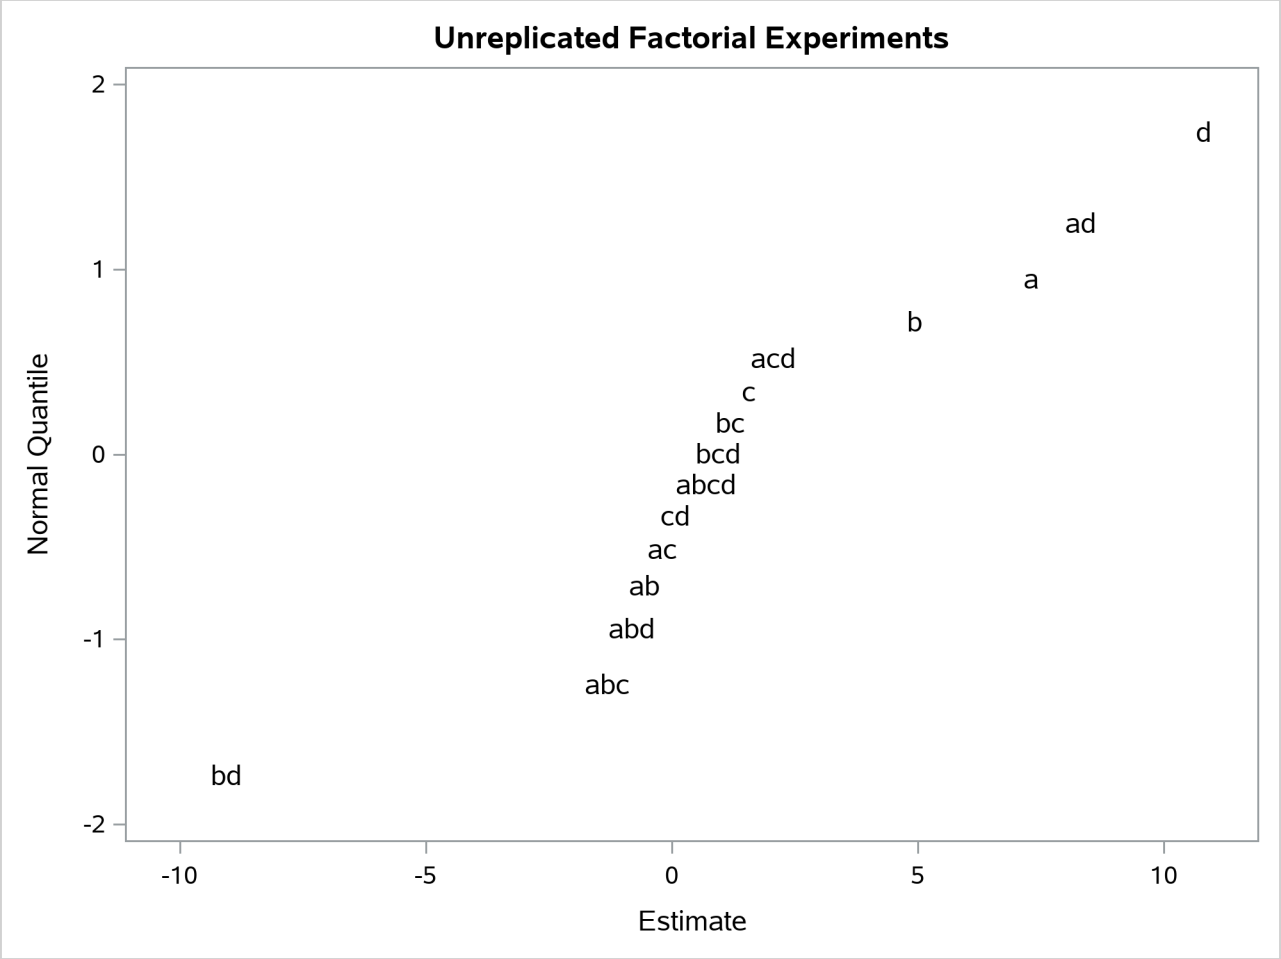
Now the normal scores for the estimates can be computed with the rank procedure as follows:

```
proc rank data=ploteff normal=blom out=qqplot;
   var est1;
   ranks normalq;
run;
```

To create the probability plot, simply plot the estimates versus their normal scores by using PROC SGPLOT as follows:

```
title "Unreplicated Factorial Experiments";
proc sgplot data=qqplot;
   scatter x=est1 y=normalq / markerchar=effect
                              markercharattrs=(size=10pt);
   xaxis label="Estimate";
   yaxis label="Normal Quantile";
run;
```

Output 13.2.1 Normal Probability Plot of Effects



The plot shown in Output 13.2.1 displays evidence that the a, b, d, ad, and bd estimates do not fit into the purely random normal model, which suggests that they may have some significant effect on the response variable. To verify this, fit a reduced model that contains only these effects.

```
proc reg data=rate;
   model y=a b d ad bd;
run;
```

The estimates for the reduced model are shown in Output 13.2.2.

Output 13.2.2 Reduced Model OLS Estimates

Unreplicated Factorial Experiments

The REG Procedure
Model: MODEL1
Dependent Variable: y

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	70.06250	1.10432	63.44	<.0001
a	1	7.31250	1.10432	6.62	<.0001
b	1	4.93750	1.10432	4.47	0.0012
d	1	10.81250	1.10432	9.79	<.0001
ad	1	8.31250	1.10432	7.53	<.0001
bd	1	-9.06250	1.10432	-8.21	<.0001

These results support the probability plot methodology.

PROC ENTROPY can directly estimate the full model without having to rely on the probability plot for insight into which effects can be significant. To illustrate this, PROC ENTROPY is run by using default parameter and error supports in the following statements:

```
proc entropy data=rate;
   model y=a b c d ab ac ad bc bd cd abc abd acd bcd abcd;
run;
```

The resulting GME estimates are shown in Output 13.2.3. Note that the parameter estimates associated with the a, b, d, ad, and bd effects are all significant.

Output 13.2.3 Full Model Entropy Results

Unreplicated Factorial Experiments

Example 13.3: Censored Data Models in PROC ENTROPY

Data available to an analyst might sometimes be censored, where only part of the actual series is observed. Consider the case in which only observations greater than some lower bound are recorded, as defined by the following process:

$$\mathbf{y} = \max\left(\mathbf{X}\boldsymbol{\beta} + \epsilon, lb\right)$$

Running ordinary least squares estimation on data generated by the preceding process is not optimal because the estimates are likely to be biased and inefficient. One alternative to estimating models with censored data is the tobit estimator. This model is supported in the QLIM procedure in SAS/ETS and in the LIFEREG procedure in SAS/STAT. PROC ENTROPY provides another alternative which can make it very easy to estimate such a model correctly.

The following DATA step generates censored data in which any negative values of the dependent variable, y, are set to a lower bound of 0:

```
data cens;
  do t = 1 to 100;
     x1 = 5 * ranuni(456);
     x2 = 10 * ranuni(456);
     y = 4.5*x1 + 2*x2 + 15 * rannor(456);
     if( y<0 ) then y = 0;
     output;
```

```
   end;
run;
```

To illustrate the effect of the censored option in PROC ENTROPY, the model is initially estimated without accounting for censoring in the following statements:

```
title "Censored Data Estimation";
proc entropy data = cens gme primal;
   priors intercept -32 32
          x1        -15 15
          x2        -15 15;
    model y = x1 x2 /
          esupports = (-25 1 25);
run;
```

Output 13.3.1 GME Estimates

Censored Data Estimation

The ENTROPY Procedure

GME Variable Estimates

Variable	Estimate	Approx Std Err	t Value	Approx Pr > |t|
x1	2.389461	0.0871	27.44	<.0001
x2	2.361062	0.0441	53.60	<.0001
intercept	5.393182	0.3262	16.53	<.0001

The previous model is reestimated by using the CENSORED option in the following statements:

```
proc entropy data = cens gme primal;
   priors intercept -32 32
          x1        -15 15
          x2        -15 15;
   model y = x1 x2 /
         esupports = (-25 1 25)
         censored(lb = 0, esupports=(-15 1 15) );
run;
```

Output 13.3.2 Entropy Estimates

Censored Data Estimation

The ENTROPY Procedure

GME Variable Estimates

Variable	Estimate	Approx Std Err	t Value	Approx Pr > |t|
x1	4.433805	0.00260	1705.39	<.0001
x2	1.467409	0.00132	1115.64	<.0001
intercept	8.253583	0.00974	847.35	<.0001

The second set of entropy estimates are much closer to the true parameter estimates of 4.5 and 2. Since another alternative available for fitting a model of censored data is a tobit model, PROC QLIM is used in the

following statements to fit a tobit model to the data:

```
proc qlim data=cens;
   model y = x1 x2;
   endogenous y ~ censored(lb=0);
run;
```

Output 13.3.3 QLIM Estimates

Censored Data Estimation

The QLIM Procedure

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	2.979455	3.824252	0.78	0.4359
x1	1	4.882284	1.019913	4.79	<.0001
x2	1	1.374006	0.513000	2.68	0.0074
_Sigma	1	13.723213	1.032911	13.29	<.0001

For these data and this code, PROC ENTROPY produces estimates that are closer to the true parameter values than those computed by PROC QLIM.

Example 13.4: Use of the PDATA= Option

It is sometimes useful to specify priors and supports by using the PDATA= option. This example illustrates how to create a PDATA= data set which contains the priors and support points for use in a subsequent PROC ENTROPY step. In order to have a model to estimate in PROC ENTROPY, you must first have data to analyze. The following DATA step generates the data used in this analysis:

```
title "Using a PDATA= data set";
data a;
   array x[4];
   do t = 1 to 100;
      ys = -5;
      do k = 1 to 4;
         x[k] = rannor( 55372 )  ;
         ys = ys + x[k] * k;
      end;
      ys = ys + rannor( 55372 );
      output;
    end;
run;
```

Next you fit these data with some arbitrary parameter support points and priors by using the following PROC ENTROPY statements:

```
proc entropy data = a gme primal;
   priors          x1  -10(2) 30(1)
                   x2  -20(3) 30(2)
                   x3  -15(4) 30(4)
```

```
                  x4  -25(3) 30(2)
           intercept  -13(4) 30(2) ;
   model ys = x1 x2 x3 x4 / esupports=(-25 0 25);
run;
```

These statements produce the output shown in Output 13.4.1.

Output 13.4.1 Output From PROC ENTROPY

Using a PDATA= data set

The ENTROPY Procedure

GME Variable Estimates

Variable	Estimate	Approx Std Err	t Value	Approx Pr > |t|
x1	1.195688	0.1078	11.09	<.0001
x2	1.844903	0.1018	18.12	<.0001
x3	3.268396	0.1136	28.77	<.0001
x4	3.908194	0.0934	41.83	<.0001
intercept	-4.94319	0.1005	-49.21	<.0001

You can estimate the same model by first creating a PDATA= data set, which includes the same information as the PRIORS statement in the preceding PROC ENTROPY step.

A data set that defines the supports and priors for the model parameters is shown in the following statements:

```
data test;
   length Variable $ 12 Equation $ 12;
   input Variable $ Equation $ Nsupport Support Prior ;
datalines;
     Intercept    .  2 -13 0.66667
     Intercept    .  2  30 0.33333
            x1    .  2 -10 0.66667
            x1    .  2  30 0.33333
            x2    .  2 -20 0.60000
            x2    .  2  30 0.40000
            x3    .  2 -15 0.50000
            x3    .  2  30 0.50000
            x4    .  2 -25 0.60000
            x4    .  2  30 0.40000
;
```

The following statements reestimate the model by using these support points:

```
proc entropy data=a gme primal pdata=test;
   model ys = x1 x2 x3 x4 / esupports=(-25 0 25);
run;
```

These statements produce the output shown in Output 13.4.2.

Output 13.4.2 Output From PROC ENTROPY with PDATA= option

Using a PDATA= data set

The ENTROPY Procedure

GME Variable Estimates

Variable	Estimate	Approx Std Err	t Value	Approx Pr > |t|
x1	1.195686	0.1078	11.09	<.0001
x2	1.844902	0.1018	18.12	<.0001
x3	3.268395	0.1136	28.77	<.0001
x4	3.908194	0.0934	41.83	<.0001
Intercept	-4.94319	0.1005	-49.21	<.0001

These results are identical to the ones produced by the previous PROC ENTROPY step.

Example 13.5: Illustration of ODS Graphics

This example illustrates how to use ODS graphics in the ENTROPY procedure. This example is a continuation of the example in the section "Simple Regression Analysis" on page 778. Graphical displays are requested by specifying the ODS GRAPHICS statement. For information about the graphics available in the ENTROPY procedure, see the section "ODS Graphics" on page 822.

The following statements show how to generate ODS graphics plots with the ENTROPY procedure. The plots are displayed in Output 13.5.1.

```
proc entropy data=coleman;
   model test_score = teach_sal prcnt_prof socio_stat
                      teach_score mom_ed;
run;
```

Output 13.5.1 Model Diagnostics Plots

- Example 14.3: Specifying the Forecasting Model 864
- Example 14.4: Extending the Independent Variables for Multivariate Forecasts 864
- Example 14.5: Illustration of ODS Graphics 866

Overview: ESM Procedure

The ESM procedure generates forecasts by using exponential smoothing models with optimized smoothing weights for many time series or transactional data.

- For typical time series, you can use the following smoothing models:
  - simple
  - double
  - linear
  - damped trend
  - seasonal
  - Winters method (additive and multiplicative)
- Additionally, transformed versions of these models are provided:
  - log
  - square root
  - logistic
  - Box-Cox

Graphics are available with the ESM procedure. For more information, see the section "ODS Graphics" on page 858.

The ESM procedure writes the time series extrapolated by the forecasts, the series summary statistics, the forecasts and confidence limits, the parameter estimates, and the fit statistics to output data sets. The ESM procedure optionally produces printed output for these results by using the Output Delivery System (ODS).

The ESM procedure can forecast both time series data, whose observations are equally spaced by a specific time interval (for example, monthly, weekly), or transactional data, whose observations are not spaced with respect to any particular time interval. Internet, inventory, sales, and similar data are typical examples of transactional data. For transactional data, the data are accumulated based on a specified time interval to form a time series prior to modeling and forecasting.

Getting Started: ESM Procedure

The ESM procedure is simple to use and does not require in-depth knowledge of forecasting methods. It can provide results in output data sets or in other output formats by using the Output Delivery System (ODS). The following examples are more fully illustrated in "Example 14.2: Forecasting of Transactional Data" on page 862.

Given an input data set that contains numerous time series variables recorded at a specific frequency, the ESM procedure can forecast the series as follows:

```
proc esm data=<input-data-set> out=<output-data-set>;
   id <time-ID-variable> interval=<frequency>;
   forecast <time-series-variables>;
run;
```

For example, suppose that the input data set SALES contains sales data recorded monthly, the variable that represents time is DATE, and the forecasts are to be recorded in the output data set NEXTYEAR. The ESM procedure could be used as follows:

```
proc esm data=sales out=nextyear;
   id date interval=month;
   forecast _numeric_;
run;
```

The preceding statements generate forecasts for every numeric variable in the input data set SALES for the next 12 months and store these forecasts in the output data set NEXTYEAR. Other output data sets can be specified to store the parameter estimates, forecasts, statistics of fit, and summary data.

By default, PROC ESM generates no printed output. If you want to print the forecasts by using the Output Delivery System (ODS), then you need to add the PRINT=FORECASTS option to the PROC ESM statement, as shown in the following example:

```
proc esm data=sales out=nextyear print=forecasts;
   id date interval=month;
   forecast _numeric_;
run;
```

Other PRINT= options can be specified to print the parameter estimates, statistics of fit, and summary data.

The ESM procedure can forecast both time series data, whose observations are equally spaced by a specific time interval (for example, monthly, weekly), or transactional data, whose observations are not spaced with respect to any particular time interval.

Given an input data set that contains transactional variables not recorded at any specific frequency, the ESM procedure accumulates the data to a specific time interval and forecasts the accumulated series as follows:

```
proc esm data=<input-data-set> out=<output-data-set>;
   id <time-ID-variable> interval=<frequency>
                         accumulate=<accumulation>;
   forecast <time-series-variables> / model=<esm>;
run;
```

For example, suppose that the input data set WEBSITES contains three variables (BOATS, CARS, PLANES) that are Internet data recorded on no particular time interval, and the variable that represents time is TIME,

which records the time of the website hit. The forecasts for the total daily values are to be recorded in the output data set NEXTWEEK. The ESM procedure could be used as follows:

```
proc esm data=websites out=nextweek lead=7;
   id time interval=dtday accumulate=total;
   forecast boats cars planes;
run;
```

The preceding statements accumulate the data into a daily time series, generate forecasts for the BOATS, CARS, and PLANES variables in the input data set (WEBSITES) for the next seven days, and store the forecasts in the output data set (NEXTWEEK). Because the MODEL= option is not specified in the FORECAST statement, a simple exponential smoothing model is fit to each series.

Syntax: ESM Procedure

The following statements are available in the ESM procedure:

PROC ESM *options* **;**
BY *variables* **;**
ID *variable* **INTERVAL=** *interval* < *options* > **;**
FORECAST *variable-list* / < *options* > **;**

Functional Summary

The statements and options that control the ESM procedure are summarized in Table 14.1.

Table 14.1 Functional Summary

Limit error and warning messages	PROC ESM	MAXERROR=

The following sections describe the PROC ESM statement and then describe the other statements in alphabetical order.

PROC ESM Statement

PROC ESM *options* **;**

You can specify the following *options*:

BACK=*n*
specifies the number of observations before the end of the data where the multistep forecasts are to begin. By default, BACK=0.

DATA=*SAS-data-set*
names the SAS data set that contains the input data for the procedure to forecast. If the DATA= option is not specified, the most recently created SAS data set is used.

LEAD=*n*
specifies the number of periods ahead to forecast (forecast lead or horizon). By default, LEAD=12.

The LEAD= value is relative to the BACK= option specification and to the last observation in the input data set or the accumulated series, and not to the last nonmissing observation of a particular series. Thus, if a series has missing values at the end, the actual number of forecasts computed for that series is greater than the LEAD= value.

MAXERROR=*number*
limits the number of warning and error messages produced during the execution of the procedure to the specified value. This option is particularly useful in BY-group processing where it can be used to suppress the recurring messages. By default, MAXERRORS=50.

NOOUTALL
specifies that only forecasts are written to the OUT= and OUTFOR= data sets. The NOOUTALL option includes only the final forecast observations in the output data sets; it does not include the one-step forecasts for the data before the forecast period.

The OUT= and OUTFOR= data set will only contain the forecast results starting at the next period following the last observation and ending with the forecast horizon specified by the LEAD= option.

OUT=*SAS-data-set*
names the output data set to contain the forecasts of the variables specified in the subsequent FORECAST statements. If an ID variable is specified, it is also included in the OUT= data set. The values are accumulated based on the ACCUMULATE= option, and forecasts are appended to these values based on the USE= option in the FORECAST statement. The OUT= data set is particularly useful in extending the independent variables. The OUT= data set can be used as the input data set in a subsequent PROC step to forecast a dependent series by using a regression modeling procedure. If the OUT= option is not specified, a default output data set is created by using the DATA*n* convention. If you do not want the OUT= data set created, use OUT=_NULL_.

OUTEST=*SAS-data-set*
names the output data set to contain the model parameter estimates and the associated test statistics and probability values. The OUTEST= data set is useful for evaluating the significance of the model parameters and understanding the model dynamics.

OUTFOR=*SAS-data-set*
names the output data set to contain the forecast time series components (actual, predicted, lower confidence limit, upper confidence limit, prediction error, prediction standard error). The OUTFOR= data set is useful for displaying the forecasts in tabular or graphical form.

OUTPROCINFO=*SAS-data-set*
names the output data set to contain information in the SAS log, specifically the number of notes, errors, and warnings and the number of series processed, forecasts requested, and forecasts failed.

OUTSTAT=*SAS-data-set*
names the output data set to contain the statistics of fit (or goodness-of-fit statistics). The OUTSTAT= data set is useful for evaluating how well the model fits the series.

OUTSUM=*SAS-data-set*
names the output data set to contain the summary statistics and the forecast summation. The summary statistics are based on the accumulated time series when the ACCUMULATE= or SETMISSING= option is specified. The forecast summations are based on the LEAD=, STARTSUM=, and USE= options. The OUTSUM= data set is useful when forecasting large numbers of series and a summary of the results are needed.

PLOT=*option* **|** **(** *options* **)**
specifies the graphical output desired. By default, the ESM procedure produces no graphical output. The following plotting options are available:

ACF	plots prediction error autocorrelation function graphics.
ALL	is the same as specifying all of the PLOT= options.
BASIC	equivalent to specifying PLOT=(CORR ERRORS MODELFORECASTS).
CORR	plots the prediction error series graphics panel containing the ACF, IACF, PACF, and white noise probability plots.
ERRORS	plots prediction error time series graphics.
FORECASTS	plots forecast graphics.
FORECASTSONLY	plots the forecast in the forecast horizon only.
IACF	plots prediction error inverse autocorrelation function graphics.
LEVELS	plots smoothed level component graphics.
MODELFORECASTS	plots the one-step ahead model forecast and its confidence bands in the historical period; the forecast and its confidence bands over the forecast horizon.
MODELS	plots model graphics.
PACF	plots prediction error partial autocorrelation function graphics.
PERIODOGRAM	plots prediction error periodogram.
SEASONS	plots smoothed seasonal component graphics.
SPECTRUM	plots periodogram and smoothed periodogram of the prediction error series in a single graph.
TRENDS	plots smoothed trend (slope) component graphics.

WN plots white noise graphics.

For example, PLOT=FORECASTS plots the forecasts for each series. The PLOT= option produces printed output for these results by using the Output Delivery System (ODS).

PRINT=*option* | **(** *options* **)**
specifies the printed output desired. By default, the ESM procedure produces no printed output. The following printing options are available:

ESTIMATES prints the results of parameter estimation.

FORECASTS prints the forecasts.

PERFORMANCE prints the performance statistics for each forecast.

PERFORMANCESUMMARY prints the performance summary for each BY group.

PERFORMANCEOVERALL prints the performance summary for all of the BY groups.

STATISTICS prints the statistics of fit.

STATES prints the backcast, initial, and final states.

SUMMARY prints the summary statistics for the accumulated time series.

ALL Same as PRINT=(ESTIMATES FORECASTS STATISTICS SUMMARY).

For example, PRINT=FORECASTS prints the forecasts, PRINT=(ESTIMATES FORECASTS) prints the parameter estimates and the forecasts, and PRINT=ALL prints all of the output.

PRINTDETAILS
specifies that output requested with the PRINT= option be printed in greater detail.

SEASONALITY=*number*
specifies the length of the seasonal cycle. For example, SEASONALITY=3 means that every group of three observations forms a seasonal cycle. The SEASONALITY= option is applicable only for seasonal forecasting models. By default, the length of the seasonal cycle is one (no seasonality) or the length implied by the INTERVAL= option specified in the ID statement. For example, INTERVAL=MONTH implies that the length of the seasonal cycle is 12.

SORTNAMES
specifies that the variables specified in the FORECAST statements are processed in sorted order.

STARTSUM=*n*
specifies the starting forecast lead (or horizon) for which to begin summation of the forecasts specified by the LEAD= option. The STARTSUM= value must be less than the LEAD= value. By default, STARTSUM=1; that is, the sum from the one-step ahead forecast (which is the first forecast in the forecast horizon) to the multistep forecast specified by the LEAD= option.

The prediction standard errors of the summation of forecasts take into account the correlation between the multistep forecasts. For more information about the STARTSUM= option, see the section "Forecast Summation" on page 852.

BY Statement

BY *variables* **;**

A BY statement can be used with PROC ESM to obtain separate dummy variable definitions for groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the option NOTSORTED or DESCENDING in the BY statement for the ESM procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Programmers Guide: Essentials*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FORECAST Statement

FORECAST *variable-list* / < *options* > **;**

The FORECAST statement lists the numeric variables in the DATA= data set whose accumulated values represent time series to be modeled and forecast. The options specify which forecast model is to be used.

A data set variable can be specified in only one FORECAST statement. Any number of FORECAST statements can be used. You can specify the following *options*:

ACCUMULATE=*option*

specifies how the data set observations are accumulated within each time period for the variables listed in the FORECAST statement. If the ACCUMULATE= option is not specified in the FORECAST statement, accumulation is determined by the ACCUMULATE= option in the ID statement. Use the ACCUMULATE= option with multiple FORECAST statements when you want different accumulation specifications for different variables. For more information, see the ACCUMULATE= option in the ID statement.

ALPHA=*number*

specifies the significance level to use in computing the confidence limits of the forecast. The ALPHA= value must be between 0 and 1. By default, ALPHA=0.05, which produces 95% confidence intervals.

MEDIAN
specifies that the median forecast values are to be estimated. Forecasts can be based on the mean or median. By default, the mean value is provided. If no transformation is applied to the time series by using the TRANSFORM= option, the mean and median forecast values are identical.

MODEL=*model-name*
specifies the forecasting model to be used to forecast the time series. You can specify the following forecasting *model-names*:

NONE	produces no forecast, but the time series is appended with missing values in the OUT= data set. This option is useful when the results stored in the OUT= data set are used in a subsequent analysis where forecasts of the independent variables are needed to forecast the dependent variable.
SIMPLE	performs simple (single) exponential smoothing.
DOUBLE	performs double (Brown) exponential smoothing.
LINEAR	performs linear (Holt) exponential smoothing.
DAMPTREND	performs damped trend exponential smoothing.
ADDSEASONAL | SEASONAL	performs additive seasonal exponential smoothing.
MULTSEASONAL	performs multiplicative seasonal exponential smoothing.
WINTERS	uses the Winters multiplicative method.
ADDWINTERS	uses the Winters additive method.

By default, MODEL=SIMPLE.

NBACKCAST=*n*
specifies the number of observations used to initialize the backcast states. The default is the entire series.

REPLACEBACK
replaces actual values that are excluded by the BACK= option with one-step-ahead forecasts in the OUT= data set.

REPLACEMISSING
replaces embedded missing values with one-step-ahead forecasts in the OUT= data set.

SETMISSING=*option* | *number*
specifies how missing values (either input or accumulated) are assigned in the accumulated time series for variables listed in the FORECAST statement. If the SETMISSING= option is not specified in the FORECAST statement, missing values are set based on the SETMISSING= option of the ID statement. For more information, see the SETMISSING= option in the ID statement.

TRANSFORM=*option*
specifies the time series transformation to be applied to the input or accumulated time series. The following transformations are provided:

NONE	no transformation.
LOG	logarithmic transformation

SQRT	square-root transformation
LOGISTIC	logistic transformation
BOXCOX(*n*)	Box-Cox transformation with parameter number where number is between –5 and 5

By default, TRANSFORM=NONE.

When the TRANSFORM= option is specified, the time series must be strictly positive. After the time series is transformed, the model parameters are estimated by using the transformed series. The forecasts of the transformed series are then computed, and finally the transformed series forecasts are inverse transformed. The inverse transform produces either mean or median forecasts depending on whether the MEDIAN option is specified. For more information, see the sections "Transformations" on page 850 and "Inverse Transformations" on page 851.

USE=*option*

specifies which forecast values are appended to the actual values in the OUT= and OUTSUM= data sets. You can specify the following *options*:

PREDICT	appends the predicted values to the actual values.
LOWER	appends the lower confidence limit values to the actual values.
UPPER	appends the upper confidence limit values to the actual values.

By default, USE=PREDICT.

Thus, the USE= option enables the OUT= and OUTSUM= data sets to be used for worst-case, best-case, average-case, and median-case decisions.

ZEROMISS=NONE | LEFT | RIGHT | BOTH

specifies how beginning or ending zero values (either input or accumulated) are interpreted in the accumulated time series for variables listed in the FORECAST statement. If the ZEROMISS= option is not specified in the FORECAST statement, beginning or ending zero values are set to missing values based on the ZEROMISS= option in the ID statement. For more information, see the ZEROMISS= option in the ID statement.

ID Statement

ID *variable* **INTERVAL=** *interval* < *options* > **;**

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date or datetime values. In addition, the ID statement specifies the (desired) frequency associated with the time series. The ID statement options also specify how the observations are accumulated and how the time ID values are aligned to form the time series to be forecast. The information specified affects all variables specified in subsequent FORECAST statements. If the ID statement is specified, the INTERVAL= option must be specified. If an ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID. You can specify the following *options*.

ACCUMULATE=*option*

specifies how the data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option. The ID variable contains the time ID values. Each time ID variable value corresponds to a specific time period. The accumulated values form the time series, which is used in subsequent model fitting and forecasting.

This option is particularly useful when there are gaps in the input data or when there are multiple input observations that coincide with a particular time period (for example, transactional data). The EXPAND procedure offers additional frequency conversions and transformations that can also be useful in creating a time series.

The following *options* determine how the observations are accumulated within each time period based on the ID variable and the frequency specified by the INTERVAL= option:

NONE No accumulation occurs; the ID variable values must be equally spaced with respect to the frequency.

TOTAL accumulates observations based on the total sum of their values.

AVERAGE | AVG accumulates observations based on the average of their values.

MINIMUM | MIN accumulates observations based on the minimum of their values.

MEDIAN | MED accumulates observations based on the median of their values.

MAXIMUM | MAX accumulates observations based on the maximum of their values.

N accumulates observations based on the number of nonmissing observations.

NMISS accumulates observations based on the number of missing observations.

NOBS accumulates observations based on the number of observations.

FIRST accumulates observations based on the first of their values.

LAST accumulates observations based on the last of their values.

STDDEV | STD accumulates observations based on the standard deviation of their values.

CSS accumulates observations based on the corrected sum of squares of their values.

USS accumulates observations based on the uncorrected sum of squares of their values.

By default, ACCUMULATE=NONE.

If the ACCUMULATE= option is specified, the SETMISSING= option is useful for specifying how accumulated missing values are treated. If missing values should be interpreted as zero, then SETMISSING=0 should be used. For more information about accumulation, see the section "Accumulation" on page 849.

ALIGN=*option*

controls the alignment of SAS dates used to identify output observations. The ALIGN= option accepts the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. BEGINNING is the default.

END=*date* | *datetime*
specifies a SAS date or datetime literal value that represents the end of the data. If the last time ID variable value is less than the END= value, the series is extended with missing values. If the last time ID variable value is greater than the END= value, the series is truncated. For example, **END='1jan2008'D** specifies that data for time periods after the first of January 2008 not be used. The option **END="&sysdate"D** uses the automatic macro variable SYSDATE to extend or truncate the series to the current date. This option and the START= option can be used to ensure that data associated with each BY group contain the same number of observations.

FORMAT=*format*
specifies the SAS format for the time ID values. If the FORMAT= option is not specified, the default format is implied from the INTERVAL= option.

INTERVAL=*interval*
specifies the frequency of the input time series or for the time series to be accumulated from the input data. For example, if the input data set consists of quarterly observations, then INTERVAL=QTR should be used. If the SEASONALITY= option is not specified, the length of the seasonal cycle is implied by the INTERVAL= option. For example, INTERVAL=QTR implies a seasonal cycle of length 4. If the ACCUMULATE= option is also specified, the INTERVAL= option determines the time periods for the accumulation of observations.

The basic intervals are YEAR, SEMIYEAR, QTR, MONTH, SEMIMONTH, TENDAY, WEEK, WEEKDAY, DAY, HOUR, MINUTE, SECOND. For more information about the intervals that can be specified, see Chapter 4, "Date Intervals, Formats, and Functions."

NOTSORTED
specifies that the time ID values are not in sorted order. The ESM procedure sorts the data with respect to the time ID prior to analysis.

SETMISSING=*option* | *number*
specifies how missing values (either input or accumulated) are assigned in the accumulated time series. If a number is specified, missing values are set to that number. If a missing value in the input data set indicates an unknown value, the SETMISSING= option should not be used. If a missing value indicates no value, SETMISSING=0 should be used. You typically use SETMISSING=0 for transactional data, because no recorded data usually implies no activity. The following options can also be used to determine how missing values are assigned:

MISSING	sets missing values to missing. The missing observations are replaced with predicted values that are computed from the exponential smoothing model.
AVERAGE | AVG	sets missing values to the accumulated average value.
MINIMUM | MIN	sets missing values to the accumulated minimum value.
MEDIAN | MED	sets missing values to the accumulated median value.
MAXIMUM | MAX	sets missing values to the accumulated maximum value.
FIRST	sets missing values to the accumulated first nonmissing value.
LAST	sets missing values to the accumulated last nonmissing value.
PREVIOUS | PREV	sets missing values to the previous accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.

NEXT sets missing values to the next accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.

By default, SETMISSING=MISSING.

START=*date* | *datetime*
specifies a SAS date or datetime literal value that represents the beginning of the data. If the first time ID variable value is greater than the START= value, the series is prefixed with missing values. If the first time ID variable value is less than the START= value, the series is truncated. This option and the END= option can be used to ensure that data associated with each BY group contain the same number of observations.

ZEROMISS=NONE | LEFT | RIGHT | BOTH
specifies how beginning and ending zero values (either input or accumulated) are interpreted in the accumulated time series. You can specify the following values:

NONE Beginning and ending zeros are unchanged.

LEFT Beginning zeros are set to missing.

RIGHT Ending zeros are set to missing.

BOTH Both beginning and ending zeros are set to missing.

By default, ZEROMISS=NONE.

If the accumulated series is all missing or zero, the series is not changed.

Details: ESM Procedure

The ESM procedure can be used to forecast time series data as well as transactional data. If the data are transactional, then the procedure must first accumulate the data into a time series before it can be forecast. The procedure uses the sequential steps in Table 14.2 to produce forecasts, with the options that control the step listed to the right.

Table 14.2 ESM Processing Steps and Control Options

Step	Operation	Option	Statements
1	Accumulation	ACCUMULATE=	ID
2	Missing value interpretation	SETMISSING=	ID, FORECAST
3	Transformations	TRANSFORM=	FORECAST
4	Parameter estimation	MODEL=	FORECAST
5	Forecasting	MODEL=, LEAD=	FORECAST, PROC ESM
6	Inverse transformation	TRANSFORM, MEDIAN	FORECAST
7	Summation of forecasts	LEAD=, STARTSUM=	PROC ESM

Each of the steps shown in Table 14.2 is described in the following sections.

Accumulation

If the ACCUMULATE= option is specified in the ID statement, data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option, and the ID variable contains the time ID values. Each time ID value corresponds to a specific time period. Accumulation is particularly useful when the input data set contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series that is used in subsequent analyses by the ESM procedure.

For example, suppose a data set contains the following observations:

```
19MAR1999    10
19MAR1999    30
11MAY1999    50
12MAY1999    20
23MAY1999    20
```

If the INTERVAL=MONTH option is specified in the ID statement, all of the preceding observations fall within three time periods: March 1999, April 1999, and May 1999. The observations are accumulated within each time period as follows.

If the ACCUMULATE=NONE option is specified, an error is generated because the ID variable values are not equally spaced with respect to the specified frequency (MONTH).

If the ACCUMULATE=TOTAL option is specified, the resulting time series is

```
01MAR1999    40
01APR1999    .
01MAY1999    90
```

If the ACCUMULATE=AVERAGE option is specified, the resulting time series is

```
01MAR1999    20
01APR1999    .
01MAY1999    30
```

If the ACCUMULATE=MINIMUM option is specified, the resulting time series is

```
01MAR1999    10
01APR1999    .
01MAY1999    20
```

If the ACCUMULATE=MEDIAN option is specified, the resulting time series is

```
01MAR1999    20
01APR1999    .
01MAY1999    20
```

If the ACCUMULATE=MAXIMUM option is specified, the resulting time series is

```
01MAR1999    30
01APR1999    .
01MAY1999    50
```

If the ACCUMULATE=FIRST option is specified, the resulting time series is

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=LAST option is specified, the resulting time series is

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=STDDEV option is specified, the resulting time series is

```
O1MAR1999    14.14
O1APR1999    .
O1MAY1999    17.32
```

As can be seen from the preceding examples, even though the data set observations contained no missing values, the accumulated time series can have missing values.

Missing Value Interpretation

Sometimes missing values should be interpreted as truly unknown values and retained as missing values in the data set. The forecasting models used by the ESM procedure can effectively handle missing values (see the section "Missing Value Modeling Issues" on page 851). However, sometimes missing values are known, such as when missing values are created from accumulation and represent no observed values for the variable. In this case, the value for the period should be interpreted as zero (no values), and the SETMISSING=0 option should be used to cause PROC ESM to recode missing values as zero. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and missing-value-recoded time series is used in subsequent analyses in PROC ESM.

Transformations

If the TRANSFORM= option is specified in the FORECAST statement, the time series is transformed prior to model parameter estimation and forecasting. Only strictly positive series can be transformed. An error is generated when the TRANSFORM= option is used with a nonpositive series.

Parameter Estimation

All the parameters (smoothing weights) associated with the exponential smoothing model used to forecast the time series (as specified by the MODEL= option) are optimized based on the data, with the default parameter restrictions imposed. If the TRANSFORM= option is specified, the transformed time series data are used to estimate the model parameters.

Missing Value Modeling Issues

The treatment of missing values varies with the forecasting model. Missing values after the start of the series are replaced with one-step-ahead predicted values, and the predicted values are used in the smoothing equations.

The treatment of missing values can also be specified with the SETMISSING= option, which changes the missing values prior to modeling.

NOTE: Even if all of the observed data are nonmissing, the ACCUMULATE= option can create missing values in the accumulated series (when the data contain no observations for some of the time periods specified by the INTERVAL= option).

Forecasting

Once the model parameters are estimated, one-step-ahead forecasts are generated for the full range of the accumulated and optionally transformed time series data, and multistep forecasts are generated from the end of the time series to the future time period specified by the LEAD= option. If there are missing values at the end of the time series, the forecast horizon will be greater than that specified by the LEAD= option.

Inverse Transformations

If the TRANSFORM= option is specified in the FORECAST statement, the forecasts of the transformed time series are inverse transformed. By default, forecasts of the mean (expected value) are generated. If the MEDIAN option is specified, median forecasts are generated.

Statistics of Fit

The statistics of fit are computed by comparing the time series data (after accumulation and missing value recoding, if specified) with the generated forecasts. If the TRANSFORM= option is specified, the statistics of fit are based on the inverse transformed forecasts.

Forecast Summation

The multistep forecasts generated by the preceding steps can optionally be summed from the STARTSUM= value to the LEAD= value. For example, if the options STARTSUM=4 and LEAD=6 are specified in the PROC ESM statement, the four-step-ahead through six-step-ahead forecasts are summed.

The forecasts are simply summed; however, the prediction error variance of this sum is computed by taking into account the correlation between the individual predictions. (These variance-related computations are performed only when no transformation is specified; that is, when TRANSFORM=NONE.) The upper and lower confidence limits for the sum of the predictions is then computed based on the prediction error variance of the sum.

The forecast summation is particularly useful when it is desirable to model in one frequency but the forecast of interest is another frequency. For example, if a time series has a monthly frequency (INTERVAL=MONTH) and you want a forecast for the third and fourth future months, a forecast summation for the third and fourth month can be obtained by specifying STARTSUM=3 and LEAD=4.

Data Set Output

The ESM procedure can create the OUT=, OUTEST=, OUTFOR=, OUTSTAT=, and OUTSUM= data sets. These data sets contain the variables listed in the BY statement and statistics related to the variables listing in the FORECAST statement. In general, if a forecasting step related to an output data set fails, the values of this step are not recorded or are set to missing in the related output data set and appropriate error and/or warning messages are recorded in the log.

OUT= Data Set

The OUT= data set contains the variables specified in the BY, ID, and FORECAST statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN= and INTERVAL= options. The values of the variables specified in the FORECAST statements are accumulated based on the ACCUMULATE= option, and missing values are interpreted based on the SETMISSING= option. If the REPLACEMISSING option is specified, embedded missing values are replaced by the one-step-ahead predicted values.

These FORECAST variables are then extrapolated based on the forecasts from the fitted models, or extended with missing values when the MODEL=NONE option is specified. If USE=LOWER is specified, the variable is extrapolated with the lower confidence limits; if USE=UPPER, the variable is extrapolated using the upper confidence limits; otherwise, the variable values are extrapolated with the predicted values. If the TRANSFORM= option is specified, the predicted values contain either mean or median forecasts depending on whether or not the MEDIAN option is specified.

If any of the forecasting steps fail for a particular variable, the variable is extended by missing values.

OUTEST= Data Set

The OUTEST= data set contains the variables specified in the BY statement as well as the variables listed below. For variables listed in FORECAST statements where the option MODEL=NONE is specified, no observations are recorded in the OUTEST= data set. For variables listed in FORECAST statements where the option MODEL=NONE is not specified, the following variables in the OUTEST= data set contain observations related to the parameter estimation step:

NAME	variable name
MODEL	forecasting model
TRANSFORM	transformation
PARM	parameter name
EST	parameter estimate
STDERR	standard errors
TVALUE	*t* values
PVALUE	probability values

If the parameter estimation step fails for a particular variable, no observations are output to the OUTEST= data set for that variable.

OUTFOR= Data Set

The OUTFOR= data set contains the variables specified in the BY statement as well as the variables listed below. For variables listed in FORECAST statements where the option MODEL=NONE is specified, no observations are recorded in the OUTFOR= data set for these variables. For variables listed in FORECAST statements where the option MODEL=NONE is not specified, the following variables in the OUTFOR= data set contain observations related to the forecasting step:

NAME	variable name
TIMEID	time ID values
ACTUAL	actual values
PREDICT	predicted values
STD	prediction standard errors
LOWER	prediction lower confidence limits
UPPER	prediction upper confidence limits
ERROR	prediction errors

If the forecasting step fails for a particular variable, no observations are recorded in the OUTFOR= data set for that variable. If the TRANSFORM= option is specified, the values in the preceding variables are the inverse transform forecasts. If the MEDIAN option is specified, the median forecasts are stored; otherwise, the mean forecasts are stored.

OUTPROCINFO= Data Set

The OUTPROCINFO= data set contains information about the run of the ESM procedure. The following variables are present:

SOURCE	set to the name of the procedure, in this case ESM
NAME	name of an item being reported; can be the number of errors, notes, or warnings, number of forecasts requested, and so on
LABEL	descriptive label for the item in _NAME_
STAGE	set to the current stage of the procedure; for PROC ESM this is set to ALL
VALUE	value of the item specified in _NAME_

OUTSTAT= Data Set

The OUTSTAT= data set contains the variables specified in the BY statement as well as the variables listed below. For variables listed in FORECAST statements where the option MODEL=NONE is specified, no observations are recorded for these variables in the OUTSTAT= data set. For variables listed in FORECAST statements where the option MODEL=NONE is not specified, the following variables in the OUTSTAT= data set contain observations related to the statistics of fit:

NAME	variable name
REGION	the region in which the statistics are calculated. Statistics calculated in the fit region are indicated by FIT. Statistics calculated in the forecast region, which happens only if the BACK= option is greater than zero, are indicated by FORECAST.
DFE	degrees of freedom error
N	number of observations used
NOBS	number of observations
NMISSA	number of missing actuals
NMISSP	number of missing predicted values
NPARMS	number of parameters
TSS	total sum of squares
SST	corrected total sum of squares
SSE	sum of square error
MSE	mean square error
UMSE	unbiased mean square error
RMSE	root mean square error
URMSE	unbiased root mean square error
MAPE	mean absolute percent error
MAE	mean absolute error
MASE	mean absolute scaled error
RSQUARE	R-square

ADJRSQ	adjusted R-square
AADJRSQ	Amemiya's adjusted R-square
RWRSQ	random walk R-square
AIC	Akaike's information criterion
AICC	finite sample corrected AIC
SBC	Schwarz Bayesian information criterion
APC	Amemiya's prediction criterion
MAXERR	maximum error
MINERR	minimum error
MINPE	minimum percent error
MAXPE	maximum percent error
ME	mean error
MPE	mean percent error
MDAPE	median absolute percent error
GMAPE	geometric mean absolute percent error
MINPPE	minimum predictive percent error
MAXPPE	maximum predictive percent error
MSPPE	mean predictive percent error
MAPPE	symmetric mean absolute predictive percent error
MDAPPE	median absolute predictive percent error
GMAPPE	geometric mean absolute predictive percent error
MINSPE	minimum symmetric percent error
MAXSPE	maximum symmetric percent error
MSPE	mean symmetric percent error
SMAPE	symmetric mean absolute percent error
MDASPE	median absolute symmetric percent error
GMASPE	geometric mean absolute symmetric percent error
MINRE	minimum relative error
MAXRE	maximum relative error
MRE	mean relative error
MRAE	mean relative absolute error
MDRAE	median relative absolute error
GMRAE	geometric mean relative absolute error
MINAPES	minimum absolute error percent of standard deviation
MAXAPES	maximum absolute error percent of standard deviation

MAPES	mean absolute error percent of standard deviation
MDAPES	median absolute error percent of standard deviation
GMAPES	geometric mean absolute error percent of standard deviation

If the statistics of fit cannot be computed for a particular variable, no observations are recorded in the OUTSTAT= data set for that variable. If the TRANSFORM= option is specified, the values in the preceding variables are computed based on the inverse transform forecasts. If the MEDIAN option is specified, the median forecasts are the basis; otherwise, the mean forecasts are the basis.

OUTSUM= Data Set

The OUTSUM= data set contains the variables specified in the BY statement as well as the variables listed below. The OUTSUM= data set records the summary statistics for each variable specified in a FORECAST statement. For variables listed in FORECAST statements where the option MODEL=NONE is specified, the values related to forecasts are set to missing for those variables in the OUTSUM= data set. For variables listed in FORECAST statements where the option MODEL=NONE is not specified, the forecast values are set based on the USE= option.

The following variables related to summary statistics are based on the ACCUMULATE= and SETMISSING= options:

NAME	variable name
STATUS	forecasting status. Nonzero values imply that no forecast was generated for the series.
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MIN	minimum value
MAX	maximum value
MEAN	mean value
STDDEV	standard deviation

The following variables related to forecast summation are based on the LEAD= and STARTSUM= options:

PREDICT	forecast summation predicted values
STD	forecast summation prediction standard errors
LOWER	forecast summation lower confidence limits
UPPER	forecast summation upper confidence limits

Variance-related computations are computed only when no transformation is specified (TRANSFORM=NONE).

The following variables related to multistep forecast are based on the LEAD= and USE= options:

LEAD*n*	multistep forecast (*n* ranges from one to the value of the LEAD= option). If USE=LOWER, this variable contains the lower confidence limits; if USE=UPPER, this variable contains the upper confidence limits; otherwise, this variable contains the predicted values.

If the forecast step fails for a particular variable, the variables that are related to forecasting are set to missing for that variable. The OUTSUM= data set contains both a summary of the (accumulated) time series and optionally its forecasts for all series.

Printed Output

The ESM procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. All output is controlled by the PRINT= and PRINTDETAILS options in the PROC ESM statement. In general, if a forecasting step that is related to printed output fails, the values of this step are not printed and appropriate error or warning messages are recorded in the log. The printed output is similar to the output data sets.

The printed output produced by the PRINT= option values is described as follows:

SUMMARY	prints the summary statistics and forecast summaries similar to the OUTSUM= data set.
ESTIMATES	prints the parameter estimates similar to the OUTEST= data set.
FORECASTS	prints the forecasts similar to the OUTFOR= data set.
PERFORMANCE	prints the performance statistics.
PERFORMANCESUMMARY	prints the performance summary for each BY group.
PERFORMANCEOVERALL	prints the performance summary for all BY groups.
STATES	prints the backcast, initial, and final smoothed states.
STATISTICS	prints the statistics of fit similar to the OUTSTAT= data set.

The PRINTDETAILS option is the opposite of the NOOUTALL option. Specifically, if PRINT=FORECASTS and the PRINTDETAILS options are specified in the PROC ESM statement, the one-step-ahead forecasts through the range of the data are printed in addition to the information related to a specific forecasting model, such as the smoothing states. If the PRINTDETAILS option is not specified, only the multistep forecasts are printed.

ODS Table Names

Table 14.3 relates the PRINT= options to ODS tables.

Table 14.3 ODS Tables Produced in PROC ESM

ODS Table Name	Description	PRINT= Option
DescStats	Descriptive statistics	SUMMARY
ForecastSummary	Forecast summary	SUMMARY
ForecastSummation	Forecast summation	SUMMARY
ParameterEstimates	Parameter estimates	ESTIMATES
Forecasts	Forecasts	FORECASTS
Performance	Performance statistics	PERFORMANCE

Table 14.3 *continued*

ODS Table Name	Description	PRINT= Option
PerformanceSummary	Performance summary	PERFORMANCESUMMARY
PerformanceOverall	Performance overall	PERFORMANCEOVERALL
SmoothedStates	Smoothed states	STATES
FitStatistics	Evaluation statistics of fit	STATISTICS
PerformanceStatistics	Performance (out-of-sample) statistics of fit	STATISTICS

The ODS table "ForecastSummary" is related to all time series within a BY group. The other tables are related to a single series within a BY group.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

This section describes the use of ODS for creating graphics with the ESM procedure. To request these graphs you must specify the PLOT= option in the PROC ESM statement.

ODS Graph Names

PROC ESM assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 14.4.

Table 14.4 ODS Graphics Produced by the PLOT= Option in PROC ESM

ODS Graph Name	Plot Description	PLOT= Option
ErrorACFNORMPlot	Standardized autocorrelation of prediction errors	ACF
ErrorACFPlot	Autocorrelation of prediction errors	ACF
ErrorHistogram	Prediction error histogram	ERRORS
ErrorCorrelationPlots	Prediction error plot panel	CORR
ErrorIACFNORMPlot	Standardized inverse autocorrelation of prediction errors	IACF

Table 14.4 *continued*

ODS Graph Name	Plot Description	PLOT= Option
ErrorIACFPlot	Inverse autocorrelation of prediction errors	IACF
ErrorPACFNORMPlot	Standardized partial autocorrelation of prediction errors	PACF
ErrorPACFPlot	Partial autocorrelation of prediction errors	PACF
ErrorPeriodogramPlot	Periodogram of prediction errors	PERIODOGRAM
ErrorPlot	Plot of prediction errors	ERRORS
ErrorSpectralDensityPlot	Combined periodogram and spectral density estimate plot	SPECTRUM
ErrorWhiteNoiseLogProbPlot	White noise log probability plot of prediction errors	WN
ErrorWhiteNoiseProbPlot	White noise probability plot of prediction errors	WN
ForecastsOnlyPlot	Forecasts only plot	FORECASTSONLY
ForecastsPlot	Forecasts plot	FORECASTS
LevelStatePlot	Smoothed level state plot	LEVELS

ModelPlot	Model plot	MODELS
SeasonStatePlot	Smoothed season state plot	SEASONS
TrendStatePlot	Smoothed trend state plot	TRENDS

Examples: ESM Procedure

Example 14.1: Forecasting of Time Series Data

This example uses retail sales data to illustrate how the ESM procedure can be used to forecast time series data.

The following DATA step creates a data set from data recorded monthly at numerous points of sale. The data set, SALES, contains a variable, DATE, that represents time and a variable for each sales item. Each value of the DATE variable is recorded in ascending order, and the values of each of the other variables represent a single time series:

```
data sales;
   format date date9.;
   input date : date9. shoes socks laces dresses

   datalines;
01JAN1994 3557 3718 6368.80 575  987 10.8200 15.0000 102.600 12410 15013
```

```
   ... more lines ...
```

The following ESM procedure statements forecast each of the monthly time series:

```
proc esm data=sales out=nextyear;
   id date interval=month;
   forecast _numeric_;
run;
```

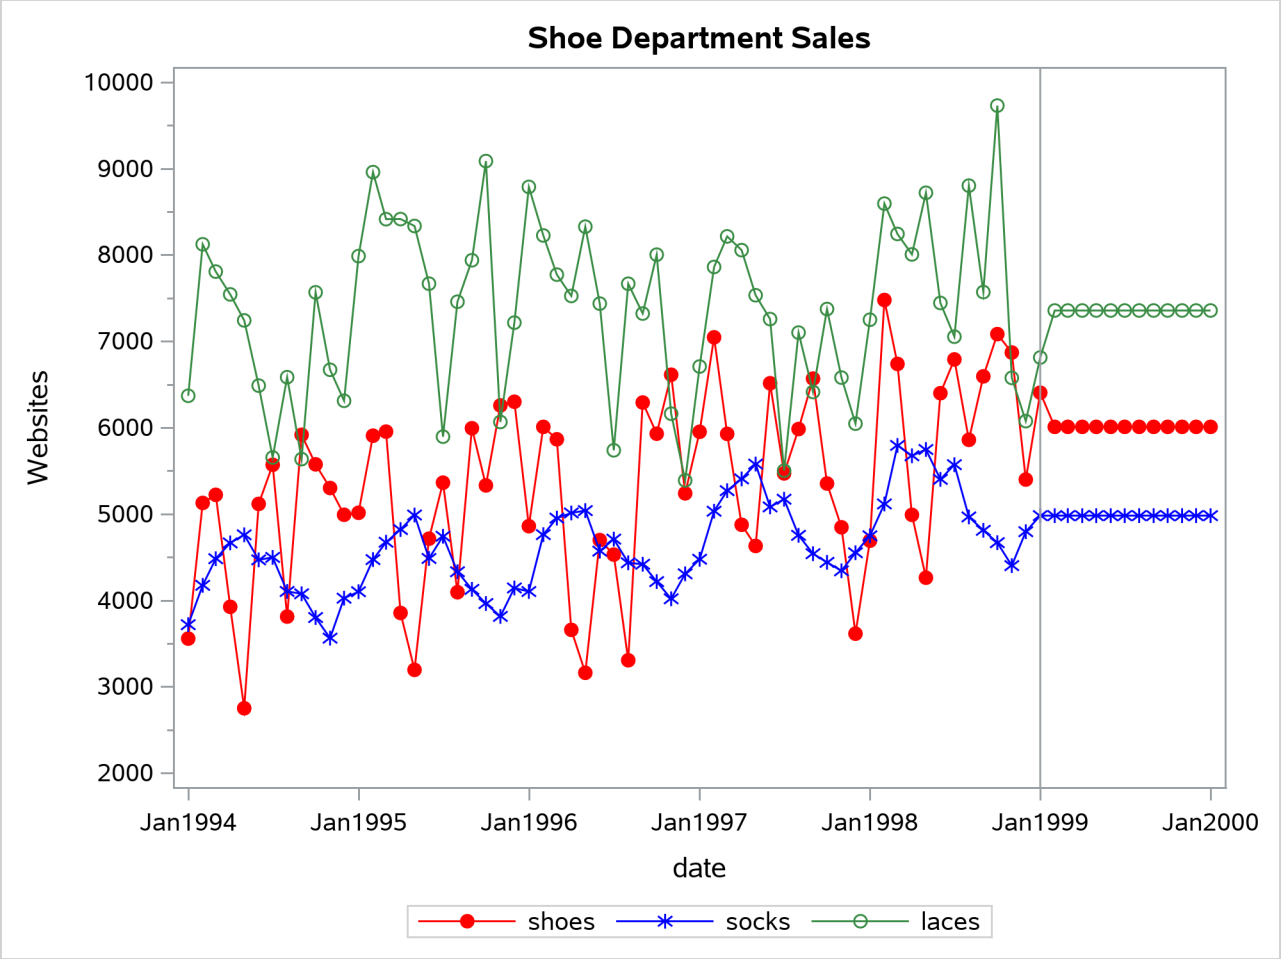
The preceding statements generate forecasts for every numeric variable in the input data set SALES for the next 12 months and store these forecasts in the output data set NEXTYEAR.

The following statements plot the forecasts:

```
title1 "Shoe Department Sales";
proc sgplot data=nextyear;
   series x=date y=shoes / markers
                           markerattrs=(symbol=circlefilled color=red)
                           lineattrs=(color=red);
   series x=date y=socks / markers
                           markerattrs=(symbol=asterisk color=blue)
                           lineattrs=(color=blue);
   series x=date y=laces / markers
                           markerattrs=(symbol=circle color=styg)
                          lineattrs=(color=styg);
   refline '01JAN1999'd / axis=x;
   xaxis values=('01JAN1994'd to '01DEC2000'd by year);
   yaxis values=(2000 to 10000 by 1000) minor label='Websites';
run;
```

The plots are shown in Output 14.1.1. The historical data are shown to the left of the reference line, and the forecasts for the next 12 monthly periods are shown to the right.

Output 14.1.1 Retail Sales Forecast Plots



The default simple exponential smoothing model is used because the MODEL= option is omitted from the FORECAST statement. Note that for simple exponential smoothing the forecasts are constant.

The following ESM procedure statements are identical to the preceding statements except that the PRINT=FORECASTS option is specified:

```
proc esm data=sales out=nextyear print=forecasts;
   id date interval=month;
   forecast _numeric_;
run;
```

In addition to forecasting each of the monthly time series, the preceding statements print the forecasts by using the Output Delivery System (ODS); the forecasts are partially shown in Output 14.1.2. This output shows the predictions, prediction standard errors, and upper and lower confidence limits for the next 12 monthly periods.

Output 14.1.2 Forecast Tables

Example 14.2: Forecasting of Transactional Data

This example illustrates how the ESM procedure can be used to forecast transactional data.

The following DATA step creates a data set from data recorded at several Internet websites. The data set WEBSITES contains a variable, TIME, that represents time and the variables ENGINE, BOATS, CARS, and PLANES that represent Internet website data. Each value of the TIME variable is recorded in ascending order, and the values of each of the other variables represent a transactional data series.

The following ESM procedure statements forecast each of the transactional data series:

```
proc esm data=websites out=nextweek lead=7;
   id time interval=dtday accumulate=total;
   forecast boats cars planes;
run;
```

The preceding statements accumulate the data into a daily time series, generate forecasts for the BOATS, CARS, and PLANES variables in the input data set WEBSITES for the next week, and the forecasts are stored in the OUT= data set NEXTWEEK.

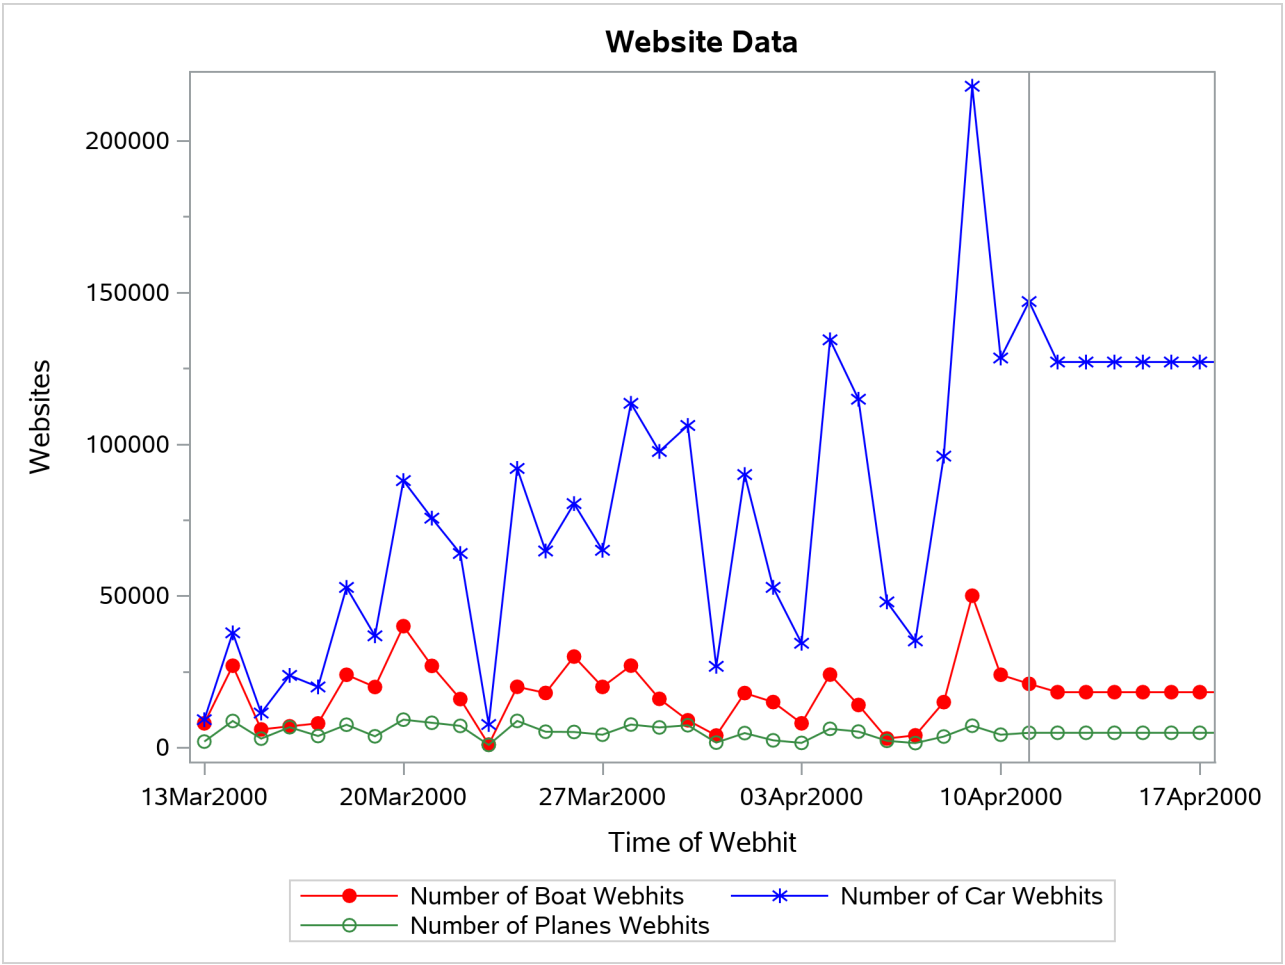
The following statements plot the forecasts related to the Internet data:

```
title1 "Website Data";
proc sgplot data=nextweek;
   series x=time y=boats / markers
                          markerattrs=(symbol=circlefilled color=red)
                          lineattrs=(color=red);
   series x=time y=cars / markers
                          markerattrs=(symbol=asterisk color=blue)
                          lineattrs=(color=blue);
```

```
    series x=time y=planes / markers
                            markerattrs=(symbol=circle color=styg)
                            lineattrs=(color=styg);
    refline '11APR2000:00:00:00'dt / axis=x;
    xaxis values=('13MAR2000:00:00:00'dt to '18APR2000:00:00:00'dt by dtweek);
    yaxis label='Websites' minor;
run;
```

The plots are shown in Output 14.2.1. The historical data are shown to the left of the reference line, and the forecasts for the next seven days are shown to the right.

Output 14.2.1 Internet Data Forecast Plots



Example 14.3: Specifying the Forecasting Model

This example illustrates how the ESM procedure can be used to specify different models for different series. Internet data from the previous example are used for this illustration.

This example forecasts the BOATS variable by using the seasonal exponential smoothing model (SEASONAL), the CARS variable by using the Winters (multiplicative) model (MULTWINTERS), and the PLANES variable by using the Log Winters (additive) model. The following ESM procedure statements forecast each of the transactional data series based on these requirements:

```
proc esm data=websites out=nextweek lead=7;
   id time interval=dtday accumulate=total;
   forecast boats   / model=seasonal;
   forecast cars    / model=multwinters;
   forecast planes  / model=addwinters transform=log;
run;
```

Example 14.4: Extending the Independent Variables for Multivariate Forecasts

In the previous example, the ESM procedure was used to forecast several transactional series variables by using univariate models. This example illustrates how the ESM procedure can be used to extend the independent variables that are associated with a multiple regression forecasting problem.

This example accumulates and forecasts the BOATS, CARS, and PLANES variables that were illustrated in the previous example. In addition, this example accumulates the ENGINES variable to form a time series that is then extended with missing values within the forecast horizon with the specification of MODEL=NONE.

```
proc esm data=websites out=nextweek lead=7;
   id time interval=dtday accumulate=total;
   forecast engines / model=none;
   forecast boats   / model=seasonal;
   forecast cars    / model=multwinters;
   forecast planes  / model=addwinters transform=log;
run;
```

The following AUTOREG procedure statements are used to forecast the ENGINES variable by regressing on the independent variables (BOATS, CARS, and PLANES):

```
proc autoreg data= nextweek;
   model engines = boats cars planes / noprint;
   output out=enginehits p=predicted;
run;
```

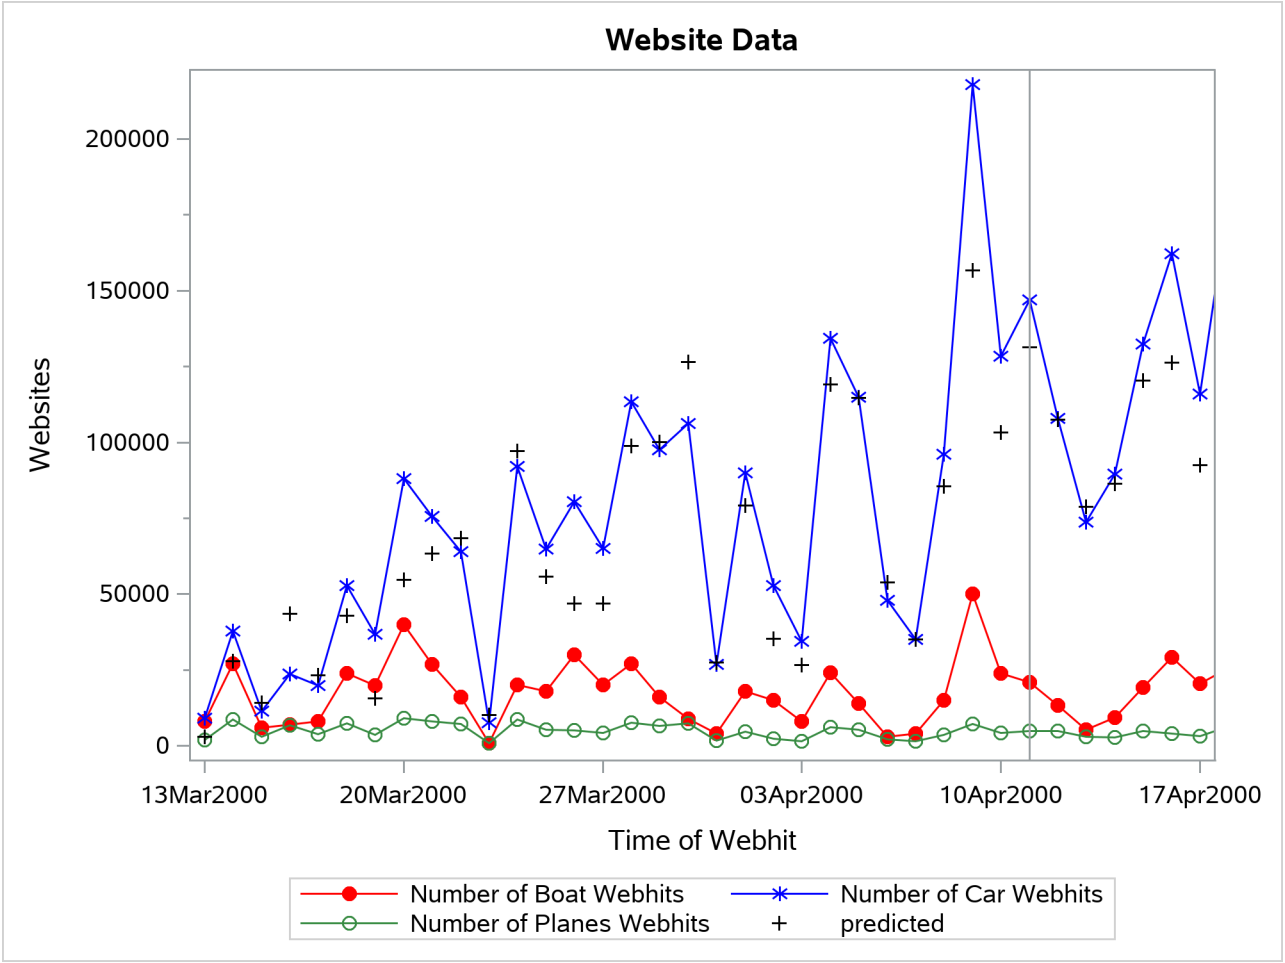
The NEXTWEEK data set created by PROC ESM is used as an input data set to PROC AUTOREG. The output data set from PROC AUTOREG contains the forecast of the variable ENGINES based on the regression model with the variables BOATS, CARS, and PLANES as regressors. For more information about autoregression models, see Chapter 8, "The AUTOREG Procedure."

The following statements plot the forecasts related to the ENGINES variable:

```
title1 "Website Data";
proc sgplot data=enginehits;
   series x=time y=boats / markers
                           markerattrs=(symbol=circlefilled color=red)
                           lineattrs=(color=red);
   series x=time y=cars / markers
                           markerattrs=(symbol=asterisk color=blue)
                           lineattrs=(color=blue);
   series x=time y=planes / markers
                           markerattrs=(symbol=circle color=styg)
                           lineattrs=(color=styg);
   scatter x=time y=predicted / markerattrs=(symbol=plus color=black);
   refline '11APR2000:00:00:00'dt / axis=x;
   xaxis values=('13MAR2000:00:00:00'dt to '18APR2000:00:00:00'dt by dtweek);
   yaxis label='Websites' minor;
run;
```

The plots are shown in Output 14.4.1. The historical data are shown to the left of the reference line, and the forecasts for the next seven daily periods are shown to the right.

Output 14.4.1 Internet Data Forecast Plots



Example 14.5: Illustration of ODS Graphics

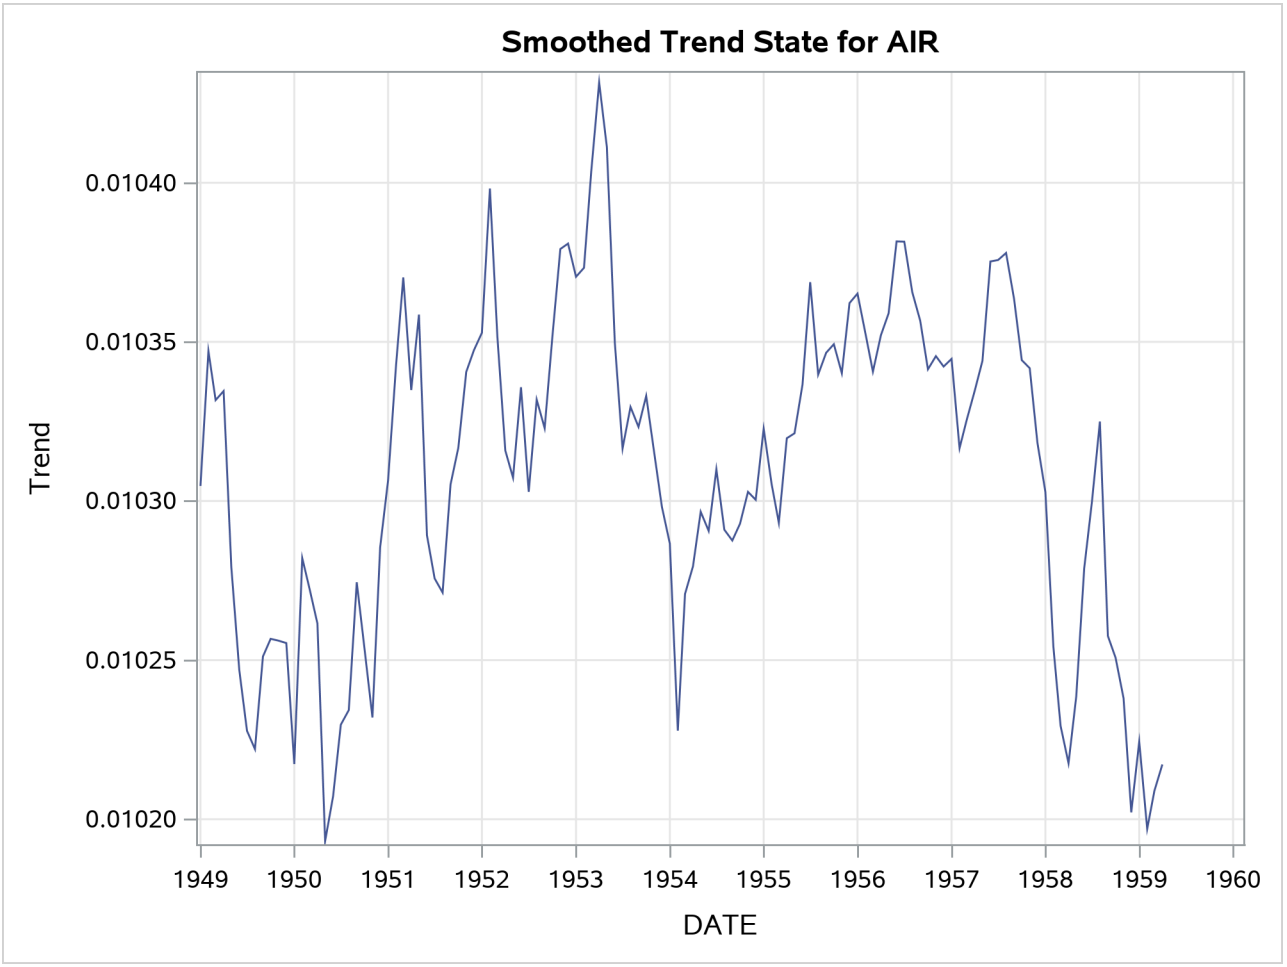
This example illustrates the use of ODS graphics in the ESM procedure and uses the SASHELP.AIR data set to forecast the time series of international airline travel.

The graphical displays are requested by specifying the PLOT= option in the PROC ESM statement. In this case, all plots are requested. Output 14.5.1 through Output 14.5.5 show a selection of the plots created.

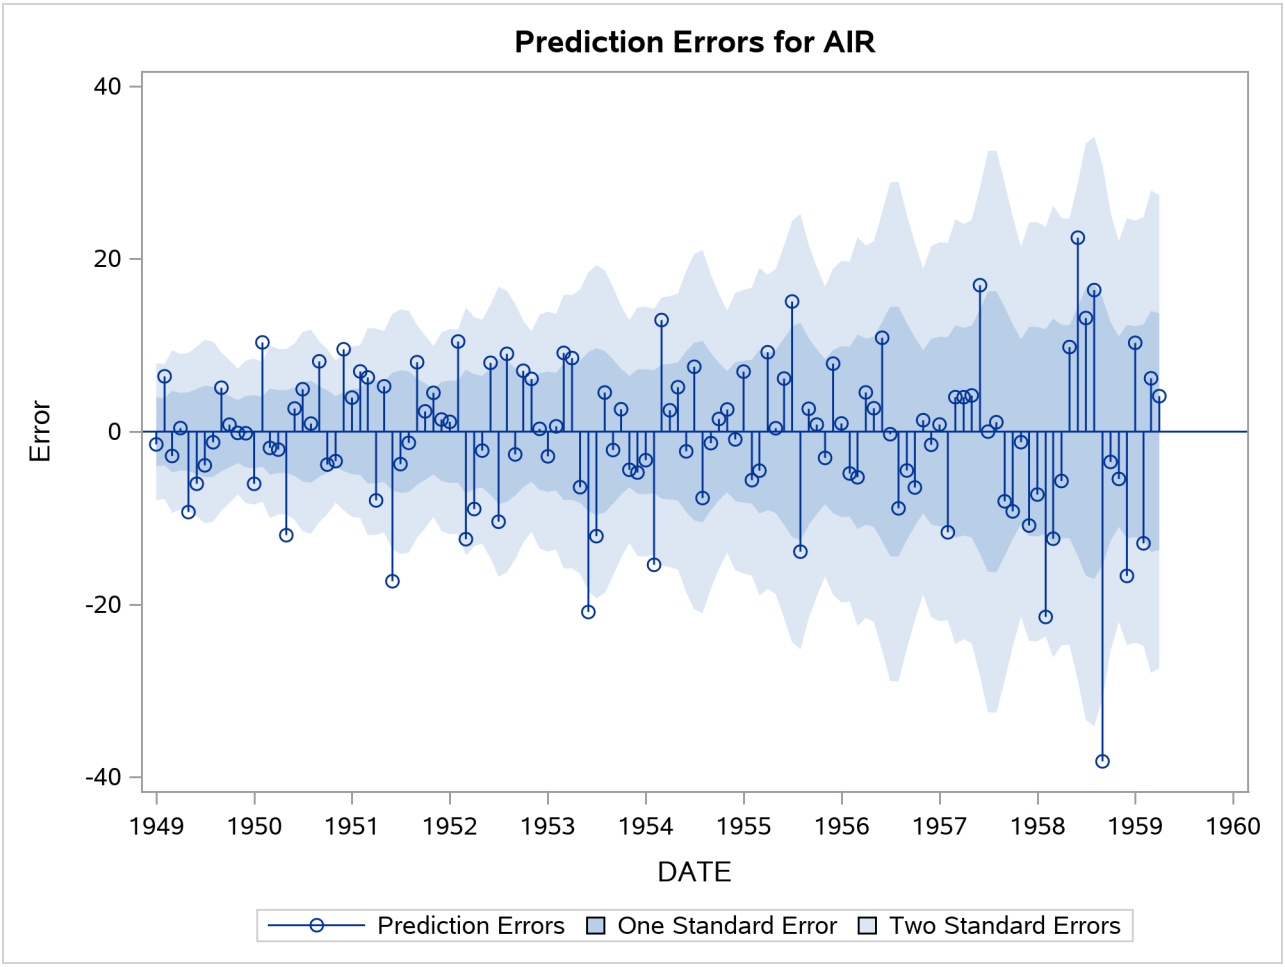
For information about the graphics available in the ESM procedure, see the section "ODS Graphics" on page 858.

```
proc esm data=sashelp.air out=_null_
         lead=20
         back=20
         print=all
         plot=all;
   id date interval=month;
   forecast air / model=addwinters transform=log;
run;
```

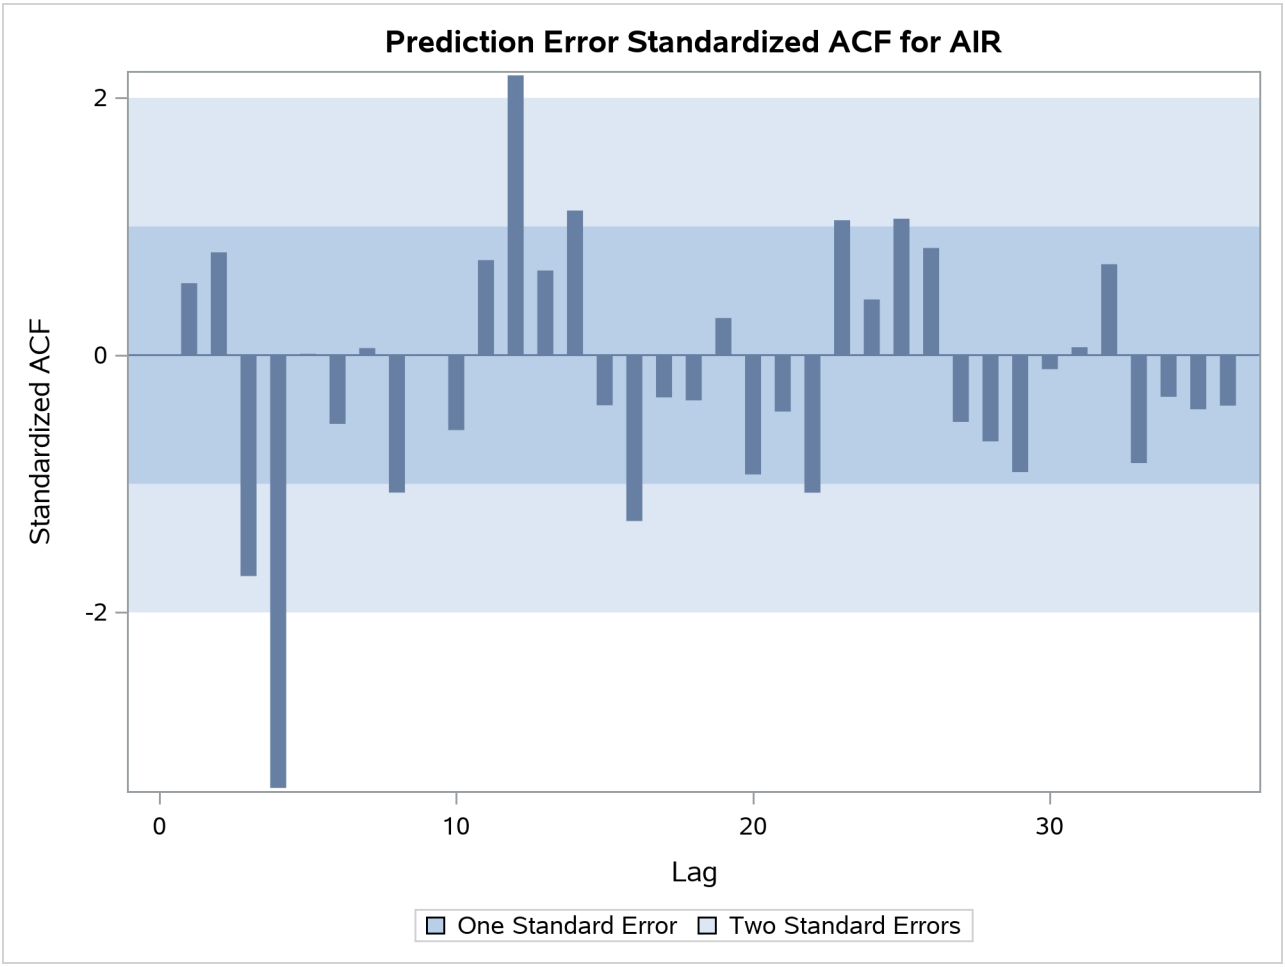
Output 14.5.1 Smoothed Trend Plot



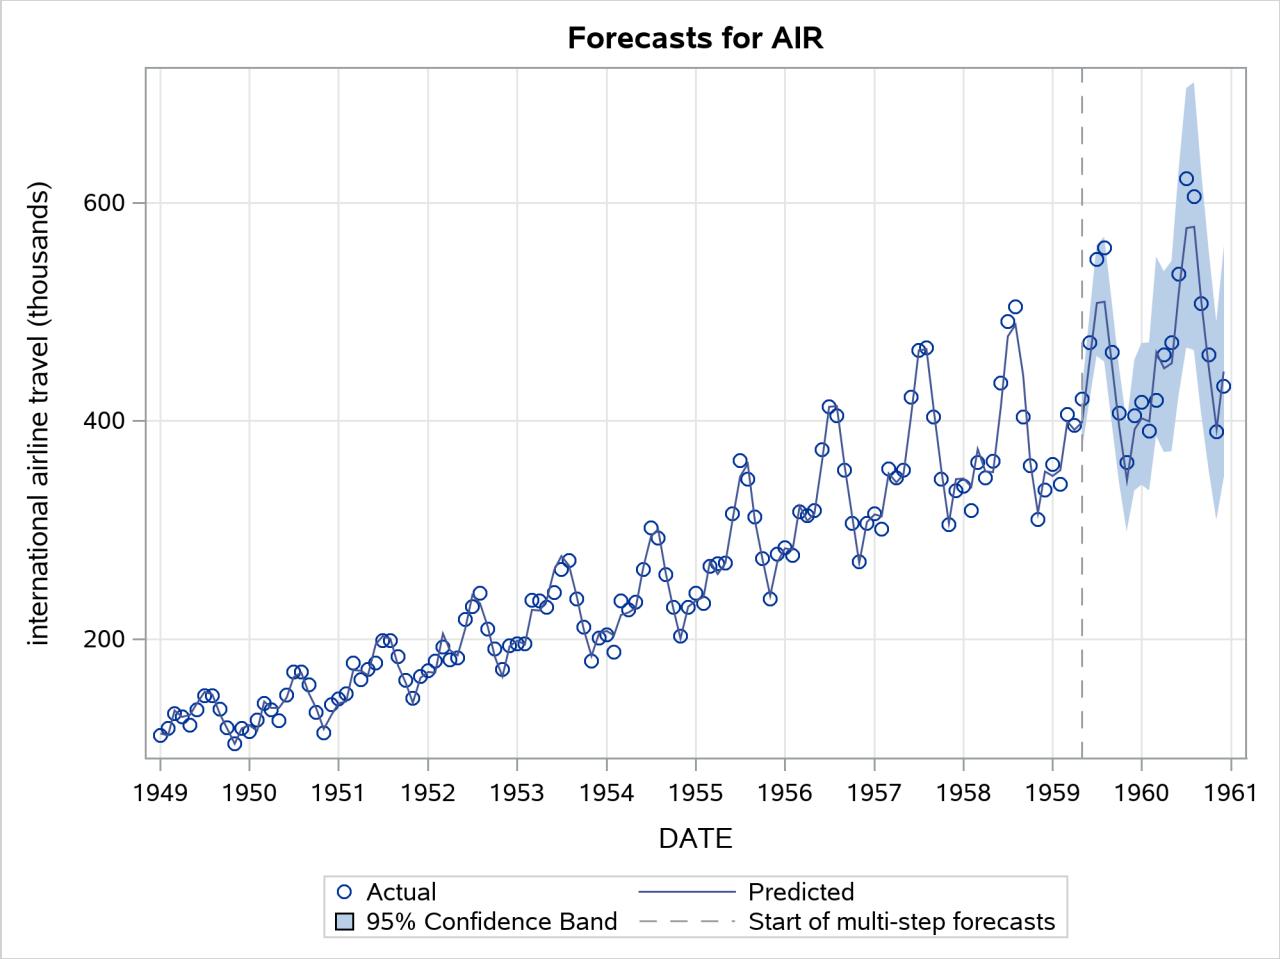
Output 14.5.2 Prediction Error Plot



Output 14.5.3 Prediction Error Standardized ACF Plot



Output 14.5.4 Forecast Plot



Output 14.5.5 Prediction Error Spectral Density

Overview: EXPAND Procedure

The EXPAND procedure converts time series from one sampling interval or frequency to another and interpolates missing values in time series. A wide array of data transformations is also supported. Using PROC EXPAND, you can collapse time series data from higher frequency intervals to lower frequency intervals, or expand data from lower frequency intervals to higher frequency intervals. For example, quarterly values can be aggregated to produce an annual series, or quarterly estimates can be interpolated from an annual series.

Time series frequency conversion is useful when you need to combine series with different sampling intervals into a single data set. For example, if you need as input to a monthly model a series that is only available quarterly, you might use PROC EXPAND to interpolate the needed monthly values.

You can also interpolate missing values in time series, either without changing series frequency or in conjunction with expanding or collapsing the series.

You can convert between any combination of input and output frequencies that can be specified by SAS time interval names. (For a complete description of SAS interval names, see Chapter 4, "Date Intervals, Formats, and Functions.") When the FROM= and TO= options are used to specify *from* and *to* intervals, PROC EXPAND automatically accounts for calendar effects such as the differing number of days in each month and leap years.

The EXPAND procedure also handles conversions of frequencies that cannot be defined by standard interval names. Using the FACTOR= option, you can interpolate any number of output observations for each group of a specified number of input observations. For example, if you specify the option FACTOR=(13:2), 13 equally spaced output observations are interpolated from each pair of input observations.

You can also convert aperiodic series, observed at arbitrary points in time, into periodic estimates. For example, a series of randomly timed quality control spot-check results might be interpolated to form estimates of monthly average defect rates.

The EXPAND procedure can also change the observation characteristics of time series. Time series observations can measure beginning-of-period values, end-of-period values, midpoint values, or period averages or totals. PROC EXPAND can convert between these cases. You can construct estimates of interval averages from end-of-period values of a variable, estimate beginning-of-period or midpoint values from interval averages, or compute averages from interval totals, and so forth.

By default, the EXPAND procedure fits cubic spline curves to the nonmissing values of variables to form continuous-time approximations of the input series. Output series are then generated from the spline approximations. Several alternate conversion methods are described in the section "Conversion Methods" on page 890. You can also interpolate estimates of the rate of change of time series by differentiating the interpolating spline curve.

Various transformations can be applied to the input series prior to interpolation and to the interpolated output series. For example, the interpolation process can be modified by transforming the input series, interpolating the transformed series, and applying the inverse of the input transformation to the output series. PROC EXPAND can also be used to apply transformations to time series without interpolation or frequency conversion.

The results of the EXPAND procedure are stored in a SAS data set. No printed output is produced.

Getting Started: EXPAND Procedure

Converting to Higher Frequency Series

To create higher frequency estimates, specify the input and output intervals with the FROM= and TO= options, and list the variables to be converted in a CONVERT statement. For example, suppose variables X, Y, and Z in the data set ANNUAL are annual time series, and you want monthly estimates. You can interpolate monthly estimates by using the following statements:

```
proc expand data=annual out=monthly from=year to=month;
   convert x y z;
run;
```

Note that interpolating values of a time series does not add any real information to the data as the interpolation process is not the same process that generated the other (nonmissing) values in the series. While time series interpolation can sometimes be useful, great care is needed in analyzing time series containing interpolated values.

Aggregating to Lower Frequency Series

PROC EXPAND provides two ways to convert from a higher frequency to a lower frequency. When a curve fitting method is used, converting to a lower frequency is no different than converting to a higher frequency—you just specify the desired output frequency with the TO= option. This provides for interpolation of missing values and allows conversion from non-nested intervals, such as converting from weekly to monthly values.

Alternatively, you can specify simple aggregation or selection without interpolation of missing values. This might be useful, for example, if you want to add up monthly values to produce annual totals, but want the annual output data set to contain values only for complete years.

To perform simple aggregation, use the METHOD=AGGREGATE option in the CONVERT statement. For example, the following statements aggregate monthly values to yearly values:

```
proc expand data=monthly out=annual
            from=month to=year;
   convert x y z / method=aggregate;
   convert a b c / method=aggregate observed=total;
   id date;
run;
```

This example assumes that the variables X, Y, and Z represent point-in-time values observed at the beginning of each month, and that the desired results are point-in-time values observed at the beginning of each year. (The default value of the OBSERVED= option is OBSERVED=(BEGINNING,BEGINNING).) The variables A, B, and C are assumed to represent monthly totals, and that the desired results are annual totals; therefore the option OBSERVED=TOTAL is specified. For more information about the OBSERVED= option, see the section "Specifying Observation Characteristics" on page 876.

Note that the AGGREGATE method can be used only if the input intervals are nested within the output intervals, as when converting from daily to monthly or from monthly to yearly frequency.

Combining Time Series with Different Frequencies

One important use of PROC EXPAND is to combine time series measured at different sampling frequencies. For example, suppose you have data on monthly money stocks (M1), quarterly gross domestic product (GDP), and weekly interest rates (INTEREST), and you want to perform an analysis of a model that uses all these variables. To perform the analysis, you first need to convert the series to a common frequency and then combine the variables into one data set.

The following statements illustrate this process for the three data sets QUARTER, MONTHLY, and WEEKLY. The data sets QUARTER and WEEKLY are converted to monthly frequency using two PROC EXPAND steps, and the three data sets are then merged using a DATA step MERGE statement to produce the data set COMBINED. The quarterly GDP data are interpolated as the total GDP over each month (OBSERVED=TOTAL), while the weekly INTEREST data are converted to average rates over each month (OBSERVED=AVERAGE).

```
proc expand data=quarter out=temp1
            from=qtr to=month;
   id date;
   convert gdp / observed=total;
run;

proc expand data=weekly out=temp2
            from=week to=month;
   id date;
   convert interest / observed=average;
run;

data combined;
   merge monthly temp1 temp2;
   by date;
run;
```

For further discussion of time series periodicity, time series dating, and time series interpolation, see Chapter 3, "Working with Time Series Data." For more information about the OBSERVED= option, see the section "Specifying Observation Characteristics" on page 876.

Interpolating Missing Values

To interpolate missing values in time series without converting the observation frequency, omit the TO= option from the PROC EXPAND statement. For example, the following statements interpolate any missing values in the time series in the data set ANNUAL:

```
proc expand data=annual out=new from=year;
   id date;
   convert x y z;
   convert a b c / observed=total;
run;
```

This example assumes that the variables X, Y, and Z represent point-in-time values observed at the beginning of each year. (The default value of the OBSERVED= option is OBSERVED=BEGINNING.) The variables A, B, and C are assumed to represent annual totals.

To interpolate missing values in variables observed at specific points in time, omit both the FROM= and TO= options and use the ID statement to supply time values for the observations. The observations do not need to be periodic or form regular time series, but the data set must be sorted by the ID variable. For example, the following statements interpolate any missing values in the numeric variables in the data set A:

```
proc expand data=a out=b;
   id date;
run;
```

If the observations are equally spaced in time, and all the series are observed as beginning-of-period values, only the input and output data sets need to be specified. For example, the following statements interpolate any missing values in the numeric variables in the data set A using a cubic spline function, assuming that the observations are at equally spaced points in time:

```
proc expand data=a out=b;
run;
```

For more information, see the section "Missing Values" on page 898.

Requesting Different Interpolation Methods

By default, a cubic spline curve is fit to the input series, and the output is computed from this interpolating curve. Other interpolation methods can be specified with the METHOD= option in the CONVERT statement. The section "Conversion Methods" on page 890 explains the available methods.

For example, the following statements convert annual series to monthly series using linear interpolation instead of cubic spline interpolation:

```
proc expand data=annual out=monthly from=year to=month;
   id date;
   convert x y z / method=join;
run;
```

Using the ID Statement

An ID statement is normally used with PROC EXPAND to specify a SAS date or datetime variable to identify the time of each input observation. An ID variable allows PROC EXPAND to do the following:

- identify the observations in the output data set
- determine the time span between observations and detect gaps in the input series caused by omitted observations
- account for calendar effects such as the number of days in each month and leap years

If you do not specify an ID variable with SAS date or datetime values, PROC EXPAND makes default assumptions that may not be what you want. For more information, see the section "ID Statement" on page 884.

Specifying Observation Characteristics

It is important to distinguish between variables that are measured at points in time and variables that represent totals or averages over an interval. Point-in-time values are often called *stocks* or *levels*. Variables that represent totals or averages over an interval are often called *flows* or *rates*.

For example, the annual series *U.S. Gross Domestic Product* represents the total value of production over the year and also the yearly average rate of production in dollars per year. However, a monthly variable *inventory* may represent the cost of a stock of goods as of the end of the month.

When the data represent periodic totals or averages, the process of interpolation to a higher frequency is sometimes called *distribution*, and the total values of the larger intervals are said to be *distributed* to the smaller intervals. The process of interpolating periodic total or average values to lower frequency estimates is sometimes called *aggregation*.

By default, PROC EXPAND assumes that all time series represent beginning-of-period point-in-time values. If a series does not measure beginning of period point-in-time values, interpolation of the data values using this assumption is not appropriate, and you should specify the correct observation characteristics of the series. The observation characteristics of the series are specified with the OBSERVED= option in the CONVERT statement.

For example, suppose that the data set ANNUAL contains variables A, B, and C that measure yearly totals, while the variables X, Y, and Z measure first-of-year values. The following statements estimate the contribution of each month to the annual totals in A, B, and C, and interpolate first-of-month estimates of X, Y, and Z:

```
proc expand data=annual out=monthly
            from=year to=month;
   id date;
   convert x y z;
   convert a b c / observed=total;
run;
```

The EXPAND procedure supports five different observation characteristics. The OBSERVED= options for these five observation characteristics are as follows:

BEGINNING	beginning-of-period values
MIDDLE	period midpoint values
END	end-of-period values
TOTAL	period totals
AVERAGE	period averages

The interpolation of each series is adjusted appropriately for its observation characteristics. When OBSERVED=TOTAL or AVERAGE is specified, the interpolating curve is fit to the data values so that the area under the curve within each input interval equals the value of the series. For OBSERVED=MIDDLE or END, the curve is fit through the data points, with the time position of each data value placed at the specified offset from the start of the interval.

For more information, see the section "OBSERVED= Option" on page 888.

Converting Observation Characteristics

The EXPAND procedure can be used to interpolate values for output series with different observation characteristics than the input series. To change observation characteristics, specify two values in the OBSERVED= option. The first value specifies the observation characteristics of the input series; the second value specifies the observation characteristics of the output series.

For example, the following statements convert the period total variable A in the data set ANNUAL to yearly midpoint estimates. This example does not change the series frequency, and the other variables in the data set are copied to the output data set unchanged.

```
proc expand data=annual out=new from=year;
   id date;
   convert a / observed=(total,middle);
run;
```

Creating New Variables

You can use the CONVERT statement to name a new variable to contain the results of the conversion. Using this feature, you can create several different versions of a series in a single PROC EXPAND step. Specify the new name after the input variable name and an equal sign:

```
convert variable=newname ... ;
```

For example, suppose you are converting quarterly data to monthly and you want both first-of-month and midmonth estimates for a beginning-of-period variable X. The following statements perform this task:

```
proc expand data=a out=b
            from=qtr to=month;
   id date;
   convert x=x_begin / observed=beginning;
   convert x=x_mid   / observed=(beginning,middle);
run;
```

Transforming Series

The interpolation methods used by PROC EXPAND assume that there are no restrictions on the range of values that series can have. This assumption can sometimes cause problems if the series must be within a certain range.

For example, suppose you are converting monthly sales figures to weekly estimates. Sales estimates should never be less than zero, but since the spline curve ignores this restriction some interpolated values may be negative. One way to deal with this problem is to transform the input series before fitting the interpolating spline and then reverse transform the output series.

You can apply various transformations to the input series using the TRANSFORMIN= option in the CONVERT statement. (The TRANSFORMIN= option can be abbreviated as TRANSFORM= or TIN=.) You can apply transformations to the output series using the TRANSFORMOUT= option. (The TRANSFORMOUT= option can be abbreviated as TOUT=.)

For example, you might use a logarithmic transformation of the input sales series and exponentiate the interpolated output series. The following statements fit a spline curve to the log of SALES and then exponentiate the output series:

```
proc expand data=a out=b from=month to=week;
   id date;
   convert sales / observed=total
                   transformin=(log)
                   transformout=(exp);
run;
```

Note that the transformations specified by the TRANSFORMIN= option are applied before the data are interpolated; the cubic spline curve or other interpolation method is fitted to transformed input data. The transformations specified by the TRANSFORMOUT= option are applied to interpolated values computed from the curves fit to the transformed input data.

As another example, suppose you are interpolating missing values in a series of market share estimates. Market shares must be between 0% and 100%, but applying a spline interpolation to the raw series can produce estimates outside of this range.

The following statements use the logistic transformation to transform proportions in the range 0 to 1 to values in the range $-\infty$ to $+\infty$. The TIN= option first divides the market shares by 100 to rescale percent values to proportions and then applies the LOGIT function. The TOUT= option applies the inverse logistic function ILOGIT to the interpolated values to convert back to proportions and then multiplies by 100 to rescale back to percentages.

```
proc expand data=a out=b;
   id date;
   convert mshare / tin=( / 100 logit )
                    tout=( ilogit * 100 );
run;
```

When more than one transformation is specified in the TRANSFORMIN= or TRANSFORMOUT= option, the transformations are applied in the order in which they are listed. Thus in the preceding example the complete input transformation is *logit(mshare/100)* (and not *logit(mshare)/100*) because the division operation is listed first in the TIN= option.

You can also use the TRANSFORM= (or TRANSFORMOUT=) option as a convenient way to do calculations normally performed with the SAS DATA step. For example, the following statements add the lead of X to the data set A. The METHOD=NONE option is used to suppress interpolation.

```
proc expand data=a method=none;
   id date;
   convert x=xlead / transform=(lead);
run;
```

Any number of operations can be listed in the TRANSFORMIN= and TRANSFORMOUT= options. For a list of the operations supported, see Table 15.2.

Syntax: EXPAND Procedure

The following statements are available in the EXPAND procedure:

PROC EXPAND *options* ;
  BY *variables* ;
  CONVERT *variables* / *options* ;
  ID *variable* ;

Functional Summary

The statements and options controlling the EXPAND procedure are summarized in Table 15.1.

Table 15.1 Functional Summary

Description	Statement	Option
Statements		
Specify options	PROC EXPAND	
Specify BY-group processing	BY	
Specify conversion options	CONVERT	
Specify the ID variable	ID	
Data Set Options		
Specify the input data set	PROC EXPAND	DATA=
Extrapolate values before or after input series	PROC EXPAND	EXTRAPOLATE
Specify the output data set	PROC EXPAND	OUT=
Write interpolating functions to a data set	PROC EXPAND	OUTEST=
Input and Output Frequencies		
Control the alignment of SAS date values	PROC EXPAND	ALIGN=
Specify frequency conversion factor	PROC EXPAND	FACTOR=
Specify input frequency	PROC EXPAND	FROM=
Specify output frequency	PROC EXPAND	TO=
Interpolation Control Options		
Specify interpolation method for all series	PROC EXPAND	METHOD=
Specify interpolation method for series	CONVERT	METHOD=
Specify observation characteristics for series	PROC EXPAND	OBSERVED=
Specify observation characteristics for series	CONVERT	OBSERVED=
Specify transformations of the input series	CONVERT	TRANSFORMIN=
specify transformations of the output series	CONVERT	TRANSFORMOUT=
Graphical Output Control Options		
Specify graphical output	PROC EXPAND	PLOTS=

The following sections describe the PROC EXPAND statement and then describe the other statements in alphabetical order.

PROC EXPAND Statement

PROC EXPAND *options* **;**

You can specify the following *options*:

Data Set Options

DATA=*SAS-data-set*
names the input data set. If the DATA= option is omitted, the most recently created SAS data set is used.

OUT=*SAS-data-set*
names the output data set containing the resulting time series. If OUT= is not specified, the data set is named using the DATA*n* convention. For more information, see the section "OUT= Data Set" on page 905.

OUTEST=*SAS-data-set*
names an output data set containing the coefficients of the spline curves fit to the input series. If the OUTEST= option is not specified, the spline coefficients are not output. For more information, see the section "OUTEST= Data Set" on page 906.

Options That Define Input and Output Frequencies

ALIGN=*option*
controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. BEGINNING is the default.

FACTOR=*n*

FACTOR=(*n* **:** *m* **)**
specifies the number of output observations to be created from the input observations. FACTOR=*n* specifies that *n* output observations are to be produced for each input observation. FACTOR=(*n* : *m*) specifies that *n* output observations are to be produced for each group of *m* input observations. FACTOR=*n* is the same as FACTOR=(*n* : 1).

In the FACTOR=() option, a comma can be used instead of a colon or the delimiter can be omitted. Thus FACTOR=(*n*, *m*) or FACTOR=(*n m*) is the same as FACTOR=(*n* : *m*).

The FACTOR= option cannot be used if the TO= option is used. The default value is FACTOR=(1:1). For more information, see the section "Frequency Conversion" on page 885.

FROM=*interval*

specifies the time interval between observations in the input data set. Examples of FROM= values are YEAR, QTR, MONTH, DAY, and HOUR. For a complete description and examples of interval specifications, see Chapter 4, "Date Intervals, Formats, and Functions."

TO=*interval*

specifies the time interval between observations in the output data set. By default, the TO= interval is generated from the combination of the FROM= and the FACTOR= values or is set to be the same as the FROM= value if FACTOR= is not specified. For a description of interval specifications, see Chapter 4, "Date Intervals, Formats, and Functions."

Options to Control the Interpolation

EXTRAPOLATE

specifies that missing values at the beginning or end of input series be replaced with values produced by a linear extrapolation of the interpolating curve fit to the input series. For more information, see the section "Extrapolation" on page 887.

By default, PROC EXPAND avoids extrapolating values beyond the first or last input value for a series and only interpolates values within the range of the nonmissing input values. Note that the extrapolated values are often not very accurate and for the SPLINE method the EXTRAPOLATE option results may be very unreasonable. The EXTRAPOLATE option is rarely used.

METHOD=*option*

METHOD=SPLINE(*constraint* **<** **,** *constraint* **>** **)**

specifies the method used to convert the data series. The methods supported are SPLINE, JOIN, STEP, AGGREGATE, and NONE. The METHOD= option specified in the PROC EXPAND statement can be overridden for particular series by the METHOD= option in the CONVERT statement. The default is METHOD=SPLINE. The *constraint* specifications for METHOD=SPLINE can have the values NOTAKNOT (the default), NATURAL, SLOPE=*value*, and/or CURVATURE=*value*. For more information about these methods, see the section "Conversion Methods" on page 890.

OBSERVED=*value*

OBSERVED=(*from-value* **,** *to-value* **)**

indicates the observation characteristics of the input time series and of the output series. Specifying the OBSERVED= option in the PROC EXPAND statement sets the default OBSERVED= value for subsequent CONVERT statements. For more information, see the sections "CONVERT Statement" on page 883 and "OBSERVED= Option" on page 888. The default is OBSERVED=BEGINNING.

Options to Control Graphical Output

PLOTS=*option* **|** **(** *options* **)**

specifies the graphical output desired. If the PLOTS= option is used, the specified graphical output is produced for each output variable that is specified by a CONVERT statement. By default, the EXPAND procedure produces no graphical output. The following PLOTS= *options* are available:

INPUT	plots the input series.
TRANSFORMIN	plots the transformed input series. The TRANSFORMIN= option must also be specified in the CONVERT statement.

CROSSINPUT plots both the input series and the transformed input series on one plot with two Y axes. The input and transformed series are shown on separate scales. The TRANSFORMIN= option must also be specified in the CONVERT statement.

JOINTINPUT plots both the input series and the transformed input series on one plot with one Y axis. The input and transformed series are shown on the same scale. The TRANSFORMIN= option must also be specified in the CONVERT statement.

CONVERTED plots the converted series after input transformations and interpolation, but before any TRANSFORMOUT= transformations are applied. The METHOD= option must also be specified in the PROC EXPAND or CONVERT statements.

TRANSFORMOUT plots the transformed output series. The TRANSFORMOUT= option must also be specified in the CONVERT statement.

CROSSOUTPUT plots both the converted series and the transformed output series on one plot with two Y axes. The converted and transformed output series are shown on separate scales. The TRANSFORMOUT= option must also be specified in the CONVERT statement.

JOINTOUTPUT plots both the converted series and the transformed output series on one plot with one Y axis. The converted and transformed output series are shown on the same scale. The TRANSFORMOUT= option must also be specified in the CONVERT statement.

OUTPUT plots the series stored in the OUT= data set. The OUTPUT option does not require any options to be specified in the CONVERT statement.

ALL produces all plots except the joint and cross plots. PLOTS=ALL is the same as PLOTS=(INPUT TRANFORMIN CONVERTED TRANSFORMOUT).

The PLOTS= option produces results associated with each CONVERT statement output variable and the options listed in the PLOTS= specification. For more information, see the section "PLOTS= Option Details" on page 908.

BY Statement

BY *variables* **;**

A BY statement can be used with PROC EXPAND to obtain separate analyses on observations in groups defined by the BY variables. The input data set must be sorted by the BY variables and be sorted by the ID variable within each BY group.

Use a BY statement when you want to interpolate or convert time series within levels of a cross-sectional variable. For example, suppose you have a data set STATE containing annual estimates of average disposable personal income per capita (DPI) by state and you want quarterly estimates by state. These statements convert the DPI series within each state:

```
proc sort data=state;
   by state date;
run;

proc expand data=state out=stateqtr from=year to=qtr;
   convert dpi;
   by state;
   id date;
run;
```

CONVERT Statement

CONVERT *variable = newname . . .* **<** */ options* **>;**

The CONVERT statement lists the variables to be processed. Only numeric variables can be processed.

For each of the variables listed, a new variable name can be specified after an equal sign to name the variable in the output data set that contains the converted values. If a name for the output series is not given, the variable in the output data set has the same name as the input variable. Variable lists may be used only when no name is given for the output series.

For example, variable lists can be specified as follows:

```
convert y1-y25 / observed=(beginning,end);
convert x--a / observed=average;
convert x-numeric-a / observed=average;
```

Any number of CONVERT statements can be used. If no CONVERT statement is used, all the numeric variables in the input data set except those appearing in the BY and ID statements are processed.

The following options can be used with the CONVERT statement:

METHOD=*option*

METHOD=SPLINE(*constraint* **<** **,** *constraint* **>** **)**

specifies the method used to convert the data series. (The method specified by the METHOD= option is applied to the input data series after applying any transformations specified by the TRANSFORMIN= option.) The methods supported are SPLINE, JOIN, STEP, AGGREGATE, and NONE. The METHOD= option specified in the PROC EXPAND statement can be overridden for particular series by the METHOD= option in the CONVERT statement. The default is METHOD=SPLINE. The *constraint* specifications for METHOD=SPLINE can have the values NOTAKNOT (the default), NATURAL, SLOPE=*value*, and/or CURVATURE=*value*. For more information about these methods, see the section "Conversion Methods" on page 890.

OBSERVED=*value*

OBSERVED=(*from-value* **,** *to-value* **)**

indicates the observation characteristics of the input time series and of the output series. The values supported are TOTAL, AVERAGE, BEGINNING, MIDDLE, and END. In addition, DERIVATIVE can be specified as the *to-value* when the SPLINE method is used.

When only one value is specified, that value specifies both the *from-value* and the *to-value*. (That is, OBSERVED=*value* is equivalent to OBSERVED=(*value*, *value*).) If the OBSERVED= op-

tion is omitted from both the PROC EXPAND and the CONVERT statements, the default is OBSERVED=(BEGINNING, BEGINNING). For more information, see the section "OBSERVED= Option" on page 888.

TRANSFORMIN=(*operation . . .* **)**
specifies a list of transformations to be applied to the input series before the interpolating function is fit. The operations are applied in the order listed. For the operations that can be specified, see the section "Transformation Operations" on page 892. The TRANSFORMIN= option can be abbreviated as TRANSIN=, TIN=, or TRANSFORM=.

TRANSFORMOUT=(*operation . . .* **)**
specifies a list of transformations to be applied to the output series. The operations are applied in the order listed. For the operations that can be specified, see the section "Transformation Operations" on page 892. The TRANSFORMOUT= option can be abbreviated as TRANSOUT= or TOUT=.

ID Statement

ID *variable* **;**

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date or datetime values.

The input data must form time series. This means that the observations in the input data set must be sorted by the ID variable (within the BY variables, if any). Moreover, there should be no duplicate observations, and no two observations should have ID values within the same time interval as defined by the FROM= option.

If the ID statement is omitted, SAS date or datetime values are generated to label the input observations. These ID values are generated by assuming that the input data set starts at a SAS date value of 0, that is, 1 January 1960. This default starting date is then incremented for each observation by the FROM= interval (using the same logic as the DATA step INTNX function). If the FROM= option is not specified, the ID values are generated as the observation count minus 1. When the ID statement is not used, an ID variable is added to the output data set named either DATE or DATETIME, depending on the value specified in the TO= option. If neither the TO= option nor the FROM= option is given, the ID variable in the output data set is named TIME.

Details: EXPAND Procedure

Frequency Conversion

Frequency conversion is controlled by the FROM=, TO=, and FACTOR= options. The possible combinations of these options are explained in the following:

None Used
If FROM=, TO=, and FACTOR= are not specified, no frequency conversion is done. The data are processed to interpolate any missing values and perform any specified transformations. Each input observation produces one output observation.

FACTOR=(n:m)
FACTOR=(*n* :*m*) specifies that *n* output observations are produced for each group of *m* input observations. The fraction *m* /*n* is reduced first: thus FACTOR=(10:6) is equivalent to FACTOR=(5:3). Note that if *m* /*n* =1, the result is the same as the case given previously under "None Used."

FROM=interval
The FROM= option used alone establishes the frequency and interval widths of the input observations. Missing values are interpolated, and any specified transformations are performed, but no frequency conversion is done.

TO=interval
When the TO= option is used without the FROM= option, output observations with the TO= frequency are generated over the range of input ID values. The first output observation is for the TO= interval containing the ID value of the first input observation; the last output observation is for the TO= interval containing the ID value of the last input observation. The input observations are not assumed to form regular time series and may represent aperiodic points in time. An ID variable is required to give the date or datetime of the input observations.

FROM=interval TO=interval
When both the FROM= and TO= options are used, the input observations have the frequency given by the FROM= interval, and the output observations have the frequency given by the TO= interval.

FROM=interval FACTOR=(n:m)
When both the FROM= and FACTOR= options are used, a TO= interval is inferred from the combination of the FROM=*interval* and the FACTOR=(*n:m*) values specified. For example, FROM=YEAR FACTOR=4 is the same as FROM=YEAR TO=QTR. Also, FROM=YEAR FACTOR=(3:2) is the same as FROM=YEAR used with TO=MONTH8. Once the implied TO= interval is determined, this combination operates the same as if FROM= and TO= had been specified. If no valid TO= interval can be constructed from the combination of the FROM= and FACTOR= options, an error is produced.

TO=interval FACTOR=(n:m)
The combination of the TO= option and the FACTOR= option is not allowed and produces an error.

ALIGN= option
Controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. BEGINNING is the default.

Converting to a Lower Frequency

When converting to a lower frequency, the results are either exact or approximate, depending on whether or not the input interval nests within the output interval and depending on the need to interpolate missing values within the series. If the TO= interval is nested within the FROM= interval (as when converting from monthly to yearly), and if there are no missing input values or partial periods, the results are exact.

When values are missing or the FROM= interval is not nested within the TO= interval (as when aggregating from weekly to monthly), the results depend on an interpolation. The METHOD=AGGREGATE option always produces exact results, never an interpolation. However, this method can only be used if the FROM= interval is nested within the TO= interval.

Identifying Observations

The variable specified in the ID statement is used to identify the observations. Usually, SAS date or datetime values are used for this variable. PROC EXPAND uses the ID variable to do the following:

- identify the time interval of the input values
- validate the input data set observations
- compute the ID values for the observations in the output data set

Identifying the Input Time Intervals

When the FROM= option is specified, observations are understood to refer to the whole time interval and not to a single time point. The ID values are interpreted as identifying the FROM= time interval containing the value. In addition, the widths of these input intervals are used by the OBSERVED= values TOTAL, AVERAGE, MIDDLE, and END.

For example, if FROM=MONTH is specified, then each observation is for the whole calendar month containing the ID value for the observation, and the width of the time interval covered by the observation is the number of days in that month. Therefore, if FROM=MONTH, the ID value '31MAR92'D is equivalent to the ID value '1MAR92'D—both of these ID values identify the same interval, March of 1992.

Widths of Input Time Intervals

When the FROM= option is not specified, the ID variable values are usually interpreted as referring to points in time. However, if an OBSERVED= option value is specified that assumes the observations refer to whole intervals and also requires interval widths (TOTAL or AVERAGE), then, in the absence of the FROM= specification, interval widths are assumed to be the time span between ID values. For the last observation, the interval width is assumed to be the same as for the next to last observation. (If neither the FROM= option nor the ID statement is specified, interval widths are assumed to be 1.0.) A note is printed in the SAS log warning that this assumption is made.

Validating the Input Data Set Observations

The ID variable is used to verify that successive observations read from the input data set correspond to sequential FROM= intervals. When the FROM= option is not used, PROC EXPAND verifies that the ID values are nonmissing and in ascending order. An error message is produced and the observation is ignored when an invalid ID value is found in the input data set.

ID values for Observations in the Output Data Set

The time unit used for the ID variable in the output data set is controlled by the interval value specified by the TO= option. If you specify a date interval for the TO= value, the ID variable values in the output data set are SAS date values. If you specify a datetime interval for the TO= value, the ID variable values in the output data set are SAS datetime values.

The date or datetime values for the ID variable for output observations are the first date or datetime of the TO= interval, unless the ALIGN= option is used to specify a different alignment. (For example, if TO=WEEK is specified, then the output dates are Sundays. If TO=WEEK.2 is specified, then the output date are Mondays.) For more information about interval specifications, see Chapter 4, "Date Intervals, Formats, and Functions."

Range of Output Observations

If no frequency conversion is done, the range of output observations is the same as in the input data set.

When frequency conversion is done, the observations in the output data set range from the earliest start of any result series to the latest end of any result series. Observations at the beginning or end of the input range for which all result values are missing are not written to the OUT= data set.

When the EXTRAPOLATE option is not used, the range of the nonmissing output results for each series is as follows. The first result value is for the TO= interval that contains the ID value of the start of the FROM= interval containing the ID value of the first nonmissing input observation for the series. The last result value is for the TO= interval that contains the end of the FROM= interval containing the ID value of the last nonmissing input observation for the series.

When the EXTRAPOLATE option is used, result values for all series are computed for the full time range covered by the input data set.

Extrapolation

The spline functions fit by the EXPAND procedure are very good at approximating continuous curves within the time range of the input data but poor at extrapolating beyond the range of the data. The accuracy of the results produced by PROC EXPAND may be somewhat less at the ends of the output series than at time periods for which there are several input values at both earlier and later times. The curves fit by PROC EXPAND should not be used for forecasting.

PROC EXPAND normally avoids extrapolation of values beyond the time range of the nonmissing input data for a series, unless the EXTRAPOLATE option is used. However, if the start or end of the input series does not correspond to the start or end of an output interval, some output values may depend in part on an extrapolation.

For example, if FROM=YEAR, TO=WEEK, and OBSERVED=BEGINNING are specified, then the first observation output for a series is for the week of 1 January of the first nonmissing input year. If 1 January of that year is not a Sunday, the beginning of this week falls before the date of the first input value, and therefore a beginning-of-period output value for this week is extrapolated.

This extrapolation is made only to the extent needed to complete the terminal output intervals that overlap the endpoints of the input series and is limited to no more than the width of one FROM= interval or one TO= interval, whichever is less. This restriction of the extrapolation to complete terminal output intervals is applied to each series separately, and it takes into account the OBSERVED= option for the input and output series.

When the EXTRAPOLATE option is used, the normal restriction on extrapolation is overridden. Output values are computed for the full time range covered by the input data set.

For the SPLINE method, extrapolation is performed by a linear projection of the trend of the cubic spline curve fit to the input data, not by extrapolation of the first and last cubic segments.

The EXTRAPOLATE option should be used with caution.

OBSERVED= Option

The values of the CONVERT statement OBSERVED= option are as follows:

BEGINNING	indicates that the data are beginning-of-period values. OBSERVED=BEGINNING is the default.
MIDDLE	indicates that the data are period midpoint values.
ENDING	indicates that the data represent end-of-period values.
TOTAL	indicates that the data values represent period totals for the time interval corresponding to the observation.
AVERAGE	indicates that the data values represent period averages.
DERIVATIVE	requests that the output series be the derivatives of the cubic spline curve fit to the input data by the SPLINE method.

If only one value is specified in the OBSERVED= option, that value applies to both the input and the output series. For example, OBSERVED=TOTAL is the same as OBSERVED=(TOTAL,TOTAL), which indicates that the input values represent totals over the time intervals corresponding to the input observations, and the converted output values also represent period totals. The value DERIVATIVE can be used only as the second OBSERVED= option value, and it can be used only when METHOD=SPLINE is specified or is the default method.

Since the TOTAL, AVERAGE, MIDDLE, and END cases require that the width of each input interval be known, both the FROM= option and an ID statement are normally required if one of these observation characteristics is specified for any series. However, if the FROM= option is not specified, each input interval is assumed to extend from the ID value for the observation to the ID value of the next observation, and the width of the interval for the last observation is assumed to be the same as the width for the next to last observation.

Scale of OBSERVED=AVERAGE Values

The average values are assumed to be expressed in the time units defined by the FROM= or TO= option. That is, the product of the average value for an interval and the width of the interval is assumed to equal the total value for the interval. For purposes of interpolation, OBSERVED=AVERAGE values are first converted to OBSERVED=TOTAL values using this assumption, and then the interpolated totals are converted back to averages by dividing by the widths of the output intervals.

For example, suppose the options FROM=MONTH, TO=HOUR, and OBSERVED=AVERAGE are specified. Since FROM=MONTH is specified, each input value is assumed to represent an average rate per day such that the product of the value and the number of days in the month is equal to the total for the month. The input values are assumed to represent a per-day rate because FROM=MONTH implies SAS date ID values that measure time in days, and therefore the widths of MONTH intervals are measured in days. If FROM=DTMONTH is used instead, the values are assumed to represent a per-second rate, because the widths of DTMONTH intervals are measured in seconds.

Since TO=HOUR is specified, the output values are scaled as an average rate per second such that the product of each output value and the number of seconds in an hour (3600) is equal to the interpolated hourly total. A per-second rate is used because TO=HOUR implies SAS datetime ID values that measure time in seconds, and therefore the widths of HOUR intervals are measured in seconds.

Note that the scale assumed for OBSERVED=AVERAGE data is important only when converting between AVERAGE and another OBSERVED= option, or when converting between SAS date and SAS datetime ID values. When both the input and the output series are AVERAGE values, and the units for the ID values are not changed, the scale assumed does not matter.

For example, suppose you are converting gross domestic product (GDP) from quarterly to monthly. The GDP values are quarterly averages measured at annual rates. If you want the interpolated monthly values to also be measured at annual rates, then the option OBSERVED=AVERAGE works fine. Since there is no change of scale involved in this problem, it makes no difference that PROC EXPAND assumes daily rates instead of annual rates.

However, suppose you want to convert GDP from quarterly to monthly and also convert from annual rates to monthly rates, so that the result is total gross domestic product for the month. Using the option OBSERVED=(AVERAGE,TOTAL) would fail, because PROC EXPAND assumes the average is scaled to daily, not annual, rates.

One solution is to rescale to quarterly totals and treat the data as totals. You could use the options TRANSFORMIN=(/ 4) OBSERVED=TOTAL. Alternatively, you could treat the data as averages but first convert to daily rates. In this case you would use the options TRANSFORMIN=(/ 365.25) OBSERVED=AVERAGE.

Results of the OBSERVED=DERIVATIVE Option

If the first value of the OBSERVED= option is BEGINNING, TOTAL, or AVERAGE, the result is the derivative of the spline curve evaluated at first-of-period ID values for the output observation. For OBSERVED=(MIDDLE,DERIVATIVE), the derivative of the function is evaluated at output interval midpoints. For OBSERVED=(END,DERIVATIVE), the derivative is evaluated at end-of-period ID values.

Conversion Methods

The SPLINE Method

The SPLINE method fits a cubic spline curve to the input values. A cubic spline is a segmented function consisting of third-degree (cubic) polynomial functions joined together so that the whole curve and its first and second derivatives are continuous.

For point-in-time input data, the spline curve is constrained to pass through the given data points. For interval total or average data, the definite integrals of the spline over the input intervals are constrained to equal the given interval totals.

For boundary constraints, the *not-a-knot* condition is used by default. This means that the first two spline pieces are constrained to be part of the same cubic curve, as are the last two pieces. Thus the spline used by PROC EXPAND by default is not the same as the commonly used natural spline, which uses zero second-derivative endpoint constraints. While De Boor (1978) recommends the *not-a-knot* constraint for cubic spline interpolation, using this constraint can sometimes produce anomalous results at the ends of the interpolated series. PROC EXPAND provides options to specify other endpoint constraints for spline curves.

To specify endpoint constraints, use the following form of the METHOD= option.

METHOD=SPLINE(*constraint* **<** **,** *constraint* **>** **)**

The first constraint specification applies to the lower endpoint, and the second constraint specification applies to the upper endpoint. If only one constraint is specified, it applies to both the lower and upper endpoints.

The *constraint* specifications can have the following values:

NOTAKNOT specifies the not-a-knot constraint. This is the default.

NATURAL specifies the *natural spline* constraint. The second derivative of the spline curve is constrained to be zero at the endpoint.

SLOPE=*value* specifies the first derivative of the spline curve at the endpoint. The value specified can be any positive or negative number, but extreme values may produce unreasonable results.

CURVATURE=*value* specifies the second derivative of the spline curve at the endpoint. The value specified can be any positive or negative number, but extreme values may produce unreasonable results. Specifying CURVATURE=0 is equivalent to specifying the NATURAL option.

For example, to specify natural spline interpolation, use the following option in the CONVERT or PROC EXPAND statement:

```
method=spline(natural)
```

For OBSERVED=BEGINNING, MIDDLE, and END series, the spline knots are placed at the beginning, middle, and end of each input interval, respectively. For total or averaged series, the spline knots are set at the start of the first interval, at the end of the last interval, and at the interval midpoints, except that there are no knots for the first two and last two midpoints.

Once the cubic spline curve is fit to the data, the spline is extended by adding linear segments at the beginning and end. These linear segments are used for extrapolating values beyond the range of the input data.

For point-in-time output series, the spline function is evaluated at the appropriate points. For interval total or average output series, the spline function is integrated over the output intervals.

The JOIN Method

The JOIN method fits a continuous curve to the data by connecting successive straight line segments. For point-in-time data, the JOIN method connects successive nonmissing input values with straight lines. For interval total or average data, interval midpoints are used as the break points, and ordinates are chosen so that the integrals of the piecewise linear curve agree with the input totals.

For point-in-time output series, the JOIN function is evaluated at the appropriate points. For interval total or average output series, the JOIN function is integrated over the output intervals.

The STEP Method

The STEP method fits a discontinuous piecewise constant curve. For point-in-time input data, the resulting step function is equal to the most recent input value. For interval total or average data, the step function is equal to the average value for the interval.

For point-in-time output series, the step function is evaluated at the appropriate points. For interval total or average output series, the step function is integrated over the output intervals.

The AGGREGATE Method

The AGGREGATE method performs simple aggregation of time series without interpolation of missing values.

If the input data are totals or averages, the results are the sums or averages, respectively, of the input values for observations corresponding to the output observations. That is, if either TOTAL or AVERAGE is specified for the OBSERVED= option, the METHOD=AGGREGATE result is the sum or mean of the input values corresponding to the output observation. For example, suppose METHOD=AGGREGATE, FROM=MONTH, and TO=YEAR are specified. For OBSERVED=TOTAL series, the result for each output year is the sum of the input values over the months of that year. If any input value is missing, the corresponding sum or mean is also a missing value.

If the input data are point-in-time values, the result value of each output observation equals the input value for a selected input observation determined by the OBSERVED= attribute. For example, suppose METHOD=AGGREGATE, FROM=MONTH, and TO=YEAR are specified. For OBSERVED=BEGINNING series, January observations are selected as the annual values. For OBSERVED=MIDDLE series, July observations are selected as the annual values. For OBSERVED=END series, December observations are selected as the annual values. If the selected value is missing, the output annual value is missing.

The AGGREGATE method can be used only when the FROM= intervals are nested within the TO= intervals. For example, you can use METHOD=AGGREGATE when FROM=MONTH and TO=QTR because months are nested within quarters. You cannot use METHOD=AGGREGATE when FROM=WEEK and TO=QTR because weeks are not nested within quarters.

In addition, the AGGREGATE method cannot convert between point-in-time data and interval total or average data. Conversions between TOTAL and AVERAGE data are allowed, but conversions between BEGINNING, MIDDLE, and END are not.

Missing input values produce missing result values for METHOD=AGGREGATE. However, gaps in the sequence of input observations are not allowed. For example, if FROM=MONTH, you may have a missing value for a variable in an observation for a given February. But if an observation for January is followed by an observation for March, there is a gap in the data, and METHOD=AGGREGATE cannot be used.

When the AGGREGATE method is used, there is no interpolating curve, and therefore the EXTRAPOLATE option is not allowed.

Alternate methods for aggregating or accumulating time series data are supported by the TIMESERIES procedure. For more information, see Chapter 38, "The TIMESERIES Procedure."

METHOD=NONE

The option METHOD=NONE specifies that no interpolation be performed. This option is normally used in conjunction with the TRANSFORMIN= or TRANSFORMOUT= option.

When METHOD=NONE is specified, there is no difference between the TRANSFORMIN= and TRANSFORMOUT= options; if both are specified, the TRANSFORMIN= operations are performed first, followed by the TRANSFORMOUT= operations. TRANSFORM= can be used as an abbreviation for TRANSFORMIN=. METHOD=NONE cannot be used when frequency conversion is specified.

Transformation Operations

The operations that can be used in the TRANSFORMIN= and TRANSFORMOUT= options are shown in Table 15.2. Operations are applied to each value of the series. Each value of the series is replaced by the result of the operation.

In Table 15.2, x_t or x represents the value of the series at a particular time period t before the transformation is applied, y_t represents the value of the result series, and N represents the total number of observations.

The notation n_{optional} indicates that the argument n_{optional} is an optional integer; the default is 1. The notation *window* is used as the argument for the moving statistics operators, and it indicates that you can specify either a number of periods *n* (where *n* is an integer) or a list of *n* weights in parentheses. The internal maximum value of the number of periods *n* is clipped at the number of observations in the series. The notation *sequence* is used as the argument for the sequence operators, and it indicates that you must specify a sequence of numbers. The notation *s* indicates the length of seasonality, and it is a required argument.

Table 15.2 Transformation Operations

Syntax	Result
+ *number*	Adds the specified *number* : $x + number$
− *number*	Subtracts the specified *number* : $x - number$
* *number*	Multiplies by the specified *number* : $x * number$
/ *number*	Divides by the specified *number* : $x / number$
ABS	Absolute value: $\|x\|$

Table 15.2 *continued*

Syntax	Result
ADJUST	Indicates that the following moving window summation or product operator should be adjusted for window width
CD_I *s*	Classical decomposition irregular component
CD_S *s*	Classical decomposition seasonal component
CD_SA *s*	Classical decomposition seasonally adjusted series
CD_TC *s*	Classical decomposition trend-cycle component
CDA_I *s*	Classical decomposition (additive) irregular component
CDA_S *s*	Classical decomposition (additive) seasonal component
CDA_SA *s*	Classical decomposition (additive) seasonally adjusted series
CEIL	Smallest integer greater than or equal to x : $\mathrm{ceil}(x)$
CMOVAVE *window*	Centered moving average
CMOVCSS *window*	Centered moving corrected sum of squares
CMOVGMEAN *window*	Centered moving geometric mean for *window* = number of periods, *n*: $(\prod_{j=j_{\min}}^{j_{\max}} x_{t+j})^{1/n}$ $j_{\min} = -(n + n \mod 2)/2 + 1$ $j_{\max} = (n - n \mod 2)/2$ for *window* = weight list, *w*: $(\prod_{j=j_{\min}}^{j_{\max}} x_{t+j}^{w_{j-j_{\min}}})^{1/\sum_{j=0}^{n-1} w_j}$
CMOVMAX *n*	Centered moving maximum
CMOVMED *n*	Centered moving median
CMOVMIN *n*	Centered moving minimum
CMOVPROD *window*	Centered moving product for *window* = number of periods, *n*: $\prod_{j=j_{\min}}^{j_{\max}} x_{t+j}$ for *window* = weight list, *w*: $(\prod_{j=j_{\min}}^{j_{\max}} x_{t+j}^{w_{j-j_{\min}}})^{1/\sum_{j=0}^{n-1} w_j}$
CMOVRANGE *n*	Centered moving range
CMOVRANK *n*	Centered moving rank
CMOVSTD *window*	Centered moving standard deviation
CMOVSUM *n*	Centered moving sum
CMOVTVALUE *window*	Centered moving *t* value
CMOVUSS *window*	Centered moving uncorrected sum of squares
CMOVVAR *window*	Centered moving variance
CUAVE n_{optional}	Cumulative average
CUCSS n_{optional}	Cumulative corrected sum of squares
CUGMEAN n_{optional}	Cumulative geometric mean
CUMAX n_{optional}	Cumulative maximum
CUMED n_{optional}	Cumulative median
CUMIN n_{optional}	Cumulative minimum
CUPROD n_{optional}	Cumulative product
CURANK n_{optional}	Cumulative rank
CURANGE n_{optional}	Cumulative range

Table 15.2 *continued*

Syntax	Result
CUSTD n_{optional}	Cumulative standard deviation
CUSUM n_{optional}	Cumulative sum
CUTVALUE n_{optional}	Cumulative t value
CUUSS n_{optional}	Cumulative uncorrected sum of squares
CUVAR n_{optional}	Cumulative variance
DIF n_{optional}	Span n difference: $x_t - x_{t-n}$
EWMA *number*	Exponentially weighted moving average of x with smoothing weight *number*, where $0 < number < 1$: $y_t = number\ x_t + (1 - number)y_{t-1}$. This operation is also called simple exponential smoothing.
EXP	Exponential function: $\exp(x)$
FDIF d	Fractional difference with difference order d where $0 < d < 0.5$
FLOOR	Largest integer less than or equal to x : $\text{floor}(x)$
FSUM d	Fractional summation with summation order d where $0 < d < 0.5$
HP_T *lambda*	Hodrick-Prescott Filter trend component where *lambda* is the nonnegative filter parameter
HP_C *lambda*	Hodrick-Prescott Filter cycle component where *lambda* is the nonnegative filter parameter
ILOGIT	Inverse logistic function: $\frac{\exp(x)}{1+\exp(x)}$
LAG n_{optional}	Value of the series n periods earlier: x_{t-n}
LEAD n_{optional}	Value of the series n periods later: x_{t+n}
LOG	Natural logarithm: $\log(x)$
LOGIT	Logistic function: $\log(\frac{x}{1-x})$
MAX *number*	Maximum of x and *number* : $\max(x, number)$
MIN *number*	Minimum of x and *number* : $\min(x, number)$
> *number*	Missing value if $x <= number$, else x
>= *number*	Missing value if $x < number$, else x
= *number*	Missing value if $x \neq number$, else x
∧= *number*	Missing value if $x = number$, else x
< *number*	Missing value if $x >= number$, else x
<= *number*	Missing value if $x > number$, else x
MOVAVE n	Backward moving average of n neighboring values: $\frac{1}{n}\sum_{j=0}^{n-1} x_{t-j}$
MOVAVE *window*	Backward weighted moving average of neighboring values: $(\sum_{j=1}^{n} w_j x_{t-n+j})/(\sum_{j=1}^{n} w_j)$
MOVCSS *window*	Backward moving corrected sum of squares
MOVGMEAN *window*	Backward moving geometric mean for *window* = number of periods, n: $(\prod_{j=1}^{n} x_{t-n+j})^{1/n}$ for *window* = weight list, w: $(\prod_{j=1}^{n} x_{t-n+j}^{w_j})^{1/\sum_{j=1}^{n} w_j}$

Table 15.2 *continued*

Syntax	Result
MOVMAX *n*	Backward moving maximum
MOVMED *n*	Backward moving median
MOVMIN *n*	Backward moving minimum
MOVPROD *window*	Backward moving product for *window* = number of periods, *n*: $\prod_{j=1}^{n} x_{t-n+j}$ for *window* = weight list, *w*: $(\prod_{j=1}^{n} x_{t-n+j}^{w_j})^{1/\sum_{j=1}^{n} w_j}$
MOVRANGE *n*	Backward moving range
MOVRANK *n*	Backward moving rank
MOVSTD *window*	Backward moving weighted standard deviation: $\sqrt{\frac{1}{n-1}\sum_{j=1}^{n} w_i (x_j - \overline{x}_w)^2}$
MOVSUM *n*	Backward moving sum
MOVTVALUE *window*	Backward moving *t* value
MOVUSS *window*	Backward moving uncorrected sum of squares
MOVVAR *window*	Backward moving variance
MISSONLY <MEAN>	Indicates that the following moving time window statistic operator should replace only missing values with the moving statistic and should leave nonmissing values unchanged. If the option MEAN is specified, then missing values are replaced by the overall mean of the series.
NEG	Changes the sign: $-x$
NOMISS	Indicates that the following moving time window statistic operator should not allow missing values
PCTDIF *n*	Percent difference of the current value and lag *n*
PCTSUM *n*	Percent summation of the current value and cumulative sum *n*-lag periods
RATIO *n*	Ratio of current value to lag *n*
RECIPROCAL	Reciprocal: $1/x$
REVERSE	Reverses the series: x_{N-t}
SCALE n_1 n_2	Scales the series between n_1 and n_2
SEQADD *sequence*	Adds sequence values to series
SEQDIV *sequence*	Divides the series by sequence values
SEQMINUS *sequence*	Subtracts sequence values to series
SEQMULT *sequence*	Multiplies the series by sequence values
SET (n_1 n_2)	Sets all values of n_1 to n_2
SETEMBEDDED (n_1 n_2)	Sets embedded values of n_1 to n_2
SETLEFT (n_1 n_2)	Sets beginning values of n_1 to n_2
SETMISS *number*	Replaces missing values in the series with the number specified
SETRIGHT (n_1 n_2)	Sets ending values of n_1 to n_2
SIGN	-1, 0, or 1 as x is < 0, equals 0, or > 0, respectively
SQRT	Square root: $\sqrt{x}$

Table 15.2 *continued*

Syntax	Result
SQUARE	Square: x^2
SUM	Cumulative sum: $\sum_{j=1}^{t} x_j$
SUM n	Cumulative sum of multiples of n-period lags: $x_t + x_{t-n} + x_{t-2n} + \cdots$
TRIM n	Sets x_t to missing a value if $t \leq n$ or $t \geq N - n + 1$
TRIMLEFT n	Sets x_t to missing a value if $t \leq n$
TRIMRIGHT n	Sets x_t to missing a value if $t \geq N - n + 1$

Moving Time Window Operators

Some operators compute statistics for a set of values within a moving time window; these are called *moving time window operators*. There are centered and backward versions of these operators.

The centered moving time window operators are CMOVAVE, CMOVCSS, CMOVGMEAN, CMOVMAX, CMOVMED, CMOVMIN, CMOVPROD, CMOVRANGE, CMOVRANK, CMOVSTD, CMOVSUM, CMOVTVALUE, CMOVUSS, and CMOVVAR. These operators compute statistics of the n values x_i for observations $t - (n + n \mod 2)/2 + 1 \leq i \leq t + (n - n \mod 2)/2$

The backward moving time window operators are MOVAVE, MOVCSS, MOVGMEAN, MOVMAX, MOVMED, MOVMIN, MOVPROD, MOVRANGE, MOVRANK, MOVSTD, MOVSUM, MOVTVALUE, MOVUSS, and MOVVAR. These operators compute statistics of the n values $x_t, x_{t-1}, \ldots, x_{t-n+1}$.

All the moving time window operators accept an argument n specifying the number of periods to include in the time window. For example, the following statement computes a five-period backward moving average of X:

```
convert x=y / transformout=( movave 5 );
```

In this example, the resulting transformation is

$$y_t = (x_t + x_{t-1} + x_{t-2} + x_{t-3} + x_{t-4})/5$$

The following statement computes a five-period centered moving average of X:

```
convert x=y / transformout=( cmovave 5 );
```

In this example, the resulting transformation is

$$y_t = (x_{t-2} + x_{t-1} + x_t + x_{t+1} + x_{t+2})/5$$

If the window with a centered moving time window operator is not an odd number, one more lead value than lag value is included in the time window. For example, the result of the CMOVAVE 4 operator is

$$y_t = (x_{t-1} + x_t + x_{t+1} + x_{t+2})/4$$

You can compute a forward moving time window operation by combining a backward moving time window operator with the REVERSE operator. For example, the following statement computes a five-period forward moving average of X:

```
convert x=y / transformout=( reverse movave 5 reverse );
```

In this example, the resulting transformation is

$$y_t = (x_t + x_{t+1} + x_{t+2} + x_{t+3} + x_{t+4})/5$$

Some of the moving time window operators enable you to specify a list of weight values to compute weighted statistics. These are CMOVAVE, CMOVCSS, CMOVGMEAN, CMOVPROD, CMOVSTD, CMOVTVALUE, CMOVUSS, CMOVVAR, MOVAVE, MOVCSS, MOVGMEAN, MOVPROD, MOVSTD, MOVTVALUE, MOVUSS, and MOVVAR.

To specify a weighted moving time window operator, enter the weight values in parentheses after the operator name. The window width n is equal to the number of weights that you specify; do not specify n.

For example, the following statement computes a weighted five-period centered moving average of X:

```
convert x=y / transformout=( cmovave( .1 .2 .4 .2 .1 ) );
```

In this example, the resulting transformation is

$$y_t = .1x_{t-2} + .2x_{t-1} + .4x_t + .2x_{t+1} + .1x_{t+2}$$

The weight values must be greater than zero. If the weights do not sum to 1, the weights specified are divided by their sum to produce the weights used to compute the statistic.

A complete time window is not available at the beginning of the series. For the centered operators a complete window is also not available at the end of the series. The computation of the moving time window operators is adjusted for these boundary conditions as follows.

For backward moving window operators, the width of the time window is shortened at the beginning of the series. For example, the results of the MOVSUM 3 operator are

$$\begin{aligned} y_1 &= x_1 \\ y_2 &= x_1 + x_2 \\ y_3 &= x_1 + x_2 + x_3 \\ y_4 &= x_2 + x_3 + x_4 \\ y_5 &= x_3 + x_4 + x_5 \\ &\cdots \end{aligned}$$

For centered moving window operators, the width of the time window is shortened at the beginning and the end of the series due to unavailable observations. For example, the results of the CMOVSUM 5 operator are

$$\begin{aligned} y_1 &= x_1 + x_2 + x_3 \\ y_2 &= x_1 + x_2 + x_3 + x_4 \\ y_3 &= x_1 + x_2 + x_3 + x_4 + x_5 \\ y_4 &= x_2 + x_3 + x_4 + x_5 + x_6 \\ &\cdots \\ y_{N-2} &= x_{N-4} + x_{N-3} + x_{N-2} + x_{N-1} + x_N \\ y_{N-1} &= x_{N-3} + x_{N-2} + x_{N-1} + x_N \\ y_N &= x_{N-2} + x_{N-1} + x_N \end{aligned}$$

For weighted moving time window operators, the weights for the unavailable or unused observations are ignored and the remaining weights renormalized to sum to 1.

Cumulative Statistics Operators

Some operators compute cumulative statistics for a set of current and previous values of the series. The cumulative statistics operators are CUAVE, CUCSS, CUMAX, CUMED, CUMIN, CURANGE, CUSTD, CUSUM, CUUSS, and CUVAR.

By default, the cumulative statistics operators compute the statistics from all previous values of the series, so that y_t is based on the set of values $x_t, x_{t-1}, \ldots, x_1$. For example, the following statement computes y_t as the cumulative sum of nonmissing x_i values for $i \leq t$:

```
convert x=y / transformout=( cusum );
```

You can specify a lag increment argument n for the cumulative statistics operators. In this case, the statistic is computed from the current and every nth previous value. When n is specified these operators compute statistics of the values $x_t, x_{t-n}, x_{t-2n}, \ldots, x_{t-in}$ for $t - in > 0$.

For example, the following statement computes y_t as the cumulative sum of nonmissing x_i values for odd i when t is odd and for even i when t is even:

```
convert x=y / transformout=( cusum 2 );
```

The results of this example are

$$
\begin{aligned}
y_1 &= x_1 \\
y_2 &= x_2 \\
y_3 &= x_1 + x_3 \\
y_4 &= x_2 + x_4 \\
y_5 &= x_1 + x_3 + x_5 \\
y_6 &= x_2 + x_4 + x_6 \\
&\ldots
\end{aligned}
$$

Missing Values

You can truncate the length of the result series by using the TRIM, TRIMLEFT, and TRIMRIGHT operators to set values to missing at the beginning or end of the series.

You can use these functions to trim the results of moving time window operators so that the result series contains only values computed from a full width time window. For example, the following statements compute a centered five-period moving average of X, and they set to missing values at the ends of the series that are averages of fewer than five values:

```
convert x=y / transformout=( cmovave 5 trim 2 );
```

Normally, the moving time window and cumulative statistics operators ignore missing values and compute their results for the nonmissing values. When preceded by the NOMISS operator, these functions produce a missing result if any value within the time window is missing.

The NOMISS operator does not perform any calculations, but serves to modify the operation of the moving time window operator that follows it. The NOMISS operator has no effect unless it is followed by a moving time window operator.

For example, the following statement computes a five-period moving average of the variable X but produces a missing value when any of the five values are missing:

```
convert x=y / transformout=( nomiss movave 5 );
```

The following statement computes the cumulative sum of the variable X but produces a missing value for all periods after the first missing X value:

```
convert x=y / transformout=( nomiss cusum );
```

Similar to the NOMISS operator, the MISSONLY operator does not perform any calculations (unless followed by the MEAN option), but it serves to modify the operation of the moving time window operator that follows it. When preceded by the MISSONLY operator, these moving time window operators replace any missing values with the moving statistic and leave nonmissing values unchanged.

For example, the following statement replaces any missing values of the variable X with an exponentially weighted moving average of the past values of X and leaves nonmissing values unchanged. The missing values are interpolated using the specified exponentially weighted moving average. (This is also called simple exponential smoothing.)

```
convert x=y / transformout=( missonly ewma 0.3 );
```

The following statement replaces any missing values of the variable X with the overall mean of X:

```
convert x=y / transformout=( missonly mean );
```

You can use the SETMISS operator to replace missing values with a specified number. For example, the following statement replaces any missing values of the variable X with the number 8.77:

```
convert x=y / transformout=( setmiss 8.77 );
```

Classical Decomposition Operators

If x_t is a seasonal time series with s observations per season, *classical decomposition* methods "break down" the time series into four components: trend, cycle, seasonal, and irregular components. The trend and cycle components are often combined to form the trend-cycle component. There are two basic forms of classical decomposition: multiplicative and additive, which are show below.

$$\begin{aligned} x_t &= TC_t S_t I_t \\ x_t &= TC_t + S_t + I_t \end{aligned}$$

where

TC_t	is the trend-cycle component
S_t	is the seasonal component or seasonal factors that are periodic with period s and with mean one (multiplicative) or zero (additive)
I_t	is the irregular or random component that is assumed to have mean one (multiplicative) or zero (additive)

For multiplicative decomposition, all of the x_t values should be positive.

The CD_TC operator computes the trend-cycle component for both the multiplicative and additive models. When s is odd, this operator computes an s-period centered moving average as follows:

$$TC_t = \sum_{k=-\lfloor s/2 \rfloor}^{\lfloor s/2 \rfloor} x_{t+k}/s$$

For example, in the case where s=5, the CD_TC s operator

```
convert x=tc / transformout=( cd_tc 5 );
```

is equivalent to the following CMOVAVE operator:

```
convert x=tc / transformout=( cmovave 5 trim 2 );
```

When s is even, the CD_TC s operator computes the average of two adjacent s-period centered moving averages as follows:

$$TC_t = \sum_{k=-\lfloor s/2 \rfloor}^{\lfloor s/2 \rfloor - 1} (x_{t+k} + x_{t+1+k})/2s$$

For example, in the case where s=12, the CD_TC s operator

```
convert x=tc / transformout=( cd_tc 12 );
```

is equivalent to the following CMOVAVE operator:

```
convert x=tc / transformout=(cmovave 12 movave 2 trim 6);
```

The CD_S and CDA_S operators compute the seasonal components for the multiplicative and additive models, respectively. First, the trend-cycle component is computed as shown previously. Second, the seasonal-irregular component is computed by $SI_t = x_t / TC_t$ for the multiplicative model and by $SI_t = x_t - TC_t$ for the additive model. The seasonal component is obtained by averaging the seasonal-irregular component for each season.

$$S_{k+js} = \sum_{t=k \bmod s} \frac{SI_t}{n/s}$$

where $0 \leq j \leq n/s$ and $1 \leq k \leq s$. The seasonal components are normalized to sum to one (multiplicative) or zero (additive).

The CD_I and CDA_I operators compute the irregular component for the multiplicative and additive models respectively. First, the seasonal component is computed as shown previously. Next, the irregular component is determined from the seasonal-irregular and seasonal components as appropriate.

$$\begin{aligned} I_t &= SI_t / S_t \\ I_t &= SI_t - S_t \end{aligned}$$

The CD_SA and CDA_SA operators compute the seasonally adjusted time series for the multiplicative and additive models, respectively. After decomposition, the original time series can be seasonally adjusted as

appropriate.

$$\begin{aligned} \tilde{x}_t &= x_t / S_t = TC_t I_t \\ \tilde{x}_t &= x_t - S_t = TC_t + I_t \end{aligned}$$

The following statements compute all the multiplicative classical decomposition components for the variable X for s=12:

```
convert x=tc / transformout=( cd_tc 12 );
convert x=s  / transformout=( cd_s  12 );
convert x=i  / transformout=( cd_i  12 );
convert x=sa / transformout=( cd_sa 12 );
```

The following statements compute all the additive classical decomposition components for the variable X for s=4:

```
convert x=tc / transformout=( cd_tc  4 );
convert x=s  / transformout=( cda_s  4 );
convert x=i  / transformout=( cda_i  4 );
convert x=sa / transformout=( cda_sa 4 );
```

The X12 and X11 procedures provide other methods for seasonal decomposition. See Chapter 44, "The X12 Procedure," and Chapter 43, "The X11 Procedure."

Fractional Operators

For fractional operators, the parameter, d, represents the order of fractional differencing. Fractional summation is the inverse operation of fractional differencing.

Examples of Usage

Suppose that X is a fractionally integrated time series variable of order d=0.25. Fractionally differencing X forms a time series variable Y, which is not integrated.

```
convert x=y / transformout=(fdif 0.25);
```

Suppose that Z is a non-integrated time series variable. Fractionally summing Z forms a time series W, which is fractionally integrated of order $d = 0.25$.

```
convert z=w / transformout=(fsum 0.25);
```

Moving Rank Operators

For the rank operators, the ranks are computed based on the current value with respect to the cumulative, centered, or moving window values. If the current value is missing, the transformed current value is set to missing. If the NOMISS option was previously specified and if any missing values are present in the moving window, the transformed current value is set to missing. Otherwise, redundant values from the moving window are removed and the rank of the current value is computed among the unique values of the moving window.

Examples of Usage

The trades of a particular security are recorded for each weekday in a variable named PRICE. Given the historical daily trades, the ranking of the price of this security for each trading day, considering its entire past history, can be computed as follows:

```
convert price=history / transformout=( curank );
```

The ranking of the price of this security for each trading day considering the previous week's history can be computed as follows:

```
convert price=lastweek / transformout=( movrank 5 );
```

The ranking of the price of this security for each trading day considering the previous two week's history can be computed as follows:

```
convert price=twoweek / transformout=( movrank 10 );
```

Moving Product and Geometric Mean Operators

For the product and geometric mean operators, the current transformed value is computed based on the (weighted) product of the cumulative, centered, or moving window values. If missing values are present in the moving window and the NOMISS operator is previously specified, the current transformed value is set to missing. Otherwise, the current transformed value is set to the product of the nonmissing values within the moving window. If a geometric mean operator is specified for a window of size *n*, the *n*th root of the product is taken. In cases where weights are specified explicitly, both the product and geometric mean operators normalize these exponents so that they sum to one.

Examples of Usage

The interest rates for a savings account are recorded for each month in the data set variable RATES. The cumulative interest rate for each month considering the entire account past history can be computed as follows:

```
convert rates=history / transformout=( + 1 cuprod - 1);
```

The interest rate for each quarter considering the previous quarter's history can be computed as follows:

```
convert rates=lastqtr / transformout=( + 1 movprod 3 - 1);
```

The average interest rate for the previous quarter's history can be computed as follows:

```
convert rates=lastqtr / transformout=( + 1 movprod (1 1 1) - 1);
```

Sequence Operators

For the sequence operators, the sequence values are used to compute the transformed values from the original values in a sequential fashion. You can add to or subtract from the original series or you can multiply or divide by the sequence values. The first sequence value is applied to the first observation of the series, the second sequence value is applied to the second observation of the series, and so on until the end of the sequence is reached. At this point, the first sequence value is applied to the next observation of the series and the second sequence value on the next observation and so on.

Let $v_1, \ldots, v_m$ be the sequence values and let $x_t, t = 1, \ldots N$, be the original time series. The transformed series, y_t, is computed as follows:

$$
\begin{aligned}
y_1 &= x_1 \; op \; v_1 \\
y_2 &= x_2 \; op \; v_2 \\
&\ldots \\
y_m &= x_m \; op \; v_m \\
y_{m+1} &= x_{m+1} \; op \; v_1 \\
y_{m+2} &= x_{m+2} \; op \; v_2 \\
&\ldots \\
y_{2m} &= x_{2m} \; op \; v_m \\
y_{2m+1} &= x_{2m+1} \; op \; v1 \\
y_{2m+2} &= x_{2m+2} \; op \; v2 \\
&\ldots
\end{aligned}
$$

where $op = +, -, *,$ or $/$.

Examples of Usage

The multiplicative seasonal indices are 0.9, 1.2. 0.8, and 1.1 for the four quarters. Let SEASADJ be a quarterly time series variable that has been seasonally adjusted in a multiplicative fashion. To restore the seasonality to SEASADJ, use the following transformation:

```
convert seasadj=seasonal /
        transformout=(seqmult (0.9 1.2 0.8 1.1));
```

The additive seasonal indices are 4.4, –1.1, –2.1, and –1.2 for the four quarters. Let SEASADJ be a quarterly time series variable that has been seasonally adjusted in additive fashion. To restore the seasonality to SEASADJ, use the following transformation:

```
convert seasadj=seasonal /
        transformout=(seqadd (4.4 -1.1 -2.1 -1.2));
```

Set Operators

For the set operators, the first parameter, n_1, represents the value to be replaced and the second parameter, n_2, represents the replacement value. The replacement can be localized to the beginning, middle, or end of the series.

Examples of Usage

Suppose that a store opened recently and that the sales history is stored in a database that does not recognize missing values. Even though demand may have existed prior to the stores opening, this database assigns the value of zero. Modeling the sales history may be problematic because the sales history is mostly zero. To compensate for this deficiency, the leading zero values should be set to missing with the remaining zero values unchanged (representing no demand).

```
convert sales=demand / transformout=(setleft (0 .));
```

Likewise, suppose a store is closed recently. The demand might still be present; hence, a recorded value of zero does not accurately reflect actual demand.

```
convert sales=demand / transformout=(setright (0 .));
```

Scale Operator

For the scale operator, the first parameter, n_1, represents the value associated with the minimum value ($x_{\min}$) and the second parameter, n_2, represents the value associated with the maximum value ($x_{\max}$) of the original series (x_t). The scale operator rescales the original data to be between the parameters n_1 and n_2 as follows:

$$y_t = ((n_2 - n_1)/(x_{\max} - x_{\min}))(x_t - x_{\min}) + n_1$$

Examples of Usage

Suppose that two new product sales histories are stored in the variables X and Y and you want to determine their adoption rates. In order to compare their adoption histories, the variables must be scaled for comparison.

```
convert x=w / transformout=(scale 0 1);
convert y=z / transformout=(scale 0 1);
```

Adjust Operator

For the moving summation and product window operators, the window widths at the beginning and end of the series are smaller than those in the middle of the series. Likewise, if there are embedded missing values, the window width is smaller than specified. When preceded by the ADJUST operator, the moving summation (MOVSUM CMOVSUM) and moving product operators (MOVPROD CMOVPROD) are adjusted by the window width.

For example, suppose the variable X has 10 values, and the moving summation operator of width 3 is applied to X to create the variable Y with window width adjustment and the variable Z without adjustment.

```
convert x=y / transformout=(adjust movsum 3);
convert x=z / transformout=(movsum 3);
```

The preceding transformations result in the following relationship between Y and Z: $y_1 = 3z_1$, $y_2 = \frac{3}{2}z_2$, $y_t = z_t$ for $t > 2$ because the first two window widths are smaller than 3.

For example, suppose the variable X has 10 values and the moving multiplicative operator of width 3 is applied to X to create the variable Y with window width adjustment and the variable Z without adjustment.

```
convert x=y / transformout=(adjust movprod 3);
convert x=z / transformout=(movprod 3);
```

The preceding transformations result in the following: $y_1 = z_1^3$, $y_2 = z_2^{3/2}$, $y_t = z_t$ for $t > 2$ because the first two window widths are smaller than 3.

Moving T-Value Operators

The moving *t*-value operators (CUTVALUE, MOVTVALUE, CMOVTVALUE) compute the *t*-value of the cumulative series or moving window. They can be viewed as combinations of the moving average (CUAVE, MOVAVE, CMOVAVE) and the moving standard deviation (CUSTD, MOVSTD, CMOVSTD), respectively.

Percent Operators

The percentage operators compute the percent summation and the percent difference of the current value and the $\mathrm{lag}(n)$. The percent summation operator (PCTSUM) computes $y_t = 100x_t/\mathrm{cusum}(x_{t-n})$. If any of the values of the preceding equation are missing or the cumulative summation is zero, the result is set to missing. The percent difference operator (PCTDIF) computes $y_t = 100(x_t - x_{t-n})/x_{t-n}$. If any of the values of the preceding equation are missing or the lag value is zero, the result is set to missing.

For example, suppose the variable X contains the series. The percent summation of lag 4 is applied to X to create the variable Y. The percent difference of lag 4 is applied to X to create the variable Z.

```
convert x=y / transformout=(pctsum 4);
convert x=z / transformout=(pctdif 4);
```

Ratio Operators

The ratio operator computes the ratio of the current value and the $\mathrm{lag}(n)$ value. The ratio operator (RATIO) computes $y_t = x_t/x_{t-n}$. If any of the values of the preceding equation are missing or the lag value is zero, the result is set to missing.

For example, suppose the variable X contains the series. The ratio of the current value and the lag 4 value of X is assigned to the variable Y. The percent ratio of the current value and lag 4 value of X is assigned to the variable Z.

```
convert x=y / transformout=(ratio 4);
convert x=z / transformout=(ratio 4 * 100);
```

OUT= Data Set

The OUT= output data set contains the following variables:

- the BY variables, if any
- an ID variable that identifies the time period for each output observation
- the result variables
- if no frequency conversion is performed (so that there is one output observation corresponding to each input observation), all the other variables in the input data set are copied to the output data set

The ID variable in the output data set is named as follows:

- If an ID statement is used, the new ID variable has the same name as the variable used in the ID statement.

- If no ID statement is used, but the FROM= option is used, then the name of the ID variable is either DATE or DATETIME, depending on whether the TO= option indicates SAS date or SAS datetime values.
- If neither an ID statement nor the TO= option is used, the ID variable is named TIME.

OUTEST= Data Set

The OUTEST= data set contains the coefficients of the spline curves fit to the input series. The OUTEST= data set is of interest if you want to verify the interpolating curve PROC EXPAND uses, or if you want to use this function in another context, (for example, in a SAS/IML program).

The OUTEST= data set contains the following variables:

- the BY variables, if any
- VARNAME, a character variable containing the name of the input variable to which the coefficients apply
- METHOD, a character variable containing the value of the METHOD= option used to fit the series
- OBSERVED, a character variable containing the first letter of the OBSERVED= option name for the input series
- the ID variable that contains the lower breakpoint (or "knot") of the spline segment to which the coefficients apply. The ID variable has the same name as the variable used in the ID statement. If an ID statement is not used, but the FROM= option is used, then the name of the ID variable is DATE or DATETIME, depending on whether the FROM= option indicates SAS date or SAS datetime values. If neither an ID statement nor the FROM= option is used, the ID variable is named TIME.
- CONSTANT, the constant coefficient for the spline segment
- LINEAR, the linear coefficient for the spline segment
- QUAD, the quadratic coefficient for the spline segment
- CUBIC, the cubic coefficient for the spline segment

For each BY group, the OUTEST= data set contains observations for each polynomial segment of the spline curve fit to each input series. To obtain the observations defining the spline curve used for a series, select the observations where the value of VARNAME equals the name of the series.

The observations for a series in the OUTEST= data set encode the spline function fit to the series as follows. Let a_i, b_i, c_i, and d_i be the values of the variables CUBIC, QUAD, LINEAR, and CONSTANT, respectively, for the ith observation for the series. Let x_i be the value of the ID variable for the ith observation for the series. Let n be the number of observations in the OUTEST= data set for the series. The value of the spline function evaluated at a point x is

$$f(x) = a_i(x - x_i)^3 + b_i(x - x_i)^2 + c_i(x - x_i) + d_i$$

where the segment number i is selected as follows:

$$i = \begin{cases} i & x_i \le x < x_{i+1}, 1 \le i < n \\ 1 & x < x_1 \\ n & x \ge x_n \end{cases}$$

In other words, if x is between the first and last ID values ($x_1 \le x < x_n$), use the observation from the OUTEST= data set with the largest ID value less than or equal to x. If x is less than the first ID value x_1, then $i = 1$. If x is greater than or equal to the last ID value ($x \ge x_n$), then $i = n$.

For METHOD=JOIN, the curve is a linear spline, and the values of CUBIC and QUAD are 0. For METHOD=STEP, the curve is a constant spline, and the values of CUBIC, QUAD, and LINEAR are 0. For METHOD=AGGREGATE, no coefficients are output.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

This section describes the use of ODS for creating graphics with the EXPAND procedure. To request these graphs, you must specify the PLOTS= option in the PROC EXPAND statement.

ODS Graph Names

PROC EXPAND assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 15.3.

Table 15.3 ODS Graphics Produced by PROC EXPAND

ODS Graph Name	Plot Description	PLOTS= Options
ConvertedSeriesPlot	Converted Series Plot	CONVERTED OUTPUT ALL
CrossInputSeriesPlot	Cross Input Series Plot	CROSSINPUT
CrossOutputSeriesPlot	Cross Output Series Plot	CROSSOUTPUT
InputSeriesPlot	Input Series Plot	INPUT JOINTINPUT ALL
JointInputSeriesPlot	Joint Input Series Plot	JOINTINPUT
JointOutputSeriesPlot	Joint Output Series Plot	JOINTOUTPUT
OutputSeriesPlot	Output Series Plot	SERIES | OUTPUT
TransformedInputSeriesPlot	Transformed Input Series Plot	TRANSFORMIN OUTPUT ALL
TransformedOutputSeriesPlot	Transformed Output Series Plot	TRANSFORMOUT OUTPUT ALL

PLOTS= Option Details

Some plots are produced for a series only if the relevant options are also specified. For example, if PLOTS=TRANSFORMIN is specified, then the TRANSFORMIN plot is not produced for a variable unless the TRANSFORMIN= option is specified in a CONVERT statement for that variable. The PLOTS=TRANSFORMIN option plots the series after the input transformation (TRANSFORMIN= option) is applied.

The PLOTS=CONVERTED option plots the series after the input transformation (TRANSFORMIN= option) is applied and after frequency conversion (METHOD= option). If there is no frequency conversion for an output variable, the converted series plot is not produced.

The PLOTS=TRANSFORMOUT option plots the series after the output transformation (TRANSFORMOUT= option) is applied. If the TRANFORMOUT= option is not specified in the CONVERT statement for an output variable, the output transformation plot is not produced.

The PLOTS=OUTPUT option plots the series after it has undergone input transformation (TRANSFORMIN= option), frequency conversion (METHOD= option), and output transformation (TRANSFORMOUT= option) if these CONVERT statement options were specified.

Cross and Joint Plots

The PLOTS= option values CROSSINPUT and CROSSOUTPUT produce graphs that overlay plots of two series by using two Y axes and with each of the two plots shown at a separate scale. These plots are called cross plots.

The PLOTS= option values JOINTINPUT and JOINTOUTPUT produce graphs that overlay plots of two series by using a single Y axis and with both of the plots shown on the same scale. These plots are called joint plots. The joint graphics options (PLOTS=JOINTINPUT or PLOTS=JOINTOUTPUT) plot the (input or converted) series and the transformed series on the same scale; therefore if the transformation changes, the range of the series these plots might be hard to visualize.

The PLOTS=CROSSINPUT option plots both the input series and the series after the input transformation (TRANSFORMIN= option) is applied. The left vertical axis refers to the input series, while the right vertical axis refers to the series after the transformation. If the TRANFORMIN= option is not specified in the CONVERT statement for an output variable, then the cross input plot is not produced for that variable.

The PLOTS=JOINTINPUT option jointly plots both the input series and the series after the input transformation (TRANSFORMIN= option) is applied. If the TRANSFORMIN= option is not specified in the CONVERT statement for an output variable, then the joint input plot is not produced for that variable.

The PLOTS=CROSSOUTPUT option plots both the converted series and the converted series after the output transformation (TRANSFORMOUT= option) is applied. The left vertical axis refers to the input series, while the right vertical axis refers to the series after the transformation. If the TRANSFORMOUT= option is not specified in the CONVERT statement for an output variable, then the cross output plot is not produced for that variable.

The PLOTS=JOINTOUTPUT option jointly plots both the converted series and the converted series after the output transformation (TRANSFORMOUT= option) is applied. If the TRANSFORMOUT= option is not specified in the CONVERT statement for an output variable, then the joint output plot is not produced for that variable.

Requesting All Plots

The PLOTS=ALL option is a convenient way to specify all the plots except the OUTPUT plots and the joint and cross plots. The option PLOTS=(ALL OUTPUT JOINTINPUT JOINTOUTPUT CROSSINPUT CROSSOUTPUT) requests that all possible plots be produced.

Examples: EXPAND Procedure

Example 15.1: Combining Monthly and Quarterly Data

This example combines monthly and quarterly data sets by interpolating monthly values for the quarterly series. The series are extracted from two small sample data sets stored in the SASHELP library. These data sets were contributed by Citicorp Data Base services and contain selected U.S. macro economic series.

The quarterly series gross domestic product (GDP) and implicit price deflator (GD) are extracted from SASHELP.CITIQTR. The monthly series industrial production index (IP) and unemployment rate (LHUR) are extracted from SASHELP.CITIMON. Only observations for the years 1990 and 1991 are selected. PROC EXPAND is then used to interpolate monthly estimates for the quarterly series, and the interpolated series are merged with the monthly data.

The following statements extract and print the quarterly data, shown in Output 15.1.1:

```
data qtrly;
   set sashelp.citiqtr;
   where date >= '1jan1990'd &
         date <  '1jan1992'd ;
   keep date gdp gd;
run;

title "Quarterly Data";
proc print data=qtrly;
run;
```

Output 15.1.1 Quarterly Data Set

Quarterly Data

Obs	DATE	GD	GDP
1	1990:1	111.100	5422.40
2	1990:2	112.300	5504.70
3	1990:3	113.600	5570.50
4	1990:4	114.500	5557.50
5	1991:1	115.900	5589.00

Example 15.2: Illustration of ODS Graphics

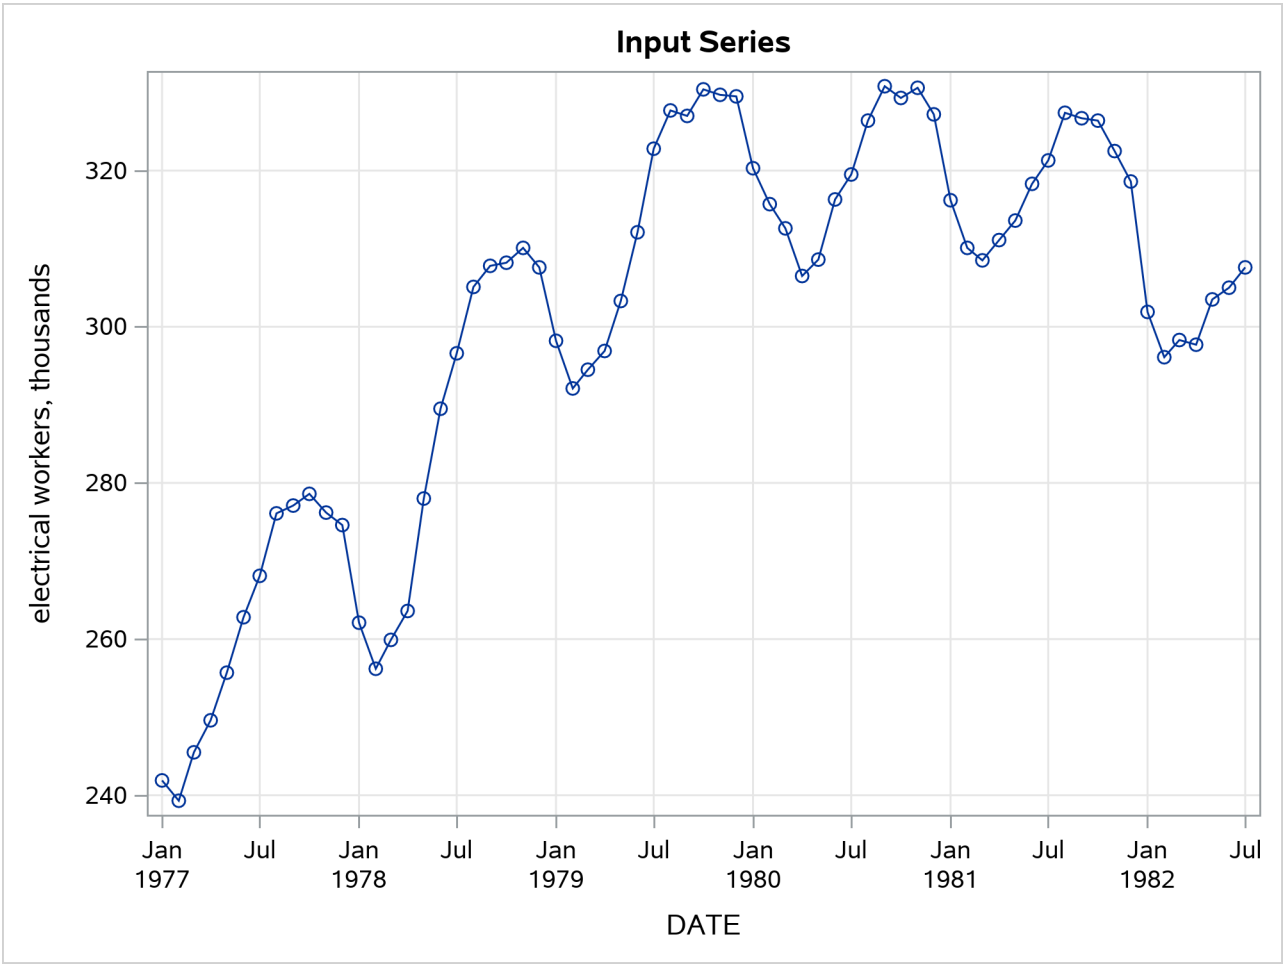
This example illustrates the use of ODS graphics with PROC EXPAND.

The graphical displays are requested by specifying the PLOTS= option in the PROC EXPAND statement. For information about the graphics available in the EXPAND procedure, see the section "ODS Graphics" on page 907.

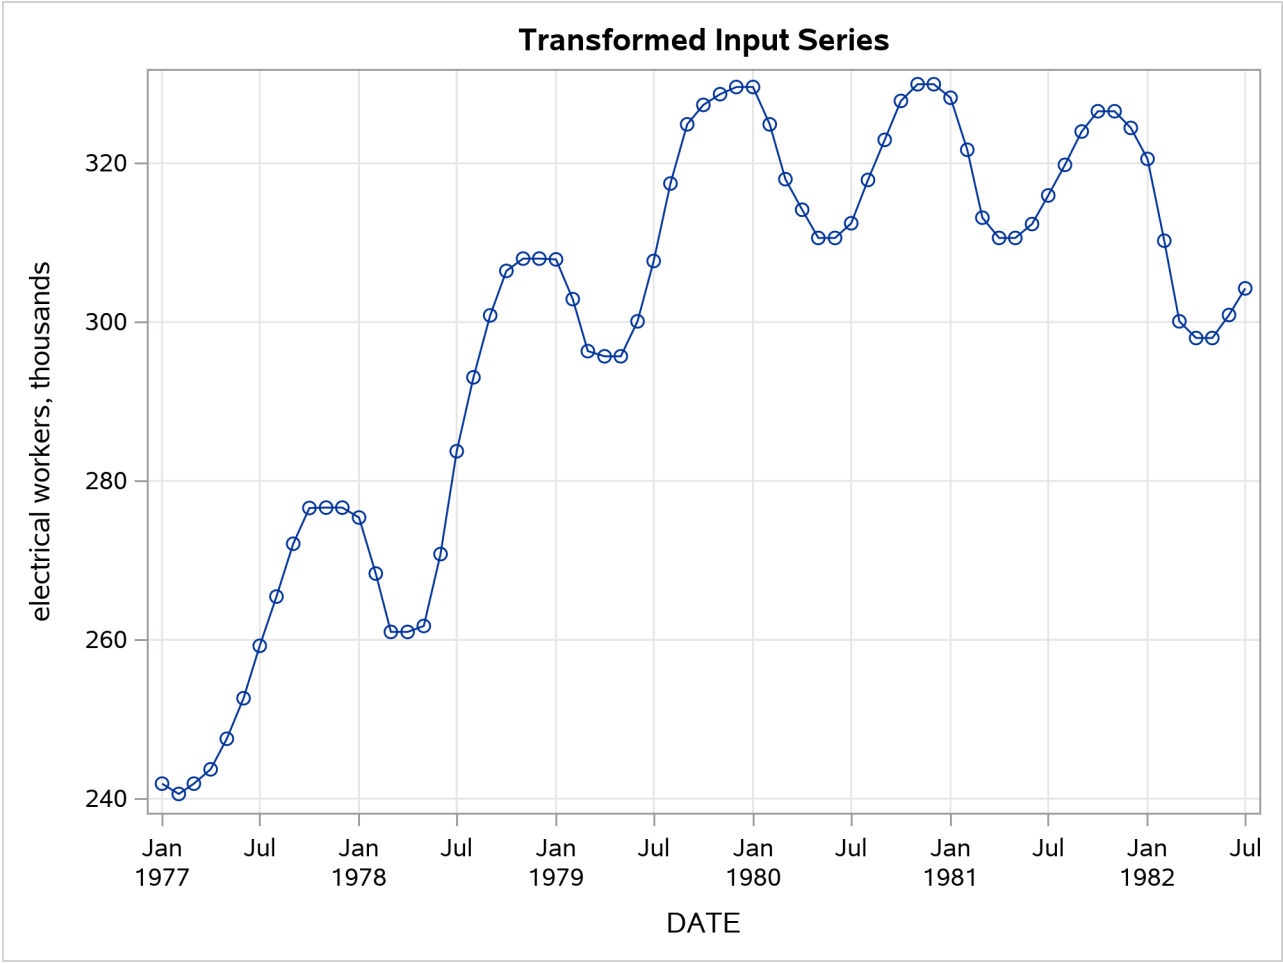
The following statements utilize the SASHELP.WORKERS data set to convert the time series of electrical workers from monthly to quarterly frequency and display ODS graphics plots. The PLOTS=ALL option is specified to request the plots of the input series, the transformed input series, the converted series, and the transformed output series. Figure 15.2.1 through Figure 15.2.4 show these plots.

```
proc expand data=sashelp.workers out=out
            from=month to=qtr
            plots=all;
   id date;
   convert electric=eout / method=spline
                           transformin=(movmed 4)
                           transformout=(movave 3);
run;
```

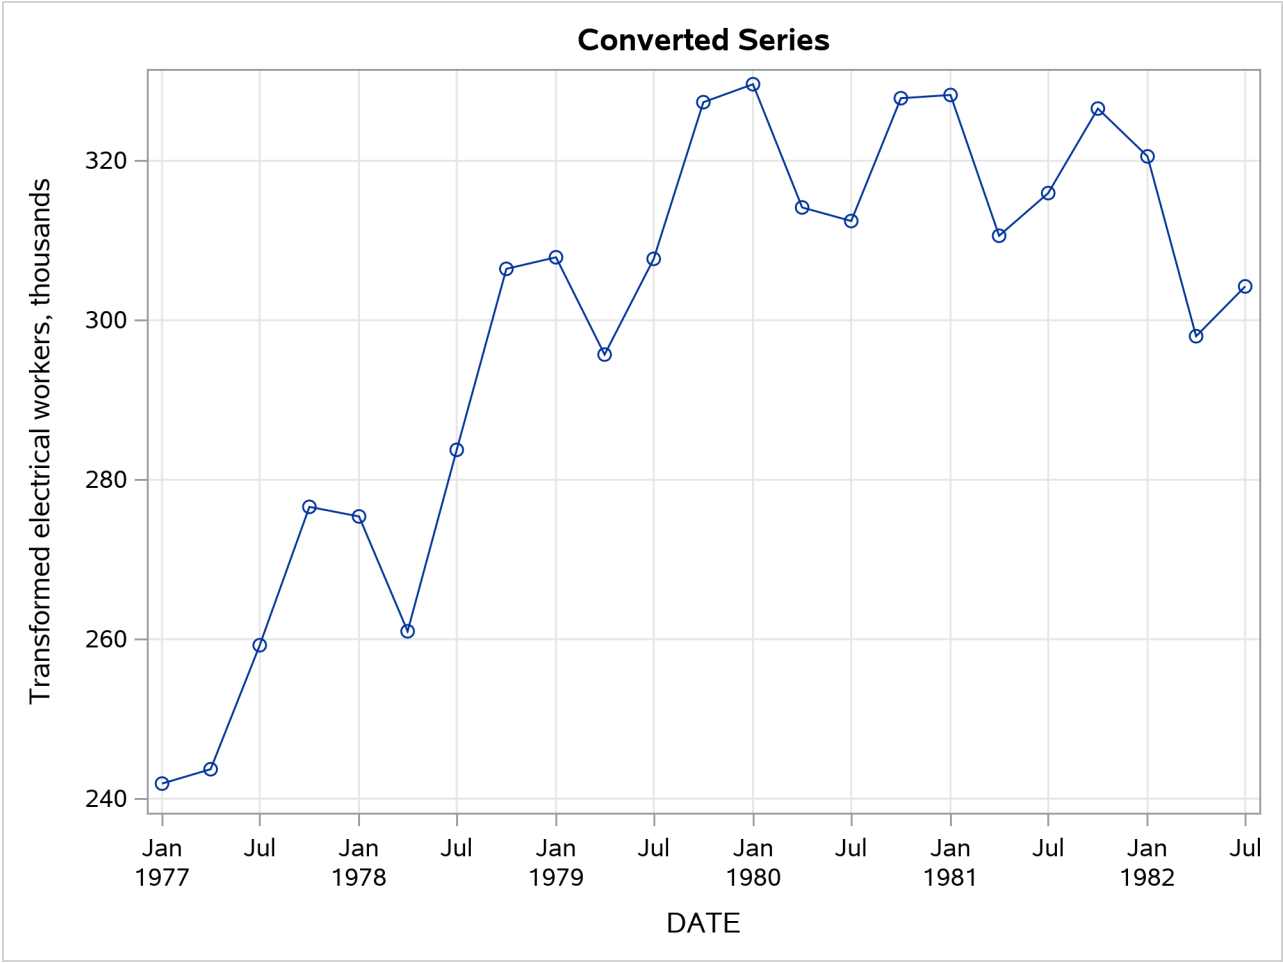
Output 15.2.1 Input Series Plot



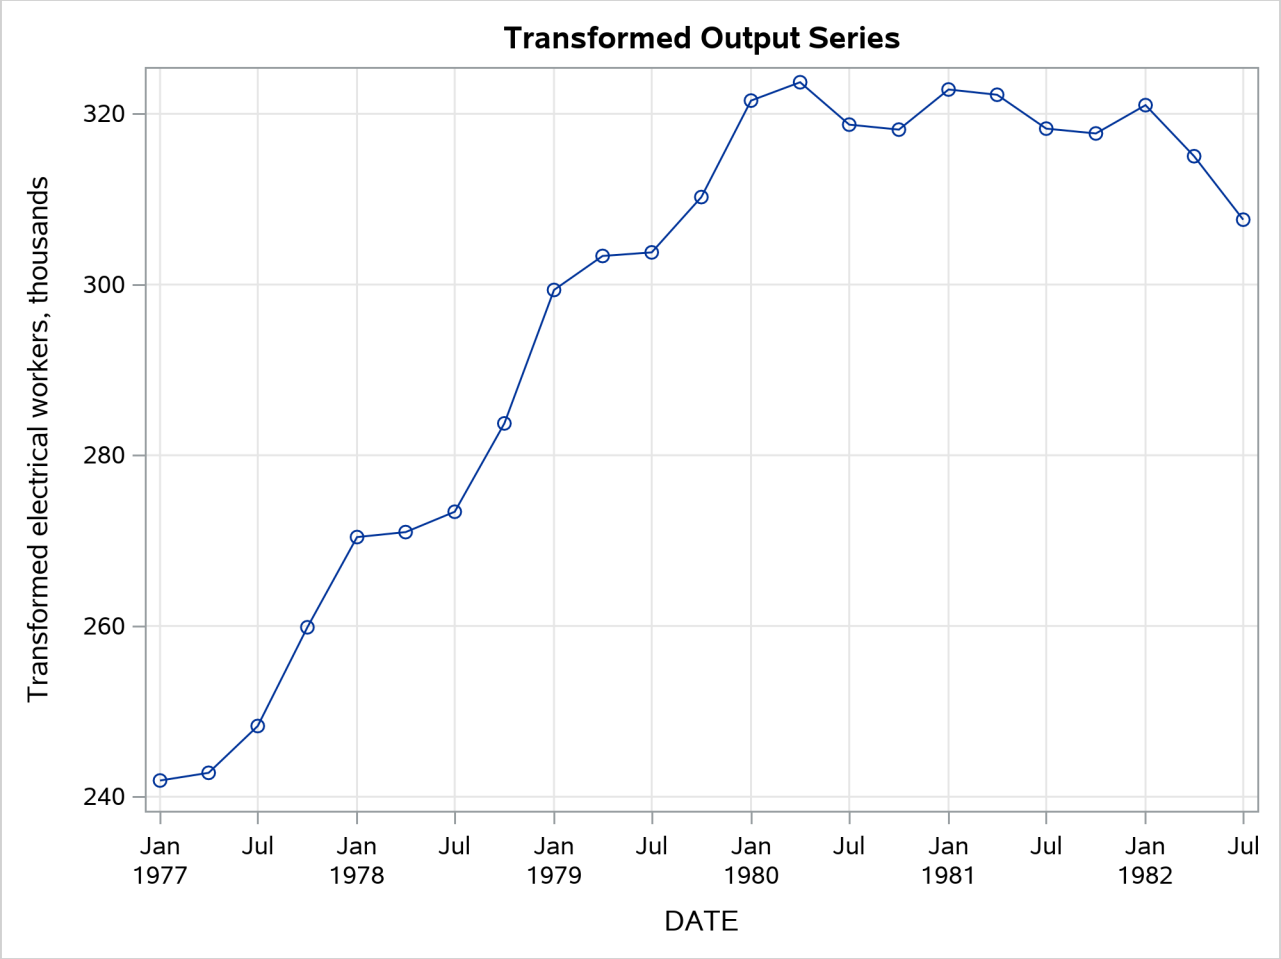
Output 15.2.2 Transformed Input Series Plot—Four-Period Moving Median



Output 15.2.3 Converted Plot of Transformed Input Series



Output 15.2.4 Transformed Output Series Plot—Three-Period Moving Average



Example 15.3: Interpolating Irregular Observations

This example shows the interpolation of a series of values measured at irregular points in time. The data are hypothetical. Assume that a series of randomly timed quality control inspections are made and defect rates for a process are measured. The problem is to produce two reports: estimates of monthly average defect rates for the months within the period covered by the samples, and a plot of the interpolated defect rate curve over time.

The following statements read and print the input data, as shown in Output 15.3.1:

```
data samples;
  input date : date9. defects @@;
  label defects = "Defects per 1000 Units";
  format date date9.;
datalines;
13jan1992    55    27jan1992   73    19feb1992   84    8mar1992   69

   ... more lines ...
```

```
title "Sampled Defect Rates";
proc print data=samples;
run;
```

Output 15.3.1 Measured Defect Rates

Sampled Defect Rates

Obs	date	defects
1	13JAN1992	55
2	27JAN1992	73
3	19FEB1992	84

5	27MAR1992	66
6	05APR1992	77
7	29APR1992	63
8	11MAY1992	81
9	25MAY1992	89
10	07JUN1992	94
11	23JUN1992	105
12	11JUL1992	97
13	15AUG1992	112
14	29AUG1992	89
15	10SEP1992	77
16	27SEP1992	82

To compute the monthly estimates, use PROC EXPAND with the TO=MONTH option and specify OBSERVED=(BEGINNING,AVERAGE). The following statements interpolate the monthly estimates:

```
proc expand data=samples
            out=monthly
            to=month
            plots=(input output);
  id date;
  convert defects / observed=(beginning,average);
run;
```

The following PROC PRINT step prints the results, as shown in Output 15.3.2:

```
title "Estimated Monthly Average Defect Rates";
proc print data=monthly;
run;
```

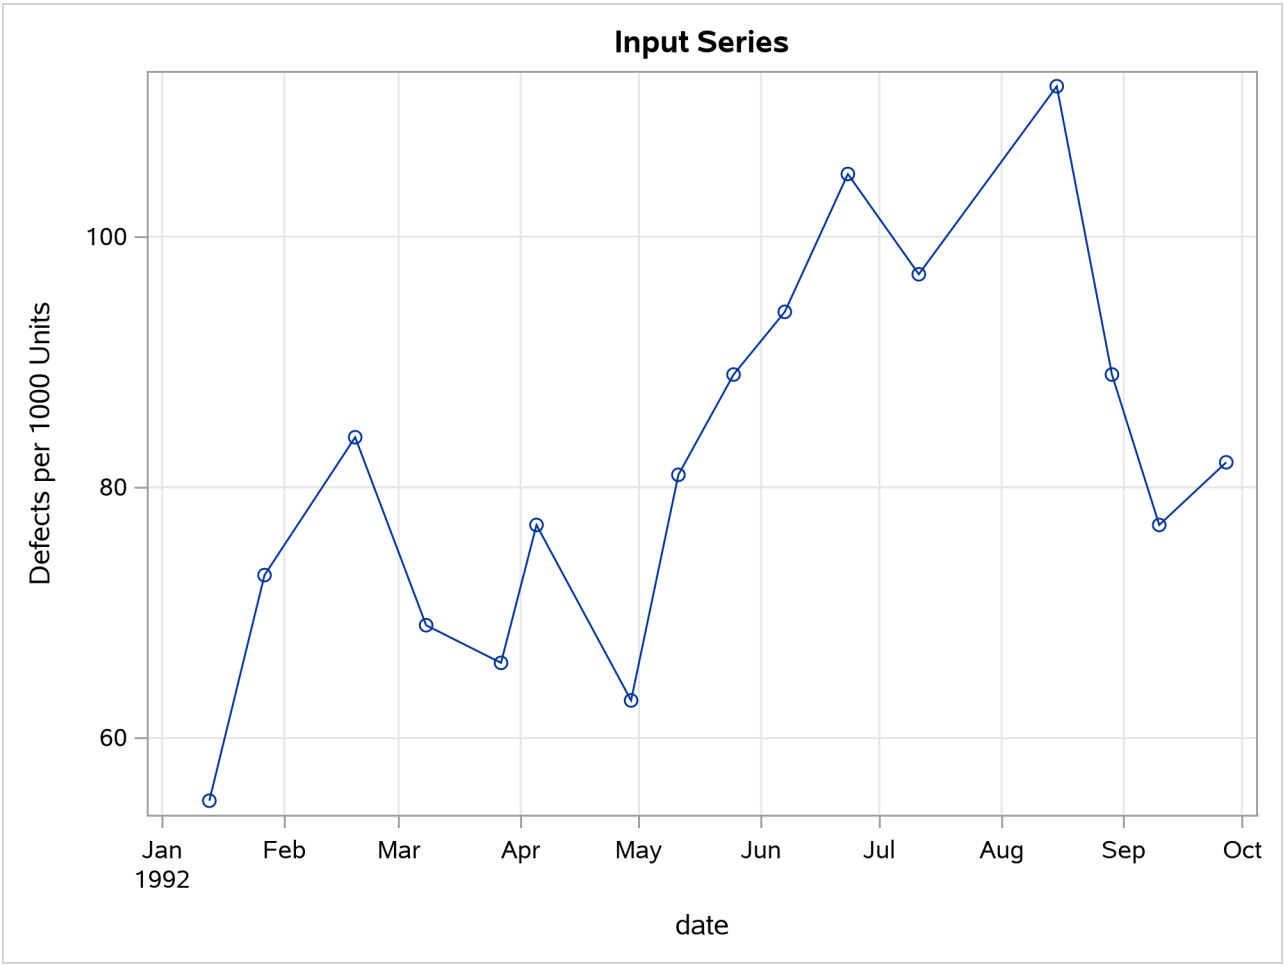
Output 15.3.2 Monthly Average Estimates

Estimated Monthly Average Defect Rates

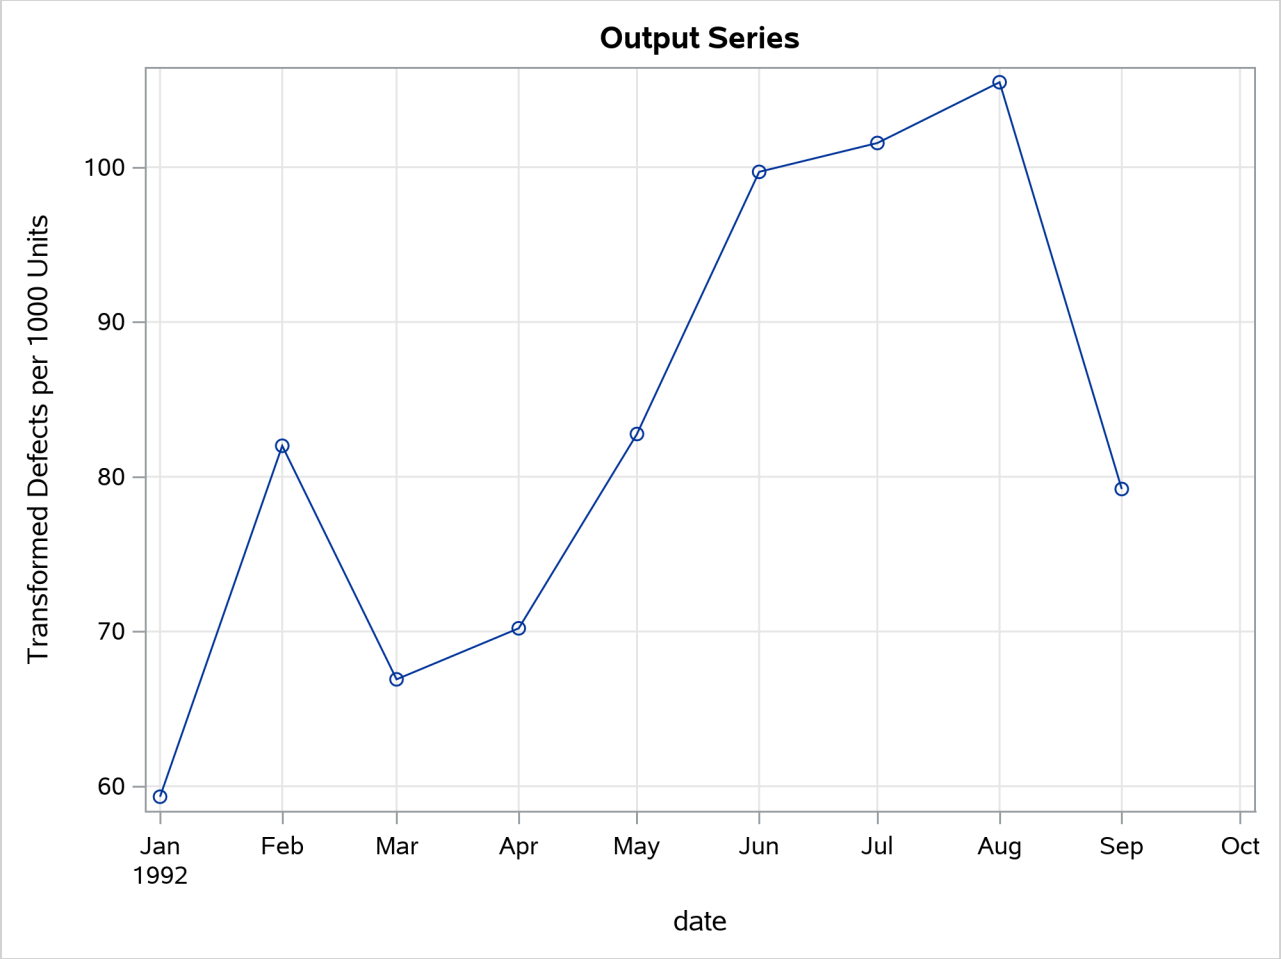
Obs	date	defects
1	JAN1992	59.323
2	FEB1992	82.000
3	MAR1992	66.909
4	APR1992	70.205
5	MAY1992	82.762
6	JUN1992	99.701
7	JUL1992	101.564
8	AUG1992	105.491
9	SEP1992	79.206

The plots produced by PROC EXPAND are shown in Output 15.3.3.

Output 15.3.3 Interpolated Defects Rate Curve



Output 15.3.3 *continued*



Example 15.4: Using Transformations

This example shows the use of PROC EXPAND to perform various transformations of time series. The following statements read in monthly values for a variable X:

```
data test;
   input year qtr x;
   date = yyq( year, qtr );
   format date yyqc.;
datalines;
1989 3 5238
1989 4 5289
1990 1 5375
1990 2 5443
1990 3 5514
1990 4 5527
1991 1 5557
1991 2 5615
;
```

The following statements use PROC EXPAND to compute lags and leads and a 3-period moving average of the X series:

```
proc expand data=test out=out method=none;
   id date;
   convert x = x_lag2   / transformout=(lag 2);
   convert x = x_lag1   / transformout=(lag 1);
   convert x;
   convert x = x_lead1  / transformout=(lead 1);
   convert x = x_lead2  / transformout=(lead 2);
   convert x = x_movave / transformout=(movave 3);
run;

title "Transformed Series";
proc print data=out;
run;
```

Because there are no missing values to interpolate and no frequency conversion, the METHOD=NONE option is used to prevent PROC EXPAND from performing unnecessary computations. Because no frequency conversion is done, all variables in the input data set are copied to the output data set. The CONVERT X; statement is included to control the position of X in the output data set. This statement can be omitted, in which case X is copied to the output data set following the new variables computed by PROC EXPAND.

The results are shown in Output 15.4.1.

Output 15.4.1 Output Data Set with Transformed Variables

Transformed Series

Overview: HPCDM Procedure

In many loss modeling applications, the loss events are analyzed by modeling the severity (magnitude) of loss and the frequency (count) of loss separately. The primary goal of preparing these models is to estimate the aggregate loss—that is, the total loss that occurs over a period of time for which the frequency model is applicable. For example, an insurance company might want to assess the expected and worst-case losses for a particular business line, such as automobile insurance, over an entire year given the models for the number of losses in a year and the severity of each loss. A bank might want to assess the value-at-risk (VaR), a measure of the worst-case loss, for a portfolio of assets given the frequency and severity models for each asset type.

Loss severity and loss frequency are random variables, so the aggregate loss is also a random variable. Instead of preparing a point estimate of the expected aggregate loss, it is more desirable to estimate its probability distribution, because this enables you to infer various aspects of the aggregate loss such as measures of location, scale (variability), and shape in addition to percentiles. For example, the value-at-risk that banks or insurance companies use to compute regulatory capital requirements is usually the estimate of the 97.5th or 99th percentile from the aggregate loss distribution.

Let N represent the frequency random variable for the number of loss events that occur in the time period of interest. Let X represent the severity random variable for the magnitude of one loss event. Then, the aggregate loss S is defined as

$$S = \sum_{j=1}^{N} X_j$$

The goal is to estimate the probability distribution of S. Let $F_X(x)$ denote the cumulative distribution function (CDF) of X, $F_X^{*n}(x)$ denote the n-fold convolution of the CDF of X, and $\Pr(N = n)$ denote the probability of seeing n losses as per the frequency distribution. The CDF of S is theoretically computable as

$$F_S(s) = \sum_{n=0}^{\infty} \Pr(N = n) \cdot F_X^{*n}(x)$$

This probability distribution model of S, characterized by the CDF $F_S(s)$, is referred to as a *compound distribution model* (CDM). The HPCDM procedure computes an estimate of the CDM, given the distribution models of X and N.

PROC HPCDM accepts the severity model of X as estimated by the SEVERITY procedure. It accepts the frequency model of N as estimated by the COUNTREG procedure. Both the SEVERITY and COUNTREG procedures are part of SAS/ETS software. Both procedures allow models of X and N to be conditional on external factors (regressors). In particular, you can model the severity distribution such that its scale parameter depends on severity regressors, and you can model the frequency distribution such that its mean depends on frequency regressors. The frequency model can also be a zero-inflated model. PROC HPCDM uses the estimates of model parameters and the values of severity and frequency regressors to estimate the compound distribution model.

Direct computation of F_S is usually a difficult task because of the need to compute the n-fold convolution. Klugman, Panjer, and Willmot (1998, Ch. 4) suggest some relatively efficient recursion and inversion methods for certain combinations of severity and frequency distributions. However, those methods assume that distributions of N and X are fixed and all Xs are identically distributed. When the distributions of X

and N are conditional on regressors, each set of regressor values results in a different distribution. So you must repeat the recursion and inversion methods for each combination of regressor values, and this repetition makes these methods prohibitively expensive. PROC HPCDM instead estimates the compound distribution by using a Monte Carlo simulation method, which can use all available computational resources to generate a sufficiently large, representative sample of the compound distribution while accommodating the dependence of distributions of X and N on external factors. Conceptually, the simulation method works as follows:

1. Use the specified frequency model to draw a value N, which represents the number of loss events.
2. Use the specified severity model to draw N values, each of which represents the magnitude of loss for each of the N loss events.
3. Add the N severity values from step 2 to compute aggregate loss S as

$$S = \sum_{j=1}^{N} X_j$$

   This forms one sample point of the CDM.

Steps 1 through 3 are repeated M number of times, where M is specified by you, to obtain the representative sample of the CDM. PROC HPCDM analyzes this sample to compute empirical estimates of various summary statistics of the compound distribution such as the mean, variance, skewness, and kurtosis in addition to percentiles such as the median, the 95th percentile, the 99th percentile, and so on. You can also use PROC HPCDM to write the entire simulated sample to an output data set and to produce the plot of the empirical distribution function (EDF), which serves as a nonparametric estimate of F_S.

The simulation process gets more complicated when the frequency and severity models contain regression effects. The CDM is then conditional on the given values of regressors. The simulation process essentially becomes a scenario analysis, because you need to specify the expected values of the regressors that together represent the scenario for which you want to estimate the CDM. PROC HPCDM enables you to specify an input data set that contains the scenario. If you are modeling a group of entities together (such as a portfolio of multiple assets or a group of insurance policies), each with a different set of characteristics, then the scenario consists of more than one observation, and each observation corresponds to a different entity. PROC HPCDM enables you to specify such a group scenario in the input data set and performs a realistic simulation of loss events that each entity can generate.

PROC HPCDM also enables you to specify externally simulated counts. This is useful if you have an empirical frequency model or if you estimate the frequency model by using a method other than PROC COUNTREG and simulate counts by using such a model. You can specify M replications of externally simulated counts. For each of the replications, in step 1 of the simulation, instead of using the frequency model, PROC HPCDM uses the count N that you specify. If the severity model contains regression effects, then you can specify the scenario to simulate for each of the M replications.

If the parameters of your severity and frequency models have uncertainty associated with them, and they usually do, then you can use PROC HPCDM to conduct parameter perturbation analysis to assess the effect of parameter uncertainty on the estimates of CDM. If you specify that P perturbed samples be generated, then the parameter set is perturbed P times, and each time PROC HPCDM makes a random draw from either the univariate normal distribution of each parameter or the multivariate normal distribution over all parameters. For each of the P perturbed parameter sets, a full compound distribution sample is simulated and summarized.

This process yields P number of estimates for each summary statistic and percentile, which are then used to provide you with estimates of the location and variability of each summary statistic and percentile.

You can also use PROC HPCDM to compute the distribution of an aggregate *adjusted* loss. For example, in insurance applications, you might want to compute the distribution of the *amount paid* in a given time period after applying adjustments such as deductible and policy limit to each individual loss. PROC HPCDM enables you to specify SAS programming statements to adjust each severity value. If X_j^a represents the adjusted severity value, then PROC HPCDM computes S^a, an aggregate adjusted loss, as

$$S^a = \sum_{j=1}^{N} X_j^a$$

All the analyses that PROC HPCDM conducts for the aggregate unadjusted loss, including scenario analysis and parameter perturbation analysis, are also conducted for the aggregate adjusted loss, thereby giving you a comprehensive picture of the adjusted compound distribution model.

Getting Started: HPCDM Procedure

This section outlines the use of the HPCDM procedure to fit compound distribution models. The examples are intended as a gentle introduction to some of the features of the procedure.

Estimating a Simple Compound Distribution Model

This example illustrates the simplest use of PROC HPCDM. Assume that you are an insurance company that has used the historical data about the number of losses per year and the severity of each loss to determine that the Poisson distribution is the best distribution for the loss frequency and that the gamma distribution is the best distribution for the severity of each loss. Now, you want to estimate the distribution of an aggregate loss to determine the worst-case loss that can be incurred by your policyholders in a year. In other words, you want to estimate the compound distribution of $S = \sum_{i=1}^{N} X_i$, where the loss frequency, N, follows the fitted Poisson distribution and the severity of each loss event, X_i, follows the fitted gamma distribution.

If your historical count and severity data are stored in the data sets Work.ClaimCount and Work.ClaimSev, respectively, then you need to ensure that you use the following PROC COUNTREG and PROC SEVERITY steps to fit and store the parameter estimates of the frequency and severity models:

```
/* Fit an intercept-only Poisson count model and
   write estimates to an item store */
proc countreg data=claimcount;
   model numLosses= / dist=poisson;
   store countStorePoisson;
run;

/* Fit severity models and write estimates to a data set */
proc severity data=claimsev criterion=aicc outest=sevest covout plots=none;
   loss lossValue;
   dist _predefined_;
run;
```

The STORE statement in the PROC COUNTREG step saves the count model information, including the parameter estimates, in the Work.CountStorePoisson item store. An item store contains the model information in a binary format that cannot be modified after it is created. You can examine the contents of an item store that is created by a PROC COUNTREG step by specifying a combination of the RESTORE= option and the SHOW statement in another PROC COUNTREG step. For more information, see Chapter 11, "The COUNTREG Procedure."

The OUTEST= option in the PROC SEVERITY statement stores the estimates of all the fitted severity models in the Work.SevEst data set. Let the best severity model that the PROC SEVERITY step chooses be the gamma distribution model.

You can now submit the following PROC HPCDM step to simulate an aggregate loss sample of size 10,000 by specifying the count model's item store in the COUNTSTORE= option and the severity model's data set of estimates in the SEVERITYEST= option:

```
/* Simulate and estimate Poisson-gamma compound distribution model */
proc hpcdm countstore=countStorePoisson severityest=sevest
           seed=13579 nreplicates=10000 plots=(edf(alpha=0.05) density)
           print=(summarystatistics percentiles);
   severitymodel gamma;
   output out=aggregateLossSample samplevar=aggloss;
   outsum out=aggregateLossSummary mean stddev skewness kurtosis
          p01 p05 p95 p995=var pctlpts=90 97.5;
run;
```

The SEVERITYMODEL statement requests that an aggregate sample be generated by compounding only the gamma distribution and the frequency distribution. Specifying the SEED= value helps you get an identical sample each time you execute this step, provided that you use the same execution environment. The execution environment is the combination of the operating environment and the number of threads that are used for execution.

Upon completion, PROC HPCDM creates the two output data sets that you specify in the OUT= options of the OUTPUT and OUTSUM statements. The Work.AggregateLossSample data set contains 10,000 observations such that the value of the AggLoss variable in each observation represents one possible aggregate loss value that you can expect to see in one year. Together, the set of the 10,000 values of the AggLoss variable represents one sample of compound distribution. PROC HPCDM uses this sample to compute the empirical estimates of various summary statistics and percentiles of the compound distribution. The Work.AggregateLossSummary data set contains the estimates of mean, standard deviation, skewness, and kurtosis that you specify in the OUTSUM statement. It also contains the estimates of the 1st, 5th, 90th, 95th, 97.5th, and 99.5th percentiles that you specify in the OUTSUM statement. The value-at-risk (VaR) is an aggregate loss value such that there is a very low probability that an observed aggregate loss value exceeds the VaR. One of the commonly used probability levels to define VaR is 0.005, which makes the 99.5th percentile an empirical estimate of the VaR. Hence, the OUTSUM statement of this example stores the 99.5th percentile in a variable named VaR. VaR is one of the widely used measures of worst-case risk.

Some of the default output and some of the output that you have requested by specifying the PRINT= option are shown in Figure 16.1.

Figure 16.1 Information, Summary Statistics, and Percentiles of the Poisson-Gamma Compound Distribution

The HPCDM Procedure
Severity Model: Gamma
Count Model: Poisson

Compound Distribution Information	
Severity Model	Gamma Distribution
Count Model	Poisson Model in Item Store WORK.COUNTSTOREPOISSON

Sample Summary Statistics			
Mean	4076.8	**Median**	3440.2
Standard Deviation	3442.6	**Interquartile Range**	4523.9
Variance	11851305.5	**Minimum**	0
Skewness	1.14554	**Maximum**	27971.5
Kurtosis	1.75272	**Sample Size**	10000

Sample Percentiles	
Percentile	**Value**
1	0
5	0
25	1430.7
50	3440.2
75	5954.6
90	8743.8
95	10740.0
97.5	12453.3
99	14738.1
99.5	16406.8
Percentile Method = 5	

The "Sample Summary Statistics" table indicates that for the given parameter estimates of the Poisson frequency and gamma severity models, you can expect to see a mean aggregate loss of 4,076.8 and a median aggregate loss of 3,440.2 in a year. The "Sample Percentiles" table indicates that there is a 0.5% chance that the aggregate loss exceeds 16,406.8, which is the VaR estimate, and a 2.5% chance that the aggregate loss exceeds 12,453.3. These summary statistic and percentile estimates provide a quantitative picture of the compound distribution. You can also visually analyze the compound distribution by examining the plots that PROC HPCDM prepares. The first plot in Figure 16.2 shows the empirical distribution function (EDF), which is a nonparametric estimate of the cumulative distribution function (CDF). The second plot shows the histogram and the kernel density estimate, which are nonparametric estimates of the probability density function (PDF).

Figure 16.2 Nonparametric CDF and PDF Plots of the Poisson-Gamma Compound Distribution

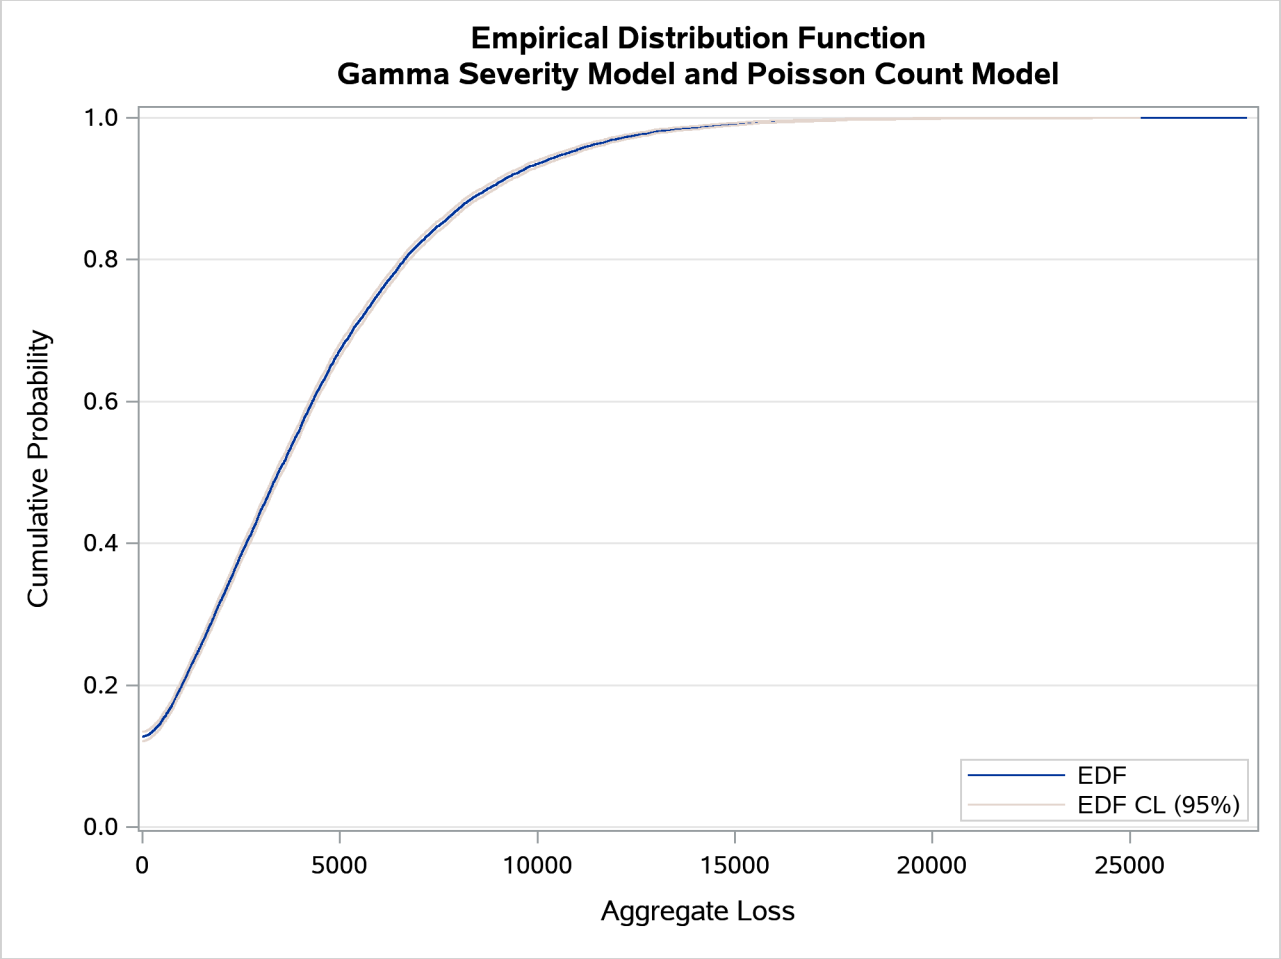

Figure 16.2 *continued*

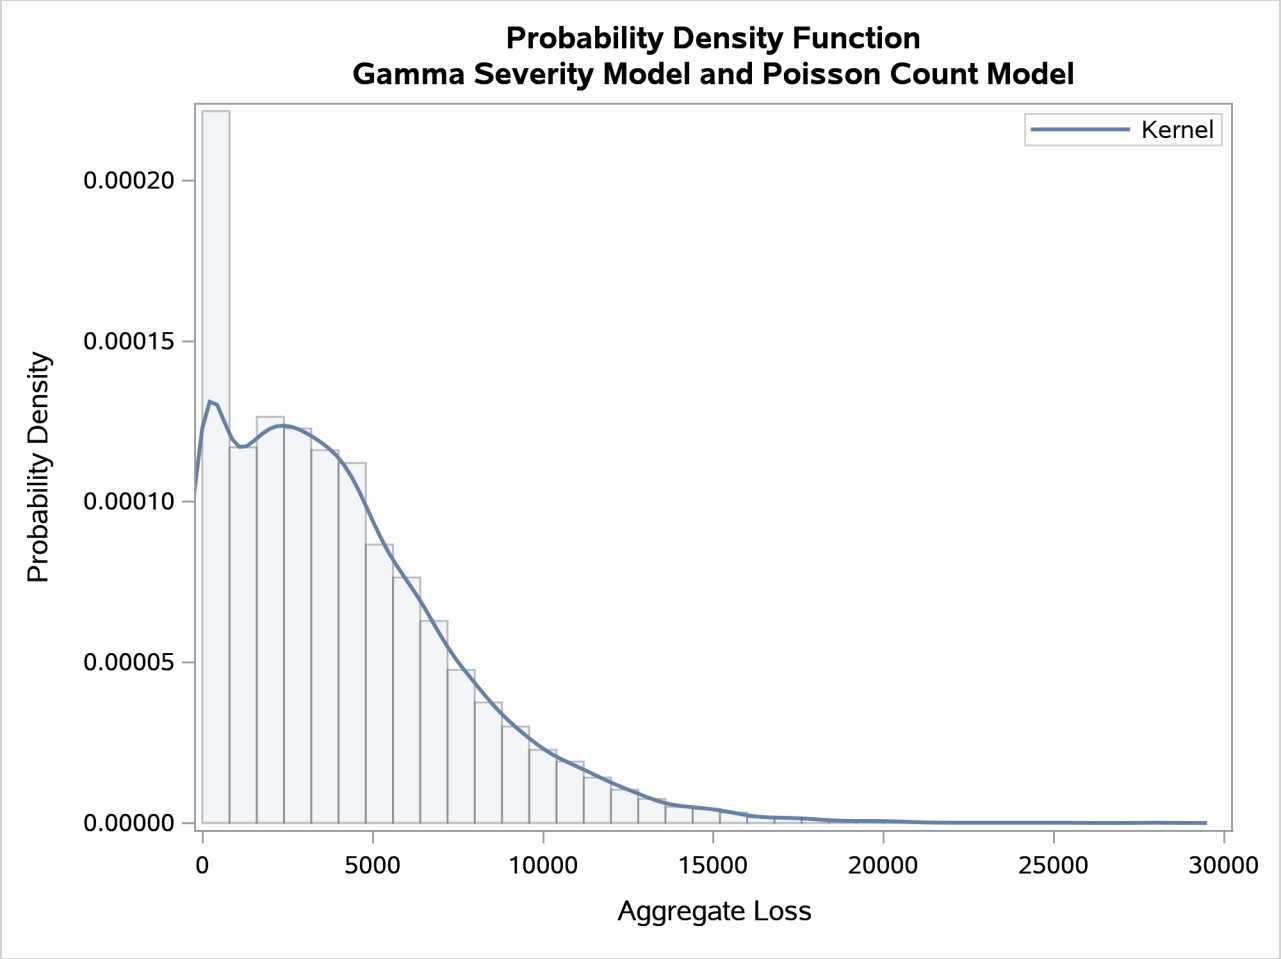

The plots confirm the right skew that is indicated by the estimate of skewness in Figure 16.1 and a relatively fat tail, which is indicated by comparing the maximum and the 99.5th percentiles in Figure 16.1.

Analyzing the Effect of Parameter Uncertainty on the Compound Distribution

Continuing with the previous example, note that you have fitted the frequency and severity models by using the historical data. Even if you choose the best-fitting models, the true underlying models are not known exactly. This fact is reflected in the uncertainty that is associated with the parameters of your models. Any compound distribution estimate that is computed by using these uncertain parameter estimates is inherently uncertain. You can request that PROC HPCDM conduct parameter perturbation analysis, which assesses the effect of the parameter uncertainty on the estimates of the compound distribution by simulating multiple samples, each with parameters that are randomly perturbed from their mean estimates.

The following PROC HPCDM step adds the NPERTURBEDSAMPLES= option to the PROC HPCDM statement to request that perturbation analysis be conducted and the PRINT=PERTURBSUMMARY option to request that a summary of the perturbation analysis be displayed:

```
/* Conduct parameter perturbation analysis of
   the Poisson-gamma compound distribution model */
proc hpcdm countstore=countStorePoisson severityest=sevest
           seed=13579 nreplicates=10000 nperturbedsamples=30
           print(only)=(perturbsummary) plots=none;
   severitymodel gamma;
   output out=aggregateLossSample samplevar=aggloss;
   outsum out=aggregateLossSummary mean stddev skewness kurtosis
          p01 p05 p95 p995=var pctlpts=90 97.5;
run;
```

The Work.AggregateLossSummary data set contains the specified summary statistics and percentiles for all 30 perturbed samples. You can identify a perturbed sample by the value of the _DRAWID_ variable. The first few observations of the Work.AggregateLossSummary data set are shown in Figure 16.3. For the first observation, the value of the _DRAWID_ variable is 0, which represents an unperturbed sample—that is, the aggregate sample that is simulated without perturbing the parameters from their means.

Figure 16.3 Summary Statistics and Percentiles of the Perturbed Samples

SEVERITYMODEL	_COUNTMODEL_	_DRAWID_	_SAMPLEVAR_	N	MEAN	STDDEV

1.07704	1.41288	0	0	9606.49	11489.24	13304.55	17662.93
1.11500	1.58827	0	0	8890.20	10732.59	12600.30	16581.44
1.14044	1.61876	0	0	8671.02	10546.62	12323.83	16333.81
1.09693	1.35455	0	0	8561.27	10322.30	11986.43	15829.09
1.16766	1.75264	0	0	9328.43	11299.10	13240.13	17417.01

The PRINT=PERTURBSUMMARY option in the preceding PROC HPCDM step produces the "Sample Perturbation Analysis" and "Sample Percentile Perturbation Analysis" tables that are shown in Figure 16.4. The tables show that you can expect a mean aggregate loss of about 4,098.5 and the standard error of the mean is 172.1. If you want to use the VaR estimate to determine the amount of reserves that you need to maintain to cover the worst-case loss, then you should consider not only the mean estimate of the 99.5th

percentile, which is about 16,448.2, but also the standard error of 708.9 to account for the effect of uncertainty in your frequency and severity parameter estimates.

Scenario Analysis

The distributions of loss frequency and loss severity often depend on exogenous variables (regressors). For example, the number of losses and the severity of each loss that an automobile insurance policyholder incurs might depend on the characteristics of the policyholder and the characteristics of the vehicle. When you fit frequency and severity models, you need to account for the effects of such regressors on the probability distributions of the counts and severity. The COUNTREG procedure enables you to model regression effects on the mean of the count distribution, and the SEVERITY procedure enables you to model regression effects on the scale parameter of the severity distribution. When you use these models to estimate the compound distribution model of the aggregate loss, you need to specify a set of values for all the regressors, which represents the state of the world for which the simulation is conducted. This is referred to as the what-if or scenario analysis.

Consider that you, as an automobile insurance company, have postulated that the distribution of the loss event frequency depends on five regressors (external factors): age of the policyholder, gender, type of car, annual miles driven, and policyholder's education level. Further, the distribution of the severity of each loss depends on three regressors: type of car, safety rating of the car, and annual household income of the policyholder (which can be thought of as a proxy for the luxury level of the car). Note that the frequency model regressors and severity model regressors can be different, as illustrated in this example.

Let these regressors be recorded in the variables Age (scaled by a factor of 1/50), Gender (1: female, 2: male), CarType (1: sedan, 2: sport utility vehicle), AnnualMiles (scaled by a factor of 1/5,000), Education (1: high school graduate, 2: college graduate, 3: advanced degree holder), CarSafety (scaled to be between 0 and 1, the safest being 1), and Income (scaled by a factor of 1/100,000), respectively. Let the historical data about the number of losses that various policyholders incur in a year be recorded in the NumLoss variable of the Work.LossCounts data set, and let the severity of each loss be recorded in the LossAmount variable of the Work.Losses data set.

The following PROC COUNTREG step fits the count regression model and stores the fitted model information in the Work.CountregModel item store:

```
/* Fit negative binomial frequency model for the number of losses */
proc countreg data=losscounts;
   model numloss = age gender carType annualMiles education / dist=negbin;
   store work.countregmodel;
run;
```

You can examine the parameter estimates of the count model that are stored in the Work.CountregModel item store by submitting the following statements:

```
/* Examine the parameter estimates for the model in the item store */
proc countreg restore=work.countregmodel;
   show parameters;
run;
```

The "Parameter Estimates" table that is displayed by the SHOW statement is shown in Figure 16.5.

Figure 16.5 Parameter Estimates of the Count Regression Model

ITEM STORE CONTENTS: WORK.COUNTREGMODEL

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	0.910479	0.090515	10.06	<.0001
age	1	-0.626803	0.058547	-10.71	<.0001
gender	1	1.025034	0.032099	31.93	<.0001
carType	1	0.615165	0.031153	19.75	<.0001
annualMiles	1	-1.010276	0.017512	-57.69	<.0001
education	1	-0.280246	0.021677	-12.93	<.0001
_Alpha	1	0.318403	0.020090	15.85	<.0001

The following PROC SEVERITY step fits the severity scale regression models for all the common distributions that are predefined in PROC SEVERITY:

```
/* Fit severity models for the magnitude of losses */
proc severity data=losses plots=none outest=work.sevregest print=all;
   loss lossamount;
   scalemodel carType carSafety income;
   dist _predef_;
   nloptions maxiter=100;
run;
```

The comparison of fit statistics of various scale regression models is shown in Figure 16.6. The scale regression model that is based on the lognormal distribution is deemed the best-fitting model according to the likelihood-based statistics, whereas the scale regression model that is based on the generalized Pareto distribution (GPD) is deemed the best-fitting model according to the EDF-based statistics.

Weibull	128429		128439		128439		128475		6.21268		190.73733		13.45425	

Note: The asterisk (*) marks the best model according to each column's criterion.

Now, you are ready to analyze the distribution of the aggregate loss that can be expected from a specific policyholder—for example, a 59-year-old male policyholder with an advanced degree who earns 159,870 and drives a sedan that has a very high safety rating about 11,474 miles annually. First, you need to encode and scale this information into the appropriate regressor variables of a data set. Let that data set be named Work.SinglePolicy, with an observation as shown in Figure 16.7.

Figure 16.7 Scenario Analysis Data for One Policyholder

age	gender	carType	annualMiles	education	carSafety	income
1.18	2	1	2.2948	3	0.99532	1.5987

Now, you can submit the following PROC HPCDM step to analyze the compound distribution of the aggregate loss that is incurred by the policyholder in the Work.SinglePolicy data set in a given year by using the frequency model from the Work.CountregModel item store and the two best severity models, lognormal and GPD, from the Work.SevRegEst data set:

```
/* Simulate the aggregate loss distribution for the scenario
   with single policyholder */
proc hpcdm data=singlePolicy nreplicates=10000 seed=13579 print=all
           countstore=work.countregmodel severityest=work.sevregest;
   severitymodel logn gpd;
```

```
    outsum out=onepolicysum mean stddev skew kurtosis median
          pctlpts=97.5 to 99.5 by 1;
run;
```

The displayed results from the preceding PROC HPCDM step are shown in Figure 16.8.

When you use a severity scale regression model, it is recommended that you verify the severity scale regressors that are used by PROC HPCDM by examining the Scale Model Regressors row of the "Compound Distribution Information" table. PROC HPCDM detects the severity regressors automatically by examining the variables in the SEVERITYEST= and DATA= data sets. If those data sets contain variables that you did not include in the SCALEMODEL statement in PROC SEVERITY, then such variables can be treated as severity regressors. One common mistake that can lead to this situation is to fit a severity model by using the BY statement and forget to specify the identical BY statement in the PROC HPCDM step; this can cause PROC HPCDM to treat BY variables as scale model regressors. In this example, Figure 16.8 confirms that the correct set of scale model regressors is detected.

Percentile Method = 5	

The "Sample Summary Statistics" and "Sample Percentiles" tables in Figure 16.8 show estimates of the aggregate loss distribution for the lognormal severity model. The average expected loss is about 214, and the worst-case loss, if approximated by the 97.5th percentile, is about 1,340. The percentiles table shows that

the distribution is highly skewed to the right; this is also confirmed by the skewness estimate. The median estimate of 0 can be interpreted in two ways. One way is to conclude that the policyholder will not incur any loss in 50% of the years during which he or she is insured. The other way is to conclude that 50% of policyholders who have the characteristics of this policyholder will not incur any loss in a given year. However, there is a 2.5% chance that the policyholder will incur a loss that exceeds 1,340 in any given year and a 0.5% chance that the policyholder will incur a loss that exceeds 2,665 in any given year.

If the aggregate loss sample is simulated by using the GPD severity model, then the results are as shown in Figure 16.9. The average and worst-case losses are 213 and 1,337, respectively. These estimates are very close to the values that are predicted by the lognormal severity model.

The scenario that you just analyzed contains only one policyholder. You can extend the scenario to include multiple policyholders. Let the Work.GroupOfPolicies data set record information about five different policyholders, as shown in Figure 16.10.

Figure 16.10 Scenario Analysis Data for Multiple Policyholders

policyholderId	age	gender	carType	annualMiles	education	carSafety	income
1	1.18	2	1	2.2948	3	0.99532	1.59870
2	0.66	2	1	2.6718	2	0.86412	0.84459
3	0.64	2	2	1.9528	1	0.86478	0.50177
4	0.46	1	2	2.6402	2	0.27062	1.18870
5	0.62	1	1	1.7294	1	0.32830	0.37694

The following PROC HPCDM step conducts a scenario analysis for the aggregate loss that is incurred by all five policyholders in the Work.GroupOfPolicies data set together in one year:

```
/* Simulate the aggregate loss distribution for the scenario
   with multiple policyholders */
proc hpcdm data=groupOfPolicies nreplicates=10000 seed=13579 print=all
           countstore=work.countregmodel severityest=work.sevregest
           plots=(conditionaldensity(rightq=0.95)) nperturbedSamples=50;
   severitymodel logn gpd;
   outsum out=multipolicysum mean stddev skew kurtosis median
         pctlpts=97.5 to 99.5 by 1;
run;
```

The preceding PROC HPCDM step conducts perturbation analysis by simulating 50 perturbed samples. The perturbation summary results for the lognormal severity model are shown in Figure 16.11, and the results for the GPD severity model are shown in Figure 16.12. If the severity of each loss follows the fitted lognormal distribution, then you can expect that the group of policyholders together incurs an average loss of 5,300 $\pm$ 328 and a worst-case loss of 15,734 $\pm$ 960 when you define the worst-case loss as the 97.5th percentile.

Figure 16.11 Perturbation Analysis of Losses from Multiple Policyholders with Lognormal Severity Model

The HPCDM Procedure
Severity Model: Logn
Count Model: NegBin(p=2)

Compound Distribution Information	
Severity Model	Lognormal Distribution

Count Model	NegBin(p=2) Model in Item Store WORK.COUNTREGMODEL

Sample Perturbation Analysis		
Statistic	**Estimate**	**Standard Error**
Mean	5299.8	327.70569
Standard Deviation	4151.9	269.78790
Variance	17311274	2254196.7
Skewness	2.14414	1.24620
Kurtosis	16.65290	58.38318
Number of Perturbed Samples = 50		
Size of Each Sample = 10000		

Figure 16.11 *continued*

Sample Percentile Perturbation Analysis		
Percentile	**Estimate**	**Standard Error**
1	194.20187	28.77686
5	742.04381	59.84686
25	2379.0	154.80380
50	4324.3	272.87497
75	7113.4	438.24370
95	13101.5	805.58237
97.5	15734.1	960.35241
98.5	17746.7	1098.9
99	19384.7	1189.9
99.5	22409.7	1433.0
Number of Perturbed Samples = 50		
Size of Each Sample = 10000		

If the severity of each loss follows the fitted GPD distribution, then you can expect an average loss of 5,236 $\pm$ 365 and a worst-case loss of 14,992 $\pm$ 1,014.

If you decide to use the 99.5th percentile to define the worst-case loss, then the worst-case loss is 22,410 $\pm$ 1,433 for the lognormal severity model and 20,246 $\pm$ 1,400 for the GPD severity model. The numbers for lognormal and GPD are well within two standard errors of each other, which indicates that the aggregate loss distribution is less sensitive to the choice of these two severity distributions in this particular example; you can use the results from either of them.

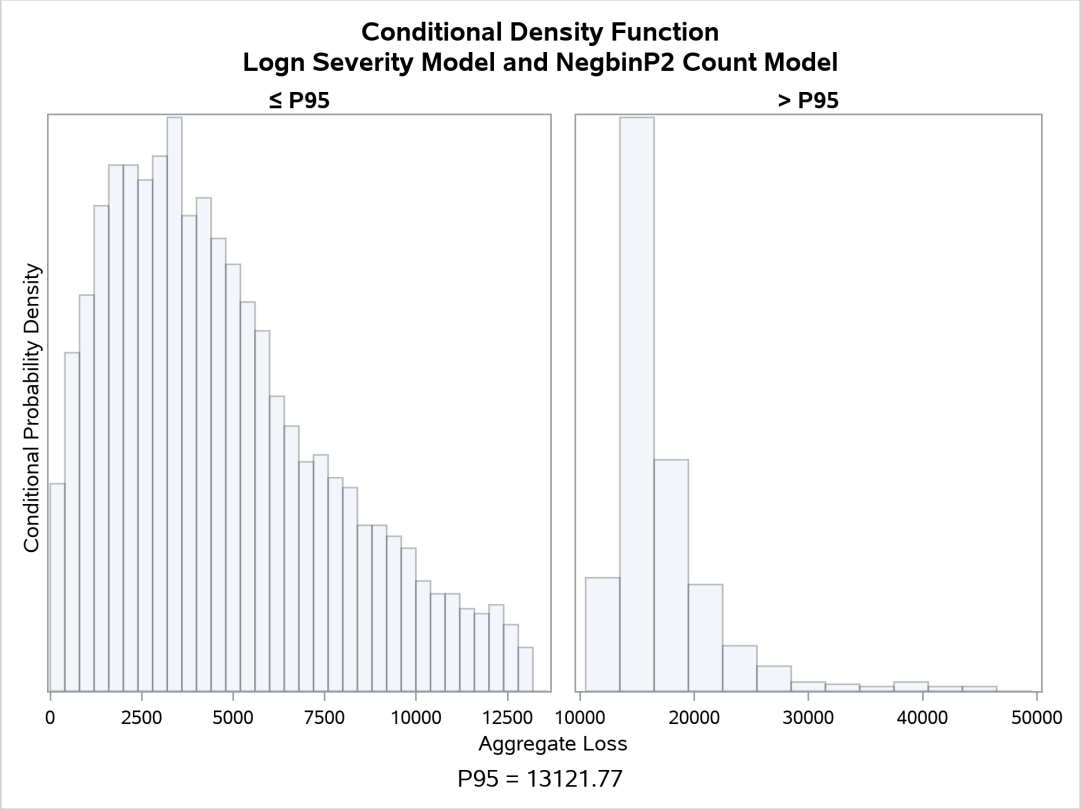
The PLOTS=CONDITIONALDENSITY option that is used in the preceding PROC HPCDM step prepares the conditional density plots for the body and right-tail regions of the density function of the aggregate loss. The plots for the aggregate loss sample that is generated by using the lognormal severity model are shown in Figure 16.13. The plot on the left side is the plot of $\Pr(Y|Y \leq 13{,}122)$, where the limit 13,122 is the 95th percentile as specified by the RIGHTQ=0.95 option. The plot on the right side is the plot of $\Pr(Y|Y > 13{,}122)$, which helps you visualize the right-tail region of the density function. You can also request the plot of the left tail by specifying the LEFTQ= suboption of the CONDITIONALDENSITY option if you want to explore the details of the left tail region. Note that the conditional density plots are always produced by using the unperturbed sample.

Figure 16.13 Conditional Density Plots for the Aggregate Loss of Multiple Policyholders



Syntax: HPCDM Procedure

Suppresses all displayed and graphical output	PROC HPCDM	NOPRINT
Specifies which graphical output to prepare	PROC HPCDM	PLOTS=
Specifies which displayed output to prepare	PROC HPCDM	PRINT=

PROC HPCDM Statement

PROC HPCDM *options* **;**

The PROC HPCDM statement invokes the procedure. You can specify the following *options*, which are listed in alphabetical order.

ADJUSTEDSEVERITY=*symbol-name*

ADJSEV=*symbol-name*

names the symbol that represents the adjusted severity value in the SAS programming statements that you specify. The *symbol-name* is a SAS name that conforms to the naming conventions of a SAS variable. For more information, see the section "Programming Statements" on page 952.

COUNTSTORE=*SAS-item-store*

names the item store that contains all the information about the frequency (count) model. The COUNTREG procedure generates this item store when you use the STORE statement.

The exogenous variables in the frequency model, if any, are deduced from this item store. The DATA= data set must contain all those variables.

If you specify a BY statement in the PROC COUNTREG step that creates the COUNTSTORE= item store, then you must specify an identical BY statement in the PROC HPCDM step.

You must specify this option if you do not specify the EXTERNALCOUNTS statement. This option is ignored if you specify the EXTERNALCOUNTS statement, because PROC HPCDM does not need to simulate frequency counts internally when you specify externally simulated counts.

DATA=*SAS-data-set*

names the input data set that contains the values of regression variables in frequency or severity models and severity adjustment variables that you use in the programming statements.

The DATA= data set specifies information about the scenario for which you want to estimate the aggregate loss distribution. The interpretation of the contents of the data set depends on whether you specify the EXTERNALCOUNTS statement. For more information, see the section "Specifying Scenario Data in the DATA= Data Set" on page 953.

MAXCOUNTDRAW=*number*

MAXCOUNT=*number*

specifies an upper limit on the number of loss events (count) that is used for simulating one aggregate loss sample point. If the *number* is equal to $N_{\max}$, then any count that is greater than $N_{\max}$ is assumed to be equal to $N_{\max}$, and only $N_{\max}$ severity draws are made to compute one point in the aggregate loss sample.

If you specify this option and also specify the COUNTSTORE= item store, then the limit is applied to each count that PROC HPCDM randomly draws from the count distribution in the COUNTSTORE= item store. Any count draw that is larger than the *number* is replaced by the *number*.

If you specify this option and also specify the EXTERNALCOUNTS statement, then the limit is applied to each observation in the DATA= data set, and any value of the COUNT= variable that is larger than the *number* is replaced by the *number*.

If you do not specify this option, then a default value of 1,000 is used.

If you specify a *number* that is significantly larger than 1,000, then PROC HPCDM might take a very long time to complete the simulation, especially when some counts are closer to the limit.

NOPRINT

turns off all displayed and graphical output. If you specify this option, then PROC HPCDM ignores any value that you specify for the PRINT= or PLOTS= option.

NPERTURBEDSAMPLES=*number*

NPERTURB=*number*

requests that parameter perturbation analysis be conducted. The model parameters are perturbed the specified *number* of times and a separate full sample is simulated for each set of perturbed parameter values. The summary statistics and percentiles are computed for each such perturbed sample, and their

values are aggregated across the samples to compute the mean and standard deviation of each summary statistic and percentile.

The parameter perturbation procedure makes random draws of parameter values from a multivariate normal distribution if the covariance estimates of the parameters are available. For the multivariate normal distribution of severity model parameters, PROC HPCDM attempts to read the covariance estimates from the SEVERITYEST= data set or the SEVERITYSTORE= item store. For the multivariate normal distribution of count model parameters, PROC HPCDM attempts to read the covariance estimates from the COUNTSTORE= store. If covariance estimates are not available or valid, then for each parameter, a random draw is made from the univariate normal distribution that has mean and standard deviation equal to the point estimate and the standard error, respectively, of that parameter. If neither covariance nor standard error estimates are available, then perturbation analysis is not conducted.

If you specify the PRINT=ALL or PRINT=PERTURBSUMMARY option, then the summary of perturbation analysis is printed for the core summary statistics and the percentiles of the aggregate loss distribution. If you specify the OUTSUM statement, then the requested summary statistics are written to the OUTSUM= data set for each perturbed sample. You can also optionally request that each perturbed sample be written in its entirety to the OUT= data set by specifying the PERTURBOUT option in the OUTPUT statement.

For more information on the parameter perturbation analysis, see the section "Parameter Perturbation Analysis" on page 969.

NREPLICATES=*number*

NREP=*number*

specifies a *number* that controls the size of the compound distribution sample that PROC HPCDM simulates. The *number* is interpreted differently based on whether you specify the EXTERNALCOUNTS statement.

If you do not specify the EXTERNALCOUNTS statement, then the sample size is equal to the *number* that you specify for this option. If you do not specify this option, then a default value of 100,000 is used.

If you specify the EXTERNALCOUNTS statement, then the number of replicates that you specify in the DATA= data set is multiplied by the *number* that you specify for this option to get the total size of the compound distribution sample. If you do not specify this option, then a default value of 1 is used.

PCTLDEF=*percentile-method*

specifies the method to compute the percentiles of the compound distribution. The *percentile-method* can be 1, 2, 3, 4, or 5. The default method is 5. For more information, see the description of the PCTLDEF= option in the UNIVARIATE procedure in the *Base SAS Procedures Guide: Statistical Procedures*.

PERTURBMETHOD=*perturbation-method*

specifies a method to perturb the parameters of the severity and count models. This option has no effect if you do not specify the NPERTURBEDSAMPLES= option. You can specify one of the following *perturbation-method*s:

ASYNC | 0
causes each thread of computation to use its own set of perturbed model parameters. In particular, each thread uses its own pseudorandom number generator (PRNG) to perturb the model parameters, which is the same PRNG as the PRNG that the thread uses for making random draws from the severity or count distributions. Because each thread's PRNG starts with a different seed and because random draws that pertain to perturbation are interleaved with random draws that are made from the severity or count distributions, each thread effectively uses a different set of perturbed models parameters even though it is simulating a subset of the same, global perturbed sample.

This method is computationally slightly more efficient because it does not need to synchronize the set of perturbed parameters among threads. However, each perturbed sample that it produces is conceptually a collection of smaller, distinct perturbed samples that belong to different compound distribution models.

SYNC | 1
specifies that all threads of computation use the same (synchronized) set of perturbed model parameters. When you specify this option, PROC HPCDM in concept uses a single, dedicated PRNG to perturb the model parameters and shares those parameters with all threads.

This method ensures that all observations of a particular perturbed sample belong to the same compound distribution model, because each thread uses the same set of perturbed model parameters.

It is recommended that you specify the SYNC method. By default, PERTURBMETHOD=ASYNC to ensure that the current release of PROC HPCDM produces, by default, the same perturbation results as releases prior to SAS/ETS 15.1.

PLOTS < (*global-plot-options*) > =*plot-request-option*

PLOTS < (*global-plot-options*) > =(*plot-request-option . . . plot-request-option*)
specifies the desired graphical output.

By default, the HPCDM procedure produces no graphical output.

You can specify the following *global-plot-option*:

ONLY
turns off the default graphical output and prepares only the requested plots.

If you specify more than one *plot-request-option*, then separate them with spaces and enclose them in parentheses. The following *plot-request-options* are available:

ALL
displays all the graphical output.

CONDITIONALDENSITY (*conditional-density-plot-options*)

CONDPDF (*conditional-density-plot-options*)
prepares a group of plots of the conditional density functions estimates. The group contains at most three plots, each conditional on the value of the aggregate loss being in one of the three regions that are defined by the quantiles that you specify in the following *conditional-density-plot-options*:

LEFTQ=*number*
specifies the quantile in the range (0,1) that marks the end of the left-tail region. If you specify a value of l for *number*, then the left-tail region is defined as the set of values that are less than or equal to q_l, where q_l is the lth quantile. For the left-tail region, nonparametric estimates of the conditional probability density function $f_S^l(s) = \Pr[S = s | S \leq q_l]$ are plotted. The value of q_l is estimated by the $100l$th percentile of the simulated compound distribution sample.

If you do not specify this option or you specify a missing value for this option, then the left-tail region is not plotted.

RIGHTQ=*number*
specifies the quantile in the range (0,1) that marks the beginning of the right-tail region. If you specify a value of r for *number*, then the right-tail region is defined as the set of values that are greater than q_r, where q_r is the rth quantile. For the right-tail region, nonparametric estimates of the conditional probability density function $f_S^r(s) = \Pr[S = s | S > q_r]$ are plotted. The value of q_r is estimated by the $100r$th percentile of the simulated compound distribution sample.

If you do not specify this option or you specify a missing value for this option, then the right-tail region is not plotted.

You must specify nonmissing value for at least one of the preceding two options. For the region between the LEFTQ= and RIGHTQ= quantiles, which is referred to as the central or body region, nonparametric estimates of the conditional probability density function $f_S^c(s) = \Pr[S = s | q_l < S \leq q_r]$ are plotted. If you do not specify a LEFTQ= value, then q_l is assumed to be 0. If you do not specify a RIGHTQ= value, then q_r is assumed to be ∞.

DENSITY
prepares a plot of the nonparametric estimates of the probability density function (in particular, histogram and kernel density estimates) of the compound distribution.

EDF < (*edf-plot-option***) >**
prepares a plot of the nonparametric estimates of the cumulative distribution function of the compound distribution.

You can request that the confidence interval be plotted by specifying the following *edf-plot-option*:

ALPHA=*number*
specifies the confidence level in the (0,1) range that is used for computing the confidence intervals for the EDF estimates. If you specify a value of α for *number*, then the upper and lower confidence limits for the confidence level of $100(1 - \alpha)$ are plotted.

NONE
displays none of the graphical output. If you specify this option, then it overrides all other plot request options. The default graphical output is also suppressed.

Note that if the simulated sample size is large, then it can take a significant amount of time and memory to prepare the plots.

PRINT <(*global-display-option***)> =***display-option*

PRINT <(*global-display-option***)> =(***display-option . . . display-option***)**

specifies the desired displayed output. If you specify more than one *display-option*, then separate them with spaces and enclose them in parentheses.

You can specify the following *global-display-option*:

ONLY

turns off the default displayed output and displays only the requested output.

You can specify the following *display-options*:

ALL

displays all the output.

NONE

displays none of the output. If you specify this option, then it overrides all other display options. The default displayed output is also suppressed.

PERCENTILES

displays the percentiles of the compound distribution sample. This includes all the predefined percentiles, percentiles that you request in the OUTSUM statement, and percentiles that you specify for preparing conditional density plots.

PERTURBSUMMARY

displays the mean and standard deviation of the summary statistics and percentiles that are taken across all the samples produced by perturbing the model parameters. This option is valid only if you specify the NPERTURBEDSAMPLES= option in the PROC HPCDM statement.

SUMMARYSTATISTICS | SUMSTAT

displays the summary statistics of the compound distribution sample.

If you do not specify the PRINT= option or the ONLY *global-display-option*, then the default displayed output is equivalent to specifying PRINT=(SUMMARYSTATISTICS).

SEED=*number*

specifies the integer to use as the seed in generating the pseudorandom numbers that are used for simulating severity and frequency values.

If you do not specify the seed or if *number* is negative or 0, then the time of day from the computer's clock is used as the seed.

SEVERITYEST=*SAS-data-set*

names the input data set that contains the parameter estimates for the severity model. The format of this data set must be the same as the OUTEST= data set that is produced by the SEVERITY procedure.

The names of the regression variables in the scale regression model, if any, are deduced from this data set. In particular, PROC HPCDM assumes that all the variables in the SEVERITYEST= data set that do not appear in the following list are scale regression variables:

- BY variables
- _MODEL_, _TYPE_, _NAME_, and _STATUS_ variables

- variables that represent distribution parameters

The DATA= data set must contain all the regressors in the scale regression model.

To ensure that PROC HPCDM correctly matches the values of regressors and the values of regression parameter estimates, you might need to rename the regressors in the DATA= data set so that their names match the names of the regressors that you specify in the SCALEMODEL statement of the PROC SEVERITY step that fits the severity model.

If you specify a BY statement in the PROC SEVERITY step that creates the SEVERITYEST= data set, then you must specify an identical BY statement in the PROC HPCDM step. Otherwise, PROC HPCDM detects the BY variables as regression variables in the scale regression model, which might produce unexpected results.

SEVERITYSTORE=*SAS-item-store*

SEVSTORE=*SAS-item-store*

specifies the item store that contains the context and estimates of the severity model. A PROC SEVERITY step with the OUTSTORE= option creates this item store.

If your severity model contains classification or interaction effects, then you need to use this option instead of the SEVERITYEST= option to specify the severity model. If you specify this option, you cannot specify the SEVERITYEST= option.

If you specify a BY statement in the PROC SEVERITY step that creates the SEVERITYSTORE= item store, then you must specify an identical BY statement in the PROC HPCDM step.

VARDEF=*divisor*

specifies the divisor to use in the calculation of variance, standard deviation, kurtosis, and skewness of the compound distribution sample. If the sample size is N, then you can specify one of the following values for the *divisor*:

DF

sets the divisor for variance to $N - 1$. This is the default. This also changes the definitions of skewness and kurtosis.

N

sets the divisor to N.

For more information, see the section "Descriptive Statistics" on page 970.

BY Statement

BY *variable-list* **;**

You can use the BY statement in the HPCDM procedure to process the input data set in groups of observations defined by the BY variables.

If you specify the BY statement, then you must specify the DATA= option in order to specify the input data set. PROC HPCDM expects the input data set to be sorted in the order of the BY variables unless you specify the NOTSORTED option.

DISTBY Statement

DISTBY *replication-id-variable* **;**

A DISTBY statement is necessary if and only if you specify an ID= variable in the EXTERNALCOUNTS statement. In fact, the *replication-id-variable* must be the same as the ID= variable. This is required for correct simulation of the CDM in the presence of the ID= variable.

The *replication-id-variable* must not appear in the BY statement. However, the DATA= data set must be sorted as if the *replication-id-variable* were listed after the BY variables in the BY statement.

EXTERNALCOUNTS Statement

EXTERNALCOUNTS COUNT=*frequency-variable* < **ID=***replication-id-variable* > **;**

The EXTERNALCOUNTS statement enables you to specify externally simulated frequency counts. By default, PROC HPCDM internally simulates the number of loss events by using the frequency model input (COUNTSTORE= item store). However, if you specify the EXTERNALCOUNTS statement, then PROC HPCDM uses the counts that you specify in the DATA= data set and simulates only the severity values internally.

If you specify more than one EXTERNALCOUNTS statement, only the first one is used.

You must specify the following option in the EXTERNALCOUNTS statement:

COUNT=*count-variable*
specifies the variable that contains the simulated counts. This variable must be present in the DATA= data set.

You can also specify the following option in the EXTERNALCOUNTS statement:

ID=*replication-id-variable*
specifies the variable that contains the replicate identifier. This variable must be present in the DATA= data set. Furthermore, you must specify the DISTBY statement with *replication-id-variable* as the only DISTBY variable to ensure correct simulation.

The observations of DATA= data set must be arranged such that the values of the ID= variable are in increasing order in each BY group or in the entire data set if you do not specify the BY statement.

If you do not specify the ID= option, then PROC HPCDM assumes that each observation represents one replication. In other words, the observation number serves as the default replication identifier.

The simulation process of using the external counts to generate the compound distribution sample is described in the section "Simulation with External Counts" on page 957.

OUTPUT Statement

OUTPUT OUT=*SAS-data-set* < *variable-name-options* > < / *out-option* > **;**

The OUTPUT statement enables you to specify the data set to output the generated compound distribution sample.

If you specify more than one OUTPUT statement, only the first one is used.

You must specify the output data set by using the following option:

OUT=*SAS-data-set*

OUTSAMPLE=*SAS-data-set*

specifies the output data set to contain the simulated compound distribution sample. If you specify programming statements to adjust individual severity values, then this data set contains both unadjusted and adjusted samples.

You can specify the following *variable-name-options* to control the names of the variables created in the OUT= data set:

ADJSAMPLEVAR=*variable-name*

specifies the name of the variable to contain the adjusted compound distribution sample in the OUT= data set. If you do not specify the ADJSAMPLEVAR= option, then "_AGGADJSEV_" is used by default.

This option is ignored if you do not specify the ADJUSTEDSEVERITY= option and the programming statements to adjust the simulated severity values.

SAMPLEVAR=*variable-name*

specifies the name of the variable to contain the simulated sample in the OUT= data set. If you do not specify the SAMPLEVAR= option, then "_AGGSEV_" is used by default.

Further, you can request that the perturbed samples be written to the OUT= data set by specifying the following *out-option*:

PERTURBOUT

specifies that all the perturbed samples be written to the OUT= data set. Each perturbed sample is identified by the _DRAWID_ variable in the OUT= data set. A value of 0 for the _DRAWID_ variable indicates an unperturbed sample.

Separate compound distribution samples are generated for each combination of specified severity and frequency models. The _SEVERITYMODEL_ and _COUNTMODEL_ columns in the OUT= data set identify the severity and frequency models, respectively, that are used to generate the sample in the SAMPLEVAR= and ADJSAMPLEVAR= variables.

OUTSUM Statement

OUTSUM OUT=*SAS-data-set statistic-keyword*< *=variable-name* > < *. . . statistic-keyword*< *=variable-name* > > < *outsum-options* > **;**

The OUTSUM statement enables you to specify the data set in which PROC HPCDM writes the summary statistics of the compound distribution samples.

If you specify more than one OUTSUM statement, only the first one is used.

You must specify the output data set by using the following option:

OUT=*SAS-data-set*

OUTSUM=*SAS-data-set*

specifies the output data set that contains the summary statistics of each of the simulated compound distribution samples. You can control the summary statistics that appear in this data set by specifying different *statistic-keywords* and *outsum-options*.

You can request that one or more predefined statistics of the compound distribution sample be written to the OUTSUM= data set. For each specification of the form *statistic-keyword*< *=variable-name* >, the statistic that is specified by the *statistic-keyword* is written to a variable named *variable-name*. If you do not specify the *variable-name*, then the statistic is written to a variable named *statistic-keyword*. You can specify the following *statistic-keywords*:

KURTOSIS

KURT

specifies the kurtosis of the compound distribution sample.

MEAN

specifies the mean of the compound distribution sample.

MEDIAN

Q2

P50

specifies the median (the 50th percentile) of the compound distribution sample.

P01

specifies the 1st percentile of the compound distribution sample.

P05

specifies the 5th percentile of the compound distribution sample.

P95

specifies the 95th percentile of the compound distribution sample.

P99

specifies the 99th percentile of the compound distribution sample.

P99_5

P995

specifies the 99.5th percentile of the compound distribution sample.

Q1

P25

specifies the lower or 1st quartile (the 25th percentile) of the compound distribution sample.

Q3

P75

specifies the upper or 3rd quartile (the 75th percentile) of the compound distribution sample.

QRANGE

specifies the interquartile range (Q3–Q1) of the compound distribution sample.

SKEWNESS

SKEW

specifies the skewness of the compound distribution sample.

STDDEV

STD

specifies the standard deviation of the compound distribution sample.

All percentiles are computed by using the method that you specify for the PCTLDEF= option in the PROC HPCDM statement. You can also request additional percentiles to be reported in the OUTSUM= data set by specifying the following *outsum-options*:

PCTLPTS=*percentile-list*

specifies one or more percentiles that you want to be computed and written to the OUTSUM= data set. This option is useful if you need to request percentiles that are not available in the preceding list of *statistic-keyword* values. Each percentile value must belong to the (0,100) open interval. The *percentile-list* is a comma-separated list of numbers. You can also use a list notation of the form "< *number1* > *to* < *number2* > *by* < *increment* >". For example, the following two options are equivalent:

```
pctlpts=10, 20, 99.6, 99.7, 99.8, 99.9
pctlpts=10, 20, 99.6 to 99.9 by 0.1
```

The name of the variable for a given percentile value is decided by the PCTLNAME= option.

PCTLNAME=*percentile-variable-name-list*

specifies the names of the variables that contain the estimates of the percentiles that you request by using the PCTLPTS= option.

If you do not specify the PCTLNAME= option, then each percentile value *t* in the list of values in the PCTLPTS= option is written to the variable named "P*t*," where the decimal point in *t*, if any, is replaced by an underscore.

The *percentile-variable-name-list* is a space-separated list of names. You can also use a shortcut notation of <prefix>*m*–<prefix>*n* for two integers *m* and *n* ($m < n$) to generate the following list of names: <prefix>*m*, <prefix>$m + 1, \ldots,$ and <prefix>*n*. For example, the following two options are equivalent:

```
pctlname=p1 p2 pc5 pc6 pc7 pc8 pc9 pc10
pctlname=p1 p2 pc5-pc10
```

The name in *j*th position of the expanded name list of the PCTLNAME= option is used to create a variable for a percentile value in the *j*th position of the expanded value list of the PCTLPTS= option. If you specify k_n names in the PCTLNAME= option and k_v percentile values in the PCTLPTS= option, and if $k_n < k_v$, then the first k_n percentiles are written to the variables that you specify and the remaining $k_v - k_n$ percentiles are written to the variables that have the name of the form P*t*, where *t* is the text representation of the percentile value that is formed by retaining at most PCTLNDEC= digits after the decimal point and replacing the decimal point with an underscore ('_'). For example, assume you specify the options

```
pctlpts=10, 20, 99.3 to 99.5 by 0.1, 99.995
pctlname=pten ptwenty ninenine3-ninenine5
```

Then PROC HPCDM writes the 10th and 20th percentiles to pten and ptwenty variables, respectively; the 99.3rd through 99.5th percentiles to ninenine3, ninenine4, and ninenine5 variables, respectively; and the remaining 99.995th percentile to the P99_995 variable.

If a percentile value in the PCTLPTS= option matches a percentile value implied by one of the predefined percentile statistics and you specify the corresponding *statistic-keyword*, then the variable name that is implied by the *statistic-keyword*<=*variable-name*> specification takes precedence over the name that you specify in the PCTLNAME= option. For example, assume you specify the predefined percentile statistic of P95 as in the OUTSUM statement

```
outsum out=mypctls p95=ninetyfifth
        pctlpts=95 to 99 by 1 pctlname=pct95-pct99;
```

Then the 95th percentile is written to the ninetyfifth variable instead of the pct95 variable that the PCTLNAME= option implies.

PCTLNDEC=*integer-value*

specifies the maximum number of decimal places to use while creating the names of the variables for the percentile values in the PCTLPTS= option. The default value is 3. For example, for a percentile value of 99.9995, PROC HPCDM creates a variable named P99_999 by default, but if you specify PCTLNDEC=4, then the variable is named P99_9995.

The PCTLNDEC= option is used only for percentile values for which you do not specify a name in the PCTLNAME= option.

Note that all variable names in the OUTSUM= data set have a limit of 32 characters. If a name exceeds that limit, then it is truncated to contain only the first 32 characters. For more information about the variables in the OUTSUM= data set, see the section "Output Data Sets" on page 973.

PERFORMANCE Statement

PERFORMANCE *options* **;**

The PERFORMANCE statement defines performance parameters for multithreaded computing, and requests detailed results about the performance characteristics of PROC HPCDM.

For more information about the PERFORMANCE statement, see the section "PERFORMANCE Statement" (Chapter 21, *SAS/STAT User's Guide*).

SEVERITYMODEL Statement

SEVERITYMODEL *severity-model-list* **;**

The SEVERITYMODEL statement specifies one or more severity distribution models that you want to use in simulating a compound distribution sample. The *severity-model-list* is a space-separated list of names of severity models that you would use with PROC SEVERITY's DIST statement. The SEVERITYEST= data set or the SEVERITYSTORE= item store must contain all the severity models in the list. If you specify the SEVERITYEST= data set and you specify a name that does not appear in the _MODEL_ column of the SEVERITYEST= data set, then that name is ignored. Similarly, if you specify the SEVERITYSTORE= item store and a severity model by that name does not appear in the item store, then that name is ignored.

If you specify more than one SEVERITYMODEL statement, only the first one is used.

If you do not specify a SEVERITYMODEL statement, then this is equivalent to specifying all the severity models that appear in the SEVERITYEST= data set or the SEVERITYSTORE= item store.

A compound distribution sample is generated for each of the severity models by compounding that severity model with the frequency model that you specify in the COUNTSTORE= item store or the external frequency model that is encoded by the COUNT= variable that you specify in the EXTERNALCOUNTS statement.

Programming Statements

In PROC HPCDM, you can use a series of programming statements that use variables in the DATA= data set to adjust an individual severity value. The adjusted severity values are aggregated to form a separate adjusted compound distribution sample.

The programming statements are executed for each simulated individual severity value. The observation of the input data set that is used to evaluate the programming statements is determined by the simulation procedure that is described in the section "Simulation Procedure" on page 954.

For more information, see the section "Simulation of Adjusted Compound Distribution Sample" on page 961.

Details: HPCDM Procedure

Specifying Scenario Data in the DATA= Data Set

A scenario represents a state of the world for which you want to estimate the distribution of aggregate losses. The state consists of one or more entities that generate the loss events. For example, an entity might be an individual who has an insurance policy or an organization that has a workers' compensation policy. Each entity has some characteristics of its own and some external factors that affect the frequency with which it generates the losses and the severity of each loss. For example, characteristics of an individual with an automobile insurance policy can include various demographics of the individual and various features of the automobile. Characteristics of an organization with a workers' compensation policy can be the number of employees, revenue, ratio of temporary to permanent employees, and so on. The organization can also be affected by external macroeconomic factors such as GDP and unemployment of the country where the organization operates and factors that affect its industry. You need to quantify and specify all these characteristics as external factors (regressors) when you fit severity and frequency models.

You should specify all the information about a scenario in the DATA= data set that you specify in the PROC HPCDM statement. Each observation in the DATA= data set encodes the characteristics of an entity. For proper simulation of severities, you must specify in the DATA= data set all the characteristics that you use as regressors in the severity scale regression models. When you use the COUNTSTORE= option to specify the frequency model, you must specify in the DATA= data set all the characteristics that you use as regressors in the frequency model in order to properly simulate the counts. All the regressors are expected to have nonmissing values. If any of the regressors have a missing value in an observation, then that observation is ignored.

The information in the DATA= data set is interpreted as follows, based on whether you specify the EXTERNALCOUNTS statement:

- If you do not specify the EXTERNALCOUNTS statement, then all the observations in the data set form a scenario. The observations are used together to compute one random draw from the compound distribution. The total number of draws is equal to the value that you specify in the NREPLICATES= option. The simulation process is described in the section "Simulation with Regressors and No External Counts" on page 955 and illustrated using an example in the section "Illustration of Aggregate Loss Simulation Process" on page 955.
- If you specify the EXTERNALCOUNTS statement, then the DATA= data set is expected to contain multiple replications (draws) of the frequency counts that you simulate externally for a scenario. The DATA= data set must contain the COUNT= variable that you specify in the EXTERNALCOUNTS statement. The replications are identified by the observation number or the ID= variable that you specify in the EXTERNALCOUNTS statement. For each observation in a given replication, the COUNT= variable is expected to contain the count of losses that are generated by the entity associated with that observation. All the observations of a given replication are used together to compute one random draw from the compound distribution. The size of the compound distribution sample is equal to the number of distinct replications that you specify in the DATA= data set, multiplied by the value that you specify in the NREPLICATES= option. The simulation process is described in the section "Simulation with External Counts" on page 957 and illustrated using an example in the section "Illustration of the Simulation Process with External Counts" on page 958.

In both cases, an observation can also contain severity adjustment variables that you can use to adjust the severity of the losses generated by that entity, based on some policy rules. For more information about simulating the adjusted compound distribution sample, see the section "Simulation of Adjusted Compound Distribution Sample" on page 961.

If you specify severity and frequency models that have no regression effects in them and if you do not specify externally simulated counts in the EXTERNALCOUNTS statement, then you do not need to specify the DATA= data set. This case corresponds to a fixed scenario that is represented entirely by the distribution parameters of the models.

Simulation Procedure

PROC HPCDM selects a simulation procedure based on whether you specify external counts or you request that PROC HPCDM simulate the counts, and whether the severity or frequency models contain regression effects. The following sections describe the process for the different scenarios.

Simulation with No Regressors and No External Counts

If you specify severity and frequency models that have no regression effects in them, and if you do not specify externally simulated counts in the EXTERNALCOUNTS statement, then PROC HPCDM uses the following simulation procedure.

The process is described for one severity distribution, *dist*. If you specify multiple severity distributions in the SEVERITYMODEL statement, then the process is repeated for each specified distribution.

The following steps are repeated M times to generate a compound distribution sample of size M, where M is the value that you specify in the NREPLICATES= option or the default value of that option:

1. Use the frequency model that you specify in the COUNTSTORE= option to draw a value N from the count distribution. N is the number of loss events that are expected to occur in the time period that is being simulated. N is adjusted to conform to the upper limit by setting it equal to $\min(N, N_{\max})$, where $N_{\max}$ is either 1,000 or the value that you specify in the MAXCOUNTDRAW= option.

2. Draw N values, X_j $(j = 1, \ldots, N)$, from the severity distribution *dist* with parameters that you specify in the SEVERITYEST= data set or the SEVERITYSTORE= item store.

3. Add the N severity values that are drawn in step 2 to compute one point S from the compound distribution as

$$S = \sum_{j=1}^{N} X_j$$

Note that although it is more common to fit the frequency model with regressors, PROC COUNTREG enables you to fit a frequency model without regressors. If you do not specify any regressors in the MODEL statement of the COUNTREG procedure, then it fits a model that contains only an intercept.

Simulation with Regressors and No External Counts

If the severity or frequency models have regression effects and if you do not specify externally simulated counts in the EXTERNALCOUNTS statement, then you must specify a DATA= data set to provide values of the regression variables, which together represent a scenario for which you want to simulate the CDM. In this case, PROC HPCDM uses the following simulation procedure.

The process is described for one severity distribution. If you specify multiple severity distributions in the SEVERITYMODEL statement, then the process is repeated for each specified distribution.

Note that you are doing scenario analysis when regression effects are present. Let K denote the number of observations that form the scenario. This is the number of observations either in the current BY group or in the entire DATA= data set if you do not specify the BY statement. If $K > 1$, then you are modeling the scenario for a group of entities. If $K = 1$, then you are modeling the scenario for one entity.

The following steps are repeated M times to generate a compound distribution sample of size M, where M is the value that you specify in the NREPLICATES= option or the default value of that option:

1. For each observation k ($k = 1, \ldots, K$), a count N_k is drawn from the frequency model that you specify in the COUNTSTORE= option. The parameters of this model are determined by the frequency regressors in observation k. N_k represents the number of loss events that are expected to be generated by entity k in the time period that is being simulated. N_k is adjusted to conform to the upper limit by setting it equal to $\min(N_k, N_{\max})$, where $N_{\max}$ is either 1,000 or the value that you specify in the MAXCOUNTDRAW= option.

2. Counts from all observations are added to compute $N = \sum_{k=1}^{K} N_k$. N is the total number of loss events that are expected to occur in the time period that is being simulated.

3. N number of random draws are made from the severity distribution, and they are added to generate one point of the compound distribution sample. Each of the N draws uses one of the K observations. If you specify a scale regression model for the severity distribution, then the scale parameter of the severity distribution is determined by the values of the severity regressors in the observation that is chosen for that draw.

If you specify the BY statement, then a separate sample of size M is created for each BY group in the DATA= data set.

Illustration of Aggregate Loss Simulation Process

As an illustration of the simulation process, consider a very simple example of analyzing the distribution of an aggregate loss that is incurred by a set of policyholders of an automobile insurance company in a period of one year. It is postulated that the frequency and severity distributions depend on three variables: Age, Gender (1: female, 2: male), and CarType (1: sedan, 2: sport utility vehicle). So these variables are used as regressors while you fit the count model and severity scale regression model by using the COUNTREG and SEVERITY procedures, respectively. Now, consider that you want to use the fitted frequency and severity models to estimate the distribution of the aggregate loss that is incurred by a set of five policyholders together. Let the characteristics of the five policyholders be encoded in a SAS data set named Work.Scenario that has the following contents:

Obs	age	gender	carType
1	30	2	1
2	25	1	2
3	45	2	2
4	33	1	1
5	50	1	1

The column Obs contains the observation number. It is shown only for the purpose of illustration. It need not be present in the data set. The following PROC HPCDM step simulates the scenario in the Work.Scenario data set:

```
proc hpcdm data=scenario
        severityest=<severity parameter estimates data set>
        countstore=<count model store> nreplicates=<sample size>;
    severitymodel <severity distribution name(s)>;
run;
```

The following process generates a sample from the aggregate loss distribution for the scenario in the Work.Scenario data set:

1. Use the values Age=30, Gender=2, and CarType=1 in the first observation to draw a count from the count distribution. Let that count be 2. Repeat the process for the remaining four observations. Let the counts be as shown in the Count column in the following table:

Obs	age	gender	carType	count
1	30	2	1	2
2	25	1	2	1
3	45	2	2	2
4	33	1	1	3
5	50	1	1	0

   Note that the Count column is shown for illustration only; it is not added as a variable to the DATA= data set.

2. The simulated counts from all the observations are added to get a value of $N = 8$. This means that for this particular sample point, you expect a total of eight loss events in a year from these five policyholders.

3. For the first observation, the scale parameter of the severity distribution is computed by using the values Age=30, Gender=2, and CarType=1. That value of the scale parameter is used together with estimates of the other parameters from the SEVERITYEST= data set to make two draws from the severity distribution. Each of the draws simulates the magnitude of the loss that is expected from the first policyholder. The process is repeated for the remaining four policyholders. The fifth policyholder does not generate any loss event for this particular sample point, so no severity draws are made by using the fifth observation. Let the severity draws, rounded to integers for convenience, be as shown in the _SEV_ column in the following table:

Obs	age	gender	carType	count	_sev_
1	30	2	1	2	350 2100
2	25	1	2	1	4500

```
3        45       2          2          2        700   4300
4        33       1          1          3        600   1500   950
5        50       1          1          0
```

Note that the _SEV_ column is shown for illustration only; it is not added as a variable to the DATA= data set.

PROC HPCDM adds the severity values of the eight draws to compute an aggregate loss value of 15,000. After recording this amount in the sample, the process returns to step 1 to compute the next point in the aggregate loss sample. For example, in the second iteration, the count distribution of each policyholder might generate one loss event for a total of five loss events, and the five severity draws from the severity distributions that govern each of the policyholders might add up to 5,000. Then, the value of 5,000 is recorded as the second point in the aggregate loss sample. The process continues until M aggregate loss sample points are simulated, where the M is the value that you specify in the NREPLICATES= option.

Simulation with External Counts

If you specify externally simulated counts by using the EXTERNALCOUNTS statement, then each replication in the input data set represents the loss events generated by an entity. An entity can be an individual or organization for which you want to estimate the compound distribution. If an entity has any characteristics that are used as external factors (regressors) in developing the severity scale regression model, then you must specify the values of those factors in the DATA= data set. If you specify the ID= variable, then multiple observations for the same replication ID represent different entities in a group for which you are simulating the CDM.

PROC HPCDM uses the following simulation procedure in the presence of externally simulated counts.

The process is described for one severity distribution. If you specify multiple severity distributions in the SEVERITYMODEL statement, then the process is repeated for each specified distribution.

Let there be M distinct replications in the current BY group of the DATA= data set or in the entire DATA= data set if you do not specify the BY statement. A replication is identified by either the observation number or the value of the ID= variable that you specify in the EXTERNALCOUNTS statement.

For each of the M values of the replication identifier, the following steps are executed R times, where R is the value of the NREPLICATES= option or the default value of that option:

1. Compute the total number of losses, N. If there are K ($K \geq 1$) observations for the current value of the replication identifier, then $N = \sum_{k=1}^{K} N_k$, where N_k is the value of the COUNT= variable for observation k, after it is adjusted to conform to the upper limit of either 1,000 or the value that you specify in the MAXCOUNTDRAW= option.

2. N number of random draws are made from the severity distribution, and they are added to generate one point of the compound distribution sample.

This process generates a compound distribution sample of size $M \times R$. If you specify the BY statement, then a separate sample of size $M \times R$ is created for each BY group in the DATA= data set.

Illustration of the Simulation Process with External Counts

In order to illustrate the simulation process, consider the following simple example. In this example, your severity model does not contain any regressors. An example that uses a severity scale regression model is illustrated later. Assume that you have made 10 random draws from an external count model and recorded them in the ExtCount variable of a SAS data set named Work.Counts1 as follows:

```
Obs      extCount
1        3
2        2
3        0
4        1
5        3
6        4
7        1
8        2
9        0
10       5
```

Because the data set does not contain an ID= variable, the observation number that is shown in the Obs column acts as the replicate identifier. The following PROC HPCDM step simulates an aggregate loss sample by using the Work.Counts1 data set:

```
proc hpcdm data=work.counts1 nreplicates=5
        severityest=<severity parameter estimates data set>;
    severitymodel <severity distribution name(s)>;
    externalcounts count=extCount;
run;
```

The simulation process works as follows:

1. For the first replication, which is associated with the first observation, three severity values are drawn from the severity distribution by using the parameter estimates that you specify in the SEVERITYEST= data set. If the severity values are 150, 500, and 320, then their sum of 970 is recorded as the first point of the aggregate loss sample. Because the value of the NREPLICATES= option is 5, this process of drawing three severity values and adding them to form a point of the aggregate loss sample is repeated four more times to generate a total of five sample points that correspond to the first observation.
2. For the second replication, two severity values are drawn from the severity distribution. If the severity values are 450 and 100, then their sum of 550 is recorded as a point of the aggregate loss sample. This process of drawing two severity values and adding them to form a point of the aggregate loss sample is repeated four more times to generate a total of five sample points that correspond to the second observation.
3. The process continues until all the replications, which are observations in this case, are exhausted.

The process results in an aggregate loss sample of size 50, which is equal to the number of replications in the data set (10) multiplied by the value of the NREPLICATES= option (5).

Now, consider an example in which the severity models in the SEVERITYEST= data set are scale regression models. In this case, the severity distribution that is used for drawing the severity value is decided by the values of regressors in the observation that is being processed. Consider that you want to simulate the aggregate loss that is incurred by one policyholder and you have recorded, in the ExtCount variable, the results of 10 random draws from an external count model. The DATA= data set has the following contents:

Obs	age	gender	carType	extCount
1	30	2	1	5
2	30	2	1	2
3	30	2	1	0
4	30	2	1	1
5	30	2	1	3
6	30	2	1	4
7	30	2	1	1
8	30	2	1	2
9	30	2	1	0
10	30	2	1	5

The simulation process in this case is the same as the process in the previous case of no regressors, except that the severity distribution that is used for drawing the severity values has a scale parameter that is determined by the values of the regressors Age, Gender, and CarType in the observation that is being processed. In this particular example, all observations have the same value for all regressors, indicating that you are modeling a scenario in which the characteristics of the policyholder do not change during the time for which you have simulated the number of events. You can also model a scenario in which the characteristics of the policyholder change by recording those changes in the values of the appropriate regressors.

Extending this example further, consider that you want to analyze the distribution of the aggregate loss that is incurred by a group of policyholders, as in the example in the section "Illustration of Aggregate Loss Simulation Process" on page 955. Let the Work.Counts2 data set record multiple replications of the number of losses that might be generated by each policyholder. The contents of the Work.Counts2 data set are as follows:

Obs	replicateId	age	gender	carType	extCount
1	1	30	2	1	2
2	1	25	1	2	1
3	1	45	2	2	3
4	1	33	1	1	5
5	1	50	1	1	1
6	2	30	2	1	3
7	2	25	1	2	2
8	1	45	2	2	0
9	2	33	1	1	4
10	2	50	1	1	1

The ReplicateId variable records the identifier for the replication. Each replication contains multiple observations, such that each observation represents one of the policyholders that you are analyzing. For simplicity, only the first two replications are shown here.

The following PROC HPCDM step simulates an aggregate loss sample by using the Work.Counts2 data set:

```
proc hpcdm data=work.counts2 nreplicates=3
        severityest=<severity parameter estimates data set>;
    severitymodel <severity distribution name(s)>;
    distby replicateId;
    externalcounts count=extCount id=replicateId;
    output out=aggloss samplevar=totalLoss;
run;
```

When you specify an ID= variable in the EXTERNALCOUNTS statement, you must specify the same ID= variable in the DISTBY statement. Further, the DATA= set must be sorted in ascending order of the ID= variable values.

The simulation process works as follows:

1. First, the five observations of the first replication (ReplicateId=1 are analyzed. For the first observation (Obs=1), the scale parameter of the severity distribution is computed by using the values Age=30, Gender=2, and CarType=1. That value of the scale parameter is used together with estimates of the other parameters from the SEVERITYEST= data set to make two draws from the severity distribution. Next, the regressor values of the second observation are used to compute the scale parameter of the severity distribution, which is used to make one severity draw. The process continues such that the regressor values in the third, fourth, and fifth observations are used to decide the severity distribution to make three, five, and one draws from, respectively. Let the severity values that are drawn from the observations of this replication be as shown in the _SEV_ column in the following table, where the _SEV_ column is shown for illustration only; it is not added as a variable to the DATA= data set:

Obs	replicateId	age	gender	carType	extCount	_sev_
1	1	30	2	1	2	700 500
2	1	25	1	2	1	5000
3	1	45	2	2	3	900 1400 300
4	1	33	1	1	5	350 2000 150 800 600
5	1	50	1	1	1	250

   The values of all 12 severity draws are added to compute and record the value of 12,950 as the first point of the aggregate loss sample. Because you specify NREPLICATES=3 in the PROC HPCDM step, this process of making 12 severity draws from the respective observations is repeated two more times to generate a total of three sample points for the first replication.

2. The five observations of the second replication (ReplicateId=2) are analyzed next to draw three, two, four, and one severity values from the severity distributions, with scale parameters that are decided by the regressor values in the sixth, seventh, ninth, and tenth observations, respectively. The 10 severity values are added to form a point of the aggregate loss sample. This process of making 10 severity draws from the respective observations is repeated two more times to generate a total of three sample points for the second replication.

If your Work.Counts2 data set contains 10,000 distinct values of ReplicateId, then 30,000 observations are written to the Work.AggLoss data set that you specify in the OUTPUT statement of the preceding PROC HPCDM step. Because you specify SAMPLEVAR=TotalLoss in the OUTPUT statement, the aggregate loss sample is available in the TotalLoss column of the Work.AggLoss data set.

Simulation of Adjusted Compound Distribution Sample

If you specify programming statements that adjust the severity value, then a separate adjusted compound distribution sample is also generated.

Your programming statements are expected to implement an adjustment function f that uses the unadjusted severity value, X_j, to compute and return an adjusted severity value, X_j^a. To compute X_j^a, you might also use the sum of unadjusted severity values and the sum of adjusted severity values.

Formally, if N denotes the number of loss events that are to be simulated for the current replication of the simulation process, then for the severity draw, X_j, of the jth loss event ($j = 1, \ldots, N$), the adjusted severity value is

$$X_j^a = f(X_j, S_{j-1}, S_{j-1}^a)$$

where $S_{j-1} = \sum_{l=1}^{j-1} X_l$ is the aggregate unadjusted loss before X_j is generated and $S_{j-1}^a = \sum_{l=1}^{j-1} X_l^a$ is the aggregate adjusted loss before X_j is generated. The initial values of both types of aggregate losses are set to 0. In other words, $S_0 = 0$ and $S_0^a = 0$.

The aggregate adjusted loss for the replication is S_N^a, which is denoted by S^a for simplicity, and is defined as

$$S^a = \sum_{j=1}^{N} X_j^a$$

In your programming statements that implement f, you can use the following keywords as placeholders for the input arguments of the function f:

SEV
indicates the placeholder for X_j, the unadjusted severity value. PROC HPCDM generates this value as described in the section "Simulation with No Regressors and No External Counts" on page 954 (step 2) or the section "Simulation with Regressors and No External Counts" on page 955 (step 3). PROC HPCDM supplies this value to your program.

CUMSEV
indicates the placeholder for S_{j-1}, the sum of unadjusted severity values that PROC HPCDM generates before X_j is generated. PROC HPCDM supplies this value to your program.

CUMADJSEV
indicates the placeholder for S_{j-1}^a, the sum of adjusted severity values that are computed by your programming statements before X_j is generated and adjusted. PROC HPCDM supplies this value to your program.

In your programming statements, you must assign the value of X_j^a, the output of function f, to a symbol that you specify in the ADJUSTEDSEVERITY= option in the PROC HPCDM statement. PROC HPCDM uses the final assigned value of this symbol as the value of X_j^a.

You can use most DATA step statements and functions in your program. The DATA step file and the data set I/O statements (for example, INPUT, FILE, SET, and MERGE) are not available. However, some functionality of the PUT statement is supported. For more information, see the section "PROC FCMP and DATA Step Differences" in *Base SAS Procedures Guide*.

The simulation process that generates the aggregate adjusted loss sample is identical to the process that is described in the section "Simulation with Regressors and No External Counts" on page 955 or the section "Simulation with External Counts" on page 957, except that after making each of the N severity draws, PROC HPCDM executes your severity adjustment programming statements to compute the adjusted severity (X_j^a). All the N adjusted severity values are added to compute S^a, which forms a point of the aggregate adjusted loss sample. The process is illustrated using an example in the section "Illustration of Aggregate Adjusted Loss Simulation Process" on page 964.

Using Severity Adjustment Variables

If you do not specify the DATA= data set, then your ability to adjust the severity value is limited, because you can use only the current severity draw, sums of unadjusted and adjusted severity draws that are made before the current draw, and some constant numbers to encode your adjustment policy. That is sufficient if you want to estimate the distribution of aggregate adjusted loss for only one entity. However, if you are simulating a scenario that contains more than one entity, then it might be more useful if the adjustment policy depends on factors that are specific to each entity that you are simulating. To do that, you must specify the DATA= data set and encode such factors as *adjustment variables* in the DATA= data set. Let A denote the set of values of the adjustment variables. Then, the form of the adjustment function f that computes the adjusted severity value becomes

$$X_j^a = f(X_j, S_{j-1}, S_{j-1}^a, A)$$

PROC HPCDM reads the values of adjustment variables from the DATA= data set and supplies the set of those values (A) to your severity adjustment program. For an invocation of f with an unadjusted severity value of X_j, the values in set A are read from the same observation that is used to simulate X_j.

All adjustment variables that you use in your program must be present in the DATA= data set. You must not use any keyword for a placeholder symbol as a name of any variable in the DATA= data set, whether the variable is a severity adjustment variable or a regressor in the frequency or severity model. Further, the following restrictions apply to the adjustment variables:

- You can use only numeric-valued variables in PROC HPCDM programming statements. This restriction also implies that you cannot use SAS functions or call routines that require character-valued arguments, unless you pass those arguments as constant (literal) strings or characters.
- You cannot use functions that create lagged versions of a variable in PROC HPCDM programming statements. If you need lagged versions, then you can use a DATA step before the PROC HPCDM step to add those versions to the input data set.

The use of adjustment variables is illustrated using an example in the section "Illustration of Aggregate Adjusted Loss Simulation Process" on page 964.

Aggregate Adjusted Loss Simulation for a Multi-entity Scenario

If you are simulating a scenario that consists of multiple entities, then you can use some additional pieces of information in your severity adjustment program. Let the scenario consist of K entities and let N_k denote the number of loss events that are incurred by kth entity ($k = 1, \ldots, K$) in the current iteration of the simulation process. Each value of N_k is adjusted to conform to the upper limit of either 1,000 or the value that you

specify in the MAXCOUNTDRAW= option. The total number of severity draws that need to be made is $N = \sum_{k=1}^{K} N_k$. The aggregate adjusted loss is now defined as

$$S^a = \sum_{k=1}^{K} \sum_{j=1}^{N_k} X^a_{k,j}$$

where $X^a_{k,j}$ is an adjusted severity value of the jth draw ($j = 1, \ldots, N_k$) for the kth entity, and the form of the adjustment function f that computes $X^a_{k,j}$ is

$$X^a_{k,j} = f(X_{k,j}, S_{k,j-1}, S^a_{k,j-1}, S_{n-1}, S^a_{n-1}, A)$$

where $X_{k,j}$ is the value of the jth draw of unadjusted severity for the kth entity. $S_{k,j-1} = \sum_{l=1}^{j-1} X_{k,l}$ and $S^a_{k,j-1} = \sum_{l=1}^{j-1} X^a_{k,l}$ are the aggregate unadjusted loss and the aggregate adjusted loss, respectively, for the kth entity before $X_{k,j}$ is generated. The index n ($n = 1, \ldots, N$) keeps track of the total number of severity draws, across all entities, that are made before $X_{k,j}$ is generated. So $S_{n-1} = \sum_{l=1}^{n-1} X_l$ and $S^a_{n-1} = \sum_{l=1}^{n-1} X^a_l$ are the aggregate unadjusted loss and aggregate adjusted loss, respectively, for all the entities that are processed before $X_{k,j}$ is generated. Note that S_{n-1} and S^a_{n-1} include the $j - 1$ draws that are made for the kth entity before $X_{k,j}$ is generated.

The initial values of all types of aggregate losses are set to 0. In other words, $S_0 = 0$, $S^a_0 = 0$, and for all values of k, $S_{k,0} = 0$ and $S^a_{k,0} = 0$.

PROC HPCDM uses the final value that you assign to the ADJUSTEDSEVERITY= symbol in your programming statements as the value of $X^a_{k,j}$.

In your severity adjustment program, you can use the following two additional placeholder keywords:

CUMSEVFOROBS
: indicates the placeholder for $S_{k,j-1}$, which is the total loss that is incurred by the kth entity before the current loss event. PROC HPCDM supplies this value to your program.

CUMADJSEVFOROBS
: indicates the placeholder for $S^a_{k,j-1}$, which is the total adjusted loss that is incurred by the kth entity before the current loss event. PROC HPCDM supplies this value to your program.

The previously described placeholder symbols _CUMSEV_ and _CUMADJSEV_ represent S_{n-1} and S^a_{n-1}, respectively. If you have only one entity in the scenario ($K = 1$), then the values of _CUMSEVFOROBS_ and _CUMADJSEVFOROBS_ are identical to the values of _CUMSEV_ and _CUMADJSEV_, respectively.

There is one caveat when a scenario consists of more than one entity ($K > 1$) and when you use any of the symbols for cumulative severity values (_CUMSEV_, _CUMADJSEV_, _CUMSEVFOROBS_, or _CUMADJSEVFOROBS_) in your programming statements. In this case, to make the simulation realistic, it is important to randomize the order of N severity draws across K entities. For more information, see the section "Randomizing the Order of Severity Draws across Observations of a Scenario" on page 966.

Illustration of Aggregate Adjusted Loss Simulation Process

This section continues the example in the section "Simulation with Regressors and No External Counts" on page 955 to illustrate the simulation of aggregate adjusted loss.

Recall that the earlier example simulates a scenario that consists of five policyholders. Assume that you want to compute the distribution of the aggregate amount paid to all the policyholders in a year, where the payment for each loss is decided by a deductible and a per-payment limit. To begin with, you must record the deductible and limit information in the input DATA= data set. The following table shows the DATA= data set from the earlier example, extended to include two variables, Deductible and Limit:

Obs	age	gender	carType	deductible	limit
1	30	2	1	250	5000
2	25	1	2	500	3000
3	45	2	2	100	2000
4	33	1	1	500	5000
5	50	1	1	200	2000

The variables Deductible and Limit are referred to as severity adjustment variables, because you need to use them to compute the adjusted severity. Let AmountPaid represent the value of adjusted severity that you are interested in. Further, let the following SAS programming statements encode your logic of computing the value of AmountPaid:

```
amountPaid = MAX(_sev_ - deductible, 0);
amountPaid = MIN(amountPaid, MAX(limit - _cumadjsevforobs_, 0));
```

PROC HPCDM supplies your program with values of the placeholder symbols _SEV_ and _CUMADJSEVFOROBS_, which represent the value of the current unadjusted severity draw and the sum of adjusted severity values from the previous draws, respectively, for the observation that is being processed. The use of _CUMADJSEVFOROBS_ helps you ensure that the payment that is made to a given policyholder in a year does not exceed the limit that is recorded in the Limit variable.

In order to simulate a sample for the aggregate of AmountPaid, you need to submit a PROC HPCDM step whose structure is like the following:

```
proc hpcdm data=<data set name> adjustedseverity=amountPaid
       severityest=<severity parameter estimates data set>
       countstore=<count model store>;
    severitymodel <severity distribution name(s)>;

    amountPaid = MAX(_sev_ - deductible, 0);
    amountPaid = MIN(amountPaid, MAX(limit - _cumadjsevforobs_, 0));
run;
```

The simulation process of one replication that generates one point of the aggregate loss sample and the corresponding point of the aggregate adjusted loss sample is as follows:

1. Use the values Age=30, Gender=2, and CarType=1 in the first observation to draw a count from the count distribution. Let that count be 3. Repeat the process for the remaining four observations. Let the counts be as shown in the Count column in the following table:

Obs	age	gender	carType	deductible	limit	count
1	30	2	1	250	5000	2
2	25	1	2	500	3000	1
3	45	2	2	100	2000	2
4	33	1	1	500	5000	3
5	50	1	1	200	2000	0

Note that the Count column is shown for illustration only; it is not added as a variable to the DATA= data set.

2. The simulated counts from all the observations are added to get a value of $N = 8$. This means that for this particular replication, you expect a total of eight loss events in a year from these five policyholders.

3. For the first observation, the scale parameter of the severity distribution is computed by using the values Age=30, Gender=2, and CarType=1. That value of the scale parameter is used together with estimates of the other parameters from the SEVERITYEST= data set to make two draws from the severity distribution. The process is repeated for the remaining four policyholders. The fifth policyholder does not generate any loss event for this particular replication, so no severity draws are made by using the fifth observation. Let the severity draws, rounded to integers for convenience, be as shown in the _SEV_ column in the following table, where the _SEV_ column is shown for illustration only; it is not added as a variable to the DATA= data set:

Obs	age	gender	carType	deductible	limit	count	_sev_		
1	30	2	1	250	5000	2	350	2100	
2	25	1	2	500	3000	1	4500		
3	45	2	2	100	2000	2	700	4300	
4	33	1	1	200	5000	3	600	1500	950
5	50	1	1	200	2000	0			

The sample point for the aggregate unadjusted loss is computed by adding the severity values of eight draws, which gives an aggregate loss value of 15,000. The unadjusted aggregate loss is also referred to as the ground-up loss.

For each of the severity draws, your severity adjustment programming statements are executed to compute the adjusted severity, which is the value of AmountPaid in this case. For the draws in the preceding table, the values of AmountPaid are as follows:

Obs	deductible	limit	_sev_	_cumadjsevforobs_	amountPaid
1	250	5000	350	0	100
1	250	5000	2100	100	1850
2	500	3000	4500	0	3000
3	100	2000	700	0	600
3	100	2000	4300	600	1400
4	200	5000	600	0	400
4	200	5000	1500	400	1300
4	200	5000	950	1700	750

The adjusted severity values are added to compute the cumulative payment value of 9,400, which forms the first sample point for the aggregate adjusted loss.

After recording the aggregate unadjusted and aggregate adjusted loss values in their respective samples, the process returns to step 1 to compute the next sample point unless the specified number of sample points have been simulated.

In this particular example, you can verify that the order in which the 8 loss events are simulated does not affect the aggregate adjusted loss. As a simple example, consider the following order of draws that is different from the consecutive order that was used in the preceding table:

Obs	deductible	limit	_sev_	_cumadjsevforobs_	amountPaid
4	200	5000	600	0	400
3	100	2000	4300	0	2000
1	250	5000	350	0	100
3	100	2000	700	2000	0
4	200	5000	950	400	750
1	250	5000	2100	100	1850
2	500	3000	4500	0	3000
4	200	5000	1500	1150	1300

Although the payments that are made for individual loss events differ, the aggregate adjusted loss is still 9,400.

However, in general, when you use a cumulative severity value such as _CUMADJSEVFOROBS_ in your program, the order in which the draws are processed affects the final value of aggregate adjusted loss. For more information, see the sections "Randomizing the Order of Severity Draws across Observations of a Scenario" on page 966 and "Illustration of the Need to Randomize the Order of Severity Draws" on page 967.

Randomizing the Order of Severity Draws across Observations of a Scenario

If you specify a scenario that consists of a group of more than one entity, then it is assumed that each entity generates its loss events independently from other entities. In other words, the time at which the loss event of one entity is generated or recorded is independent of the time at which the loss event of another entity is generated or recorded. If entity k generates N_k loss events, where N_k is adjusted to conform to the upper limit of either 1,000 or the value that you specify in the MAXCOUNTDRAW= option, then the total number of loss events for a group of K entities is $N = \sum_{k=1}^{K} N_k$. To simulate the aggregate loss for this group, N severity draws are made and aggregated to compute one point of the compound distribution sample. However, to honor the assumption of independence among entities, the order of those N severity draws must be randomized across K entities such that no entity is preferred over another.

The K entities are represented by K observations of the scenario in the DATA= data set. If you specify external counts, the K observations correspond to the observations that have the same replication identifier value. If you do not specify the external counts, then the K observations correspond to all the observations in the BY group or in the entire DATA= set if you do not specify the BY statement.

The randomization process over K observations is implemented as follows. First, one of the K observations is chosen at random and one severity value is drawn from the severity distribution implied by that observation, then another observation is chosen at random and one severity value is drawn from its implied severity distribution, and so on. In each step, the total number of events that are simulated for the selected observation k is incremented by 1. When all N_k events for an observation k are simulated, observation k is retired and the process continues with the remaining observations until a total of N severity draws are made. Let $k(j)$

denote a function that implements this randomization by returning an observation k ($k = 1, \ldots, K$) for the jth draw ($j = 1, \ldots, N$). The aggregate loss computation can then be formally written as

$$S = \sum_{j=1}^{N} X_{k(j)}$$

where $X_{k(j)}$ denotes the severity value that is drawn by using observation $k(j)$.

If you do not specify a scale regression model for severity, then all severity values are drawn from the same severity distribution. However, if you specify a scale regression model for severity, then the severity draw is made from the severity distribution that is determined by the values of regressors in observation k. In particular, the scale parameter of the distribution depends on the values of regressors in observation k. If $R(l)$ denotes the scale regression model for observation l and $X_{R(l)}$ denotes the severity value drawn from scale regression model $R(l)$, then the aggregate loss computation can be formally written as

$$S = \sum_{j=1}^{N} X_{R(k(j))}$$

This randomization process is especially important in the context of simulating an adjusted compound distribution sample when your severity adjustment program uses the aggregate adjusted severity observed so far to adjust the next severity value. For an illustration of the need to randomize in such cases, see the next section.

Illustration of the Need to Randomize the Order of Severity Draws

This section uses the example of the section "Illustration of Aggregate Adjusted Loss Simulation Process" on page 964, but with the following PROC HPCDM step:

```
proc hpcdm data=<data set name> adjustedseverity=amountPaid
       severityest=<severity parameter estimates data set>
       countstore=<count model store>;
    severitymodel <severity distribution name(s)>;

    if (_cumadjsev_ > 15000) then
        amountPaid = 0;
    else do;
        penaltyFactor = MIN(3, 15000/(15000 - _cumadjsev_));
        amountPaid = MAX(0, _sev_ - deductible * penaltyFactor);
    end;
run;
```

The severity adjustment statements in the preceding steps compute the value of AmountPaid by using the following provisions in the insurance policy:

- There is a limit of 15,000 on the total amount that can be paid in a year to the group of policyholders that is being simulated. The amount of payment for each loss event depends on the total amount of payments before that loss event.
- The penalty for incurring more losses is imposed in the form of an increased deductible. In particular, the deductible is increased by the ratio of the maximum cumulative payment (15,000) to the amount that remains available to pay for future losses in the year. The factor by which the deductible can be raised has a limit of three.

This example illustrates only step 3 of the simulation process, where randomization is done. It assumes that step 2 of the simulation process is identical to the step 2 in the example in the section "Illustration of Aggregate Adjusted Loss Simulation Process" on page 964. At the beginning of step 3, let the severity draws from all the observations be as shown in the _SEV_ column in the following table:

Obs	age	gender	carType	deductible	count	_sev_		
1	30	2	1	250	2	350	2100	
2	25	1	2	500	1	4500		
3	45	2	2	100	2	700	4300	
4	33	1	1	200	3	600	1500	950
5	50	1	1	200	0			

If the order of these eight draws is not randomized, then all the severity draws for the first observation are adjusted before all the severity draws of the second observation, and so on. The execution of the severity adjustment program leads to the following sequence of values for AmountPaid:

Obs	deductible	_sev_	_cumadjsev_	penaltyFactor	amountPaid
1	250	350	0	1	100
1	250	2100	100	1.0067	1848.32
2	500	4500	1948.32	1.1493	3925.36
3	100	700	5873.68	1.6436	535.64
3	100	4300	6409.32	1.7461	4125.39
4	200	600	10534.72	3	0
4	200	1500	10534.72	3	900
4	200	950	11434.72	3	350

The preceding sequence of simulating loss events results in a cumulative payment of 11,784.72.

If the sequence of draws is randomized over observations, then the computation of the cumulative payment might proceed as follows for one instance of randomization:

Obs	deductible	_sev_	_cumadjsev_	penaltyFactor	amountPaid
2	500	4500	0	1	4000
1	250	350	4000	1.3636	9.09
3	100	700	4009.09	1.3648	563.52
4	200	950	4572.61	1.4385	662.30
4	200	1500	5234.91	1.5361	1192.78
1	250	2100	6427.69	1.7498	1662.54
4	200	600	8090.24	2.1708	165.83
3	100	4300	8256.07	2.2242	4077.58

In this example, a policyholder is identified by the value in the Obs column. As the table indicates, PROC HPCDM randomizes the order of loss events not only across policyholders but also across the loss events that a given policyholder incurs. The particular sequence of loss events that is shown in the table results in a cumulative payment of 12,333.65. This differs from the cumulative payment that results from the previously considered nonrandomized sequence of loss events, which tends to penalize the fourth policyholder by always processing her payments after all other payments, with a possibility of underestimating the total paid amount. This comparison not only illustrates that the order of randomization affects the aggregate adjusted loss sample but also corroborates the arguments about the importance of order randomization that are made at the beginning of the section "Randomizing the Order of Severity Draws across Observations of a Scenario" on page 966.

Parameter Perturbation Analysis

It is important to realize that most of the parameters of the frequency and severity models are estimated and there is uncertainty associated with the parameter estimates. Any compound distribution estimate that is computed by using these uncertain parameter estimates is inherently uncertain. The aggregate loss sample that is simulated by using the mean estimates of the parameters is just one possible sample from the compound distribution. If information about parameter uncertainty is available, then it is recommended that you conduct parameter perturbation analysis that generates multiple samples of the compound distribution, in which each sample is simulated by using a set of perturbed parameter estimates. You can use the NPERTURBEDSAMPLES= option in the PROC HPCDM statement to specify the number of perturbed samples to be generated. The set of perturbed parameter estimates is created by making a random draw of the parameter values from their joint probability distribution. If you specify NPERTURBEDSAMPLES=*P*, then PROC HPCDM creates *P* sets of perturbed parameters and each set is used to simulate a full aggregate sample. The summary analysis of *P* such aggregate loss samples results in a set of *P* estimates for each summary statistic and percentile of the compound distribution. The mean and standard deviation of this set of *P* estimates quantify the uncertainty that is associated with the compound distribution.

The parameter uncertainty information is available in the form of either the variance-covariance matrix of the parameter estimates or standard errors of the parameters estimates. If the variance-covariance matrix is available and is positive definite, then PROC HPCDM assumes that the joint probability distribution of the parameter estimates is a multivariate normal distribution, $\mathcal{N}(\boldsymbol{\mu}, \Sigma)$, where the mean vector $\boldsymbol{\mu}$ is the set of point parameter estimates and Σ is the variance-covariance matrix. If the variance-covariance matrix is not available or is not positive definite, then PROC HPCDM assumes that each parameter has a univariate normal distribution, $\mathcal{N}(\mu, \sigma^2)$, where μ is the point estimate of the parameter and σ is the standard error of the parameter estimate.

To make the random draws from the multivariate normal distribution of all parameters or the univariate distributions of individual parameters, PROC HPCDM uses a pseudorandom number generator (PRNG) that is controlled by the PERTURBMETHOD= option as follows:

- PERTURBMETHOD=ASYNC is the legacy method that releases prior to SAS/ETS 15.1 used and is the default for the current release. This method allows each thread to use a different PRNG for perturbation, which in fact is the same PRNG that the thread uses for making random draws from the severity or frequency distributions. Using different PRNGs and interleaving perturbation-related random draws with severity and count random draws causes each thread to use a different set of perturbed parameters while generating a subset of the same perturbed sample; in turn, this leads to a perturbed sample that is a heterogeneous collection of smaller perturbed samples, each of which is generated from a different compound distribution model.
- PERTURBMETHOD=SYNC method is the recommended method because it uses a single PRNG to perturb the parameters and synchronizes the set of perturbed parameters across all threads. This makes each perturbed sample a homogeneous sample that corresponds to a single compound distribution model.

If you specify the severity models by using the SEVERITYEST= data set, then the point parameter estimates are expected to be available in the SEVERITYEST= data set in observations for which _TYPE_='EST', the standard errors are expected to be available in the SEVERITYEST= data set in observations for which _TYPE_='STDERR', and the variance-covariance matrix is expected to be available in the SEVERITYEST=

data set in observations for which _TYPE_='COV'. If you use the SEVERITY procedure to create the SEVERITYEST= data set, then you need to specify the COVOUT option in the PROC SEVERITY statement to make the variance-covariance estimates available in the SEVERITYEST= data set.

If you specify the severity models by using the SEVERITYSTORE= item store, then you need to specify the OUTSTORE= option in the PROC SEVERITY statement to create that item store, which includes the point parameter estimates and standard errors by default. In addition, you need to specify the COVOUT option in the PROC SEVERITY statement to make the variance-covariance estimates available in the SEVERITYSTORE= item store.

For the frequency model, you must use the COUNTREG procedure to create the COUNTSTORE= item store, which always contains the point estimates, standard errors, and variance-covariance matrix of the parameters.

If you specify the ADJUSTEDSEVERITY= option in the PROC HPCDM statement, then a separate perturbation analysis is conducted for the distribution of the aggregate adjusted loss.

Descriptive Statistics

This section provides computational details for the descriptive statistics that are computed for each aggregate loss sample. You can also save these statistics in an OUTSUM= data set by specifying appropriate keywords in the OUTSUM statement.

This section gives specific details about the moment statistics. For more information about the methods of computing percentile statistics, see the description of the PCTLDEF= option in the UNIVARIATE procedure in the *Base SAS Procedures Guide: Statistical Procedures*.

Standard algorithms (Fisher 1973) are used to compute the moment statistics. The computational methods that the HPCDM procedure uses are consistent with those that other SAS procedures use for calculating descriptive statistics.

Mean

The sample mean is calculated as

$$\bar{y} = \frac{\sum_{i=1}^{n} y_i}{n}$$

where n is the size of the generated aggregate loss sample and y_i is the ith value of the aggregate loss.

Standard Deviation

The standard deviation is calculated as

$$s = \sqrt{\frac{1}{d}\sum_{i=1}^{n}(y_i - \bar{y})^2}$$

where n is the size of the generated aggregate loss sample, y_i is the ith value of the aggregate loss, $\bar{y}$ is the sample mean, and d is the divisor controlled by the VARDEF= option in the PROC HPCDM statement:

$$d = \begin{cases} n-1 & \text{if VARDEF=DF (default)} \\ n & \text{if VARDEF=N} \end{cases}$$

Skewness

The sample skewness, which measures the tendency of the deviations to be larger in one direction than in the other, is calculated as

$$\frac{1}{d_s}\sum_{i=1}^{n}\left(\frac{y_i-\bar{y}}{s}\right)^3$$

where n is the size of the generated aggregate loss sample, y_i is the ith value of the aggregate loss, $\bar{y}$ is the sample mean, s is the sample standard deviation, and d_s is the divisor controlled by the VARDEF= option in the PROC HPCDM statement:

$$d_s = \begin{cases} \frac{(n-1)(n-2)}{n} & \text{if VARDEF=DF (default)} \\ n & \text{if VARDEF=N} \end{cases}$$

If VARDEF=DF, then n must be greater than 2.

The sample skewness can be positive or negative; it measures the asymmetry of the data distribution and estimates the theoretical skewness $\sqrt{\beta_1} = \mu_3\mu_2^{-\frac{3}{2}}$, where μ_2 and μ_3 are the second and third central moments. Observations that are normally distributed should have a skewness near zero.

Kurtosis

The sample kurtosis, which measures the heaviness of tails, is calculated as in Table 16.2 depending on the value that you specify in the VARDEF= option.

Table 16.2 Formulas for Kurtosis

VARDEF= Value	Formula
DF (default)	$\frac{n(n+1)}{(n-1)(n-2)(n-3)}\sum_{i=1}^{n}\left(\frac{y_i-\bar{y}}{s}\right)^4 - \frac{3(n-1)^2}{(n-2)(n-3)}$
N	$\frac{1}{n}\sum_{i=1}^{n}\left(\frac{y_i-\bar{y}}{s}\right)^4 - 3$

In these formulas, n is the size of the generated aggregate loss sample, y_i is the ith value of the aggregate loss, $\bar{y}$ is the sample mean, and s is the sample standard deviation. If VARDEF=DF, then n must be greater than 3.

The sample kurtosis measures the heaviness of the tails of the data distribution. It estimates the adjusted theoretical kurtosis denoted as $\beta_2 - 3$, where $\beta_2 = \frac{\mu_4}{\mu_2{}^2}$ and μ_4 is the fourth central moment. Observations that are normally distributed should have a kurtosis near zero.

Input Specification

PROC HPCDM accepts the DATA= and SEVERITYEST= data sets and the COUNTSTORE= and SEVERITYSTORE= item stores as input. This section details the information that they are expected to contain.

DATA= Data Set

If you specify the BY statement, then the DATA= data set must contain all the BY variables that you specify in the BY statement and the data set must be sorted by the BY variables unless the BY statement includes the NOTSORTED option.

If the severity models in the SEVERITYEST= data set or the SEVERITYSTORE= item store contain any scale regressors, then all those regressors must be present in the DATA= data set.

If you specify the programming statements to compute an aggregate adjusted loss, and if your specified ADJUSTEDSEVERITY= symbol depends on severity adjustment variables, then the DATA= data set must contain all such variables.

The rest of the contents of the DATA= data set depends on whether you specify the EXTERNALCOUNTS statement. If you specify the EXTERNALCOUNTS statement, then the DATA= data set is expected to contain the COUNT= and ID= variables that you specify in the EXTERNALCOUNTS statement. If you do not specify the EXTERNALCOUNTS statement, then the DATA= data set must contain all the regressors, including zero model regressors, that are present in the count model that the COUNTSTORE= item store contains.

You do not need to specify the DATA= data set if *all* the following conditions are true:

- You do not specify the BY statement.
- You specify the severity models such that none of them are scale regression models.
- You do not specify the EXTERNALCOUNTS statement.
- You specify a COUNTSTORE= item store such that the count model contains no count regressors.
- Your severity adjustment programming statements, if you specify any, do not use any external input.

If you specify the BY statement, then PROC HPCDM analyzes only the BY groups that are present in the input source of the severity and count models. If neither the severity models nor the count models contain regression effects, then the DATA= data set must contain BY variables and one row for each BY group that you want PROC HPCDM to analyze.

SEVERITYEST= Data Set

The SEVERITYEST= data set is expected to contain the parameter estimates of the severity models. This is a required data set; you must specify it whenever you use PROC HPCDM.

The SEVERITYEST= data set must have the same format as the OUTEST= data set that is created by the SEVERITY procedure. For more information, see the description of the OUTEST= data set in the SEVERITY procedure in the *SAS/ETS User's Guide*.

If you specify the BY statement, then the SEVERITYEST= data set must contain all the BY variables that you specify in the BY statement. If you do not specify the NOTSORTED option in the BY statement, then the SEVERITYEST= data set must be sorted by the BY variables.

SEVERITYSTORE= Item Store

The SEVERITYSTORE= item store is expected to be created by using the OUTSTORE= option in a PROC SEVERITY statement. For more information, see the description of the OUTSTORE= option in the SEVERITY procedure in the *SAS/ETS User's Guide*.

You must specify this item store when you do not specify the SEVERITYEST= data set. Also, if your severity model is a scale regression model that contains classification or interaction effects, then you cannot use the SEVERITYEST= data set. You must specify such severity models by specifying the SEVERITYSTORE= item store.

If you specify the BY statement, then the SEVERITYSTORE= item store must have been created by using a PROC SEVERITY step that uses an identical BY statement.

COUNTSTORE= Item Store

The COUNTSTORE= item store is expected to be created by using the STORE statement in the COUNTREG procedure. You must specify the COUNTSTORE= item store when you do not specify the EXTERNAL-COUNTS statement. For more information, see the description of the STORE statement in the COUNTREG procedure in the *SAS/ETS User's Guide*.

If you specify the BY statement, then the COUNTSTORE= item store must have been created by using a PROC COUNTREG step that uses an identical BY statement.

Output Data Sets

PROC HPCDM writes the output data sets that you specify in the OUT= option of the OUTPUT and OUTSUM statements. The contents of these output data sets are described in the sections "OUTSAMPLE= Data Set" on page 973 and "OUTSUM= Data Set" on page 974, respectively.

OUTSAMPLE= Data Set

The OUTSAMPLE= data set records the full sample of the aggregate loss and aggregate adjusted loss.

If you specify the BY statement, then the data are organized in BY groups and the data set contains variables that you specify in the BY statement. In addition, the OUTSAMPLE= data set contains the following variables:

SEVERITYMODEL
: indicates the name of the severity distribution model.

COUNTMODEL
: indicates the name of the count model. If you specify the EXTERNALCOUNTS statement, then the value of this variable is "_EXTERNAL_". If you specify the COUNTSTORE= option, then the value of this variable is "_COUNTSTORE_".

<unadjusted sample variable>
: indicates the value of the unadjusted aggregate loss. The name of this variable is the value of the SAMPLEVAR= option in the OUTPUT statement. If you do not specify the SAMPLEVAR= option, then the variable is named _AGGSEV_.

<adjusted sample variable>
: indicates the value of the adjusted aggregate loss. This variable is created only when you specify the programming statements and the ADJUSTEDSEVERITY= option in the PROC HPCDM statement. The name of this variable is the value of the ADJSAMPLEVAR= option in the OUTPUT statement. If you do not specify the ADJSAMPLEVAR= option, then the variable is named _AGGADJSEV_.

DRAWID
: indicates the identifier for the perturbed sample. This variable is created only when you specify the NPERTURBEDSAMPLES= option in the PROC HPCDM statement. The value of this variable identifies the perturbed sample. A value of 0 for the _DRAWID_ variable indicates an unperturbed sample.

OUTSUM= Data Set

The OUTSUM= data set records the summary statistics and percentiles of the compound distributions of aggregate loss and aggregate adjusted loss. Only the estimates that you request in the OUTSUM statement are written to the OUTSUM= data set. For more information about the method of naming the variables that correspond to the summary statistics or percentiles, see the description of the OUTSUM statement.

If you specify the BY statement, then the data are organized in BY groups and the data set contains variables that you specify in the BY statement. In addition, the OUTSUM= data set contains the following variables:

SEVERITYMODEL
: indicates the name of the severity distribution model.

COUNTMODEL
: indicates the name of the count model. If you specify the EXTERNALCOUNTS statement, then the value of this variable is "_EXTERNAL_". If you specify the COUNTSTORE= option, then the value of this variable is "_COUNTSTORE_".

SAMPLEVAR
: indicates the name of the aggregate loss sample. For an unadjusted sample, the value of the variable is the value of the SAMPLEVAR= option that you specify in the OUTPUT statement or the default value of _AGGSEV_. For an adjusted sample, the value of the variable is the value of the ADJSAMPLEVAR= option that you specify in the OUTPUT statement or the default value of _AGGADJSEV_.

DRAWID
: indicates the identifier for the perturbed sample. This variable is created only when you specify the NPERTURBEDSAMPLES= option in the PROC HPCDM statement. The value of this variable identifies the perturbed sample. A value of 0 for _DRAWID_ indicates an unperturbed sample.

Displayed Output

The HPCDM procedure optionally produces displayed output by using the Output Delivery System (ODS). All output is controlled by the PRINT= option in the PROC HPCDM statement. Table 16.3 relates the PRINT= options to ODS tables.

Table 16.3 ODS Tables Produced in PROC HPCDM

ODS Table Name	Description	Option
CompoundInfo	Compound distribution information	Default
DataSummary	Input data summary	Default
Percentiles	Percentiles of the aggregate loss sample	PRINT=PERCENTILES
PerformanceInfo	Execution environment information that pertains to the computational performance	Default
PerturbedPctlSummary	Perturbation analysis of percentiles	PRINT=PERTURBSUMMARY and NPERTURBEDSAMPLES > 0
PerturbedSummary	Perturbation analysis of summary statistics	PRINT=PERTURBSUMMARY and NPERTURBEDSAMPLES > 0
SummaryStatistics	Summary statistics of the aggregate loss sample	PRINT=SUMMARYSTATISTICS
Timing	Timing information for various computational stages of the procedure	DETAILS (PERFORMANCE statement)

PRINT= Option

This section provides detailed descriptions of the tables that are displayed by using different PRINT= options.

- If you do not specify the PRINT= option and if you do not specify the NOPRINT or PRINT=NONE options, then by default PROC HPCDM produces the CompoundInfo, DataSummary, and SummaryStatistics ODS tables.

  The "Compound Distribution Information" table (ODS name: CompoundInfo) displays the information about the severity and count models.

  The "Input Data Summary" table (ODS name: DataSummary) is displayed when you specify the DATA= data set. The table displays the total number of observations and the valid number of observations in the data set. If you specify the EXTERNALCOUNTS statement, then the table also displays the number of replications and total number of loss events across all replications.

- If you specify PRINT=PERCENTILES, the "Percentiles" table (ODS name: Percentiles) is displayed for the distribution of the aggregate loss. The table contains estimates of all the predefined percentiles in addition to the percentiles that you request in the OUTSUM statement.

If you specify the programming statements and the ADJUSTEDSEVERITY= symbol, then an additional table is displayed for the distribution of the aggregate adjusted loss. This table also contains estimates of all the predefined percentiles in addition to the percentiles that you request in the OUTSUM statement.

- If you specify PRINT=PERTURBSUMMARY, two tables are displayed for the distribution of the aggregate loss. The "Perturbed Summary Statistics" table (ODS name: PerturbedSummary) displays the summary of the effect of perturbing model parameters on the following five summary statistics of the distribution: mean, standard deviation, variance, skewness, and kurtosis. The "Perturbed Percentiles" table (ODS name: PerturbedPctlSummary) displays the perturbation summary for all the predefined percentiles in addition to the percentiles that you request in the OUTSUM statement.

  The tables are displayed only if you specify a value greater than 0 for the NPERTURBEDSAMPLES= option.

  If you specify a value of *P* for the NPERTURBEDSAMPLES= option, then for each summary statistic and percentile, an average and standard error of the set of *P* values of that summary statistic or percentile are displayed in the respective perturbation summary tables.

  If you specify the programming statements and the ADJUSTEDSEVERITY= symbol, then additional perturbation summary tables are displayed for the distribution of the aggregate adjusted loss.

- If you specify PRINT=SUMMARYSTATISTICS, the "Summary Statistics" table (ODS name: SummaryStatistics) is displayed for the distribution of the aggregate loss. The table contains estimates of the following summary statistics: the number of observations in the sample, maximum value in the sample, minimum value in the sample, mean, median, standard deviation, interquartile range, variance, skewness, and kurtosis.

  If you specify the programming statements and the ADJUSTEDSEVERITY= symbol, then an additional table of summary statistics is displayed for the distribution of the aggregate adjusted loss.

Performance Information

The "Performance Information" table (ODS name: PerformanceInfo) is produced by default. It displays the number of threads that are used. It also confirms that the procedure always uses the single-machine execution mode.

If you specify the DETAILS option in the PERFORMANCE statement, PROC HPCDM also produces a "Timing" table (ODS name: Timing) that displays elapsed times (absolute and relative) for the main tasks of the procedure.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

This section describes the use of ODS for creating graphics with the HPCDM procedure.

NOTE: If you request simulation of an aggregate loss sample of large size, either by specifying a large value for the NREPLICATES= option or by including a large number of replicates in the DATA= data set that you specify in conjunction with the EXTERNALCOUNTS statement, then it is recommended that you not request any plots, because creating plots that have large numbers of points can require a very large amount of hardware resources and can take a very long time. You can disable the generation of plots either by submitting the ODS GRAPHICS OFF statement before submitting the PROC HPCDM step or by specifying the PLOTS=NONE option in the PROC HPCDM statement. It is recommended that you request plots only when the sample size is less than 100,000.

ODS Graph Names

PROC HPCDM assigns a name to each graph that it creates by using ODS. You can use these names to selectively refer to the graphs. The names are listed in Table 16.4.

Table 16.4 ODS Graphics Produced by PROC HPCDM

ODS Graph Name	Plot Description	PLOTS= Option
ConditionalDensityPlot	Conditional density plot	CONDITIONALDENSITY
DensityPlot	Probability density function plot	DENSITY
EDFPlot	Empirical distribution function plot	EDF

Conditional Density Plot

The conditional density plot helps you visually analyze two or three regions of the compound distribution by displaying a density function estimate that is conditional on the values of the aggregate loss that fall in those regions. You can specify the region boundaries in terms of quantiles by using the LEFTQ= and RIGHTQ= suboptions of the PLOTS=CONDITIONALDENSITY option. This is especially useful if you want to see the distribution of aggregate loss values in the right- and left-tail regions.

If you specify the programming statements and the ADJUSTEDSEVERITY= symbol, then a separate set of conditional density plots are displayed for the aggregate adjusted loss.

Probability Density Function Plot

The probability density function (PDF) plot shows the nonparametric estimates of the PDF of the aggregate loss distribution. This plot includes histogram and kernel density estimates.

If you specify the programming statements and the ADJUSTEDSEVERITY= symbol, then a separate density plot is displayed for the aggregate adjusted loss.

Empirical Distribution Function Plot

The empirical density function (EDF) plot shows the nonparametric estimate of the cumulative distribution function of the aggregate loss distribution. You can specify the ALPHA= suboption of the PLOTS=EDF option to request that the upper and lower confidence limits be plotted for each EDF estimate. By default, the confidence interval is not plotted.

If you specify the programming statements and the ADJUSTEDSEVERITY= symbol, then a separate EDF plot is displayed for the aggregate adjusted loss.

Examples: HPCDM Procedure

Example 16.1: Estimating the Probability Distribution of Insurance Payments

The primary outcome of running PROC HPCDM is the estimate of the compound distribution of aggregate loss, given the distributions of frequency and severity of the individual losses. This aggregate loss is often referred to as the ground-up loss. If you are an insurance company or a bank, you are also interested in acting on the ground-up loss by computing an entity that is derived from the ground-up loss. For example, you might want to estimate the distribution of the amount that you are expected to pay for the losses or the distribution of the amount that you can offload onto another organization, such as a reinsurance company. PROC HPCDM enables you to specify a severity adjustment program, which is a sequence of SAS programming statements that adjust the severity of the individual loss event to compute the entity of interest. Your severity adjustment program can use external information that is recorded as variables in the observations of the DATA= data set in addition to placeholder symbols for information that PROC HPCDM generates internally, such as the severity of the current loss event (_SEV_) and the sum of the adjusted severity values of the events that have been simulated thus far for the current sample point (_CUMADJSEV_). If you are doing a scenario analysis such that a scenario contains more than one observation, then you can also access the cumulative severity and cumulative adjusted severity for the current observation by using the _CUMSEVFOROBS_ and _CUMADJSEVFOROBS_ symbols.

This example continues the example of the section "Scenario Analysis" on page 930 to illustrate how you can estimate the distribution of the aggregate amount that is paid to a group of policyholders. Let the amount that is paid to an individual policyholder be computed by using what is usually referred to as a *disappearing deductible* (Klugman, Panjer, and Willmot 1998, Ch. 2). If X denotes the ground-up loss that a policyholder incurs, d denotes the lower limit on the deductible, d' denotes the upper limit on the deductible, and u denotes the limit on the total payments that are made to a policyholder in a year, then Y, the amount that is paid to the

policyholder for each loss event, is defined as follows:

$$Y = \begin{cases} 0 & X \le d \\ d' \frac{X-d}{d'-d} & d < X \le d' \\ X & d' < X \le u \\ u & X > u \end{cases}$$

You can encode this logic by using a set of SAS programming statements.

Extend the Work.GroupOfPolicies data set in the example in the section "Scenario Analysis" on page 930 to include the following three additional variables for each policyholder: LowDeductible to record d, HighDeductible to record d', and Limit to record u. The data set contains the observations as shown in Output 16.1.1.

Output 16.1.1 Scenario Analysis Data for Multiple Policyholders with Policy Provisions

policyholderId	age	gender	carType	annualMiles	education	carSafety	income
1	1.18	2	1	2.2948	3	0.99532	1.59870
2	0.66	2	2	2.8148	1	0.05625	0.67539
3	0.82	1	2	1.6130	2	0.84146	1.05940
4	0.44	1	1	1.2280	3	0.14324	0.24110
5	0.44	1	1	0.9670	2	0.08656	0.65979

lowDeductible	highDeductible	limit	annualLimit
400	1400	7500	10000
300	1300	2500	20000
100	1100	5000	10000
300	800	5000	20000
100	1100	5000	20000

The following PROC HPCDM step estimates the compound distributions of the aggregate loss and the aggregate amount that is paid to the group of policyholders in the Work.GroupOfPolicies data set by using the count model that is stored in the Work.CountregModel item store and the lognormal severity model that is stored in the Work.SevRegEst data set:

```
/* Simulate the aggregate loss distribution and aggregate adjusted
   loss distribution for the scenario with multiple policyholders */
proc hpcdm data=groupOfPolicies nreplicates=10000 seed=13579 print=all
           countstore=work.countregmodel severityest=work.sevregest
           plots=(edf pdf) nperturbedSamples=50
           adjustedseverity=amountPaid;
   severitymodel logn;

   if (_sev_ <= lowDeductible) then
      amountPaid = 0;
   else do;
      if (_sev_ <= highDeductible) then
         amountPaid = highDeductible *
            (_sev_-lowDeductible)/(highDeductible-lowDeductible);
      else
         amountPaid = MIN(_sev_, limit); /* imposes per-loss payment limit */
   end;
```

```
run;
```

The preceding step uses a severity adjustment program to compute the value of the symbol AmountPaid and specifies that symbol in the ADJUSTEDSEVERITY= option in the PROC HPCDM step. The program is executed for each simulated loss event. The PROC HPCDM supplies your program with the value of the severity in the _SEV_ placeholder symbol.

The "Sample Summary Statistics" table in Output 16.1.2 shows the summary statistics of the compound distribution of the aggregate ground-up loss. The "Adjusted Sample Summary Statistics" table shows the summary statistics of the compound distribution of the aggregate AmountPaid. The average aggregate payment is about 4,361, as compared to the average aggregate ground-up loss of 5,906.

Output 16.1.2 Summary Statistics of Compound Distributions of the Total Loss and Total Amount Paid

The HPCDM Procedure
Severity Model: Logn
Count Model: NegBin(p=2)

Compound Distribution Information	
Severity Model	Lognormal Distribution
Scale Model Regressors	carType carSafety income
Count Model	NegBin(p=2) Model in Item Store WORK.COUNTREGMODEL

Skewness	1.11692	**Maximum**	23657.4
Kurtosis	1.64518	**Sample Size**	10000

The perturbation summary of the distribution of AmountPaid is shown in Output 16.1.3. It shows that you can expect to pay a median of 3,796 $\pm$ 271 to this group of five policyholders in a year. Also, if the 99.5th percentile defines the worst case, then you can expect to pay 15,573 $\pm$ 859 in the worst-case.

Output 16.1.3 Perturbation Summary of the Total Amount Paid

Adjusted Sample Percentile Perturbation Analysis		
Percentile	**Estimate**	**Standard Error**
1	0.94036	6.15322
5	386.17494	65.79399
25	1988.9	188.59978

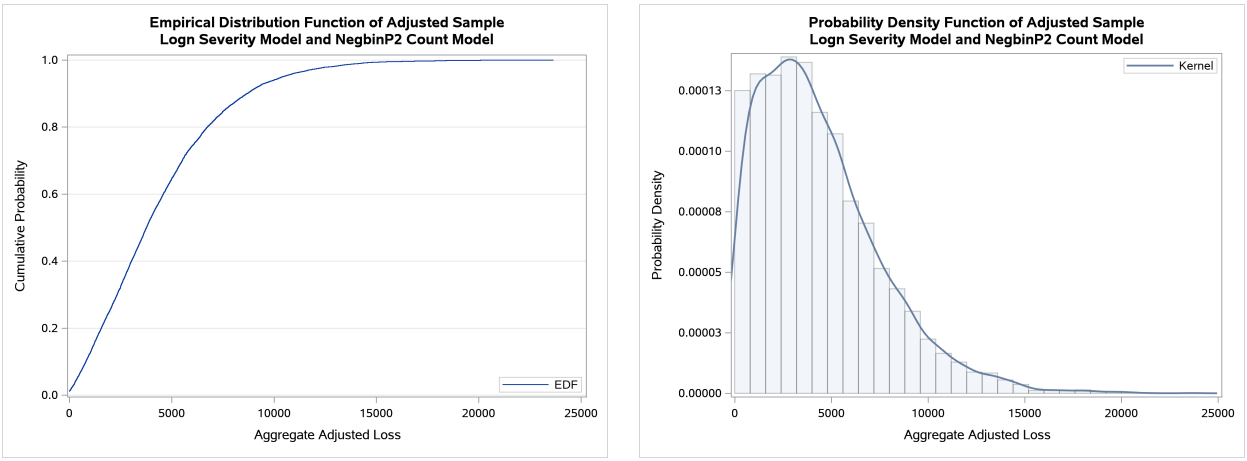
99	14108.5	827.74239
99.5	15573.1	858.66726
Number of Perturbed Samples = 50		
Size of Each Sample = 10000		

The empirical distribution function (EDF) and probability density function plots of the aggregate adjusted loss are shown in Output 16.1.4. Both plots indicate a heavy-tailed distribution of the total amount paid.

Output 16.1.4 PDF and EDF Plots of the Compound Distribution of the Total Amount Paid



Now consider that, in the future, you want to modify the policy provisions to add a limit on the total amount of payment that is made to an individual policyholder in one year and to impose a group limit of 15,000 on the total amount of payments that are made to the group as a whole in one year. You can analyze the effects of these modified policy provisions on the distribution of the aggregate paid amount by recording the individual policyholder's annual limit in the AnnualLimit variable of the input data set and then modifying your severity adjustment program by using the placeholder symbols _CUMADJSEVFOROBS_ and _CUMADJSEV_ as shown in the following PROC HPCDM step:

```
/* Simulate the aggregate loss distribution and aggregate adjusted
   loss distribution for the modified set of policy provisions */
proc hpcdm data=groupOfPolicies nreplicates=10000 seed=13579 print=all
           countstore=work.countregmodel severityest=work.sevregest
           plots=none nperturbedSamples=50
           adjustedseverity=amountPaid;
```

```
   severitymodel logn;

   if (_sev_ <= lowDeductible) then
      amountPaid = 0;
   else do;
      if (_sev_ <= highDeductible) then
         amountPaid = highDeductible *
            (_sev_-lowDeductible)/(highDeductible-lowDeductible);
      else
         amountPaid = MIN(_sev_, limit); /* imposes per-loss payment limit */

      /* impose policyholder's annual limit */
      amountPaid = MIN(amountPaid, MAX(0,annualLimit - _cumadjsevforobs_));

      /* impose group's annual limit */
      amountPaid = MIN(amountPaid, MAX(0,15000 - _cumadjsev_));
   end;
run;
```

The results of the perturbation analysis for these modified policy provisions are shown in Output 16.1.5. When compared to the results of Output 16.1.3, the additional policy provisions of restricting the total payment to the policyholder and the group have reduced the median payment slightly, but the provisions have reduced the worst-case payment (99.5th percentile) to 14,755 $\pm$ 392 from 15,573 $\pm$ 859.

Output 16.1.5 Perturbation Summary of the Total Amount Paid for Modified Policy Provisions

The HPCDM Procedure

Example 16.2: Using Externally Simulated Count Data

The COUNTREG procedure enables you to estimate count regression models that are based on the most commonly used discrete distributions, such as the Poisson, negative binomial (both $p = 1$ and $p = 2$), and Conway-Maxwell-Poisson distributions. PROC COUNTREG also enables you to fit zero-inflated models that are based on Poisson, negative binomial ($p = 2$), and Conway-Maxwell-Poisson distributions. However, there might be situations in which you want to use some other method of fitting count regression models. For example, if you are modeling the number of loss events that are incurred by two financial instruments such that there is some dependency between the two, then you might use some multivariate frequency modeling methods and simulate the counts for each instrument by using the dependency structure between the count model parameters of the two instruments. As another example, you might want to use different types of count models for different BY groups in your data; this is not possible in PROC COUNTREG. So you need to simulate the counts for such BY groups externally. PROC HPCDM enables you to supply externally simulated counts by using the EXTERNALCOUNTS statement. PROC HPCDM then does not need to simulate the counts internally; it simulates only the severity of each loss event by using the severity model estimates that you specify in the SEVERITYEST= data set or the SEVERITYSTORE= item store. The simulation process is described and illustrated in the section "Simulation with External Counts" on page 957.

Consider that you are a bank, and as part of quantifying your operational risk, you want to estimate the aggregate loss distributions for two lines of business, retail banking and commercial banking, by using some key risk indicators (KRIs). Assume that your model fitting and model selection process has determined that the Poisson regression model and negative binomial regression model are the best-fitting count models for number of loss events that are incurred in the retail banking and commercial banking businesses, respectively. Let CorpKRI1, CorpKRI2, CbKRI1, CbKRI2, and CbKRI3 be the KRIs that are used in the count regression model of the commercial banking business, and let CorpKRI1, RbKRI1, and RbKRI2 be the KRIs that are used in the count regression model of the retail banking business. Some examples of corporate-level KRIs (CorpKRI1 and CorpKRI2 in this example) are the ratio of temporary to permanent employees and the number of security breaches that are reported during a year. Some examples of KRIs that are specific to the commercial banking business (CbKRI1, CbKRI2, and CbKRI3 in this example) are number of credit defaults, proportion of financed assets that are movable, and penalty claims against your bank because of processing delays. Some examples of KRIs that are specific to the retail banking business (RbKRI1 and RbKRI2 in this example) are number of credit cards that are reported stolen, fraction of employees who have not undergone fraud detection training, and number of forged drafts and checks that are presented in a year.

Let the severity of each loss event in the commercial banking business be dependent on two KRIs, CorpKRI1 and CbKRI2. Let the severity of each loss event in the retail banking business be dependent on three KRIs, CorpKRI2, RbKRI1, and RbKRI3. Note that for each line of business, the set of KRIs that are used for the severity model is different from the set of KRIs that are used for the count model, although there is some overlap between the two sets. Further, the severity model for retail banking includes a new regressor (RbKRI3) that is not used for any of the count models. Such use of different sets of KRIs for count and severity models is typical of real-world applications.

Let the parameter estimates of the negative binomial and Poisson regression models, as determined by PROC COUNTREG, be available in the Work.CountEstEx2NB2 and Work.CountEstEx2Poisson data sets, respectively. These data sets are produced by using the OUTEST= option in the respective PROC COUNTREG statements. Let the parameter estimates of the best-fitting severity models, as determined by PROC SEVERITY, be available in the Work.SevEstEx2Best data set. You can find the code to prepare these data sets in the PROC HPCDM sample program *hcdmex02.sas*.

Now, consider that you want to estimate the distribution of the aggregate loss for a scenario, which is represented by a specific set of KRI values. The following DATA step illustrates one such scenario:

```
/* Generate a scenario data set for a single operating condition */
data singleScenario (keep=corpKRI1 corpKRI2 cbKRI1 cbKRI2 cbKRI3
                          rbKRI1 rbKRI2 rbKRI3);
   array x{8} corpKRI1 corpKRI2 cbKRI1 cbKRI2 cbKRI3 rbKRI1 rbKRI2 rbKRI3;
   call streaminit(5151);
   do i=1 to dim(x);
      x(i) = rand('NORMAL');
   end;
   output;
run;
```

The Work.SingleScenario data set contains all the KRIs that are included in the count and severity models of both business lines. Note that if you standardize or scale the KRIs while fitting the count and severity models, then you must apply the same standardization or scaling method to the values of the KRIs that you specify in the scenario. In this particular example, all KRIs are assumed to be standardized.

The following DATA step uses the scenario in the Work.SingleScenario data set to simulate 10,000 replications of the number of loss events that you might observe for each business line and writes the simulated counts to the NumLoss variable of the Work.LossCounts1 data set:

```
/* Simulate multiple replications of the number of loss events that
   you can expect in the scenario being analyzed */
data lossCounts1 (keep=line corpKRI1 corpKRI2 cbKRI2 rbKRI1 rbKRI3 numloss);
   array cxR{3} corpKRI1 rbKRI1 rbKRI2;
   array cbetaR{4} _TEMPORARY_;
   array cxC{5} corpKRI1 corpKRI2 cbKRI1 cbKRI2 cbKRI3;
   array cbetaC{6} _TEMPORARY_;

   retain theta;
   if _n_ = 1 then do;
      call streaminit(5151);
      * read count model estimates *;
      set countEstEx2NB2(where=(line='CommercialBanking' and _type_='PARM'));
      cbetaC(1) = Intercept;
      do i=1 to dim(cxC);
         cbetaC(i+1) = cxC(i);
      end;
      alpha = _Alpha;
      theta = 1/alpha;

      set countEstEx2Poisson(where=(line='RetailBanking' and _type_='PARM'));
      cbetaR(1) = Intercept;
      do i=1 to dim(cxR);
         cbetaR(i+1) = cxR(i);
      end;
   end;

   set singleScenario;
   do iline=1 to 2;
      if (iline=1) then line = 'CommercialBanking';
      else line = 'RetailBanking';
```

```
      do repid=1 to 10000;
         * draw from count distribution *;
         if (iline=1) then do;
            xbeta = cbetaC(1);
            do i=1 to dim(cxC);
               xbeta = xbeta + cxC(i) * cbetaC(i+1);
            end;
            Mu = exp(xbeta);
            p = theta/(Mu+theta);
            numloss = rand('NEGB',p,theta);
         end;
         else do;
            xbeta = cbetaR(1);
            do i=1 to dim(cxR);
               xbeta = xbeta + cxR(i) * cbetaR(i+1);
            end;
            numloss = rand('POISSON', exp(xbeta));
         end;
         output;
      end;
   end;
run;
```

The Work.LossCounts1 data set contains the NumLoss variable in addition to the KRIs that are used by the severity regression model, which are needed by PROC HPCDM to simulate the aggregate loss.

By default, PROC HPCDM computes an aggregate loss distribution by using each of the severity models that you specify in the SEVERITYMODEL statement. However, you can restrict PROC HPCDM to use only a subset of the severity models for a given BY group by modifying the SEVERITYEST= data set to include only the estimates of the desired severity models in each BY group, as illustrated in the following DATA step:

```
/* Keep only the best severity model for each business line
   and set coefficients of unused regressors in each model to 0 */
data sevestEx2Best;
    set sevestEx2;
    if ((line = 'CommercialBanking' and _model_ = 'Logn')) then do;
        corpKRI2 = 0; rbKRI1 = 0; rbKRI3 = 0;
        output;
    end;
    else if ((line = 'RetailBanking' and _model_ = 'Gamma')) then do;
        corpKRI1 = 0; cbKRI2 = 0;
        output;
    end;
run;
```

Note that the preceding DATA step also sets the coefficients of the unused regressors in each model to 0. This is important because PROC HPCDM uses all the regressors that it detects from the SEVERITYEST= data set for each severity model.

Now, you are ready to estimate the aggregate loss distribution for each line of business by submitting the following PROC HPCDM step, in which you specify the EXTERNALCOUNTS statement to request that external counts in the NumLoss variable of the DATA= data set be used for simulation of the aggregate loss:

```
/* Estimate the distribution of the aggregate loss for both
   lines of business by using the externally simulated counts */
proc hpcdm data=lossCounts1 seed=13579 print=all
           severityest=sevestEx2Best;
   by line;
   externalcounts count=numloss;
   severitymodel logn gamma;
run;
```

Each observation in the Work.LossCounts1 data set represents one replication of the external counts simulation process. For each such replication, the preceding PROC HPCDM step makes as many severity draws from the severity distribution as the value of the NumLoss variable and adds the severity values from those draws to compute one sample point of the aggregate loss. The severity distribution that is used for making the severity draws has a scale parameter value that is decided by the KRI values in the given observation and the regression parameter values that are read from the Work.SevEstEx2Best data set.

The summary statistics and percentiles of the aggregate loss distribution for the commercial banking business, which uses the lognormal severity model, are shown in Output 16.2.1. The "Input Data Summary" table indicates that each of the 10,000 observations in the BY group is treated as one replication and that there are a total of 19,028 loss events produced by all the replications together. For the scenario in the Work.SingleScenario data set, you can expect the commercial banking business to incur an average aggregate loss of 643 units, as shown in the "Sample Summary Statistics" table, and the chance that the loss will exceed 4,762 units is 0.5%, as shown in the "Sample Percentiles" table.

Output 16.2.1 Aggregate Loss Summary for Commercial Banking Business

When you conduct the simulation and estimation for a scenario that contains only one observation, you assume that the operating environment does not change over the period of time that is being analyzed. That assumption might be valid for shorter durations and stable business environments, but often the operating environments change, especially if you are estimating the aggregate loss over a longer period of time. So you might want to include in your scenario all the possible operating environments that you expect to see during the analysis time period. Each environment is characterized by its own set of KRI values. For example, the operating conditions might change from quarter to quarter, and you might want to estimate the aggregate loss distribution for the entire year. You start the estimation process for such scenarios by creating a scenario data set. The following DATA step creates the Work.MultiConditionScenario data set, which consists of four operating environments, one for each quarter:

```
/* Generate a scenario data set for multiple operating conditions */
data multiConditionScenario (keep=opEnvId corpKRI1 corpKRI2
      cbKRI1 cbKRI2 cbKRI3 rbKRI1 rbKRI2 rbKRI3);
   array x{8} corpKRI1 corpKRI2 cbKRI1 cbKRI2 cbKRI3 rbKRI1 rbKRI2 rbKRI3;
   call streaminit(5151);
   do opEnvId=1 to 4;
      do i=1 to dim(x);
         x(i) = rand('NORMAL');
      end;
      output;
   end;
run;
```

All four observations of the Work.MultiConditionScenario data set together form one scenario. When simulating the external counts for such multi-entity scenarios, one replication consists of the possible number of loss events that can occur as a result of each of the four operating environments. In any given replication, some operating environments might not produce any loss event or all four operating environments might produce some loss events. Assume that you use a DATA step to create the Work.LossCounts2 data set that contains, for each business line, 10,000 replications of the loss counts and that you identify each replication by using the RepId variable. You can find the DATA step code to prepare the Work.LossCounts2 data set in the PROC HPCDM sample program *hcdmex02.sas*.

Output 16.2.3 shows some observations of the Work.LossCounts2 data set for each business line. For the first replication (RepId=1) of the commercial banking business, only operating environments 3 and 4 incur loss events, whereas the other environments incur no loss events. For the second replication (RepId=2), all operating environments incur at least one loss event. For the first replication (RepId=1) of the retail banking business, operating environments 2, 3, and 4 incur two, one, and three loss events, respectively.

Output 16.2.3 Snapshot of the External Counts Data with Replication Identifier

line	opEnvId	corpKRI1	corpKRI2	cbKRI2	rbKRI1	rbKRI3	repid	numloss
CommercialBanking	1	0.45224	0.40661	-0.33680	-1.08692	-2.20557	1	0

CommercialBanking	1	0.45224	0.40661	-0.33680	-1.08692	-2.20557	2	2
CommercialBanking	2	-0.03799	0.98670	-0.03752	1.94589	1.22456	2	5
CommercialBanking	3	-0.29120	-0.45239	0.98855	-0.37208	-1.51534	2	12
CommercialBanking	4	0.87499	-0.67812	-0.04839	-1.44881	0.78221	2	12
RetailBanking	1	0.45224	0.40661	-0.33680	-1.08692	-2.20557	1	0
RetailBanking	2	-0.03799	0.98670	-0.03752	1.94589	1.22456	1	2
RetailBanking	3	-0.29120	-0.45239	0.98855	-0.37208	-1.51534	1	1
RetailBanking	4	0.87499	-0.67812	-0.04839	-1.44881	0.78221	1	3
RetailBanking	1	0.45224	0.40661	-0.33680	-1.08692	-2.20557	2	2
RetailBanking	2	-0.03799	0.98670	-0.03752	1.94589	1.22456	2	2
RetailBanking	3	-0.29120	-0.45239	0.98855	-0.37208	-1.51534	2	0
RetailBanking	4	0.87499	-0.67812	-0.04839	-1.44881	0.78221	2	1

You can now use this simulated count data to estimate the distribution of the aggregate loss that is incurred in all four operating environments by submitting the following PROC HPCDM step, in which you specify the

replication identifier variable RepId in the ID= option of the EXTERNALCOUNTS statement:

```
/* Estimate the distribution of the aggregate loss for both
   lines of business by using the externally simulated counts
   for the multiple operating environments */
proc hpcdm data=lossCounts2 seed=13579 print=all
           severityest=sevestEx2Best plots=density;
   by line;
   distby repid;
   externalcounts count=numloss id=repid;
   severitymodel logn gamma;
run;
```

Note that when you specify the ID= variable in the EXTERNALCOUNTS statement, you must also specify that variable in the DISTBY statement. Within each BY group, for each value of the RepId variable, one point of the aggregate loss sample is simulated by using the process that is described in the section "Simulation with External Counts" on page 957.

The summary statistics and percentiles of the distribution of the aggregate loss, which is the aggregate of the losses across all four operating environments, are shown in Output 16.2.4 for the commercial banking business. The "Input Data Summary" table indicates that there are 10,000 replications in the BY group and that a total of 145,721 loss events are generated across all replications. The "Sample Percentiles" table indicates that you can expect a median aggregate loss of 4,761 units and a worst-case loss, as defined by the 99.5th percentile, of 17,051 units from the commercial banking business when you combine losses that result from all four operating environments.

Output 16.2.4 Aggregate Loss Summary for the Commercial Banking Business in Multiple Operating Environments

The HPCDM Procedure

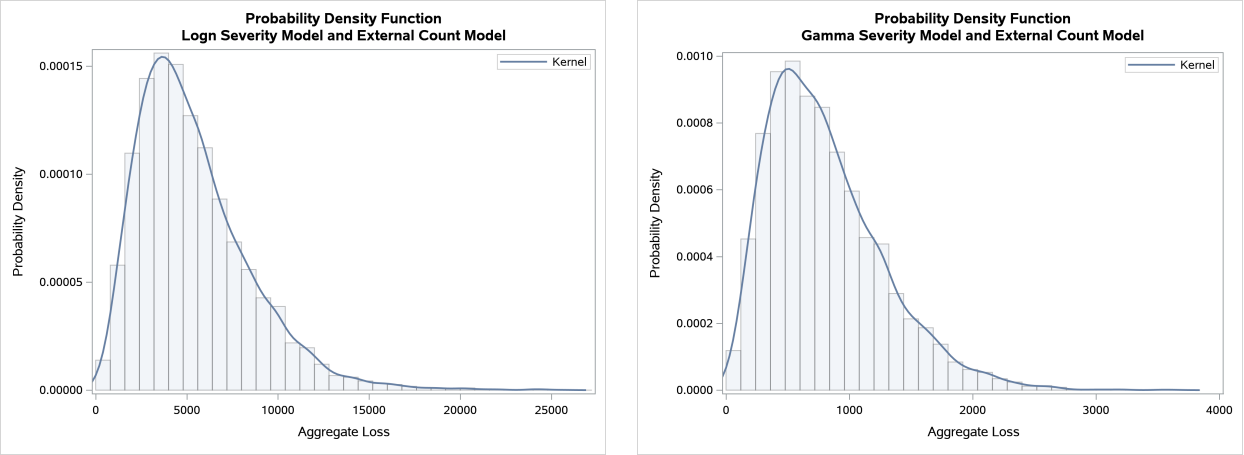
The probability density functions of the aggregate loss for the commercial and retail banking businesses are shown in Output 16.2.5. In addition to the difference in scales of the losses in the two businesses, you can see that the aggregate loss that is incurred in the commercial banking business has a heavier right tail than the aggregate loss that is incurred in the retail banking business.

Output 16.2.5 Density Plots of the Aggregate Losses for Commercial Banking (left) and Retail Banking (right) Businesses



Example 16.3: Scenario Analysis with Rich Regression Effects and BY Groups

This example illustrates scenario analysis when frequency and severity models use regression models that contain classification and interaction effects. It also illustrates how you can analyze scenarios for multiple groups of observations in one PROC HPCDM step without your having to simulate counts externally.

The example in the section "Scenario Analysis" on page 930 encodes the discrete-valued, nominal (nonordinal) variables Gender, CarType, and Education as numerical variables with an implied order. For example, a high school diploma is assigned a smaller number than an advanced degree. This method of forcing an order on otherwise nonordinal (categorical) variables is not natural and might lead to biased estimates. A more accurate approach is to treat such variables as classification variables that enter the statistical analysis or model not through their values but through their levels. For example, when you specify Education as a classification variable, the modeling process creates different parameters for the Education = 'High School' and Education = 'Advanced Degree' levels and estimates a regression coefficient for each. When you specify such variables in the CLASS statement of PROC COUNTREG and PROC SEVERITY, those procedures perform the appropriate levelization for you, which is the process of finding and transforming levels into regression parameters. For more information, see the description of the CLASS statement in Chapter 28, "The SEVERITY Procedure."

In addition to specifying nominal variables as classification (CLASS) variables, you can include interaction effects in severity and frequency models. For example, you might want to evaluate how the distribution of losses that are incurred by a policyholder with a college degree who drives an SUV differs from that of a policyholder with an advanced degree who drives a sedan. You can do this by including an interaction between CarType and Education in your severity model. Similarly, if you want to evaluate how the number of losses that a policyholder incurs per year varies by the number of annual miles for different types of cars, you can include an interaction between CarType and AnnualMiles in your frequency model. Analyzing such

a rich set of regression effects can help you make more accurate predictions about the frequency and severity distributions of losses. PROC HPCDM is designed to use such rich models to simulate a more accurate distribution of the aggregate loss.

As an example of the process, first, let the following programming statements fit the severity and count models that contain a certain set of regression effects:

```
proc severity data=losses(where=(not(missing(lossAmount))))
        covout outstore=work.sevstore print=all plots=none;
    by region;
    loss lossAmount;
    class carType gender education;
    scalemodel carType gender carSafety income education*carType
               income*gender carSafety*income;
    dist logn burr;
run;

proc countreg data=losscounts covout;
   by region;
   class gender carType education;
   model numloss = age income gender carType*annualmiles education / dist=negbin;
   zeromodel numloss ~ age income carType education;
   store cstore;
run;
```

Note the following points about these statements:

- You can find the code that prepares the Work.Losses and Work.LossCounts data sets in the PROC HPCDM sample program *hcdmex03.sas*. The data sets are organized in groups of observations that represent data from two regions, East and West. You can analyze both groups at once by specifying the BY statement with Region as the BY variable.
- Both severity and count models use three CLASS variables. The severity model includes three interaction effects (Education*CarType, Income*Gender, and CarSafety*Income) and four main effects. PROC SEVERITY uses the same set of regression effects in the scale regression model of each of the two distributions that you specify in the DIST statement, which are LOGN and BURR in this example.
- The count model is a mixture of two models: a model to estimate the occurrence of zero loss events and a model to estimate nonzero counts. The zero model is a regression model with four main effects and the default logistic link function. The model for nonzero counts is a negative binomial model with one interaction effect (CarType*AnnualMiles) and four main effects.

The "Parameter Estimates" table of the lognormal severity model in Output 16.3.1 for the Region='East' BY group shows that Income*Gender and CarSafety*Income effects are not statistically significant. The "Parameter Estimates" table in Output 16.3.2 shows that those two effects are not statistically significant for the Burr severity model also.

Output 16.3.1 Parameter Estimates for LOGN Severity Model for Region=East

region=East

The "Parameter Estimates" table of the count model in Output 16.3.3 shows that the income and Inf_income parameters are insignificant. This implies that the income effect is not significant for the main and zero inflation parts of the count model.

The results for the Region='West' BY group are not shown here, but you can execute the sample program *hcdmex03.sas* to verify that the same parameters are statistically insignificant in severity and count models of that BY group as well. However, in general, you might find that some effects are significant for some BY groups but insignificant for other BY groups. In such cases, for more accurate results, it is recommended that you create a separate data set for each set of similar BY groups and invoke the SEVERITY, COUNTREG, and HPCDM procedures on each data set to separately analyze each set of similar BY groups.

The following modified PROC SEVERITY and PROC COUNTREG steps refit the severity and count models, respectively, after removing the insignificant effects:

```
/* Re-fit models after removing insignificant effects. */
proc severity data=losses(where=(not(missing(lossAmount))))
        covout outstore=work.sevstore print=all plots=none;
    by region;
    loss lossAmount;
    class carType gender education;
    scalemodel carType gender carSafety income education*carType;
    dist logn burr;
run;

proc countreg data=losscounts covout;
```

```
    by region;
    class gender carType education;
    model numloss = age gender carType*annualmiles education / dist=negbin;
    zeromodel numloss ~ age carType education;
    store cstore;
run;
```

Note that the PROC SEVERITY step uses the OUTSTORE= option to store the parameter estimates in an item store. When your scale regression model contains classification or interaction effects, you must store the parameter estimates in an item store instead of storing them in an OUTEST= data set, because PROC HPCDM cannot obtain the necessary information about classification or interaction effects from an OUTEST= data set.

The "Parameter Estimates" tables in Output 16.3.4 and Output 16.3.5 show that all parameters are now statistically significant, most at the 95% confidence level and a few at the 90% confidence level. If you want every parameter to be significant at the 95% confidence level, then you might want to continue the process by removing the carType effect with a *p*-value of 0.0607 from the ZEROMODEL statement and refitting the count model. However, for the purpose of this example, the preceding models are declared to be satisfactory, and the effect selection process stops here.

You need to follow this process of model inspection and effect selection before you use the severity and count models with the HPCDM procedure. For count models, you can use the automatic effect (variable) selection feature of PROC COUNTREG. For more information, see the description of the SELECT= option in the MODEL statement of Chapter 11, "The COUNTREG Procedure." For severity models, you need to perform effect selection manually by inspecting the estimates and refitting the model after removing one or a few insignificant effects at a time until you find the final set of significant effects. Although it is not shown in this example, you can also decide which set of effects is better by comparing the fit statistics of two models; the better model might contain certain effects at lower confidence levels than the usual 95% or 90% confidence levels. In fact, the SELECT=INFO option of PROC COUNTREG uses the AIC or BIC of the entire model to select the set of effects instead of using the *p*-values of individual parameters. You might also want to use some domain knowledge to retain certain effects in the model even if their confidence level is not very high.

For severity models, you also need to inspect the "All Fit Statistics" table to decide which severity distributions you want to use for aggregate loss modeling. The table in Output 16.3.6 shows that the lognormal distribution is the best according to the majority of fit statistics, so you can choose that. However, in some cases, you might see that the likelihood-based fit statistics (–2 log likelihood, AIC, AICC, BIC) choose one distribution and the EDF-based statistics (KS, AD, CvM) choose another distribution. In such cases, it is recommended that before making your final decision, you conduct aggregate loss simulation by using both severity distributions and compare the summary statistics and percentiles that each severity distribution produces.

Output 16.3.6 Comparison of Severity Distributions for Region=East

region=East

All Fit Statistics

Distribution	-2 Log Likelihood		AIC		AICC		BIC		KS		AD		CvM	
Logn	45280	*	45300	*	45300	*	45364	*	10.31771	*	613.78765		46.37913	*
Burr	45346		45368		45368		45437		10.90815		519.83495	*	49.71973	

Note: The asterisk (*) marks the best model according to each column's criterion.

After you have satisfactorily estimated the severity and frequency models, it is time to estimate the distribution of the aggregate loss by using the HPCDM procedure. The scenario data set must contain the final set of regressors that are used in both the severity model and the frequency model. Note that even if your models contain interaction effects, your scenario data set needs to contain only the columns for individual variables of the effects. PROC HPCDM internally performs *levelization* of each observation, which is the process of expanding the variable values to match them with the parameters of each effect. A typical scenario for an insurance application might consist of a large number of policyholders, but for illustration purposes, this

example uses a small scenario of only a few policyholders per region. Output 16.3.7 shows the contents of the Work.Scenario data set, and the following PROC HPCDM step simulates the aggregate losses for that scenario:

```
proc hpcdm data=scenario nreplicates=10000 seed=123 print=all
           severitystore=work.sevstore countstore=work.cstore
           nperturb=30;
   by region;
   severitymodel logn;
   outsum out=agglossStats mean stddev skewness kurtosis pctlpts=(90 97.5 99.5);
run;
```

Output 16.3.7 Work.Scenario Data Set for BY-Group Processing

Obs	region	gender	carType	education	age	annualmiles	carSafety	income

Overview: HPCOPULA Procedure

The HPCOPULA procedure is a high-performance version of the SAS/ETS COPULA procedure, which simulates data from a specified copula.

Unlike the COPULA procedure, which can be run only on one thread, the HPCOPULA procedure takes advantage of a computing environment in which the optimization task can be distributed to multiple threads. When several threads are used, the result is a highly parallel computation that provides a dramatic gain in performance.

By default, PROC HPCOPULA performs computations on multiple threads.

PROC HPCOPULA Features

The HPCOPULA procedure enables you to simulate a specified copula, and it supports the following types of copulas:

- normal copula
- *t* copula
- Archimedean copulas:
  - Clayton copula
  - Frank copula
  - Gumbel copula

Getting Started: HPCOPULA Procedure

This example illustrates the use of PROC HPCOPULA. The data are daily returns on several major stocks. The main purpose of this example is to simulate from the joint distribution of stock returns a new sample of a specified size, provided that the parameter estimates of the copula model that is used are available.

In the following statements, the DEFINE statement specifies a normal copula named COP, and the CORR= option specifies that the data set Estimates be used as the source for the model parameters. The NDRAWS=1000000 option in the SIMULATE statement generates one million observations from the normal copula. The OUTUNIFORM= option specifies the name of the SAS data set to contain the simulated sample that has uniform marginal distributions. The PERFORMANCE statement requests that the analytic computations use two threads. Note that this syntax does not require the DATA= option.

```
/* Copula simulation of uniforms */
proc hpcopula;
   var ret_ibm ret_msft ret_bp ret_ko ret_duk;
   define cop normal (corr = estimates);
```

```
    simulate cop / ndraws     = 1000000
                   outuniform = simulated_uniforms;
    PERFORMANCE nthreads=2 details;
run;
```

The simulated data are contained in the new SAS data set, Simulated_Uniforms.

Syntax: HPCOPULA Procedure

The following statements are available in the HPCOPULA procedure:

PROC HPCOPULA *options* **;**
VAR *variables* **;**
DEFINE *name copula-type* < *(parameter-value-options . . .)* > **;**
SIMULATE < *copula-name-list* > */ options* **;**
PERFORMANCE < *performance-options* > **;**

Functional Summary

Table 17.1 summarizes the statements and options that the HPCOPULA procedure uses.

Table 17.1 Functional Summary

Description	Statement	Option
Data Set Options		
Specifies the input data set that contains the correlation matrix for elliptical copulas	DEFINE	CORR=
Declaring the Role of Variables		
Specifies the names of the variables to use in copula fitting or in simulation	VAR	
Copula Simulation Options		
Specifies the random sample size	SIMULATE	NDRAWS=
Specifies the random number generator seed	SIMULATE	SEED=
Output Control Options		
Specifies the output data set to contain the random samples from the simulation with uniform marginal distribution	SIMULATE	OUTUNIFORM=

PROC HPCOPULA Statement

PROC HPCOPULA ;

The PROC HPCOPULA statement invokes the HPCOPULA procedure.

DEFINE Statement

DEFINE *name copula-type* < *(parameter-value-options . . .)* > **;**

The DEFINE statement specifies the relevant information about the copula that is used for the simulation. You can specify the following arguments:

name specifies the name of the copula definition. You can be use this *name* later in the SIMULATE statement.

copula-type specifies the type of copula. You must specify one of the following copula types, which are described in the section "Details: HPCOPULA Procedure" on page 1004:

NORMAL fits the normal copula.

T fits the *t* copula.

CLAYTON fits the Clayton copula.

FRANK fits the Frank copula.

GUMBEL fits the Gumbel copula.

parameter-value-options
specify the input parameters that are used to simulate the specified copula. These options must be appropriate for the type of copula specified. You can specify the following *parameter-value-options*:

CORR=*SAS-data-set*
specifies the data set that contains the correlation matrix to use for elliptical copulas. If the correlation matrix is valid but its elements are not submitted in order, then you must provide the variable names in the first column of the matrix, and these names must match the variable names in the VAR statement. See Output 17.1.1 for an example of a correlation matrix input in this form. If the correlation matrix elements are submitted in order, the first column of variable names is not required. You can use this option for normal and *t* copulas.

DF=*value*
specifies the degrees of freedom. You can use this option for *t* copulas.

THETA=*value*
specifies the parameter value for the Archimedean copulas.

The DEFINE statement is used with the SIMULATE statement.

SIMULATE Statement

SIMULATE < *copula-name-list* > / *options* **;**

The SIMULATE statement simulates data from a specified copula model. The copula name specification is the name of a defined copula as specified by *name* in the DEFINE statement. You can specify the following *options*:

NDRAWS=*integer*
specifies the number of draws to generate for this simulation. By default, NDRAWS=100.

OUTUNIFORM=*SAS-data-set*
specifies the output data set to contain the result of the simulation in uniform margins. You can use this option when MARGINALS=UNIFORM or MARGINALS=EMPIRICAL. If MARGINALS=EMPIRICAL, then this option enables you to obtain the samples that are simulated from the joint distribution specified by the copula, where all marginal distributions are uniform. The data are not created if you do not specify this option.

SEED=*integer*
specifies the seed for generating random numbers for the simulation. If you do not provide the seed, a random number is used as the seed.

PERFORMANCE Statement

PERFORMANCE < *performance-options* > **;**

The PERFORMANCE statement specifies *performance-options* to control the multithreaded computing environment and requests detailed performance results of the HPCOPULA procedure. You can specify the following *performance-options*:

DETAILS
requests a table that shows a timing breakdown of the PROC HPCOPULA steps.

NTHREADS=*n*
specifies the number of threads for analytic computations and overrides the SAS system option THREADS | NOTHREADS. If you do not specify the NTHREADS= option, PROC HPCOPULA creates one thread for the analytic computations.

For more information about the PERFORMANCE statement, see the section "PERFORMANCE Statement" (Chapter 21, *SAS/STAT User's Guide*).

VAR Statement

VAR *variables* **;**

The VAR statement specifies the variable names in the input data set that is specified by the DATA= option in the PROC HPCOPULA statement. The subset of variables in the data set is used for the copula models in the FIT statement. If there is no input data set, the VAR statement creates the list of variable names for the SIMULATE statement.

Details: HPCOPULA Procedure

Sklar's Theorem

The copula models are tools for studying the dependence structure of multivariate distributions. The usual joint distribution function contains the information both about the marginal behavior of the individual random variables and about the dependence structure between the variables. The copula is introduced to decouple the marginal properties of the random variables and the dependence structures. An m-dimensional *copula* is a joint distribution function on $[0, 1]^m$, where all marginal distributions are standard uniform. The common notation for a copula is $C(u_1, \ldots, u_m)$.

The Sklar (1959) theorem shows the importance of copulas in modeling multivariate distributions. The first part of the theorem states that a copula can be derived from any joint distribution functions, and the second part asserts the opposite: that any copula can be combined with any set of marginal distributions to result in a multivariate distribution function. The theorem follows:

- Let F be a joint distribution function, and let $F_j, j = 1, \ldots, m$, be the marginal distributions. Then there exists a copula $C : [0, 1]^m \rightarrow [0, 1]$ such that

  $$F(x_1, \ldots, x_m) = C(F_1(x_1), \ldots, F_m(x_m))$$

  for all $x_1, \ldots, x_m$ in $[-\infty, \infty]$. Moreover, if the margins are continuous, then C is unique; otherwise C is uniquely determined on $\mathrm{Ran}F_1 \times \cdots \times \mathrm{Ran}F_m$, where $\mathrm{Ran}F_j = F_j([-\infty, \infty])$ is the range of F_j.

- The converse is also true. That is, if C is a copula and $F_1, \ldots, F_m$ are univariate distribution functions, then the multivariate function that is defined in the preceding equation is a joint distribution function with marginal distributions $F_j, j = 1, \ldots, m$.

Dependence Measures

There are three basic types of dependence measures: linear correlation, rank correlation, and tail dependence. Linear correlation is given by

$$\rho \equiv \text{corr}(X, Y) = \frac{\text{cov}(X, Y)}{\sqrt{\text{var}(X)}\sqrt{\text{var}(Y)}}$$

The linear correlation coefficient contains very limited information about the joint properties of the variables. A well-known property is that zero correlation does not imply independence, whereas independence implies zero correlation. In addition, there are distinct bivariate distributions that have the same marginal distribution and the same correlation coefficient. These results suggest that caution must be used in interpreting the linear correlation.

Another statistical measure of dependence is rank correlation, which is nonparametric. For example, Kendall's tau is the covariance between the sign statistics $X_1 - \tilde{X}_1$ and $X_2 - \tilde{X}_2$, where $(\tilde{X}_1, \tilde{X}_2)$ is an independent copy of (X_1, X_2):

$$\rho_\tau \equiv E[\text{sign}(X_1 - \tilde{X}_1)(X_2 - \tilde{X}_2)]$$

The sign function (sometimes written as sgn) is defined as

$$\text{sign}(x) = \begin{cases} -1 & \text{if} x \leq 0 \\ 0 & \text{if} x = 0 \\ 1 & \text{if} x \geq 0 \end{cases}$$

Spearman's rho is the correlation between the transformed random variables:

$$\rho_S(X_1, X_2) \equiv \rho(F_1(X_1), F_2(X_2))$$

The variables are transformed by their distribution functions so that the transformed variables are uniformly distributed on $[0, 1]$. The rank correlations depend only on the copula of the random variables and are indifferent to the marginal distributions. Like linear correlation, rank correlation has its limitations. In particular, different copulas result in the same rank correlation.

A third measure, tail dependence, focuses on only part of the joint properties between the variables. Tail dependence measures the dependence when both variables have extreme values. Formally, they can be defined as the conditional probabilities of quantile exceedances. There are two types of tail dependence:

- Upper tail dependence is defined as

  $$\lambda_u(X_1, X_2) \equiv \lim_{q->1^-} P(X_2 > F_2^{-1}(q) | X_1 > F_1^{-1}(q))$$

  when the limit exists and $\lambda_u \in [0, 1]$. Here F_j^{-1} is the quantile function (that is, the inverse of the CDF).

- Lower tail dependence is defined symmetrically.

Normal Copula

Let $u_j \sim U(0,1)$ for $j = 1, \ldots, m$, where $U(0,1)$ represents the uniform distribution on the $[0,1]$ interval. Let Σ be the correlation matrix, where $m(m-1)/2$ parameters satisfy the positive semidefiniteness constraint. The normal copula can be written as

$$C_\Sigma(u_1, u_2, \ldots, u_m) = \mathbf{\Phi}_\Sigma\Big(\Phi^{-1}(u_1), \ldots, \Phi^{-1}(u_m)\Big)$$

where Φ is the distribution function of a standard normal random variable and $\mathbf{\Phi}_\Sigma$ is the m-variate standard normal distribution with mean vector 0 and covariance matrix Σ. That is, the distribution $\mathbf{\Phi}_\Sigma$ is $N_m(0, \Sigma)$.

Simulation

For the normal copula, the input of the simulation is the correlation matrix Σ. The normal copula can be simulated by the following steps, in which $\boldsymbol{U} = (U_1, \ldots, U_m)$ denotes one random draw from the copula:

1. Generate a multivariate normal vector $\boldsymbol{Z} \sim N(0, \Sigma)$, where Σ is an m-dimensional correlation matrix.
2. Transform the vector $\boldsymbol{Z}$ into $\boldsymbol{U} = (\Phi(Z_1), \ldots, \Phi(Z_m))^T$, where Φ is the distribution function of univariate standard normal.

The first step can be achieved by Cholesky decomposition of the correlation matrix $\Sigma = LL^T$, where L is a lower triangular matrix with positive elements on the diagonal. If $\tilde{\boldsymbol{Z}} \sim N(0, I)$, then $L\tilde{\boldsymbol{Z}} \sim N(0, \Sigma)$.

Student's *t* Copula

Let $\Theta = \{(\nu, \Sigma) : \nu \in (1, \infty), \Sigma \in \mathbb{R}^{m \times m}\}$, and let t_ν be a univariate t distribution with ν degrees of freedom.

The Student's t copula can be written as

$$C_\Theta(u_1, u_2, \ldots, u_m) = \boldsymbol{t}_{\nu,\Sigma}\Big(t_\nu^{-1}(u_1), t_\nu^{-1}(u_2), \ldots, t_\nu^{-1}(u_m)\Big)$$

where $\boldsymbol{t}_{\nu,\Sigma}$ is the multivariate Student's t distribution that has a correlation matrix Σ with ν degrees of freedom.

Simulation

The input parameters for the simulation are (ν, Σ). The t copula can be simulated by the following steps:

1. Generate a multivariate vector $\boldsymbol{X} \sim t_m(\nu, 0, \Sigma)$ that follows the centered t distribution with ν degrees of freedom and correlation matrix Σ.
2. Transform the vector $\boldsymbol{X}$ into $\boldsymbol{U} = (t_\nu(X_1), \ldots, t_\nu(X_m))^T$, where t_ν is the distribution function of univariate t distribution with ν degrees of freedom.

To simulate centered multivariate t random variables, you can use the property that $\boldsymbol{X} \sim t_m(\nu, 0, \Sigma)$ if $\boldsymbol{X} = \sqrt{\nu/s}\boldsymbol{Z}$, where $\boldsymbol{Z} \sim N(0, \Sigma)$ and the univariate random variable $s \sim \chi^2_\nu$.

Archimedean Copulas

Overview of Archimedean Copulas

Let function $\phi : [0,1] \rightarrow [0,\infty)$ be a strict Archimedean copula generator function, and suppose that its inverse ϕ^{-1} is completely monotonic on $[0,\infty)$. A strict generator is a decreasing function $\phi : [0,1] \rightarrow [0,\infty)$ that satisfies $\phi(0) = \infty$ and $\phi(1) = 0$. A decreasing function $f(t) : [a,b] \rightarrow (-\infty,\infty)$ is completely monotonic if it satisfies

$$(-1)^k \frac{d^k}{dt^k} f(t) \geq 0, k \in \mathbb{N}, t \in (a,b)$$

An Archimedean copula is defined as follows:

$$C(u_1,u_2,\ldots,u_m) = \phi^{-1}\Big(\phi(u_1) + \cdots + \phi(u_m)\Big)$$

The Archimedean copulas available in the HPCOPULA procedure are the Clayton copula, the Frank copula, and the Gumbel copula.

Clayton Copula

Let the generator function $\phi(u) = \theta^{-1}\left(u^{-\theta} - 1\right)$. A Clayton copula is defined as

$$C_\theta(u_1,u_2,\ldots,u_m) = \left[\sum_{i=1}^{m} u_i^{-\theta} - m + 1\right]^{-1/\theta}$$

where $\theta > 0$.

Frank Copula

Let the generator function be

$$\phi(u) = -\log\left[\frac{\exp(-\theta u) - 1}{\exp(-\theta) - 1}\right]$$

A Frank copula is defined as

$$C_\theta(u_1,u_2,\ldots,u_m) = \frac{1}{\theta}\log\left\{1 + \frac{\prod_{i=1}^{m}[\exp(-\theta u_i) - 1]}{[\exp(-\theta) - 1]^{m-1}}\right\}$$

where $\theta \in (-\infty,\infty)\backslash\{0\}$ for $m = 2$ and $\theta > 0$ for $m \geq 3$.

Gumbel Copula

Let the generator function $\phi(u) = (-\log u)^{\theta}$. A Gumbel copula is defined as

$$C_{\theta}(u_1, u_2, \ldots, u_m) = \exp\left\{-\left[\sum_{i=1}^{m}(-\log u_i)^{\theta}\right]^{1/\theta}\right\}$$

where $\theta > 1$.

Simulation

Suppose that the generator of the Archimedean copula is ϕ. Then the simulation method that uses a Laplace-Stieltjes transformation of the distribution function is given by Marshall and Olkin (1988), where $\tilde{F}(t) = \int_0^{\infty} e^{-tx} dF(x)$:

1. Generate a random variable V that has the distribution function F such that $\tilde{F}(t) = \phi^{-1}(t)$.
2. Draw samples from the independent uniform random variables $X_1, \ldots, X_m$.
3. Return $\boldsymbol{U} = (\tilde{F}(-\log(X_1)/V), \ldots, \tilde{F}(-\log(X_m)/V))^T$.

The Laplace-Stieltjes transformations are as follows:

- For the Clayton copula, $\tilde{F} = (1+t)^{-1/\theta}$, and the distribution function F is associated with a gamma random variable that has a shape parameter of θ^{-1} and a scale parameter of 1.
- For the Gumbel copula, $\tilde{F} = \exp(-t^{1/\theta})$, and F is the distribution function of the stable variable $\mathrm{St}(\theta^{-1}, 1, \gamma, 0)$, where $\gamma = [\cos(\pi/(2\theta))]^{\theta}$.
- For the Frank copula where $\theta > 0$, $\tilde{F} = -\log\{1 - \exp(-t)[1 - \exp(-\theta)]\}/\theta$, and F is a discrete probability function $P(V = k) = (1 - \exp(-\theta))^k/(k\theta)$. This probability function is related to a logarithmic random variable that has a parameter value of $1 - e^{-\theta}$.

For more information about simulating a random variable from a stable distribution, see Theorem 1.19 in Nolan (2010). For more information about simulating a random variable from a logarithmic series, see Chapter 10.5 in Devroye (1986).

For a Frank copula where $m = 2$ and $\theta < 0$, the simulation can be done through conditional distributions as follows:

1 Draw independent v_1, v_2 from a uniform distribution.

2 Let $u_1 = v_1$.

3 Let $u_2 = -\frac{1}{\theta}\log\left(1 + \frac{v_2(1-e^{-\theta})}{v_2(e^{-\theta v_1}-1)-e^{-\theta v_1}}\right)$.

OUTUNIFORM= Data Sets

The number of columns and the names of columns in OUTUNIFORM= data sets match the number and names of the *variables* in the VAR statement.

Examples: HPCOPULA Procedure

Example 17.1: Simulating Default Times

Suppose the correlation structure that is required for a normal copula function is already known. For example, the correlation structure can be estimated from the historical data on default times in some industries, but this estimation is not within the scope of this example. The correlation structure is saved in a SAS data set called Inparm. The following statements and their output in Output 17.1.1 show that the correlation parameter is set at 0.8:

```
proc print data = inparm;
run;
```

Output 17.1.1 Copula Correlation Matrix

Obs	Y1	Y2
1	1.0	0.8
2	0.8	1.0

The following statements use PROC HPCOPULA to simulate the data:

```
/* simulate the data from bivariate normal copula */
proc hpcopula;
   var Y1-Y2;
   define cop normal (corr=inparm);
   simulate cop /
            ndraws     = 1000000
            seed       = 1234
            outuniform = normal_unifdata;
   PERFORMANCE nthreads=4 details
               host="&GRIDHOST" install="&GRIDINSTALLLOC";
run;
```

The VAR statement specifies the list of variables that contains the simulated data. The DEFINE statement assigns the name COP and specifies a normal copula that reads the correlation matrix from the Inparm data set. The SIMULATE statement refers to the COP label that is defined in the VAR statement and specifies several options: the NDRAWS= option specifies a sample size, the SEED= option specifies 1234 as the random number generator seed, and the OUTUNIFORM=NORMAL_UNIFDATA option names the output data set to contain the result of simulation in uniforms. The PERFORMANCE statement requests that the

analytic computations be performed on four threads. Output 17.1.2 shows the run time of this particular simulation experiment.

Output 17.1.2 Run-Time Performance

Performance Information	
Execution Mode	Single-Machine
Number of Threads	4

Procedure Task Timing		
Task	**Seconds**	**Percent**
Simulation of Model	0.24	100.00%

The following DATA step transforms the variables from zero-one uniformly distributed to nonnegative exponentially distributed with parameter 0.5 and adds three indicator variables to the data set: SURVIVE1 and SURVIVE2 are equal to 1 if company 1 or company 2, respectively, has remained in business for more than three years, and SURVIVE is equal to 1 if both companies survived the same period together.

```
/* default time has exponential marginal distribution with parameter 0.5 */
data default;
   set normal_unifdata;
   array arr{2} Y1-Y2;
   array time{2} time1-time2;
   array surv{2} survive1-survive2;
   lambda = 0.5;
   do i=1 to 2;
      time[i] = -log(1-arr[i])/lambda;
      surv[i] = 0;
      if (time[i] >3) then surv[i]=1;
   end;
   survive = 0;
   if (time1 >3) && (time2 >3) then survive = 1;
run;
```

The first analysis step is to look at correlations between survival times of the two companies. You can perform this step by using the CORR procedure as follows:

```
proc corr data = default pearson kendall;
   var time1 time2;
run;
```

Output 17.1.3 shows the output of this code. The output contains some descriptive statistics and two measures of correlation: Pearson and Kendall. Both measures indicate high and statistically significant dependence between the life spans of the two companies.

Output 17.1.3 Default Time Descriptive Statistics and Correlations

The CORR Procedure

2 Variables:	time1	time2

Output 17.1.3 *continued*

Simple Statistics

Variable	N	Mean	Std Dev	Median	Minimum	Maximum
time1	1000000	2.00023	1.99883	1.38633	3.85293E-6	24.18938
time2	1000000	1.99897	1.99965	1.38476	6.43006E-6	25.85567

Pearson Correlation Coefficients, N = 1000000
Prob > |r| under H0: Rho=0

	time1	time2
time1	1.00000	0.77046 <.0001
time2	0.77046 <.0001	1.00000

Kendall Tau b Correlation Coefficients, N = 1000000
Prob > |tau| under H0: Tau=0

	time1	time2
time1	1.00000	0.59046 <.0001
time2	0.59046 <.0001	1.00000

The second and final step is to empirically estimate the default probabilities of the two companies. This is done by using the FREQ procedure as follows:

```
proc freq data=default;
   table survive survive1-survive2;
run;
```

The results are shown in Output 17.1.4.

Output 17.1.4 Probabilities of Default

The FREQ Procedure

survive	Frequency	Percent	Cumulative Frequency	Cumulative Percent
0	852317	85.23	852317	85.23
1	147683	14.77	1000000	100.00

survive1	Frequency	Percent	Cumulative Frequency	Cumulative Percent
0	776594	77.66	776594	77.66
1	223406	22.34	1000000	100.00

survive2	Frequency	Percent	Cumulative Frequency	Cumulative Percent
0	777292	77.73	777292	77.73
1	222708	22.27	1000000	100.00

Output 17.1.4 shows that the empirical default probabilities are 78% and 78%. Assuming that these companies are independent yields the probability estimate that both companies default during the period of three years

as 0.78*0.78=0.61 (61%). Comparing this naive estimate with the much higher actual 85% joint default probability illustrates that neglecting the correlation between the two companies significantly underestimates the probability of default.

Overview: HPCOUNTREG Procedure

The HPCOUNTREG procedure is a high-performance version of the COUNTREG procedure in SAS/ETS software. Like the COUNTREG procedure, the HPCOUNTREG procedure fits regression models in which the dependent variable takes nonnegative integer or count values.

By default, PROC HPCOUNTREG performs computations in multiple threads.

PROC HPCOUNTREG Features

The HPCOUNTREG procedure estimates the parameters of a count regression model by maximum likelihood techniques.

The HPCOUNTREG procedure supports the following models for count data:

- Poisson regression
- Conway-Maxwell-Poisson regression
- negative binomial regression with quadratic and linear variance functions (Cameron and Trivedi 1986)
- zero-inflated Poisson (ZIP) model (Lambert 1992)
- zero-inflated Conway-Maxwell-Poisson (ZICMP) model
- zero-inflated negative binomial (ZINB) model
- fixed-effects and random-effects Poisson models for panel data
- fixed-effects and random-effects negative binomial models for panel data

The following list summarizes some basic features of the HPCOUNTREG procedure:

- is multithreaded during all phases of analytic execution
- has model-building syntax that uses CLASS and effect-based MODEL statements familiar from SAS/ETS analytic procedures
- performs maximum likelihood estimation
- supports multiple link functions
- uses the WEIGHT statement for weighted analysis

- uses the FREQ statement for grouped analysis
- uses the OUTPUT statement to produce a data set that contains predicted probabilities and other observationwise statistics

Getting Started: HPCOUNTREG Procedure

Except for its ability to operate in the multithreaded environment, the HPCOUNTREG procedure is similar to other regression model procedures in the SAS System. For example, the following statements are used to estimate a Poisson regression model:

```
proc hpcountreg data=one ;
   model y = x / dist=poisson ;
run;
```

The response variable y is numeric and has nonnegative integer values.

This section illustrates two simple examples that use PROC HPCOUNTREG. The data are taken from Long (1997). This study examines how factors such as gender (fem), marital status (mar), number of young children (kid5), prestige of the graduate program (phd), and number of articles published by a scientist's mentor (ment) affect the number of articles (art) published by the scientist.

The first 10 observations are shown in Figure 18.1.

Figure 18.1 Article Count Data

Obs	art	fem	mar	kid5	phd	ment
1	3	0	1	2	1.38000	8.0000
2	0	0	0	0	4.29000	7.0000
3	4	0	0	0	3.85000	47.0000
4	1	0	1	1	3.59000	19.0000
5	1	0	1	0	1.81000	0.0000
6	1	0	1	1	3.59000	6.0000
7	0	0	1	1	2.12000	10.0000
8	0	0	1	0	4.29000	2.0000
9	3	0	1	2	2.58000	2.0000
10	3	0	1	1	1.80000	4.0000

The following SAS statements estimate the Poisson regression model. The model is executed in single-machine mode with two threads.

```
/*-- Poisson Regression --*/
proc hpcountreg data=long97data;
   model art = fem mar kid5 phd ment / dist=poisson method=quanew;
   performance nthreads=2  details;
run;
```

The "Model Fit Summary" table that is shown in Figure 18.2 lists several details about the model. By default, the HPCOUNTREG procedure uses the Newton-Raphson optimization technique. The maximum log-likelihood value is shown, in addition to two information measures—Akaike's information criterion (AIC) and Schwarz's Bayesian information criterion (SBC)—which can be used to compare competing Poisson models. Smaller values of these criteria indicate better models.

Figure 18.2 Estimation Summary Table for a Poisson Regression

The HPCOUNTREG Procedure

Model Fit Summary	
Dependent Variable	art
Number of Observations	915
Data Set	WORK.LONG97DATA
Model	Poisson
Log Likelihood	-1651
Maximum Absolute Gradient	0.0002080
Number of Iterations	13
Optimization Method	Quasi-Newton
AIC	3314
SBC	3343

Figure 18.3 shows the parameter estimates of the model and their standard errors. All covariates are significant predictors of the number of articles, except for the prestige of the program (phd), which has a p-value of 0.6271.

Figure 18.3 Parameter Estimates of Poisson Regression

Parameter Estimates					
Parameter	**DF**	**Estimate**	**Standard Error**	**t Value**	**Pr > |t|**
Intercept	1	0.3046	0.1030	2.96	0.0031
fem	1	-0.2246	0.05461	-4.11	<.0001
mar	1	0.1552	0.06137	2.53	0.0114
kid5	1	-0.1849	0.04013	-4.61	<.0001
phd	1	0.01282	0.02640	0.49	0.6271
ment	1	0.02554	0.002006	12.73	<.0001

To allow for variance greater than the mean, you can fit the negative binomial model instead of the Poisson model by specifying the DIST=NEGBIN option, as shown in the following statements. Whereas the Poisson model requires that the conditional mean and conditional variance be equal, the negative binomial model allows for overdispersion, in which the conditional variance can exceed the conditional mean.

```
/*-- Negative Binomial Regression --*/
proc hpcountreg data=long97data;
   model art = fem mar kid5 phd ment / dist=negbin(p=2) method=quanew;
   performance nthreads=2 details;
run;
```

Figure 18.4 shows the fit summary and Figure 18.5 shows the parameter estimates.

Figure 18.4 Estimation Summary Table for a Negative Binomial Regression

The HPCOUNTREG Procedure

Model Fit Summary	
Dependent Variable	art
Number of Observations	915
Data Set	WORK.LONG97DATA
Model	NegBin
Log Likelihood	-1561
Maximum Absolute Gradient	0.0000666
Number of Iterations	16
Optimization Method	Quasi-Newton
AIC	3136
SBC	3170

Figure 18.5 Parameter Estimates of Negative Binomial Regression

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Pr > |t|
Intercept	1	0.2561	0.1386	1.85	0.0645
fem	1	-0.2164	0.07267	-2.98	0.0029
mar	1	0.1505	0.08211	1.83	0.0668
kid5	1	-0.1764	0.05306	-3.32	0.0009
phd	1	0.01527	0.03604	0.42	0.6718
ment	1	0.02908	0.003470	8.38	<.0001
_Alpha	1	0.4416	0.05297	8.34	<.0001

The parameter estimate for _Alpha of 0.4416 is an estimate of the dispersion parameter in the negative binomial distribution. A t test for the hypothesis $H_0 : \alpha = 0$ is provided. It is highly significant, indicating overdispersion ($p < 0.0001$).

The null hypothesis $H_0 : \alpha = 0$ can be also tested against the alternative $\alpha > 0$ by using the likelihood ratio test, as described by Cameron and Trivedi (1998, pp. 45, 77–78). The likelihood ratio test statistic is equal to $-2(\mathcal{L}_P - \mathcal{L}_{NB}) = -2(-1651 + 1561) = 180$, which is highly significant, providing strong evidence of overdispersion.

Syntax: HPCOUNTREG Procedure

The following statements are available in the HPCOUNTREG procedure. Items within angle brackets (< >) or square brackets ([ ]) are optional.

PROC HPCOUNTREG <*options*> ;
BOUNDS *bound1* [*, bound2 . . .*] ;
BY *variables* ;
CLASS *variables* ;
DISPMODEL *dependent variable* ∼ < *dispersion-related regressors* > ;
FREQ *freq-variable* ;
INIT *initialization1* < *, initialization2 . . .* > ;
MODEL *dependent-variable* **=** *regressors* </ *options*> ;
OUTPUT <*output-options*> ;
PERFORMANCE *performance-options* ;
RESTRICT *restriction1* [*, restriction2 . . .*] ;
TEST *equation1* < *, equation2. . .* > / < *test-options* > ;
WEIGHT *variable* </ *option*> ;
ZEROMODEL *dependent-variable* ∼ *zero-inflated-regressors* </ *options*> ;

There can be only one MODEL statement. The ZEROMODEL statement, if used, must appear after the MODEL statement. If a FREQ or WEIGHT statement is specified more than once, the variable specified in the first instance is used.

Functional Summary
