Let $r_i=\mu_i/(\sigma_\mu\sqrt{2})$. Then $\mu_i=(\sigma_\mu\sqrt{2})r_i$ and $d\mu_i=(\sigma_\mu\sqrt{2})dr_i$. Making the change of variable and letting the error effects be additive produce

$$L_i=\frac{1}{\sqrt{\pi}}\int_{-\infty}^{+\infty}\exp(-r_i^2)\left[\prod_{t=1}^{T_i} g(y_{it},\mathbf{x}_{it}'\boldsymbol{\beta}+(\sigma_\mu\sqrt{2})r_i;\boldsymbol{\theta})\right]dr_i$$

This likelihood function is in a form that can be approximated accurately by using Gauss-Hermite quadrature, which eliminates the integration. Thus, the log-likelihood function can be approximated with

$$\ln L_h=\sum_{i=1}^{N}\ln\left[\frac{1}{\sqrt{\pi}}\sum_{h=1}^{H} w_h\prod_{t=1}^{T_i} g(y_{it},\mathbf{x}_{it}'\boldsymbol{\beta}+(\sigma_\mu\sqrt{2})r_h;\boldsymbol{\theta})\right]$$

where w_h and r_h are the weights and nodes for the Hermite quadrature of degree H. PROC QLIM maximizes $\ln L_h$ when the Hermite quadrature option is specified (METHOD=HERMITE in the RANDOM statement).

[1] When sequences are created in multiple dimensions, the initial part of the series is usually eliminated because the initial terms of multiple Halton sequences are highly correlated. However, there is no such correlation for a single dimension.

Bayesian Analysis

To perform Bayesian analysis, you must specify a BAYES statement. Unless otherwise stated, all options in this section are options in the BAYES statement.

By default, PROC QLIM uses the random walk Metropolis algorithm to obtain posterior samples. For the implementation details of the Metropolis algorithm in PROC QLIM, such as the blocking of the parameters and tuning of the covariance matrices, see the sections "Blocking of Parameters" on page 1974 and "Tuning the Proposal Distribution" on page 1974.

The Bayes theorem states that

$$p(\theta|\mathbf{y}) \propto \pi(\theta)L(y|\theta)$$

where θ is a parameter or a vector of parameters and $\pi(\theta)$ is the product of the prior densities that are specified in the PRIOR statement. The term $L(y|\theta)$ is the likelihood associated with the MODEL statement.

Blocking of Parameters

In a multivariate parameter model, all the parameters are updated in one single block (by default or when you specify the SAMPLING=MULTIMETROPOLIS option). This could be inefficient, especially when parameters have vastly different scales. As an alternative, you could update the parameters one at the time (by specifying SAMPLING=UNIMETROPOLIS).

Tuning the Proposal Distribution

One key factor in achieving high efficiency of a Metropolis-based Markov chain is finding a good proposal distribution for each block of parameters. This process is called tuning. The tuning phase consists of a number of loops controlled by the options MINTUNE and MAXTUNE. The MINTUNE= option controls the minimum number of tuning loops and has a default value of 2. The MAXTUNE= option controls the maximum number of tuning loops and has a default value of 24. Each loop is iterated the number of times specified by the NTU= option, which has a default of 500. At the end of every loop, PROC QLIM examines the acceptance probability for each block. The acceptance probability is the percentage of NTU proposed values that have been accepted. If this probability does not fall within the acceptance tolerance range (see the following section), the proposal distribution is modified before the next tuning loop.

A good proposal distribution should resemble the actual posterior distribution of the parameters. Large sample theory states that the posterior distribution of the parameters approaches a multivariate normal distribution (see Gelman et al. 2004, Appendix B; Schervish 1995, Section 7.4). That is why a normal proposal distribution often works well in practice. The default proposal distribution in PROC QLIM is the normal distribution.

Scale Tuning

The acceptance rate is closely related to the sampling efficiency of a Metropolis chain. For a random walk Metropolis, a high acceptance rate means that most new samples occur right around the current data point. Their frequent acceptance means that the Markov chain is moving rather slowly and not exploring the parameter space fully. A low acceptance rate means that the proposed samples are often rejected; hence the chain is not moving much. An efficient Metropolis sampler has an acceptance rate that is neither too high nor too low. The scale c in the proposal distribution $q(\cdot|\cdot)$ effectively controls this acceptance probability.

Roberts, Gelman, and Gilks (1997) show that if both the target and proposal densities are normal, the optimal acceptance probability for the Markov chain should be around 0.45 in a one-dimension problem and should asymptotically approach 0.234 in higher-dimension problems. The corresponding optimal scale is 2.38, which is the initial scale that is set for each block.

Because of the nature of stochastic simulations, it is impossible to fine-tune a set of variables so that the Metropolis chain has exactly the desired acceptance rate that you want. In addition, Roberts and Rosenthal (2001) empirically demonstrate that an acceptance rate between 0.15 and 0.5 is at least 80% efficient, so there is really no need to fine-tune the algorithms to reach an acceptance probability that is within a small tolerance of the optimal values. PROC QLIM works with a probability range, determined by TargetAcceptance ± 0.075. If the observed acceptance rate in a given tuning loop is less than the lower bound of the range, the scale is reduced; if the observed acceptance rate is greater than the upper bound of the range, the scale is increased. During the tuning phase, a scale parameter in the normal distribution is adjusted as a function of the observed acceptance rate and the target acceptance rate. PROC QLIM uses the following updating scheme,[2]

$$c_{\text{new}} = \frac{c_{\text{cur}} \cdot \Phi^{-1}(p_{\text{opt}}/2)}{\Phi^{-1}(p_{\text{cur}}/2)}$$

where c_{cur} is the current scale, p_{cur} is the current acceptance rate, and p_{opt} is the optimal acceptance probability.

Covariance Tuning

To tune a covariance matrix, PROC QLIM takes a weighted average of the old proposal covariance matrix and the recent observed covariance matrix, based on the number samples (as specified by the NTU= option) NTU samples in the current loop. The formula to update the covariance matrix is

$$\text{COV}_{\text{new}} = 0.75\ \text{COV}_{\text{cur}} + 0.25\ \text{COV}_{\text{old}}$$

There are two ways to initialize the covariance matrix:

- The default is an identity matrix that is multiplied by the initial scale of 2.38 and divided by the square root of the number of estimated parameters in the model. A number of tuning phases might be required before the proposal distribution is tuned to its optimal stage, because the Markov chain needs to spend time to learn about the posterior covariance structure. If the posterior variances of your parameters vary by more than a few orders of magnitude, if the variances of your parameters are much different from 1, or if the posterior correlations are high, then the proposal tuning algorithm might have difficulty forming an acceptable proposal distribution.
- Alternatively, you can use a numerical optimization routine, such as the quasi-Newton method, to find a starting covariance matrix. The optimization is performed on the joint posterior distribution, and the covariance matrix is a quadratic approximation at the posterior mode. In some cases this is a better and more efficient way of initializing the covariance matrix. However, there are cases, such as when the number of parameters is large, where the optimization could fail to find a matrix that is positive definite. In those cases, the tuning covariance matrix is reset to the identity matrix.

[2] Roberts and associates demonstrate that the relationship between acceptance probability and scale in a random walk Metropolis scheme is $p = 2\Phi\left(-\sqrt{I}c/2\right)$, where c is the scale, p is the acceptance rate, Φ is the CDF of a standard normal, and $I \equiv E_f[(f'(x)/f(x))^2]$, $f(x)$ is the density function of samples (Roberts, Gelman, and Gilks 1997; Roberts and Rosenthal 2001). This relationship determines the updating scheme, with I replaced by the identity matrix to simplify calculation.

A by-product of the optimization routine is that it also finds the maximum a posteriori (MAP) estimates with respect to the posterior distribution. The MAP estimates are used as the initial values of the Markov chain.

For more information, see the INIT statement.

Initial Values of the Markov Chains

You can assign initial values to any parameters. (For more information, see the INIT statement.) If you use the optimization option PROPCOV=, then PROC QLIM starts the tuning at the optimized values. This option overwrites the provided initial values. If you specify the RANDINIT option, the information that the INIT statement provides is overwritten.

Aggregation of Multiple Chains

When you want to exploit the possibility of running several MCMC instances at the same time (NTRDS=*n*>1), you face the problem of aggregating the chains. In ordinary applications, each MCMC instance can easily obtain stationary samples from the entire posterior distribution. In these applications, you can use the option AGGREGATION=UNWEIGHTED. This option piles up one chain on top of another and makes no particular adjustment. However, when the posterior distribution is characterized by multiple distinct posterior modes, some of the MCMC instances fail to obtain stationary samples from the entire posterior distribution. You can use the option AGGREGATION=WEIGHTED when the posterior samples from each MCMC instance approximate well only a part of the posterior distribution.

The main idea behind the option AGGREGATION=WEIGHTED is to consider the entire posterior distribution to be similar to a mixture distribution. When you are sampling with multiple threads, each MCMC instance samples from one of the mixture components. Then the samples from each mixture component are aggregated together using a resampling scheme in which weights are proportional to the nonnormalized posterior distribution.

Description of the Algorithm

The preliminary step of the aggregation that is implied by the option AGGREGATION=WEIGHTED is to run several (K) independent instances of the MCMC algorithm. Each instance searches for a set of stationary samples. Notice that the concept of stationarity is weaker: each instance might be able to explore not the entire posterior but only portions of it. In the next equation, each column represents the output from one MCMC instance:

$$\begin{pmatrix} x_{11} \\ x_{21} \\ \cdots \\ x_{n1} \end{pmatrix} \begin{pmatrix} x_{12} \\ x_{22} \\ \cdots \\ x_{n2} \end{pmatrix} \cdots \begin{pmatrix} x_{1K} \\ x_{2K} \\ \cdots \\ x_{nK} \end{pmatrix} \sim \text{globally/locally sampled from the posterior}$$

If the length of each chain is less than n, you can augment the corresponding chain by subsampling the chain itself. Each chain is then sorted with respect to the nonnormalized posterior density: $\pi(x_{[1].}) \leq \pi(x_{[2].}) \leq \cdots \pi(x_{[n].})$. Therefore,

$$\begin{pmatrix} x_{11} \\ x_{21} \\ \cdots \\ x_{n1} \end{pmatrix} \begin{pmatrix} x_{12} \\ x_{22} \\ \cdots \\ x_{n2} \end{pmatrix} \cdots \begin{pmatrix} x_{1K} \\ x_{2K} \\ \cdots \\ x_{nK} \end{pmatrix} \rightarrow \begin{pmatrix} x_{[1]1} \\ x_{[2]1} \\ \cdots \\ x_{[n]1} \end{pmatrix} \begin{pmatrix} x_{[1]2} \\ x_{[2]2} \\ \cdots \\ x_{[n]2} \end{pmatrix} \cdots \begin{pmatrix} x_{[1]K} \\ x_{[2]K} \\ \cdots \\ x_{[n]K} \end{pmatrix}$$

The final step is to use a multinomial sampler to resample each row i with weights proportional to the nonnormalized posterior densities:

$$\widetilde{x}_{(i-1)K+1}, \widetilde{x}_{(i-1)K+2}, \ldots, \widetilde{x}_{(i-1)K+K} \sim \text{Multinom}\left[x_{[i]1}, x_{[i]2}, \ldots, x_{[i]K}; \pi(x_{[i]1}), \pi(x_{[i]2}), \ldots, \pi(x_{[i]K})\right]$$

The resulting posterior sample,

$$\widetilde{x}_1, \widetilde{x}_2, \ldots, \widetilde{x}_K, \ldots, \widetilde{x}_{(i-1)K+1}, \widetilde{x}_{(i-1)K+2}, \ldots, \widetilde{x}_{(i-1)K+K}, \ldots, \widetilde{x}_{(n-1)K+1}, \widetilde{x}_{(n-1)K+2}, \ldots, \widetilde{x}_{nK}$$

is a good approximation of the posterior distribution that is characterized by multiple modes.

Automated Initialization of MCMC

The MCMC methods can generate samples from the posterior distribution. The correct implementation of these methods often requires the stationarity analysis, the convergence analysis and the accuracy analysis of the posterior samples. These analyses usually imply the following:

- initialization of the proposal distribution
- initialization of the chains (starting values)
- determination of the burn-in
- determination of the length of the chains.

In more general terms, this determination is equivalent to deciding whether the samples are drawn from the posterior distribution (stationarity analysis), and whether the number of samples is large enough to accurately approximate the posterior distribution (accuracy analysis). You can use the AUTOMCMC option to automate and facilitate the stationary analysis and the accuracy analysis.

Description of the Algorithm

The algorithm consists of two phases. In the first phase, the stationarity phase, the algorithm tries to generate stationary samples from the posterior distribution. In the second phase, the accuracy phase, the algorithm searches for an accurate representation of the posterior distribution. The algorithm implements the following tools:

- Geweke test to check stationarity
- Heidelberger-Welch test to check stationarity and provide a proxy for the burn-in
- Heidelberger-Welch half-test to check the accuracy of the posterior mean
- Raftery-Lewis test to check the accuracy of a given percentile (indirectly proving a proxy for the number of required samples)
- effective sample size analysis to determine a proxy of the number of required samples

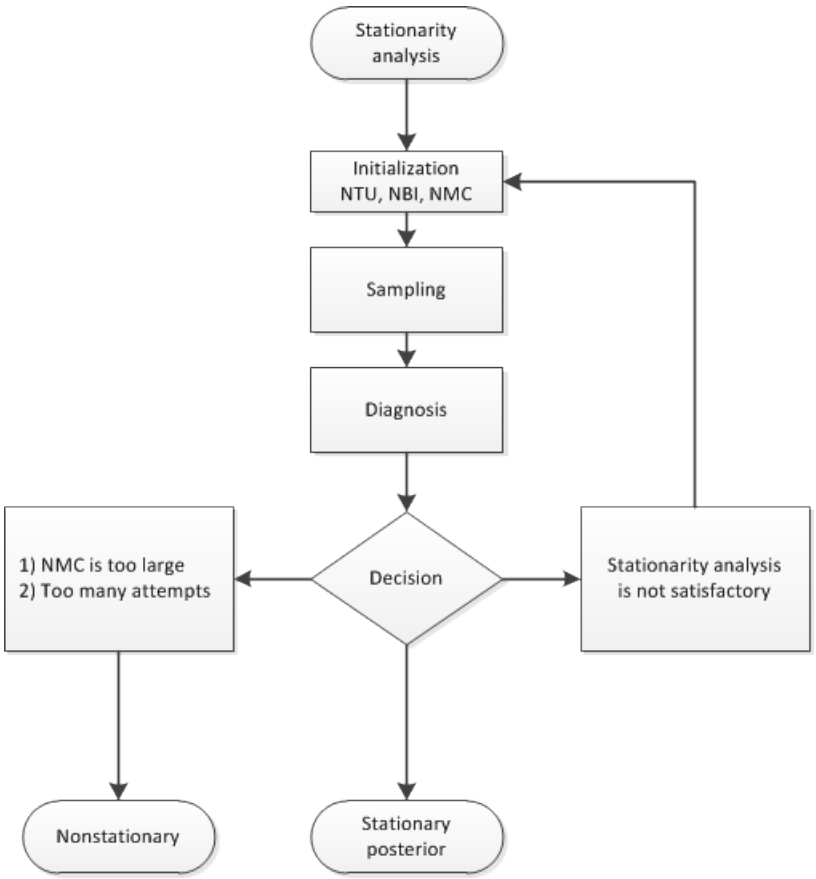
During the stationarity phase, the algorithm searches for stationarity. The number of attempts that the algorithm makes is determined by the option ATTEMPTS=*number*. During each attempt, a preliminary tuning stage chooses a proposal distribution for the MCMC sampler. At the end of the preliminary tuning phase, the algorithm analyzes tests for the stationarity of the samples. If the percentage of successful

stationary tests is equal to or greater than the percentage that is indicated by the option TOL=*value*, then the posterior sample is considered to be stationary. If the sample cannot be considered stationary, then the algorithm attempts to achieve stationarity by changing some of the initialization parameters as follows:

- increasing the number of tuning samples (NTU)
- increasing the number of posterior samples (NMC)
- increasing the burn-in (NBI)

Figure 27.8 shows a flowchart of the algorithm as it searches for stationarity.

Figure 27.8 Flowchart of the AUTOMCMC Algorithm: Stationarity Analysis



You can initialize NMC=M, NBI=B, and NTU=T during the stationarity phase by specifying NMC, NBI, and NTU as options in the BAYES statement. You can also change the minimum stationarity acceptance ratio of successful stationarity tests that are needed to exit the stationarity phase. By default, TOL=0.95. For example:

```
proc qlim data=dataset;
   ...;
   bayes nmc=M nbi=B ntu=T automcmc=( stationarity=(tol=0.95) );
   ...;
run;
```

During the accuracy phase, the algorithm attempts to determine how many posterior samples are needed. The number of attempts is determined by the option ATTEMPTS=*number*. You can choose between two different approaches to study the accuracy:

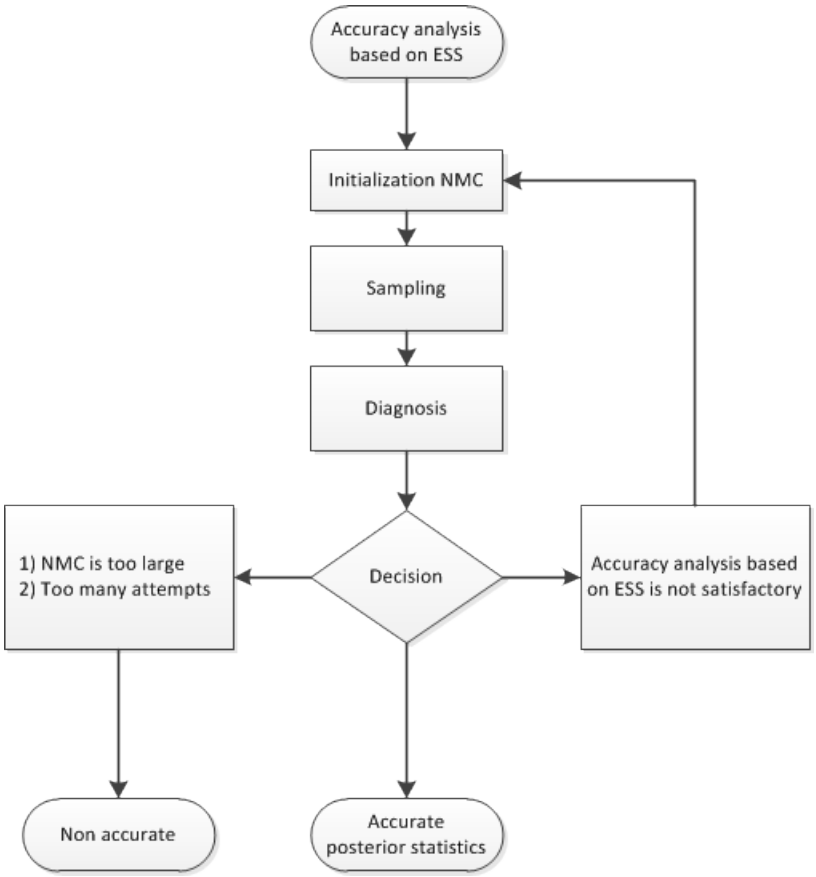
- accuracy analysis based on the effective sample size (ESS)
- accuracy analysis based on the Heidelberger-Welch half-test and the Raftery-Lewis test

If you choose the effective sample size approach, you must provide the minimum number of effective samples that are needed. You can also change the tolerance for the ESS accuracy analysis (by default, TOL=0.95). For example:

```
proc qlim data=dataset;
   ...;
   bayes automcmc=(targetess=N accuracy=(tol=0.95));
   ...;
run;
```

Figure 27.9 shows a flowchart of the algorithm based on the effective sample size approach to determine whether the samples provide an accurate representation of the posterior distribution.

Figure 27.9 Flowchart of the AUTOMCMC Algorithm: Accuracy Analysis Based on the ESS



If you choose the accuracy analysis based on the Heidelberger-Welch half-test and the Raftery-Lewis test

(the default option), then you might want to choose a posterior quantile of interest for the Raftery-Lewis test (by default, 0.025). You can also change the tolerance for the accuracy analysis (by default, TOL=0.95). Notice that the Raftery-Lewis test produces a proxy of the number of posterior sample required. In each attempt, the current number of posterior samples is compared to this proxy. If the proxy is greater than the current nmc, then the algorithm reinitializes itself. To control this reinitialization, you can use the option RLLIMITS=(LB=lb UB=ub). In particular, there are three cases:

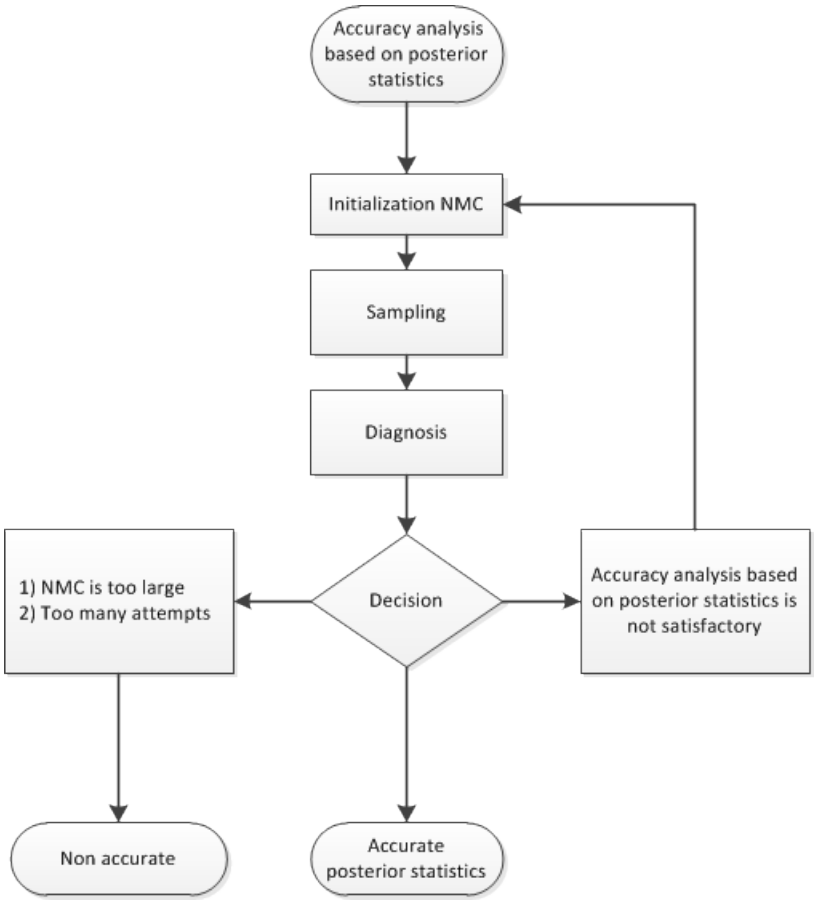
- If the proxy is greater than ub, then NMC is set equal to ub.
- If the proxy is less than lb, then NMC is set equal to lb.
- If lb is less than the proxy, which is less than ub, then NMC is set equal to the proxy.

For example:

```
proc qlim data=dataset;
   ...;
   bayes automcmc=( accuracy=(tol=0.95 targetstats=(rllimits=(lb=k1 ub=k2))) )
        raftery(q=0.025);
   ...;
run;
```

Figure 27.10 shows a flowchart of the algorithm based on the Heidelberger-Welch half-test and the Raftery-Lewis test approach to determine whether the posterior samples provide an accurate representation of the posterior distribution.

Figure 27.10 Flowchart of the AUTOMCMC Algorithm: Accuracy Analysis Based on the Heidelberger-Welch Half-Test and the Raftery-Lewis Test



Prior Distributions

The PRIOR statement is used to specify the prior distribution of the model parameters. You must specify a list of parameters, a tilde ~, and then a distribution with its parameters. You can specify multiple PRIOR statements to define independent priors. Parameters that are associated with a regressor variable are referred to by the name of the corresponding regressor variable.

You can specify the special keyword _REGRESSORS to consider all the regressors of a model. If multiple prior statements affect the same parameter, the prior that is specified is used. For example, in a regression with three regressors (X1, X2, X3) the following statements imply that the prior on X1 is NORMAL(MEAN=0, VAR=1), the prior on X2 is GAMMA(SHAPE=3, SCALE=4), and the prior on X3 is UNIFORM(MIN=0, MAX=1):

```
...
prior _Regressors ~ uniform(min=0, max=1);
prior X1 X2 ~ gamma(shape=3, scale=4);
prior X1 ~ normal(mean=0, var=1);
...
```

If a parameter is not associated with a PRIOR statement or if some of the prior hyperparameters are missing, then the default choices shown in Table 27.2 are considered.

Table 27.2 Default Values for Prior Distributions

PRIOR *distribution*	**Hyperparameter**$_1$	**Hyperparameter**$_2$	**Min**	**Max**	**Parameters Default Choice**
NORMAL	MEAN=0	VAR=1E6	$-\infty$	∞	Regression-Location-Threshold
IGAMMA	SHAPE=2.000001	SCALE=1	> 0	∞	Scale
SQIGAMMA	SHAPE=2.000001	SCALE=1	> 0	∞	Scale
GAMMA	SHAPE=1	SCALE=1	0	∞	
SQGAMMA	SHAPE=1	SCALE=1	0	∞	
UNIFORM			$-\infty$	∞	
UNIFORM			> -1	< 1	Cross-correlation
BETA	SHAPE1=1	SHAPE2=1	$-\infty$	∞	
T	LOCATION=0	DF=3	$-\infty$	∞	

For density specification, see the section "Standard Distributions" on page 1989.

Priors for Heteroscedastic Models

The choice of the prior distribution for a heteroscedastic model is particularly interesting. Based on the notation provided in section "HETERO Statement" on page 1932, you need to provide a prior for $\boldsymbol{\gamma}$. This prior is enough to induce different σ_i^2 into the analysis. The resulting inference is a compromise between two cases: the inference based on the entire sample and the inference based on a single unit $\mathbf{z}_i$. The degree of compromise is determined by $\pi(\boldsymbol{\gamma})$.

This type of modeling is similar to a method called "hierarchical Bayes," in which the prior is characterized by two levels: one for each individual $\pi(\sigma_i^2|\boldsymbol{\gamma})$ and one for the entire population $\pi(\boldsymbol{\gamma})$. In this scenario the degree of compromise between the information provided by a unit and the information provided by the entire sample is determined by the data.

The choice of the prior might not be straightforward, and it can heavily affect sampling performance. Depending on how the heteroscedastic effects are modeled, the default priors are

$$\text{if } \left[1+\exp(\mathbf{z}_i'\boldsymbol{\gamma})\right], \quad \pi(\gamma_j) = \textbf{normal}\left\{\text{mean} = \frac{1}{\bar{z}_j J}\left[\log\left(\frac{\varepsilon^4}{1+\varepsilon^2}\right)\right], \text{var} = \frac{1}{\bar{z}_j^2 J}\left[\log\left(\frac{1+\varepsilon^2}{\varepsilon^2}\right)\right]\right\}$$

$$\text{if } \left[\exp(\mathbf{z}_i'\boldsymbol{\gamma})\right], \quad \pi(\gamma_j) = \textbf{normal}\left\{\text{mean} = \frac{1}{\bar{z}_j J}\left[\log\left(\frac{1}{2}\right)\right], \text{var} = \frac{1}{\bar{z}_j^2 J}\left[\log(2)\right]\right\}$$

$$\text{if } \left(1+\mathbf{z}_i'\boldsymbol{\gamma}\right), \quad \pi(\gamma_j) = \textbf{normal}\left\{\text{mean} = 0, \text{var} = \frac{1}{\bar{z}_j^2 J}\right\}$$

$$\text{if } \left[1+(\mathbf{z}_i'\boldsymbol{\gamma})^2\right], \quad \pi(\gamma_j) = \textbf{normal}\left\{\text{mean} = \frac{(\varepsilon^2-1/2)^{1/4}}{\bar{z}_j J}, \text{var} = \frac{\varepsilon-(\varepsilon^2-1/2)^{1/2}}{\bar{z}_j^2 J}\right\}$$

where $\bar{z}_j = \frac{1}{n}\sum_{i=1}^{n} z_{ij}$, $\forall j$, and ε is a small number (by default, $\varepsilon = 0.1$ for the EXPONENTIAL link function and $\varepsilon = 0.71$ for the QUADRATIC link function).

The priors for the EXPONENTIAL and QUADRATIC link functions are not straightforward. To understand the choices, do the following:

1. Assume that

$$\mathbf{z}_i'\boldsymbol{\gamma} = z_{i1}\gamma_1 + \cdots + z_{iJ}\gamma_J \approx \bar{z}_1\gamma_1 + \cdots + \bar{z}_J\gamma_J, \qquad \forall i$$

2. Set the priors according to the link function type:

   - For the EXPONENTIAL link function, set

$$\begin{aligned} \mathrm{E}\left[\exp(\mathbf{z}_i'\boldsymbol{\gamma})\right] &\approx \mathrm{E}\left[\exp(\bar{z}_1\gamma_1)\right] \times \cdots \times \mathrm{E}\left[\exp(\bar{z}_J\gamma_J)\right] = \varepsilon \\ \mathrm{V}\left[\exp(\mathbf{z}_i'\boldsymbol{\gamma})\right] &\approx \mathrm{E}\left[\exp(2\bar{z}_1\gamma_1)\right] \times \cdots \times \mathrm{E}\left[\exp(2\bar{z}_J\gamma_J)\right] - \varepsilon^2 = 1 \end{aligned}$$

     Assume a normal prior for $\pi(\gamma_j)$, and set

$$\begin{aligned} \mathrm{E}\left[\exp(\bar{z}_j\gamma_j)\right] &= \varepsilon^{\frac{1}{J}}, \forall j \\ \mathrm{E}\left[\exp(2\bar{z}_j\gamma_j)\right] &= (1+\varepsilon^2)^{\frac{1}{J}}, \forall j \end{aligned}$$

     Based on the properties of the lognormal distribution, the prior hyperparameters for γ_j can be derived. Notice that J is the number of regressors that are used in the heterogeneous regression. If the intercept is excluded, then $\varepsilon = 1$.

   - For the QUADRATIC link function, set

$$\begin{aligned} \mathrm{E}\left[(\mathbf{z}_i'\boldsymbol{\gamma})^2\right] &\approx \left[\mathrm{E}\left(\bar{z}_1\gamma_1 + \cdots + \bar{z}_J\gamma_J\right)\right]^2 + \mathrm{V}\left[\bar{z}_1\gamma_1 + \cdots + \bar{z}_J\gamma_J\right] = \varepsilon \\ \mathrm{V}\left[(\mathbf{z}_i'\boldsymbol{\gamma})^2\right] &\approx \mathrm{E}\left[(\bar{z}_1\gamma_1 + \cdots + \bar{z}_J\gamma_J)^4\right] - \varepsilon^2 = 1 \end{aligned}$$

     Assume a normal prior for $\pi(\gamma_j)$. Based on the properties of the normal distribution, the preceding expressions return

$$\begin{aligned} \mathrm{E}\left[\bar{z}_1\gamma_1 + \cdots + \bar{z}_J\gamma_J\right] &= (\varepsilon^2 - 1/2)^{1/4} \\ \mathrm{V}\left[\bar{z}_1\gamma_1 + \cdots + \bar{z}_J\gamma_J\right] &= \varepsilon - (\varepsilon^2 - 1/2)^{1/2} \\ \varepsilon &> (1/2)^{1/2} \end{aligned}$$

     The prior hyperparameters for γ_j can be derived by setting

$$\begin{aligned} \mathrm{E}\left[\bar{z}_j\gamma_j\right] &= \frac{(\varepsilon^2 - 1/2)^{1/4}}{J}, \forall j \\ \mathrm{V}\left[\bar{z}_j\gamma_j\right] &= \frac{\varepsilon - (\varepsilon^2 - 1/2)^{1/2}}{J}, \forall j \end{aligned}$$

     Notice that J is the number of regressors that are used in the heterogeneous regression. It is important to emphasize that the restriction $\varepsilon > (1/2)^{1/2} \approx 0.71$ is likely to introduce some distortion because ε cannot be any "small" number.

Hamiltonian MC: Parameter Transformation

The QLIM procedure implements the Hamiltonian Monte Carlo No-U-Turn Sampler (NUTS) with transformation of the bounded parameters. For more information about NUTS and more in general about Hamiltonian Monte Carlo, see the section "Hamiltonian Monte Carlo Sampler" (Chapter 8, *SAS/STAT User's Guide*).

The Bayesian analysis is primarily interested in the properties of the posterior distribution,

$$p(\theta|\mathbf{y}),$$

where $\theta = (\theta_1, \ldots, \theta_k)'$ is the parameter vector associated with the model and $\mathbf{y}$ represents the data. The properties of the model and the properties of the prior distribution can impose restrictions on the domain of θ. These restrictions can reduce the efficiency of the common sampling methods. One way to improve the efficiency is to perform a parameter transformation, which maps the bounded parameters θ to the unbounded parameter $\mathbf{u}$. In a simplified scenario, four cases can be identified:

$$u_i = \begin{cases} \theta_i & \text{if } -\infty < \theta_i < \infty \\ \ln(\theta_i - \min) & \text{if } -\infty < \min \le \theta_i < \infty \\ \ln(\max - \theta_i) & \text{if } -\infty < \theta_i \le \max < \infty \\ \ln(\theta_i - \min) - \ln(\max - \theta_i) & \text{if } -\infty < \min \le \theta_i \le \max < \infty \end{cases}$$

The corresponding inverse transformations are

$$\theta_i = \begin{cases} u_i & \text{if } -\infty < \theta_i < \infty \\ \min + e^{u_i} & \text{if } -\infty < \min \le \theta_i < \infty \\ \max - e^{u_i} & \text{if } -\infty < \theta_i \le \max < \infty \\ \frac{\max e^{u_i} + \min}{e^{u_i} + 1} & \text{if } -\infty < \min \le \theta_i \le \max < \infty \end{cases}$$

with partial derivatives

$$\frac{\delta \theta_i}{\delta u_i} = \begin{cases} 1 & \text{if } -\infty < \theta_i < \infty \\ e^{u_i} & \text{if } -\infty < \min \le \theta_i < \infty \\ -e^{u_i} & \text{if } -\infty < \theta_i \le \max < \infty \\ \frac{(\max - \min) e^{u_i}}{(e^{u_i} + 1)^2} & \text{if } -\infty < \min \le \theta_i \le \max < \infty \end{cases}$$

Given the independent nature of the transformation, the corresponding Jacobian is a diagonal matrix

$$\mathrm{D}_u = \begin{bmatrix} \frac{\delta \theta_1}{\delta u_1} & & \\ & \ddots & \\ & & \frac{\delta \theta_k}{\delta u_k} \end{bmatrix}$$

which in turn implies that

$$p(\mathbf{u}|\mathbf{y}) = p(\theta|\mathbf{y})|\mathrm{Det}(\mathrm{D}_u)| = p(\theta|\mathbf{y}) \prod_{i=1}^{k} \left| \frac{\delta \theta_i}{\delta u_i} \right|$$

It is usually convenient to work on the logarithmic scale,

$$\begin{aligned}
\ln\left[p(\mathbf{u}|\mathbf{y})\right] &= \ln\left[p(\theta|\mathbf{y})\right] + \sum_{i=1}^{k} \ln\left(\left|\frac{\delta\theta_i}{\delta u_i}\right|\right) \\
\frac{\delta \ln\left[p(u_i|\mathbf{y})\right]}{\delta u_i} &= \frac{\delta \ln\left\{p[\theta_i(u_i)|\mathbf{y}]\right\}}{\delta u_i} + \frac{\delta \ln\left(|\delta\theta_i/\delta u_i|\right)}{\delta u_i} \equiv \frac{\delta \ln\left\{p(\theta_i|\mathbf{y})\right\}}{\delta\theta_i}\frac{\delta\theta_i}{\delta u_i} + \frac{\delta \ln\left(|\delta\theta_i/\delta u_i|\right)}{\delta u_i}
\end{aligned}$$

where

$$\frac{\delta \ln\left(|\delta\theta_i/\delta u_i|\right)}{\delta u_i} = \begin{cases} 0 & \text{if} \quad -\infty < \theta_i < \infty \\ 1 & \text{if} \quad -\infty < \min \le \theta_i < \infty \\ 1 & \text{if} \quad -\infty < \theta_i \le \max < \infty \\ 1 - \frac{2e^{u_i}}{e^{u_i}+1} & \text{if} \quad -\infty < \min \le \theta_i \le \max < \infty \end{cases}$$

Automated MCMC

The main purpose is to provide the user with the opportunity of obtaining a good approximation of the posterior distribution without initializing the MCMC algorithm: initial values, proposal distributions, burn-in and number of samples.

The automated algorithm is composed of two phases: tuning and sampling. In the tuning phase, there are two main concerns: the choice of a good proposal distribution and the search for the stationary region of the posterior distribution. In the sampling phase, the algorithm will decide how many samples are necessary to obtain good approximations of the posterior mean and some quantiles of interest.

Stationarity Phase

During the stationarity phase, the algorithm tries to search for a good proposal distribution and, at the same time, to reach the stationary region of the posterior. The choice of the proposal distribution is based on the analysis of the acceptance rates. This is similar to what is done in PROC MCMC; for more information, see the section "Tuning the Proposal Distribution" (Chapter 80, *SAS/STAT User's Guide*). For the stationarity analysis, the main idea is to run two tests, Geweke (Ge) and Heidelberger-Welch (HW), on the posterior chains at the end of each attempt. For more information, see the sections "Geweke Diagnostics" (Chapter 8, *SAS/STAT User's Guide*) and "Heidelberger and Welch Diagnostics" (Chapter 8, *SAS/STAT User's Guide*). If the stationarity hypothesis is rejected, then the tuning samples are increased and the tests repeated in the next attempt. After 10 attempts, the stationarity phase will be ended regardless of the results. The tuning parameters for the first attempt are fixed:

1000	burn-in (nbi)
500	tuning samples (ntu)
1000	MCMC samples (nmc)

For the remaining attempts, the tuning parameters will be adjusted dynamically. More specifically, each parameter will be assigned an acceptance ratio (AR) of the stationarity hypothesis,

$$
\begin{array}{lll}
AR_i = 0 & \text{if} & \text{both tests reject the stationarity hypothesis} \\
AR_i = 0.5 & \text{if} & \text{one tests rejects and the other does not} \\
AR_i = 1 & \text{if} & \text{both tests do not reject the stationarity hypothesis}
\end{array}
$$

for $i = 1, \ldots, k$. For the Geweke test, the implemented significance level is 0.05. Then, an overall stationarity average (SA) for all parameters ratios is evaluated,

$$SA = \sum_{i=1}^{k} \frac{AR_i}{k}$$

and the number of tuning samples is updated accordingly:

$$
\begin{array}{lll}
\text{ntu} = \text{ntu} + 2000 & \text{if} & SA < 70\% \\
\text{ntu} = \text{ntu} + 1000 & \text{if} & 70\% \leq SA < 100\% \\
\text{ntu} = \text{ntu} & \text{if} & SA = 100\%
\end{array}
$$

The burn-in is also updated whenever stationarity is not achieved:

$$\text{nbi} = \text{nbi} + 1000$$

Moreover, the Heidelberger-Welch test also provides an indications of how much burn-in should be used. The algorithm requires this burn-in to be nbi(HW) $= 0$. If that is not the case, the burn-in will updated accordingly,

$$\text{nbi} = \max[\text{nbi}, \text{nbi(HW)}]$$

and a new attempt searching for stationarity will be implemented. This choice is motivated by the fact that the burn-in must be discarded in order to reach the stationary region of the posterior distribution.

The number of samples is updated at each attempt. However, in order to exit the stationarity phase, it will not be required nmc(RL) $= 0$. The default update is nmc $=$ nmc $+ 1000$. Depending on the outcome of the Raftery-Lewis diagnostics, if nmc $< \min\{\text{LB}[\text{nmc(RL)}], \text{nmc(RL)}\}$, the number of sampling is further updated to nmc $= \text{LB}[\text{nmc(RL)}]$. By default, $\text{LB}[\text{nmc(RL)}] = 10000$. Finally, if the number of projected samples is not sufficient to perform a stable evaluation of the Raftery-Lewis test, the number of samples is updated to nmc $= \min[\text{nmc(RL)}]$. For more information, see the section "AUTOMCMC<=(*automcmc-options*)>" on page 1921 and Chapter 8.4, "Raftery and Lewis Diagnostics" (*SAS/STAT User's Guide*).

Accuracy Phase

The main idea of the accuracy phase is to make sure that the mean and a quantile of interest are evaluated accurately. This can be tested by implementing the half-width test by Heidelberger-Welch and by analyzing the Raftery-Lewis diagnostic tool. In addition, the requirements defined in the stationarity phase will also be checked: the Geweke and the Heidelberger-Welch tests must not reject the stationary hypothesis and the burn-in predicted by the Heidelberger-Welch test must be zero.

The accuracy phase is characterized by a maximum of 10 attempts. If the algorithm exceeds this limit, the accuracy phase will end and indications on how to improve sampling will be given. The search of accuracy can be performed using two different method. The first method (the default) is triggered by the option TARGETSTATS and it is based on the accuracy analysis of the mean and a percentile of interest. The second method is triggered by the option TARGETESS and it targets a minimum number of effective samples. The accuracy phase will first update the burn-in with the information provided by the HW test: $\text{nbi} = \text{nbi} + \text{nbi(HW)}$. Then, it determines the difference between the actual number of samples and the number of samples predicted by either the RL test or the ESS: $\Delta[\text{nmc}] = \text{nmc(RL)} - \text{nmc}$, or $\Delta[\text{nmc}] = \text{nmc(ESS)} - \text{nmc}$. The new number of samples will be updated accordingly:

$$\begin{aligned}
&\text{nmc} = \text{nmc} + \text{LB}\,[\text{nmc(RL)}] && \text{if} && 0 < \Delta[\text{nmc}] \leq \text{LB}\,[\text{nmc(RL)}] \\
&\text{nmc} = \text{nmc} + \Delta[\text{nmc}] && \text{if} && \text{LB}\,[\text{nmc(RL)}] < \Delta[\text{nmc}] \leq \text{UB}\,[\text{nmc(RL)}] \\
&\text{nmc} = \text{nmc} + \text{UB}\,[\text{nmc(RL)}] && \text{if} && \text{UB}\,[\text{nmc(RL)}] < \Delta[\text{nmc}]
\end{aligned}$$

By default, $\text{LB}\,[\text{nmc(RL)}] = 10000$ and $\text{UB}\,[\text{nmc(RL)}] = 300000$.

In addition, the accuracy search triggered by the option TARGETSTATS also implements the HW half-width test to checks whether the sample mean is accurate. If the mean of any parameters is not considered to be accurate and the number of samples has not been updated based on $\Delta[\text{nmc}]$, then the number of samples is increased:

$$\text{nmc} = \text{nmc} + 5000 \quad \text{if} \quad \Delta[\text{nmc}] \leq 0$$

Marginal Likelihood

The Bayes theorem states that

$$p(\theta|\mathbf{y}) \propto \pi(\theta)L(y|\theta)$$

where θ is a vector of parameters and $\pi(\theta)$ is the product of the prior densities that are specified in the PRIOR statement. The term $L(y|\theta)$ is the likelihood that is associated with the MODEL statement. The function $\pi(\theta)L(y|\theta)$ is the nonnormalized posterior distribution over the parameter vector θ. The normalized posterior distribution (simply, the posterior distribution) is

$$p(\theta|\mathbf{y}) = \frac{\pi(\theta)L(y|\theta)}{\int_\theta \pi(\theta)L(y|\theta)d\theta}$$

The denominator $m(y) = \int_\theta \pi(\theta)L(y|\theta)d\theta$ (also called the "marginal likelihood") is a quantity of interest because it represents the probability of the data after the effect of the parameter vector has been averaged out.

Because of its interpretation, the marginal likelihood can be used in various applications, including model averaging, variable selection, and model selection.

A natural estimate of the marginal likelihood is provided by the harmonic mean,

$$m(y) = \left\{ \frac{1}{n} \sum_{i=1}^{n} \frac{1}{L(y|\theta_i)} \right\}^{-1}$$

where θ_i is a sample draw from the posterior distribution. In practical applications, this estimator has proven to be unstable.

An alternative and more stable estimator can be obtained with an importance sampling scheme. The auxiliary distribution for the importance sampler can be chosen through the cross entropy theory (Chan and Eisenstat 2015). In particular, given a parametric family of distributions, the auxiliary density function is chosen to be the one closest, in terms of the Kullback-Leibler divergence, to the probability density that would give a zero variance estimate of the marginal likelihood. In practical terms, this is equivalent to the following algorithm:

1. Choose a parametric family, $f(., \beta)$, for the parameters of the model: $f(\theta|\beta)$.
2. Evaluate the maximum likelihood estimator of β by using the posterior samples $\theta_1, \ldots, \theta_n$ as data.
3. Use $f(\theta^*|\hat{\beta}_{mle})$ to generate the importance samples $\theta_1^*, \ldots, \theta_{n^*}^*$.
4. Estimate the marginal likelihood:

$$m(y) = \frac{1}{n^*} \sum_{j=1}^{n^*} \frac{L(y|\theta_j^*)\pi(\theta_j^*)}{f(\theta_j^*|\hat{\beta}_{mle})}$$

The parametric family for the auxiliary distribution is chosen to be Gaussian. The parameters that are subject to bounds are transformed accordingly:

- If $-\infty < \theta < \infty$, then $p = \theta$.
- If $m \leq \theta < \infty$, then $q = \log(\theta - m)$.
- If $-\infty < \theta \leq M$, then $r = \log(M - \theta)$.
- If $m \leq \theta \leq M$, then $s = \log(\theta - m) - \log(M - \theta)$.

Assuming independence for the parameters that are subject to bounds, the auxiliary distribution to generate importance samples is

$$\begin{pmatrix} \mathbf{p} \\ \mathbf{q} \\ \mathbf{r} \\ \mathbf{s} \end{pmatrix} \sim \mathbf{N}\left[\begin{pmatrix} \mu_p \\ \mu_q \\ \mu_r \\ \mu_s \end{pmatrix}, \begin{pmatrix} \Sigma_p & 0 & 0 & 0 \\ 0 & \Sigma_q & 0 & 0 \\ 0 & 0 & \Sigma_r & 0 \\ 0 & 0 & 0 & \Sigma_r \end{pmatrix} \right]$$

where $\mathbf{p}$, $\mathbf{q}$, $\mathbf{r}$, and $\mathbf{s}$ are vectors that contain the transformations of the unbounded, bounded-below, bounded-above, and bounded-above-and-below parameters. Also, given the imposed independence structure, Σ_p can be a nondiagonal matrix, but Σ_q, Σ_r, and Σ_s are assumed to be diagonal matrices.

Standard Distributions

Table 27.3 through Table 27.10 show all the distribution density functions that PROC QLIM recognizes. You specify these distribution densities in the PRIOR statement.

Table 27.3 Beta Distribution

PRIOR statement	BETA(SHAPE1=a, SHAPE2=b, MIN=m, MAX=M) Note: Commonly $m = 0$ and $M = 1$.
Density	$\frac{(\theta-m)^{a-1}(M-\theta)^{b-1}}{B(a,b)(M-m)^{a+b-1}}$
Parameter restriction	$a > 0, \quad b > 0, \quad -\infty < m < M < \infty$
Range	$\begin{cases} [m, M] & \text{when } a = 1, b = 1 \\ [m, M) & \text{when } a = 1, b \neq 1 \\ (m, M] & \text{when } a \neq 1, b = 1 \\ (m, M) & \text{otherwise} \end{cases}$
Mean	$\frac{a}{a+b} \times (M - m) + m$
Variance	$\frac{ab}{(a+b)^2(a+b+1)} \times (M - m)^2$
Mode	$\begin{cases} \frac{a-1}{a+b-2} \times M + \frac{b-1}{a+b-2} \times m & a > 1, b > 1 \\ m \text{ and } M & a < 1, b < 1 \\ m & \begin{cases} a < 1, b \geq 1 \\ a = 1, b > 1 \end{cases} \\ M & \begin{cases} a \geq 1, b < 1 \\ a > 1, b = 1 \end{cases} \\ \text{not unique} & a = b = 1 \end{cases}$
Defaults	SHAPE1=SHAPE2=1, MIN $\rightarrow -\infty$, MAX $\rightarrow \infty$

Table 27.4 Gamma Distribution

PRIOR statement	GAMMA(SHAPE=a, SCALE=b)
Density	$\frac{1}{b^a \Gamma(a)} \theta^{a-1} e^{-\theta/b}$
Parameter restriction	$a > 0, b > 0$
Range	$[0, \infty)$
Mean	ab
Variance	ab^2
Mode	$(a - 1)b$
Defaults	SHAPE=SCALE=1

Table 27.5 Inverse Gamma Distribution

PRIOR statement	IGAMMA(SHAPE=a, SCALE=b)
Density	$\frac{b^a}{\Gamma(a)}\theta^{-(a+1)}e^{-b/\theta}$
Parameter restriction	$a > 0, b > 0$
Range	$0 < \theta < \infty$
Mean	$\frac{b}{a-1}, \quad a > 1$
Variance	$\frac{b^2}{(a-1)^2(a-2)}, \quad a > 2$
Mode	$\frac{b}{a+1}$
Defaults	SHAPE=2.000001, SCALE=1

Table 27.6 Normal Distribution

PRIOR statement	NORMAL(MEAN=μ, VAR=σ^2)
Density	$\frac{1}{\sigma\sqrt{2\pi}}\exp\left(-\frac{(\theta-\mu)^2}{2\sigma^2}\right)$
Parameter restriction	$\sigma^2 > 0$
Range	$-\infty < \theta < \infty$
Mean	μ
Variance	σ^2
Mode	μ
Defaults	MEAN=0, VAR=1000000

Table 27.7 Square Root Gamma Distribution

PRIOR statement	SQGAMMA(SHAPE=a, SCALE=b)
Density	$\frac{2}{b^a\Gamma(a)}\theta^{2a-1}e^{-\theta^2/b}$
Parameter restriction	$a > 0, b > 0$
Range	$[0, \infty)$
Mean	$\frac{\Gamma(a+\frac{1}{2})}{\Gamma(a)}\sqrt{b}$
Variance	$\left\{a - \left[\frac{\Gamma(a+\frac{1}{2})}{\Gamma(a)}\right]^2\right\} b$
Mode	$\sqrt{(a-\frac{1}{2})b}, \quad a \geq \frac{1}{2}$
Defaults	SHAPE=SCALE=1

For more information, see Stacy (1962).

Table 27.8 Square Root Inverse Gamma Distribution

PRIOR statement	SQIGAMMA(SHAPE=a, SCALE=b)
Density	$\frac{2b^a}{\Gamma(a)}\theta^{-(2a+1)}e^{-b/\theta^2}$
Parameter restriction	$a > 0, b > 0$
Range	$0 < \theta < \infty$
Mean	$\frac{\Gamma(a-\frac{1}{2})}{\Gamma(a)}\sqrt{b}, \qquad a > \frac{1}{2}$
Variance	$\left\{\frac{1}{a-1} - \left[\frac{\Gamma(a-\frac{1}{2})}{\Gamma(a)}\right]^2\right\} b, \qquad a > 1$
Mode	$\sqrt{\frac{b}{a+\frac{1}{2}}}$
Defaults	SHAPE=2.000001, SCALE=1

For more information, see Stacy (1962).

Table 27.9 *t* Distribution

PRIOR statement	T(LOCATION=μ, DF=ν)
Density	$\frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)\sqrt{\pi\nu}}\left[1 + \frac{(\theta-\mu)^2}{\nu}\right]^{-\frac{\nu+1}{2}}$
Parameter restriction	$\nu > 0$
Range	$-\infty < \theta < \infty$
Mean	μ, for $\nu > 1$
Variance	$\frac{\nu}{\nu-2}$, for $\nu > 2$
Mode	μ
Defaults	LOCATION=0, DF=3

Table 27.10 Uniform Distribution

PRIOR statement	UNIFORM(MIN=m, MAX=M)
Density	$\frac{1}{M-m}$
Parameter restriction	$-\infty < m < M < \infty$
Range	$\theta \in [m, M]$
Mean	$\frac{m+M}{2}$
Variance	$\frac{(M-m)^2}{12}$
Mode	Not unique
Defaults	MIN$\rightarrow -\infty$, MAX$\rightarrow \infty$

Output to SAS Data Set

XBeta, Predicted, Residual

Xbeta is the structural part on the right-hand side of the model. Predicted value is the predicted dependent variable value. For censored variables, if the predicted value is outside the boundaries, it is reported as the closest boundary. For discrete variables, it is the level whose boundaries Xbeta falls between. Residual is defined only for continuous variables and is defined as

$$Residual = Observed - Predicted$$

Error Standard Deviation

Error standard deviation is σ_i in the model. It varies only when the HETERO statement is used.

Marginal Effects

Marginal effect is defined as a contribution of one control variable to the response variable. For the binary choice model with two response categories, $\mu_0 = -\infty$, $\mu_1 = 0$, $\mu_2 = \infty$; and ordinal response model with M response categories, $\mu_0, \ldots, \mu_M$, define

$$R_{i,j} = \mu_j - \mathbf{x}_i'\boldsymbol{\beta}$$

The probability that the unobserved dependent variable is contained in the *j*th category can be written as

$$P[\mu_{j-1} < y_i^* \le \mu_j] = F(R_{i,j}) - F(R_{i,j-1})$$

The marginal effect of changes in the regressors on the probability of $y_i = j$ is then

$$\frac{\partial \text{Prob}[y_i = j]}{\partial \mathbf{x}} = [f(\mu_{j-1} - \mathbf{x}_i'\boldsymbol{\beta}) - f(\mu_j - \mathbf{x}_i'\boldsymbol{\beta})]\boldsymbol{\beta}$$

where $f(x) = \frac{dF(x)}{dx}$. In particular,

$$f(x) = \frac{dF(x)}{dx} = \begin{cases} \frac{1}{\sqrt{2\pi}} e^{-x^2/2} & \text{(probit)} \\ \frac{e^{-x}}{[1+e^{(-x)}]^2} & \text{(logit)} \end{cases}$$

The marginal effects in the Box-Cox regression model are

$$\frac{\partial E[y_i]}{\partial \mathbf{x}} = \boldsymbol{\beta} \frac{x^{\lambda_k - 1}}{y^{\lambda_0 - 1}}$$

The marginal effects in the truncated regression model are

$$\frac{\partial E[y_i | L_i < y_i^* < R_i]}{\partial \mathbf{x}} = \boldsymbol{\beta} \left[1 - \frac{(\phi(a_i) - \phi(b_i))^2}{(\Phi(b_i) - \Phi(a_i))^2} + \frac{a_i \phi(a_i) - b_i \phi(b_i)}{\Phi(b_i) - \Phi(a_i)} \right]$$

where $a_i = \frac{L_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma_i}$ and $b_i = \frac{R_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma_i}$.

The marginal effects in the censored regression model are

$$\frac{\partial E[y|\mathbf{x}_i]}{\partial \mathbf{x}} = \boldsymbol{\beta} \times \text{Prob}[L_i < y_i^* < R_i]$$

For models that involve higher-order or interaction variables, the marginal effects are calculated by treating these variables as independent explanatory variables. Therefore, the marginal effects of the higher-order or interaction variables ignore the polynomial nature of these variables.

Inverse Mills Ratio, Expected and Conditionally Expected Values

Expected and conditionally expected values are computed only for continuous variables. The inverse Mills ratio is computed for censored or truncated continuous, binary discrete, and selection endogenous variables.

Let L_i and R_i be the lower boundary and upper boundary, respectively, for the y_i. Define $a_i = \frac{L_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma_i}$ and $b_i = \frac{R_i - \mathbf{x}_i'\boldsymbol{\beta}}{\sigma_i}$. Then the inverse Mills ratio is defined as

$$\lambda = \frac{(\phi(a_i) - \phi(b_i))}{(\Phi(b_i) - \Phi(a_i))}$$

for a continuous variable and defined as

$$\lambda = \frac{\phi(\mathbf{x}_i'\boldsymbol{\beta})}{\Phi(\mathbf{x}_i'\boldsymbol{\beta})}$$

for a binary discrete variable.

The expected value is the unconditional expectation of the dependent variable. For a censored variable, it is

$$E[y_i] = \Phi(a_i)L_i + (\mathbf{x}_i'\boldsymbol{\beta} + \lambda\sigma_i)(\Phi(b_i) - \Phi(a_i)) + (1 - \Phi(b_i))R_i$$

For a left-censored variable ($R_i = \infty$), this formula is

$$E[y_i] = \Phi(a_i)L_i + (\mathbf{x}_i'\boldsymbol{\beta} + \lambda\sigma_i)(1 - \Phi(a_i))$$

where $\lambda = \frac{\phi(a_i)}{1-\Phi(a_i)}$.

For a right-censored variable ($L_i = -\infty$), this formula is

$$E[y_i] = (\mathbf{x}_i'\boldsymbol{\beta} + \lambda\sigma_i)\Phi(b_i) + (1 - \Phi(b_i))R_i$$

where $\lambda = -\frac{\phi(b_i)}{\Phi(b_i)}$.

For a noncensored variable, this formula is

$$E[y_i] = \mathbf{x}_i'\boldsymbol{\beta}$$

The conditional expected value is the expectation given that the variable is inside the boundaries:

$$E[y_i|L_i < y_i < R_i] = \mathbf{x}_i'\boldsymbol{\beta} + \lambda\sigma_i$$

Probability

Probability applies only to discrete responses. It is the marginal probability that the discrete response is taking the value of the observation. If the PROBALL option is specified, then the probability for all of the possible responses of the discrete variables is computed.

Technical Efficiency

Technical efficiency for each producer is computed only for stochastic frontier models.

In general, the stochastic production frontier can be written as

$$y_i = f(x_i;\beta)\exp\{v_i\}TE_i$$

where y_i denotes producer i's actual output, $f(\cdot)$ is the deterministic part of production frontier, $\exp\{v_i\}$ is a producer-specific error term, and TE_i is the technical efficiency coefficient, which can be written as

$$TE_i = \frac{y_i}{f(x_i;\beta)\exp\{v_i\}}.$$

In the case of a Cobb-Douglas production function, $TE_i = \exp\{-u_i\}$. See the section "Stochastic Frontier Production and Cost Models" on page 1950.

Cost frontier can be written in general as

$$E_i = c(y_i, w_i;\beta)\exp\{v_i\}/CE_i$$

where w_i denotes producer i's input prices, $c(\cdot)$ is the deterministic part of cost frontier, $\exp\{v_i\}$ is a producer-specific error term, and CE_i is the cost efficiency coefficient, which can be written as

$$CE_i = \frac{c(x_i, w_i;\beta)\exp\{v_i\}}{E_i}$$

In the case of a Cobb-Douglas cost function, $CE_i = \exp\{-u_i\}$. See the section "Stochastic Frontier Production and Cost Models" on page 1950. Hence, both technical and cost efficiency coefficients are the same. The estimates of technical efficiency are provided in the following subsections.

Normal–Half Normal Model

Define $\mu_* = -\epsilon\sigma_u^2/\sigma^2$ and $\sigma_*^2 = \sigma_u^2\sigma_v^2/\sigma^2$. Then, as it is shown by Jondrow et al. (1982), conditional density is as follows:

$$f(u|\epsilon) = \frac{f(u,\epsilon)}{f(\epsilon)} = \frac{1}{\sqrt{2\pi}\sigma_*}\exp\left\{-\frac{(u-\mu_*)^2}{2\sigma_*^2}\right\} \Big/ \left[1-\Phi\left(-\frac{\mu_*}{\sigma_*}\right)\right]$$

Hence, $f(u|\epsilon)$ is the density for $N^+(\mu_*, \sigma_*^2)$.

Using this result, it follows that the estimate of technical efficiency (Battese and Coelli 1988) is

$$TE1_i = E(\exp\{-u_i\}|\epsilon_i) = \left[\frac{1-\Phi(\sigma_* - \mu_{*i}/\sigma_*)}{1-\Phi(-\mu_{*i}/\sigma_*)}\right]\exp\left\{-\mu_{*i}+\frac{1}{2}\sigma_*^2\right\}$$

The second version of the estimate (Jondrow et al. 1982) is

$$TE2_i = \exp\{-E(u_i|\epsilon_i)\}$$

where

$$E(u_i|\epsilon_i) = \mu_{*i} + \sigma_* \left[\frac{\phi(-\mu_{*i}/\sigma_*)}{1 - \Phi(-\mu_{*i}/\sigma_*)} \right] = \sigma_* \left[\frac{\phi(\epsilon_i \lambda/\sigma)}{1 - \Phi(\epsilon_i \lambda/\sigma)} - \left(\frac{\epsilon_i \lambda}{\sigma} \right) \right]$$

Normal-Exponential Model

Define $A = -\tilde{\mu}/\sigma_v$ and $\tilde{\mu} = -\epsilon - \sigma_v^2/\sigma_u$. Then, as it is shown by Kumbhakar and Lovell (2000), conditional density is as follows:

$$f(u|\epsilon) = \frac{1}{\sqrt{2\pi}\sigma_v \Phi(-\tilde{\mu}/\sigma_v)} \exp\left\{ -\frac{(u - \tilde{\mu})^2}{2\sigma^2} \right\}$$

Hence, $f(u|\epsilon)$ is the density for $N^+(\tilde{\mu}, \sigma_v^2)$.

Using this result, it follows that the estimate of technical efficiency is

$$TE1_i = E(\exp\{-u_i\}|\epsilon_i) = \left[\frac{1 - \Phi(\sigma_v - \tilde{\mu}_i/\sigma_v)}{1 - \Phi(-\tilde{\mu}_i/\sigma_v)} \right] \exp\left\{ -\tilde{\mu}_i + \frac{1}{2}\sigma_v^2 \right\}$$

The second version of the estimate is

$$TE2_i = \exp\{-E(u_i|\epsilon_i)\}$$

where

$$E(u_i|\epsilon_i) = \tilde{\mu}_i + \sigma_v \left[\frac{\phi(-\tilde{\mu}_i/\sigma_v)}{1 - \Phi(-\tilde{\mu}_i/\sigma_v)} \right] = \sigma_v \left[\frac{\phi(A)}{\Phi(-A)} - A \right]$$

Normal–Truncated Normal Model

Define $\tilde{\mu} = (-\sigma_u^2 \epsilon_i + \mu \sigma_v^2)/\sigma^2$ and $\sigma_*^2 = \sigma_u^2 \sigma_v^2/\sigma^2$. Then, as it is shown by Kumbhakar and Lovell (2000), conditional density is as follows:

$$f(u|\epsilon) = \frac{1}{\sqrt{2\pi}\sigma_* [1 - \Phi(-\tilde{\mu}/\sigma_*)]} \exp\left\{ -\frac{(u - \tilde{\mu})^2}{2\sigma_*^2} \right\}$$

Hence, $f(u|\epsilon)$ is the density for $N^+(\tilde{\mu}, \sigma_*^2)$.

Using this result, it follows that the estimate of technical efficiency is

$$TE1_i = E(\exp\{-u_i\}|\epsilon_i) = \frac{1 - \Phi(\sigma_* - \tilde{\mu}_i/\sigma_*)}{1 - \Phi(-\tilde{\mu}_i/\sigma_*)} \exp\left\{ -\tilde{\mu}_i + \frac{1}{2}\sigma_*^2 \right\}$$

The second version of the estimate is

$$TE2_i = \exp\{-E(u_i|\epsilon_i)\}$$

where

$$E(u_i|\epsilon_i) = \tilde{\mu}_i + \sigma_* \left[\frac{\phi(\tilde{\mu}_i/\sigma_*)}{1 - \Phi(-\tilde{\mu}_i/\sigma_*)} \right]$$

OUTEST= Data Set

The OUTEST= data set contains all the parameters estimated in a MODEL statement. The OUTEST= option can be used when the PROC QLIM call contains one MODEL statement:

```
proc qlim data=a outest=e;
   model y = x1 x2 x3;
   endogenous y ~ censored(lb=0);
run;
```

Each parameter contains the estimate for the corresponding parameter in the corresponding model. In addition, the OUTEST= data set contains the following variables:

NAME	the name of the independent variable
TYPE	type of observation. PARM indicates the row of coefficients; STD indicates the row of standard deviations of the corresponding coefficients.
STATUS	convergence status for optimization

The rest of the columns correspond to the explanatory variables.

The OUTEST= data set contains one observation for the MODEL statement, giving the parameter estimates for that model. If the COVOUT option is specified, the OUTEST= data set includes additional observations for the MODEL statement, giving the rows of the covariance matrix of parameter estimates. For covariance observations, the value of the _TYPE_ variable is COV, and the _NAME_ variable identifies the parameter associated with that row of the covariance matrix. If the CORROUT option is specified, the OUTEST= data set includes additional observations for the MODEL statement, giving the rows of the correlation matrix of parameter estimates. For correlation observations, the value of the _TYPE_ variable is CORR, and the _NAME_ variable identifies the parameter associated with that row of the correlation matrix.

Naming

Naming of Parameters

When there is only one equation in the estimation, parameters are named in the same way as in other SAS procedures such as REG, PROBIT, and so on. The constant in the regression equation is called Intercept. The coefficients on independent variables are named by the independent variables. The standard deviation of the errors is called _Sigma. If there are Box-Cox transformations, the coefficients are named _Lambda*i*, where *i* increments from 1, or as specified by the user. The limits for the discrete dependent variable are named _Limit*i*. If the LIMIT=varying option is specified, then _Limit*i* starts from 1. If the LIMIT=varying option is not specified, then _Limit1 is set to 0 and the limit parameters start from $i = 2$. If the HETERO statement is included, the coefficients of the independent variables in the hetero equation are called _H.*x*, where *x* is the name of the independent variable. You can form the name of the parameter associated with an interaction regressor by concatenating the interacting variables with an underscore. The following example restricts the parameter that includes the interaction term to be greater than zero:

```
proc qlim data=a;
   model y = x1|x2;
   endogenous y ~ discrete;
   restrict x1_x2>0;
run;
```

When there are multiple equations in the estimation, the parameters in the main equation are named in the format of *y*.*x*, where *y* is the name of the dependent variable and *x* is the name of the independent variable. The standard deviation of the errors is called _Sigma.*y*. The correlation of the errors is called _Rho for bivariate model. For the model with three variables it is _Rho.*y1*.*y2*, _Rho.*y1*.*y3*, _Rho.*y2*.*y3*. The construction of correlation names for multivariate models is analogous. Box-Cox parameters are called _Lambda*i*.*y* and limit variables are called _Limit*i*.*y*. Parameters in the HETERO statement are named as _H.*y*.*x*. In the OUTEST= data set, all variables are changed from '.' to '_'.

Naming of Output Variables

Table 27.11 shows the option in the OUTPUT statement, with the corresponding variable names and their explanation.

Table 27.11 OUTPUT Statement Options and Variable Names

Option	Name	Explanation
PREDICTED	P_y	Predicted value of *y*
RESIDUAL	RESID_y	Residual of *y*, (y-PredictedY)
XBETA	XBETA_y	Structure part ($\mathbf{x}'\boldsymbol{\beta}$) of *y* equation
ERRSTD	ERRSTD_y	Standard deviation of error term
PROB	PROB_y	Probability that *y* is taking the observed value in this observation (discrete *y* only)
PROBALL	PROB*i*_y	Probability that *y* is taking the *i*th value (discrete *y* only)
MILLS	MILLS_y	Inverse Mills ratio for *y*
EXPECTED	EXPCT_y	Unconditional expected value of *y*
CONDITIONAL	CEXPCT_y	Conditional expected value of *y*, condition on the truncation.
MARGINAL	MEFF_x	Marginal effect of *x* on *y* ($\frac{\partial y}{\partial x}$) with single equation
	MEFF_y_x	Marginal effect of *x* on *y* ($\frac{\partial y}{\partial x}$) with multiple equations
	MEFF_P*i*_x	Marginal effect of *x* on *y* ($\frac{\partial \mathrm{Prob}(y=i)}{\partial x}$) with single equation and discrete *y*
	MEFF_P*i*_y_x	Marginal effect of *x* on *y* ($\frac{\partial \mathrm{Prob}(y=i)}{\partial x}$) with multiple equations and discrete *y*
TE1	TE1	Technical efficiency estimate for each producer proposed by Battese and Coelli (1988)
TE2	TE2	Technical efficiency estimate for each producer proposed by Jondrow et al. (1982)

If you prefer to name the output variables differently, you can use the RENAME option in the data set. For example, the following statements rename the residual of *y* as *Resid*:

```
proc qlim data=one;
   model y = x1-x10 / censored;
   output out=outds(rename=(resid_y=resid)) residual;
run;
```

ODS Table Names

PROC QLIM assigns a name to each table it creates. You can use these names to denote the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 27.12.

Table 27.12 ODS Tables Produced in PROC QLIM by the MODEL Statement and TEST Statement

ODS Table Name	Description	Option

The ODS Graphics is not supported for the random-parameters models.

Examples: QLIM Procedure

Example 27.1: Ordered Data Modeling

Cameron and Trivedi (1986, 1998) studied the number of doctor visits from the Australian Health Survey, 1977–1978. In the following data set, the dependent variable, DVISITS, contains the number of doctor visits in the past 2 weeks (0, 1, or more than 2). The explanatory variables are as follows: SEX indicates if the patient is female; AGE is the age in years divided by 100; INCOME is the annual income ($10,000); LEVYPLUS indicates if the patient has private health insurance; FREEPOOR indicates free government health insurance due to low income; FREEREPA indicates free government health insurance for other reasons; ILLNESS is the number of illnesses in the past 2 weeks; ACTDAYS is the number of days the illness caused reduced activity; HSCORE is a questionnaire score; CHCOND1 indicates a chronic condition that does not limit activity; and CHCOND2 indicates a chronic condition that limits activity.

```
title1 'Estimating an Ordinal Probit Model';

data docvisit;
   input sex age agesq income levyplus freepoor freerepa
         illness actdays hscore chcond1 chcond2 dvisits;
   y = (dvisits > 0);
   if ( dvisits > 8 ) then dvisits = 8;
datalines;

   ... more lines ...

1 0.37 0.1369 0.25  0  0  1  1  0  1  0  0  0
1 0.52 0.2704 0.65  0  0  0  0  0  0  0  0  0
0 0.72 0.5184 0.25  0  0  1  0  0  0  0  0  0
;
```

The dependent variable, DVISITS, has nine ordered values. The following SAS statements estimate the ordinal probit model:

```
/*-- Ordered Discrete Responses --*/
proc qlim data=docvisit;
   model dvisits = sex age agesq income levyplus
                   freepoor freerepa illness actdays hscore
                   chcond1 chcond2 / discrete;
run;
```

The output of the QLIM procedure for ordered data modeling is shown in Output 27.1.1.

_Limit8	1	2.789795	0.156188	17.86	<.0001

By default, ordinal probit/logit models are estimated assuming that the first threshold or limit parameter (μ_1) is 0. However, this parameter can also be estimated when the LIMIT1=VARYING option is specified. The probability that y_i^* belongs to the jth category is defined as

$$P[\mu_{j-1} < y_i^* < \mu_j] = F(\mu_j - \mathbf{x}_i'\boldsymbol{\beta}) - F(\mu_{j-1} - \mathbf{x}_i'\boldsymbol{\beta})$$

where $F(\cdot)$ is the logistic or standard normal CDF, $\mu_0 = -\infty$ and $\mu_9 = \infty$. Output 27.1.2 lists ordinal probit estimates computed in the following program. Note that the intercept term is suppressed for model identification when μ_1 is estimated.

```
/*-- Ordered Probit --*/
proc qlim data=docvisit;
   model dvisits = sex age agesq income levyplus
                   freepoor freerepa illness actdays hscore
                   chcond1 chcond2 / discrete(d=normal) limit1=varying;
run;
```

Example 27.2: Tobit Analysis

The following statements show a subset of the Mroz (1987) data set. In these data, Hours is the number of hours the wife worked outside the household in a given year, Yrs_Ed is the years of education, and Yrs_Exp is the years of work experience. A Tobit model will be fit to the hours worked with years of education and experience as covariates.

By the nature of the data, it is clear that there are a number of women who committed some positive number of hours to outside work ($y_i > 0$ is observed). There are also a number of women who did not work at all ($y_i = 0$ is observed). This produces the model

$$y_i^* = \mathbf{x}_i'\boldsymbol{\beta} + \epsilon_i$$

$$y_i = \begin{cases} y_i^* & \text{if } y_i^* > 0 \\ 0 & \text{if } y_i^* \le 0 \end{cases}$$

where $\epsilon_i \sim \text{iid} N(0, \sigma^2)$. The set of explanatory variables is denoted by $\mathbf{x}_i$.

```

The "Parameter Estimates" table has four rows. The first three of these rows correspond to the vector estimate of the regression coefficients $\boldsymbol{\beta}$. The last one is called _Sigma, which corresponds to the estimate of the error variance σ.

Example 27.3: Bivariate Probit Analysis

This example shows how to estimate a bivariate probit model. Note the INIT statement in the following program, which sets the initial values for some parameters in the optimization:

```
title1 'Estimating a Bivariate Probit Model';

data a;
   keep y1 y2 x1 x2;
   do i = 1 to 500;
      x1 = rannor( 19283 );
      x2 = rannor( 19283 );
      u1 = rannor( 19283 );
      u2 = rannor( 19283 );
      y1l = 1 + 2 * x1 + 3 * x2 + u1;
      y2l = 3 + 4 * x1 - 2 * x2 + u1*.2 + u2;
      if ( y1l > 0 ) then y1 = 1;
      else                y1 = 0;
      if ( y2l > 0 ) then y2 = 1;
      else                y2 = 0;
      output;
   end;
run;

/*-- Bivariate Probit --*/
proc qlim data=a method=qn;
   init y1.x1 2.8, y1.x2 2.1, _rho .1;
   model y1 = x1 x2;
   model y2 = x1 x2;
   endogenous y1 y2 ~ discrete;
run;
```

The output of the QLIM procedure is shown in Output 27.3.1.

Example 27.4: Sample Selection Model

This example illustrates the use of PROC QLIM for sample selection models. The data set is the one from Mroz (1987). The goal is to estimate a wage offer function for married women, accounting for potential selection bias. Of the 753 women, the wage is observed for 428 working women. The labor force participation equation estimated in the introductory example is used for selection. The wage equation uses log wage (lwage) as the dependent variable. The explanatory variables in the wage equation are the woman's years of schooling (educ), wife's labor experience (exper), and square of experience (expersq). The program is as follows:

```
/*-- Sample Selection --*/
proc qlim data=mroz;
   model inlf = nwifeinc educ exper expersq
                age kidslt6 kidsge6 /discrete;
   model lwage = educ exper expersq / select(inlf=1);
run;
```

The output of the QLIM procedure is shown in Output 27.4.1.

Note the correlation estimate is insignificant. This indicates that selection bias is not a big problem in the estimation of wage equation.

Example 27.5: Sample Selection Model with Truncation and Censoring

In this example the data are generated such that the selection variable is discrete and the variable Y is truncated from below by zero. The program follows, with the results shown in Output 27.5.1:

```
title1 'Estimating a Sample Selection Model with Truncation';

data trunc;
   keep z y x1 x2;
   do i = 1 to 500;
      x1 = rannor( 19283 );
      x2 = rannor( 19283 );
      u1 = rannor( 19283 );
      u2 = rannor( 19283 );
      z1 = 1 + 2 * x1 + 3 * x2 + u1;
      y = 3 + 4 * x1 - 2 * x2 + u1*.2 + u2;
      if ( z1 > 0 ) then z = 1;
      else z = 0;
      if y>=0 then output;
   end;
run;

/*-- Sample Selection with Truncation --*/
proc qlim data=trunc method=qn;
   model z = x1 x2 / discrete;
   model y = x1 x2 / select(z=1) truncated(lb=0);
run;
```

Output 27.5.1 Sample Selection with Truncation

Estimating a Sample Selection Model with Truncation

Example 27.7: Stochastic Frontier Models

This example illustrates the estimation of stochastic frontier production and cost models.

First, a production function model is estimated. The data for this example were collected by Christensen Associates; they represent a sample of 125 observations on inputs and output for 10 airlines between 1970 and 1984. The explanatory variables (inputs) are fuel (LF), materials (LM), equipment (LE), labor (LL), and property (LP), and (LQ) is an index that represents passengers, charter, mail, and freight transported.

The following statements create the data set:

```
title1 'Estimating a Stochastic Frontier Production Model';

data airlines;
   input TS FIRM NI LQ LF LM LE LL LP;
datalines;
```

```
1 1 15 -0.0484 0.2473 0.2335 0.2294 0.2246 0.2124
1 1 15 -0.0133 0.2603 0.2492 0.241 0.2216 0.1069
2 1 15 0.088 0.2666 0.3273 0.3365 0.2039 0.0865

   ... more lines ...
```

The following statements estimate a stochastic frontier exponential production model that uses Christensen Associates data:

```
/*-- Stochastic Frontier Production Model --*/
proc qlim data=airlines;
   model LQ=LF LM LE LL LP;
   endogenous LQ ~ frontier (type=exponential production);
run;
```

Figure 27.7.1 shows the results from this production model.

Output 27.7.1 Stochastic Frontier Production Model

Similarly, the stochastic frontier production function can be estimated with TYPE=HALF or TYPE=TRUNCATED options that represent half-normal and truncated normal production models.

In the next step, stochastic frontier cost function is estimated. The data for the cost model are provided

by Christensen and Greene (1976). The data describe costs and production inputs of 145 U.S. electricity producers in 1955. The model being estimated follows the nonhomogeneous version of the Cobb-Douglas cost function:

$$\log\left(\frac{\text{Cost}}{\text{FPrice}}\right) = \beta_0 + \beta_1 \log\left(\frac{\text{KPrice}}{\text{FPrice}}\right) + \beta_2 \log\left(\frac{\text{LPrice}}{\text{FPrice}}\right) + \beta_3 \log(\text{Output}) + \beta_4 \frac{1}{2} \log(\text{Output})^2 + \epsilon$$

All dollar values are normalized by fuel price. The quadratic log of the output is added to capture nonlinearities due to scale effects in cost functions. New variables, log_C_PF, log_PK_PF, log_PL_PF, log_y, and log_y_sq, are created to reflect transformations. The following statements create the data set and transformed variables:

```

         Output="Total output"
         LPrice="Wage rate"
         LShare="Cost share for labor"
         KPrice="Capital price index"
         KShare="Cost share for capital"
         FPrice="Fuel price"
         FShare"Cost share for fuel";
   log_C_PF=log(Cost/FPrice);
   log_PK_PF=log(KPrice/FPrice);
   log_PL_PF=log(LPrice/FPrice);
   log_y=log(Output);
   log_y_sq=log_y**2/2;
run;
```

The following statements estimate a stochastic frontier exponential cost model that uses Christensen and Greene (1976) data:

```
/*-- Stochastic Frontier Cost Model --*/
proc qlim data=electricity;
   model log_C_PF = log_PK_PF log_PL_PF log_y log_y_sq;
   endogenous log_C_PF ~ frontier (type=exponential cost);
run;
```

Output 27.7.2 shows the results.

Output 27.7.2 Exponential Distribution

Estimating a Stochastic Frontier Cost Model

The QLIM Procedure

Model Fit Summary	
Number of Endogenous Variables	1
Endogenous Variable	log_C_PF
Number of Observations	159
Log Likelihood	-23.30430
Maximum Absolute Gradient	5.33998E-6
Number of Iterations	21
Optimization Method	Quasi-Newton
AIC	60.60860
Schwarz Criterion	82.09093
Sigma	0.30750
Lambda	1.71345

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	-4.983211	0.543328	-9.17	<.0001
log_PK_PF	1	0.090242	0.109202	0.83	0.4086
log_PL_PF	1	0.504299	0.118263	4.26	<.0001
log_y	1	0.427182	0.066680	6.41	<.0001
log_y_sq	1	0.066120	0.010079	6.56	<.0001
_Sigma_v	1	0.154998	0.020271	7.65	<.0001
_Sigma_u	1	0.265581	0.033614	7.90	<.0001

Similarly, the stochastic frontier cost model can be estimated with TYPE=HALF or TYPE=TRUNCATED options that represent half-normal and truncated normal errors.

The following statements illustrate the half-normal option:

```
/*-- Stochastic Frontier Cost Model --*/
proc qlim data=electricity;
   model log_C_PF = log_PK_PF log_PL_PF log_y log_y_sq;
   endogenous log_C_PF ~ frontier (type=half cost);
run;
```

Output 27.7.3 shows the result.

Output 27.7.3 Half-Normal Distribution

Estimating a Stochastic Frontier Cost Model

The QLIM Procedure

Model Fit Summary	
Number of Endogenous Variables	1
Endogenous Variable	log_C_PF
Number of Observations	159
Log Likelihood	-34.95304
Maximum Absolute Gradient	0.0001088
Number of Iterations	22
Optimization Method	Quasi-Newton
AIC	83.90607
Schwarz Criterion	105.38840
Sigma	0.42761
Lambda	1.80031

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	-4.434634	0.690197	-6.43	<.0001
log_PK_PF	1	0.069624	0.136250	0.51	0.6093
log_PL_PF	1	0.474578	0.146812	3.23	0.0012
log_y	1	0.256874	0.080777	3.18	0.0015
log_y_sq	1	0.088051	0.011817	7.45	<.0001

_Mu	1	0.531720	0.338538	1.57	0.1163

If no PRODUCTION or COST option is specified, the stochastic frontier production model is estimated by default.

Example 27.8: Bayesian Modeling

This example illustrates how to use the QLIM procedure to perform Bayesian analysis. The generated data mimic a hypothetical scenario in which you study the number of tickets sold for a sports event given the probability of the hosting team winning and the price of the tickets. The following statements create the data set:

```
title1 'Bayesian Analysis';

ods graphics on;

data test;
   do i=1 to 200;
      e1 = rannor(8726)*2000;
      WinChance = ranuni(8772);
```

```
      Price = 10+ranexp(8773)*4;
      y = 48000 + 5000*WinChance - 100 * price +  e1;
      if y>50000 then TicketSales = 50000;
      if y<=50000 then TicketSales = y;
      output;
   end;
   keep WinChance price  y TicketSales;
run;
```

The following statements perform Bayesian analysis of a Tobit model:

```
proc qlim data=test plots(prior)=all;
   model TicketSales = WinChance price;
   endogenous TicketSales ~ censored(lb=0 ub= 50000);
   prior intercept~normal(mean=48000);
   prior WinChance~normal(mean=5000);
   prior Price~normal(mean=-100);
   bayes NBI=10000 NMC=30000 THIN=1 ntrds=1 DIAG=ALL STATS=ALL seed=2;
run;
```

Output 27.8.1 shows the results from the maximum likelihood estimation and the Bayesian analysis with diffuse prior of this Tobit model.

Output 27.8.1 Bayesian Tobit Model

Bayesian Analysis

The QLIM Procedure

Parameter Estimates

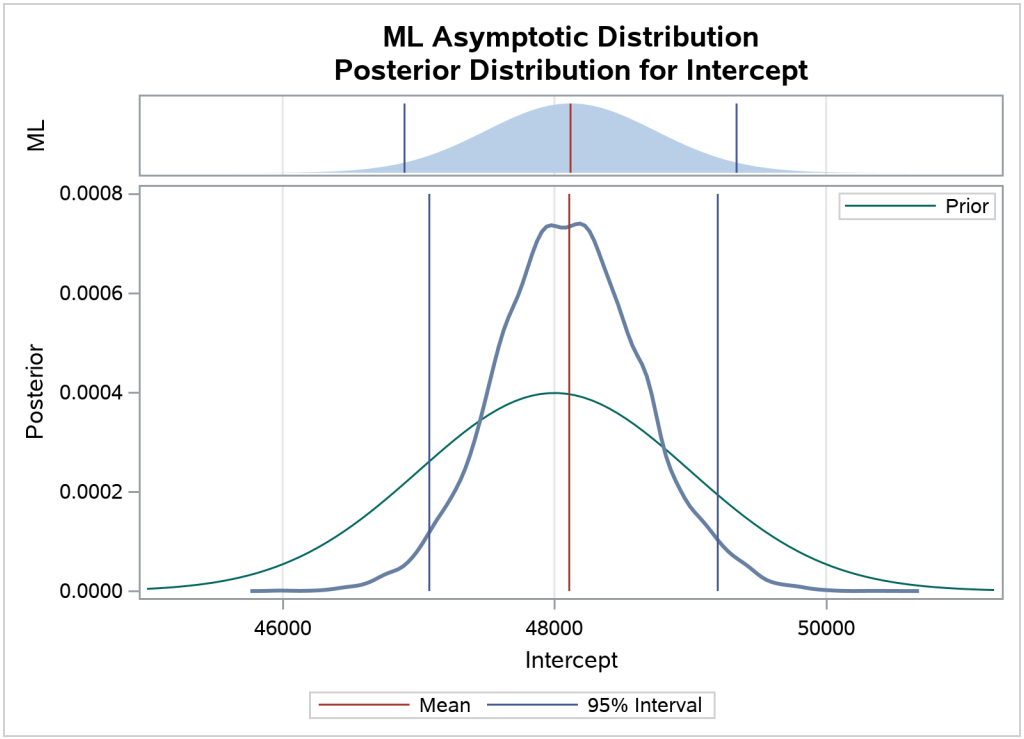
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	48119	623.565046	77.17	<.0001
WinChance	1	5242.083502	559.151223	9.38	<.0001
Price	1	-106.731665	40.660795	-2.62	0.0087
_Sigma	1	1939.607211	134.348773	14.44	<.0001

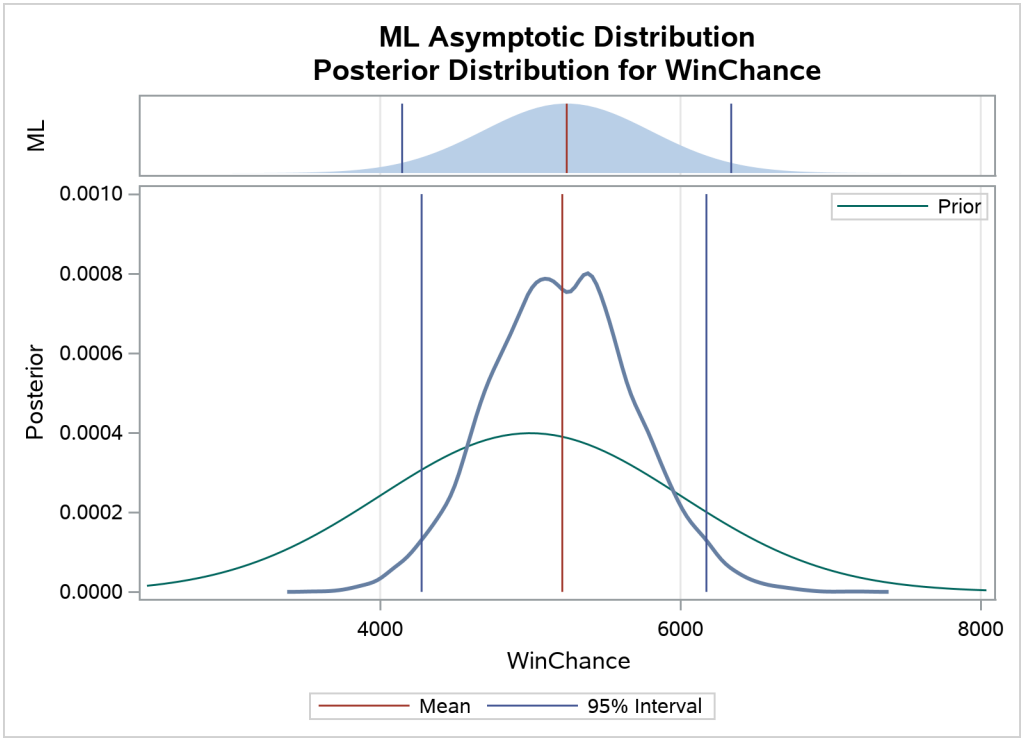
Posterior Summaries

Parameter	N	Mean	Standard Deviation	Percentiles 25%	50%	75%
Intercept	30000	48109.4	535.0	47750.5	48102.6	48460.1
WinChance	30000	5212.9	483.4	4878.8	5205.2	5533.0
Price	30000	-104.7	36.5224	-128.6	-104.2	-79.4191
_Sigma	30000	1950.9	132.9	1858.4	1945.0	2034.0

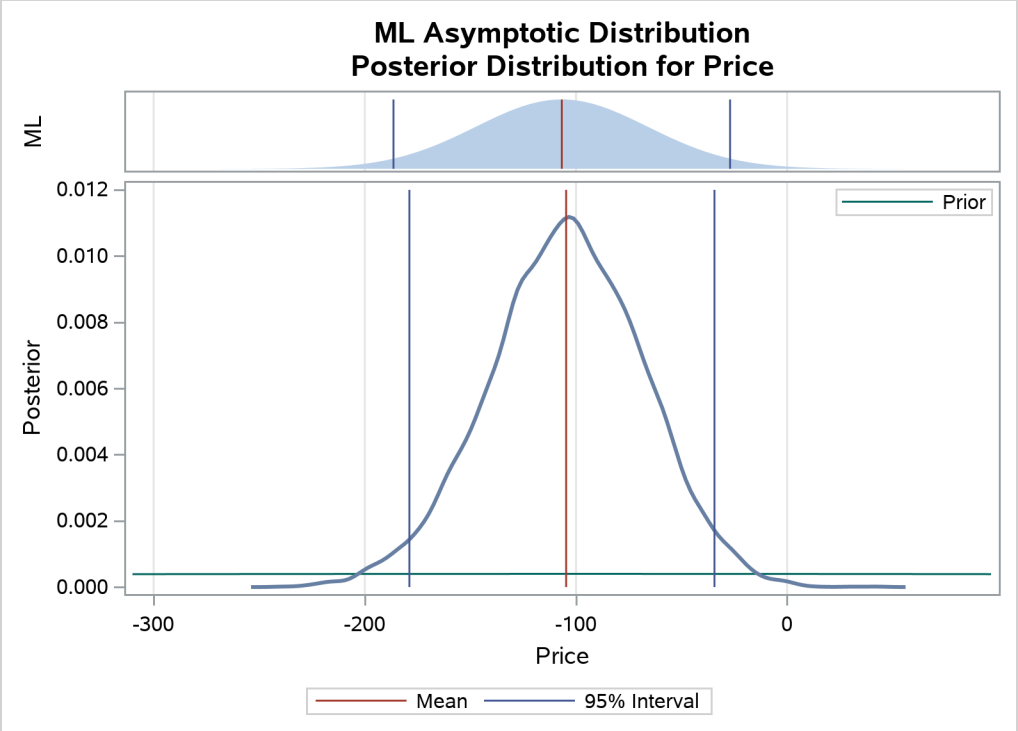
Output 27.8.2 shows a graphical representation of MLE, prior, and posterior distributions.

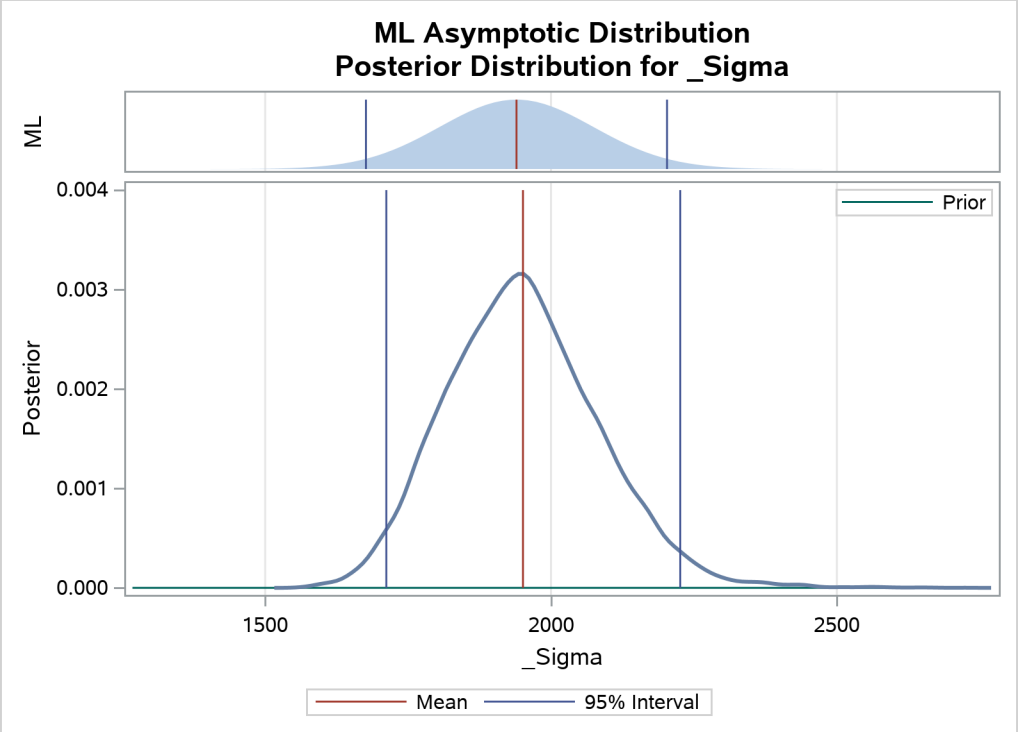
Output 27.8.2 Predictive Analysis by Observation Number





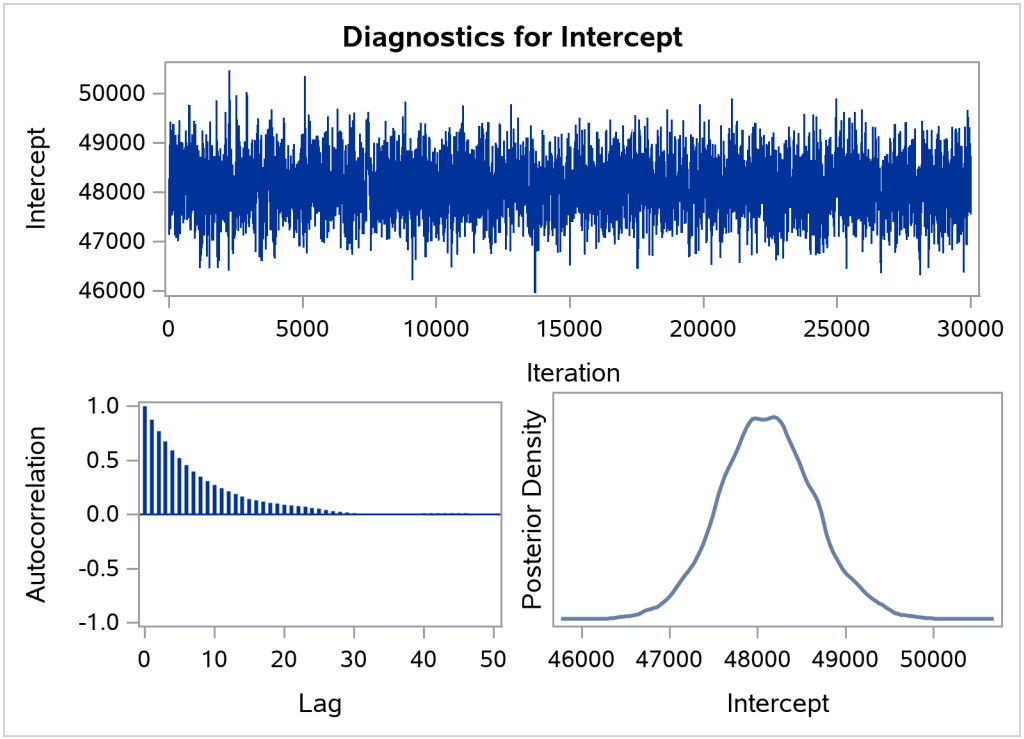
Output 27.8.2 *continued*

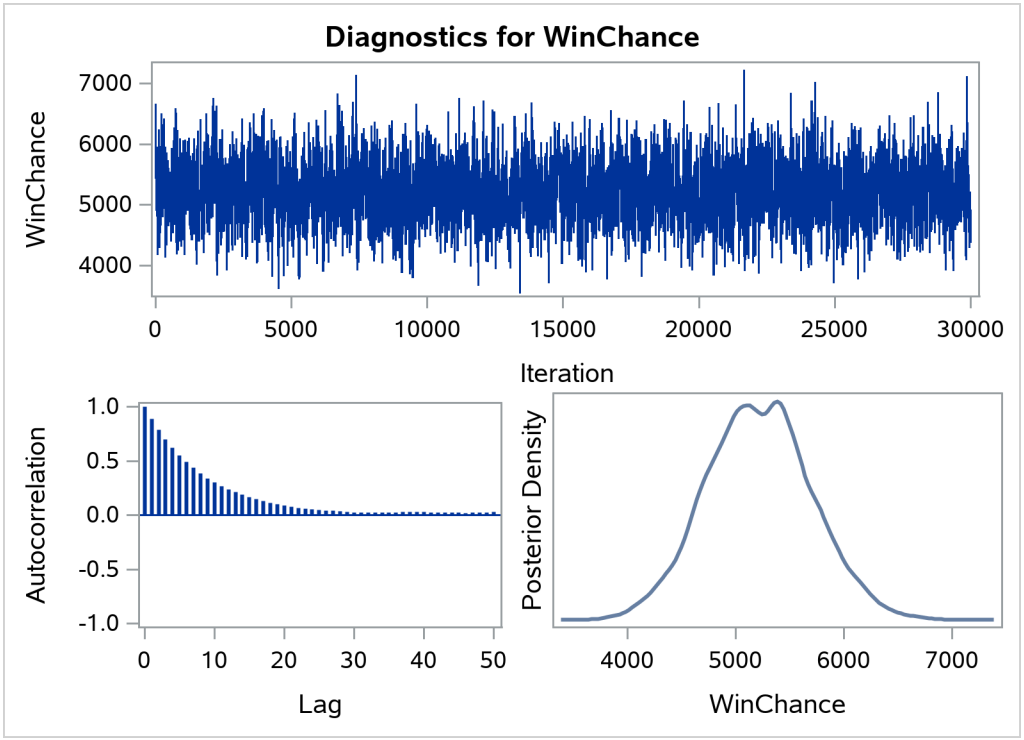




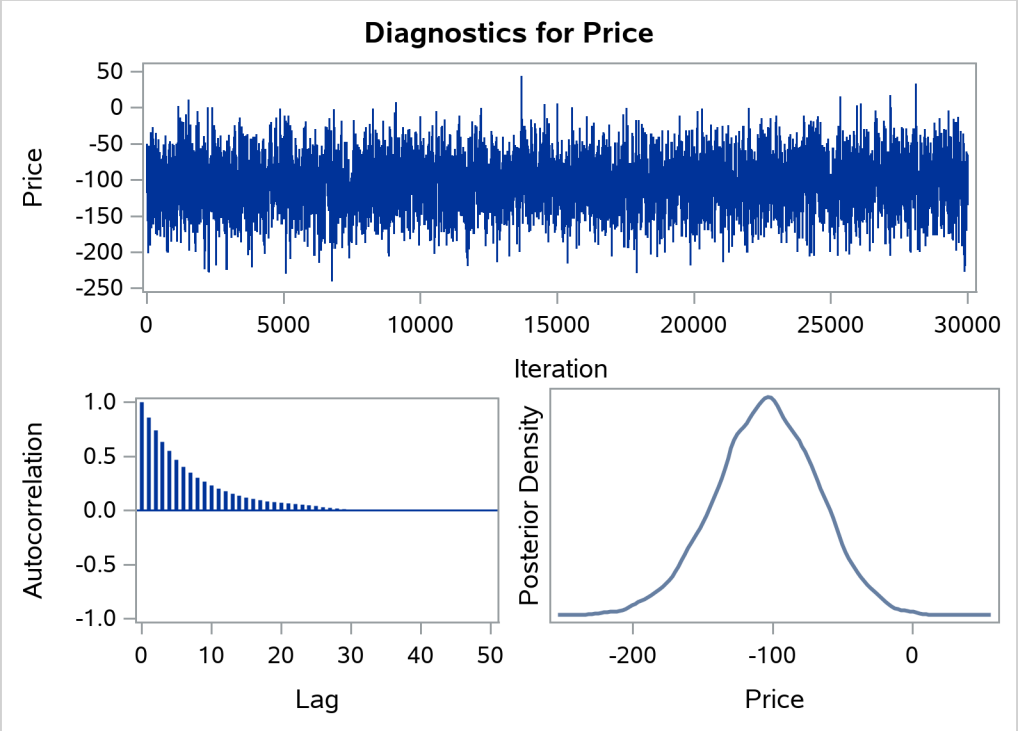
The validity of the MCMC sampling phase can be monitored with Output 27.8.3.

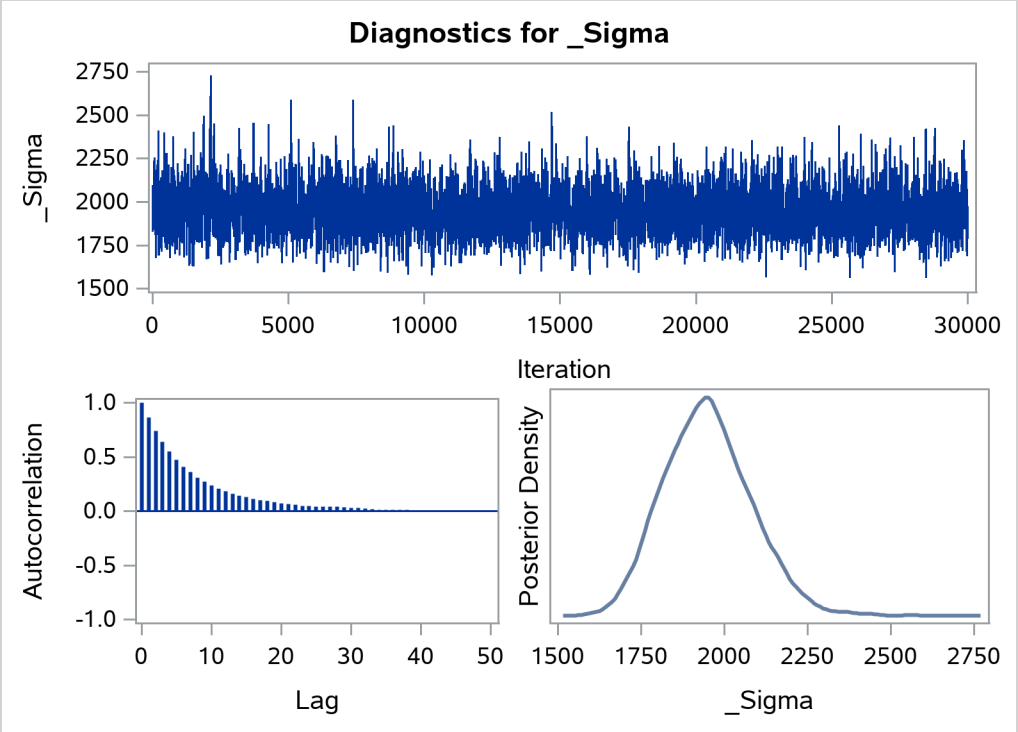
Output 27.8.3 Predictive Analysis by Observation Number





Output 27.8.3 *continued*





Finally the prior and the posterior predictive analyses are represented in Output 27.8.4.

Output 27.8.4 Predictive Analysis by Observation Number

Overview: SEVERITY Procedure

The SEVERITY procedure estimates parameters of any arbitrary continuous probability distribution that is used to model the magnitude (severity) of a continuous-valued event of interest. Some examples of such events are loss amounts paid by an insurance company and demand of a product as depicted by its sales. PROC SEVERITY is especially useful when the severity of an event does not follow typical distributions (such as the normal distribution) that are often assumed by standard statistical methods.

PROC SEVERITY provides a default set of probability distribution models that includes the Burr, exponential, gamma, generalized Pareto, inverse Gaussian (Wald), lognormal, Pareto (Type II), Tweedie, and Weibull distributions. In the simplest form, you can estimate the parameters of any of these distributions by using a list of severity values that are recorded in a SAS data set. You can optionally group the values by a set of BY variables. PROC SEVERITY computes the estimates of the model parameters, their standard errors, and their covariance structure by using the maximum likelihood method for each of the BY groups.

PROC SEVERITY can fit multiple distributions at the same time and choose the best distribution according to a selection criterion that you specify. You can use seven different statistics of fit as selection criteria. They are log likelihood, Akaike's information criterion (AIC), corrected Akaike's information criterion (AICC), Schwarz Bayesian information criterion (BIC), Kolmogorov-Smirnov statistic (KS), Anderson-Darling statistic (AD), and Cramér–von Mises statistic (CvM).

You can request the procedure to output the status of the estimation process, the parameter estimates and their standard errors, the estimated covariance structure of the parameters, the statistics of fit, estimated cumulative distribution function (CDF) for each of the specified distributions, and the empirical distribution function (EDF) estimate (which is used to compute the KS, AD, and CvM statistics of fit).

A high-performance version of PROC SEVERITY is available as the HPSEVERITY procedure in the SAS High-Performance Econometrics product. The following key features make PROC SEVERITY and PROC HPSEVERITY unique among SAS procedures that can estimate continuous probability distributions:

- Both procedures enable you to fit a distribution model when the severity values are truncated or censored or both. You can specify any combination of the following types of censoring and truncation effects: left-censoring, right-censoring, left-truncation, or right-truncation. This is especially useful

in applications with an insurance-type model where a severity (loss) is reported and recorded only if it is greater than the deductible amount (left-truncation) and where a severity value greater than or equal to the policy limit is recorded at the limit (right-censoring). Another useful application is that of interval-censored data, where you know both the lower limit (right-censoring) and upper limit (left-censoring) on the severity, but you do not know the exact value.

PROC SEVERITY also enables you to specify a *probability of observability* for the left-truncated data, which is a probability of observing values greater than the left-truncation threshold. This additional information can be useful in certain applications to more correctly model the distribution of the severity of events.

Both procedures use an appropriate estimator of the empirical distribution function (EDF). EDF is required to compute the KS, AD, and CvM statistics-of-fit. The procedures also provide the EDF estimates to your custom parameter initialization method. When you specify truncation or censoring, the EDF is estimated by using either Kaplan-Meier's product-limit estimator or Turnbull's estimator. The former is used by default when you specify only one form of censoring effect (right-censoring or left-censoring), whereas the latter is used by default when you specify both left-censoring and right-censoring effects. Both procedures compute the standard errors for all EDF estimators.

- Both procedures enable you to define any arbitrary continuous parametric distribution model and to estimate its parameters. You just need to define the key components of the distribution, such as its probability density function (PDF) and cumulative distribution function (CDF), as a set of functions and subroutines written with the FCMP procedure, which is part of Base SAS software. As long as the functions and subroutines follow certain rules, the SEVERITY and HPSEVERITY procedures can fit the distribution model defined by them.

- Both procedures can model the influence of exogenous or regressor variables on a probability distribution, as long as the distribution has a scale parameter. A linear combination of regression effects is assumed to affect the scale parameter via an exponential link function.

  If a distribution does not have a scale parameter, then either it needs to have another parameter that can be derived from a scale parameter by using a supported transformation or it needs to be reparameterized to have a scale parameter. If neither of these is possible, then regression effects cannot be modeled.

  You can easily construct many types of regression effects by using various operators on a set of classification and continuous variables. You can specify classification variables in the CLASS statement.

- Both procedures enable you to specify your own objective function to be optimized for estimating the parameters of a model. You can write SAS programming statements to specify the contribution of each observation to the objective function. You can use keyword functions such as _PDF_ and _CDF_ to generalize the objective function to any distribution. If you do not specify your own objective function, then the parameters of a model are estimated by maximizing the likelihood function of the data.

- Both procedures enable you to create scoring functions that offer a convenient way to evaluate any distribution function, such as PDF, CDF, QUANTILE, or your custom distribution function, for a fitted model on new observations.

- Both procedures use multithreading to significantly reduce the time it takes to fit a distribution model.

Getting Started: SEVERITY Procedure

This section outlines the use of the SEVERITY procedure to fit continuous probability distribution models. Three examples illustrate different features of the procedure.

A Simple Example of Fitting Predefined Distributions

The simplest way to use PROC SEVERITY is to fit all the predefined distributions to a set of values and let the procedure identify the best fitting distribution.

Consider a lognormal distribution, whose probability density function (PDF) f and cumulative distribution function (CDF) F are as follows, respectively, where Φ denotes the CDF of the standard normal distribution:

$$f(x;\mu,\sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\log(x)-\mu}{\sigma}\right)^2} \quad \text{and} \quad F(x;\mu,\sigma) = \Phi\left(\frac{\log(x)-\mu}{\sigma}\right)$$

The following DATA step statements simulate a sample from a lognormal distribution with population parameters $\mu = 1.5$ and $\sigma = 0.25$, and store the sample in the variable Y of a data set Work.Test_sev1:

```
/*------------- Simple Lognormal Example -------------*/
data test_sev1(keep=y label='Simple Lognormal Sample');
   call streaminit(45678);
   label y='Response Variable';
   Mu = 1.5;
   Sigma = 0.25;
   do n = 1 to 100;
      y = exp(Mu) * rand('LOGNORMAL')**Sigma;
      output;
   end;
run;
```

The following statements fit all the predefined distribution models to the values of Y and identify the best distribution according to the corrected Akaike's information criterion (AICC):

```
proc severity data=test_sev1 crit=aicc;
   loss y;
   dist _predefined_;
run;
```

The PROC SEVERITY statement specifies the input data set along with the model selection criterion, the LOSS statement specifies the variable to be modeled, and the DIST statement with the _PREDEFINED_ keyword specifies that all the predefined distribution models be fitted.

Some of the default output displayed by this step is shown in Figure 28.1 through Figure 28.5. First, information about the input data set is displayed followed by the "Model Selection" table, as shown in Figure 28.1. The model selection table displays the convergence status, the value of the selection criterion, and the selection status for each of the candidate models. The Converged column indicates whether the estimation process for a given distribution model has converged, might have converged, or failed. The

Selected column indicates whether a given distribution has the best fit for the data according to the selection criterion. For this example, the lognormal distribution model is selected, because it has the lowest value for the selection criterion.

Figure 28.1 Data Set Information and Model Selection Table

The SEVERITY Procedure

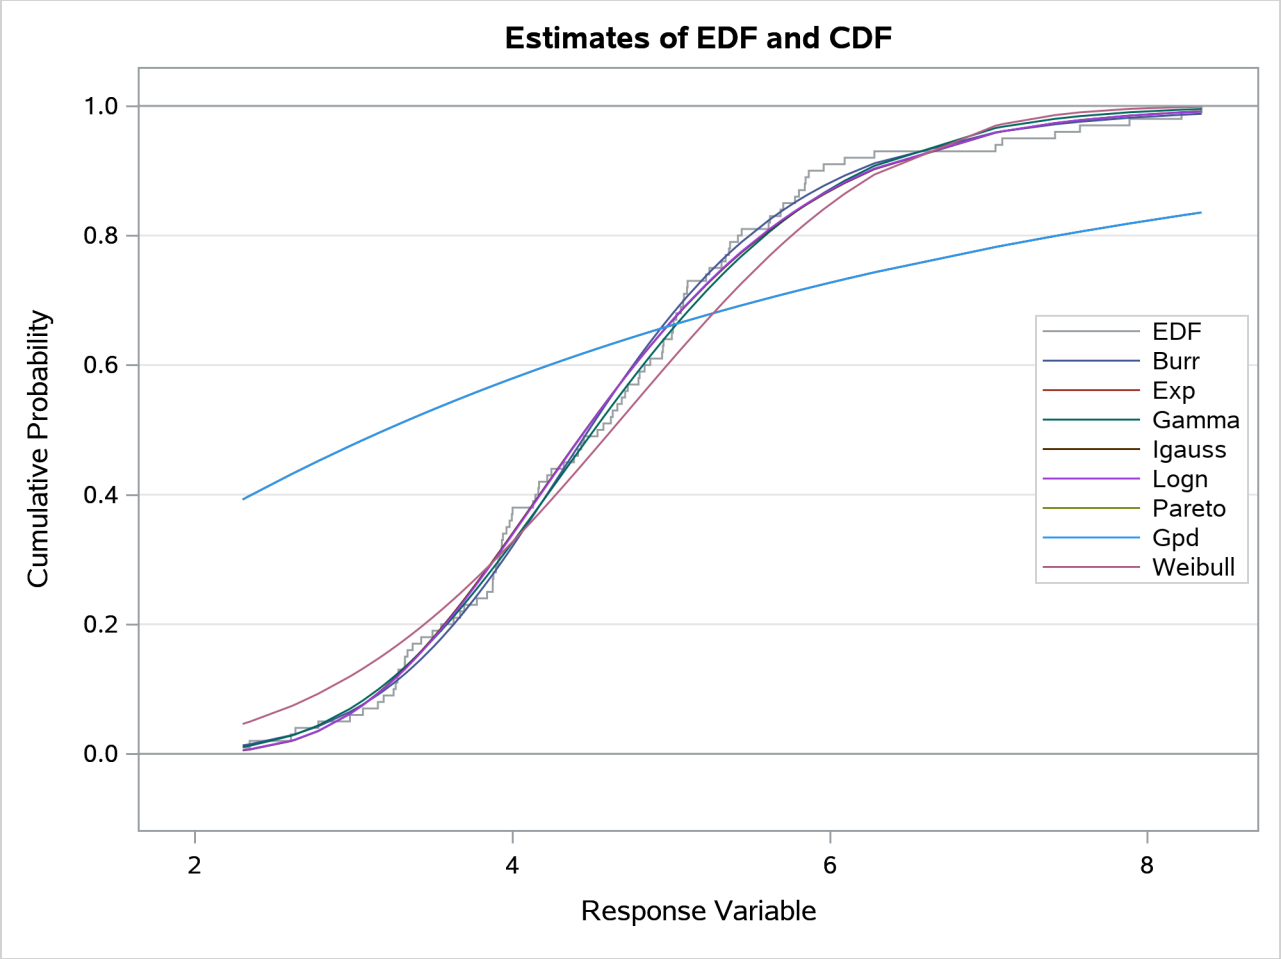
Input Data Set	
Name	WORK.TEST_SEV1
Label	Simple Lognormal Sample

Model Selection

Distribution	Converged	AICC	Selected
Burr	Yes	322.50845	No
Exp	Yes	508.12287	No
Gamma	Yes	320.50264	No
Igauss	Yes	319.61652	No
Logn	Yes	319.56579	Yes
Pareto	Yes	510.28172	No
Gpd	Yes	510.20576	No
Weibull	Yes	334.82373	No

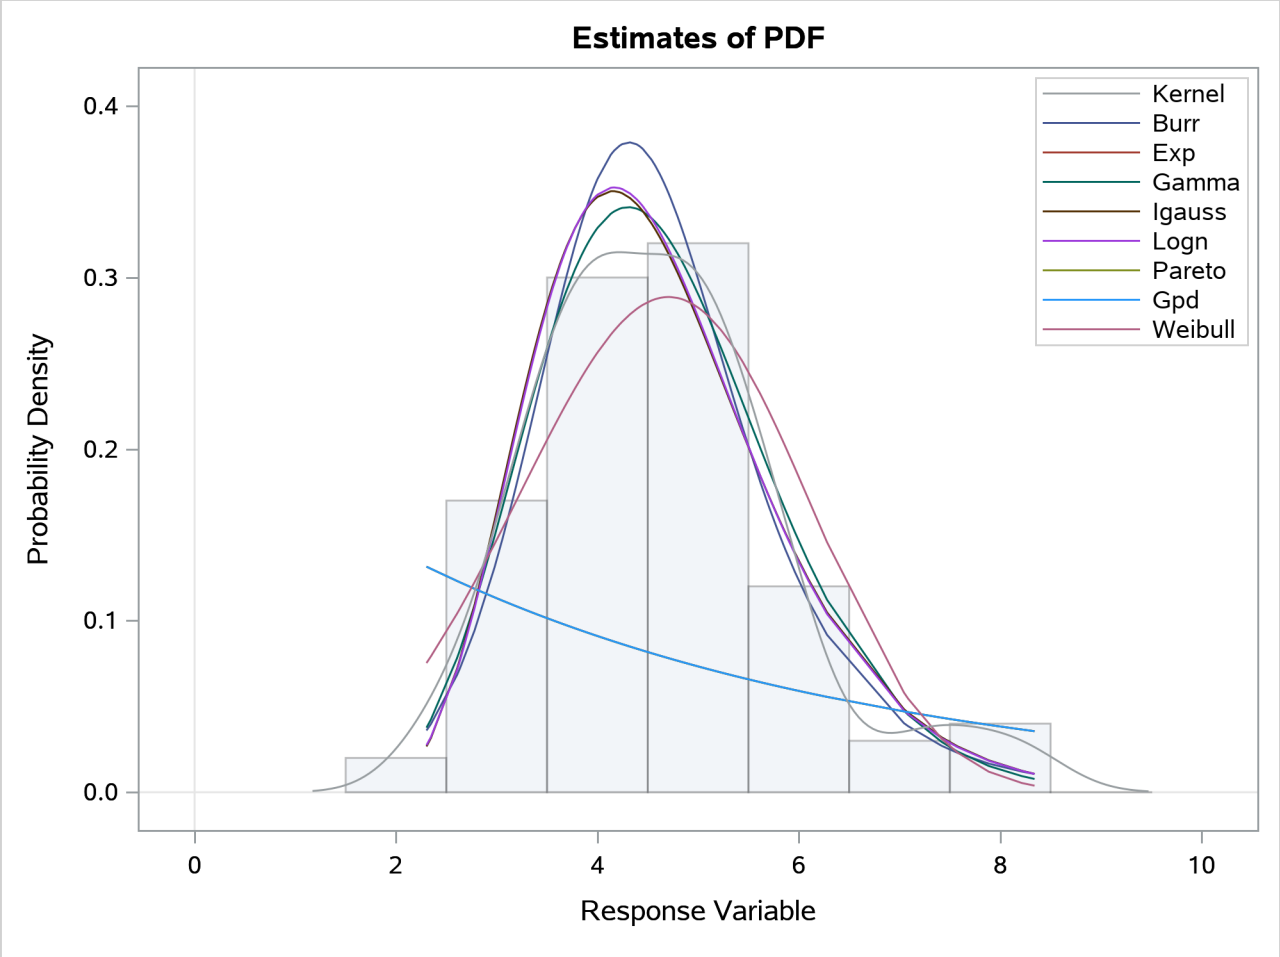
Next, two comparative plots are prepared. These plots enable you to visually verify how the models differ from each other and from the nonparametric estimates. The plot in Figure 28.2 displays the cumulative distribution function (CDF) estimates of all the models and the estimates of the empirical distribution function (EDF). The CDF plot indicates that the Exp (exponential), Pareto, and Gpd (generalized Pareto) distributions are a poor fit as compared to the EDF estimate. The Weibull distribution is also a poor fit, although not as poor as exponential, Pareto, and Gpd. The other four distributions seem to be quite close to each other and to the EDF estimate.

Figure 28.2 Comparison of EDF and CDF Estimates of the Fitted Models



The plot in Figure 28.3 displays the probability density function (PDF) estimates of all the models and the nonparametric kernel and histogram estimates. The PDF plot enables better visual comparison between the Burr, Gamma, Igauss (inverse Gaussian), and Logn (lognormal) models. The Burr and Gamma differ significantly from the Igauss and Logn distributions in the central portion of the range of Y values, while the latter two fit the data almost identically. This provides a visual confirmation of the information in the "Model Selection" table of Figure 28.1, which indicates that the AICC values of Igauss and Logn distributions are very close.

Figure 28.3 Comparison of PDF Estimates of the Fitted Models



The comparative plots are followed by the estimation information for each of the candidate models. The information for the lognormal model, which is the best fitting model, is shown in Figure 28.4. The first table displays a summary of the distribution. The second table displays the convergence status. This is followed by a summary of the optimization process which indicates the technique used, the number of iterations, the number of times the objective function was evaluated, and the log likelihood attained at the end of the optimization. Since the model with lognormal distribution has converged, PROC SEVERITY displays its statistics of fit and parameter estimates. The estimates of *Mu*=1.49605 and *Sigma*=0.26243 are quite close to the population parameters of *Mu*=1.5 and *Sigma*=0.25 from which the sample was generated. The *p*-value for each estimate indicates the rejection of the null hypothesis that the estimate is 0, implying that both the estimates are significantly different from 0.

An Example with Left-Truncation and Right-Censoring

PROC SEVERITY enables you to specify that the response variable values are left-truncated or right-censored. The following DATA step expands the data set of the previous example to simulate a scenario that is typically encountered by an automobile insurance company. The values of the variable Y represent the loss values on claims that are reported to an auto insurance company. The variable THRESHOLD records the deductible on the insurance policy. If the actual value of Y is less than or equal to the deductible, then it is unobservable and does not get recorded. In other words, THRESHOLD specifies the left-truncation of Y. LIMIT records the policy limit. If the value of Y is equal to or greater than the recorded value, then the observation is right-censored.

```
/*----- Lognormal Model with left-truncation and censoring -----*/
data test_sev2(keep=y threshold limit
        label='A Lognormal Sample With Censoring and Truncation');
   set test_sev1;
   label y='Censored & Truncated Response';
   if _n_ = 1 then call streaminit(45679);

   /* make about 20% of the observations left-truncated */
   if (rand('UNIFORM') < 0.2) then
      threshold = y * (1 - rand('UNIFORM'));
   else
      threshold = .;
   /* make about 15% of the observations right-censored */
   iscens = (rand('UNIFORM') < 0.15);
   if (iscens) then
      limit = y;
   else
      limit = .;
run;
```

The following statements use the AICC criterion to analyze which of the four predefined distributions (lognormal, Burr, gamma, and Weibull) has the best fit for the data:

```
proc severity data=test_sev2 crit=aicc
       print=all plots=(cdfperdist pp qq);
   loss y / lt=threshold rc=limit;

   dist logn burr gamma weibull;
run;
```

The LOSS statement specifies the left-truncation and right-censoring variables. The DIST statement specifies the candidate distributions. The PRINT= option in the PROC SEVERITY statement requests that all the displayed output be prepared. The PLOTS= option in the PROC SEVERITY statement requests that the CDF plot, P-P plot, and Q-Q plot be prepared for each candidate distribution in addition to the default plots.

Some of the key results prepared by PROC SEVERITY are shown in Figure 28.6 through Figure 28.13. In addition to the estimates of the range, mean, and standard deviation of Y, the "Descriptive Statistics for y" table shown in Figure 28.6 also indicates the number of observations that are left-truncated or right-censored. The "Model Selection" table in Figure 28.6 shows that models with all the candidate distributions have

converged and that the Logn (lognormal) model has the best fit for the data according to the AICC criterion.

Figure 28.6 Summary Results for the Truncated and Censored Data

The SEVERITY Procedure

Burr	Yes	302.66229	No
Gamma	Yes	299.45293	No
Weibull	Yes	309.26779	No

PROC SEVERITY also prepares a table that shows all the fit statistics for all the candidate models. It is useful to see which model would be the best fit according to each of the criteria. The "All Fit Statistics" table prepared for this example is shown in Figure 28.7. It indicates that the lognormal model is chosen by all the criteria.

Figure 28.7 Comparing All Statistics of Fit for the Truncated and Censored Data

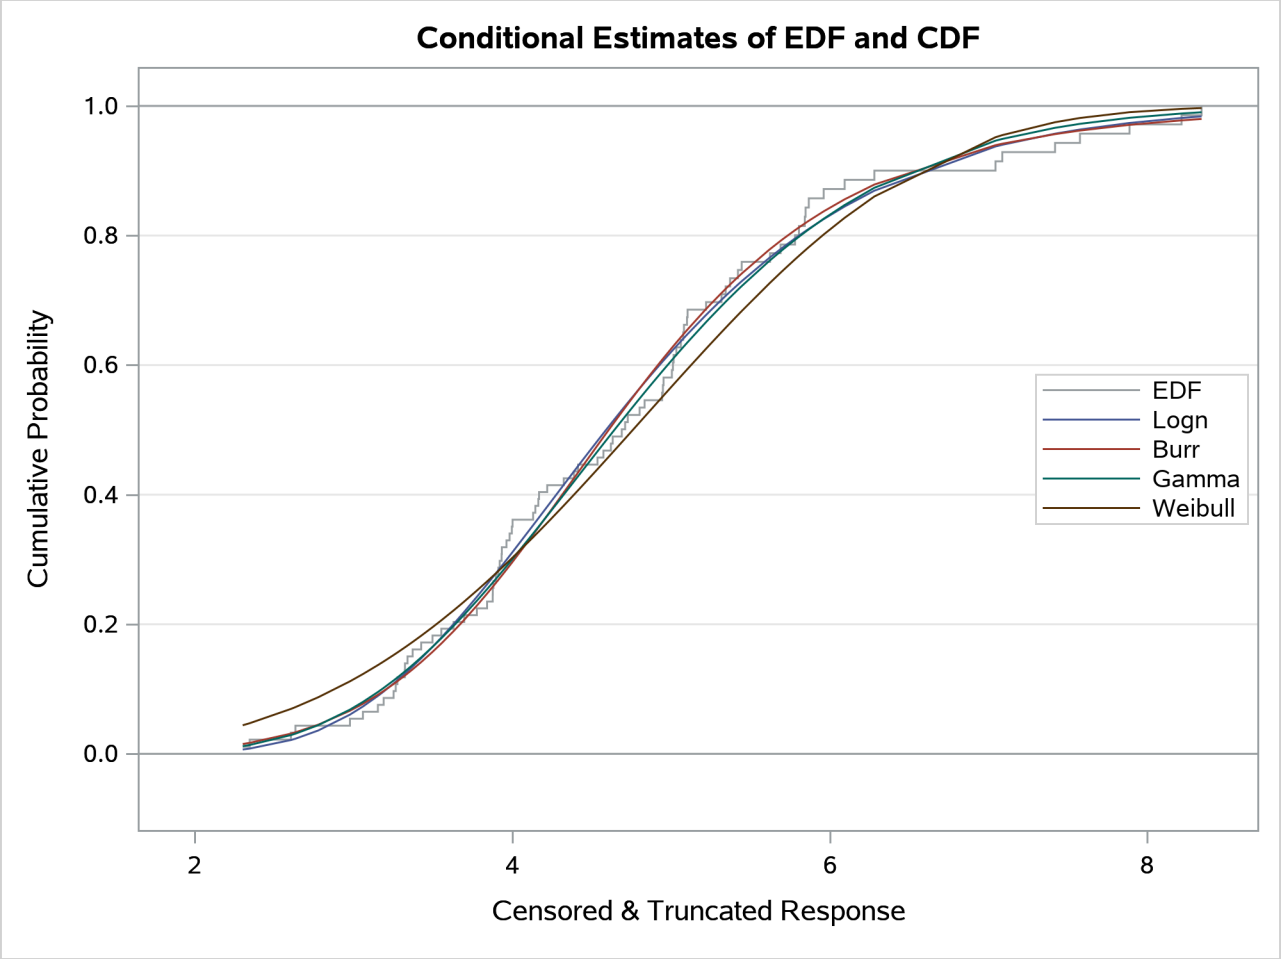
All Fit Statistics

Distribution	-2 Log Likelihood		AIC		AICC		BIC		KS		AD		CvM	
Logn	294.80301	*	298.80301	*	298.92672	*	304.01335	*	0.51824	*	0.34736	*	0.05159	*
Burr	296.41229		302.41229		302.66229		310.22780		0.66984		0.36712		0.05726	
Gamma	295.32921		299.32921		299.45293		304.53955		0.62511		0.42921		0.05526	
Weibull	305.14408		309.14408		309.26779		314.35442		0.93307		1.40699		0.17465	

Note: The asterisk (*) marks the best model according to each column's criterion.

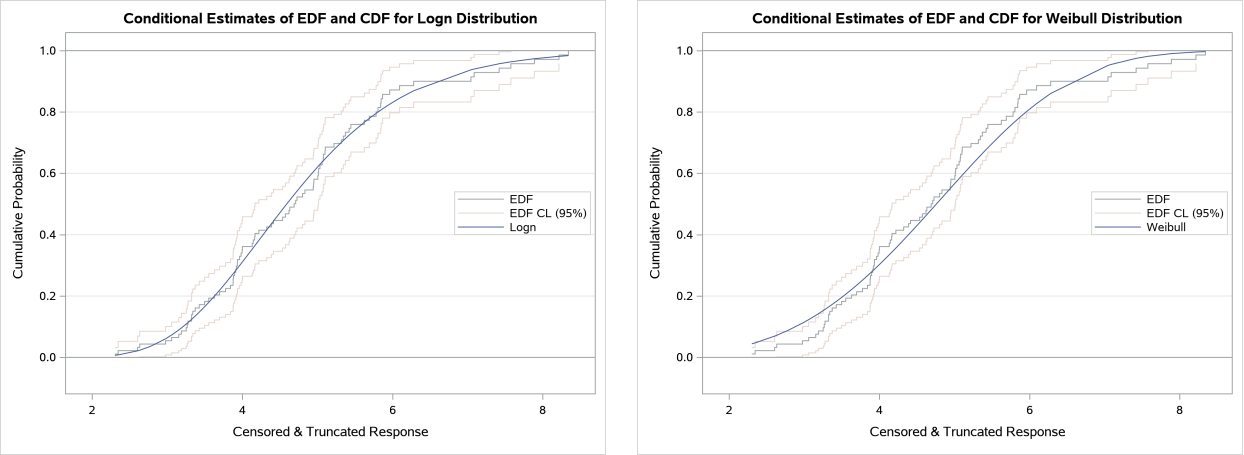
The plot that compares EDF and CDF estimates is shown in Figure 28.8. When you specify left-truncation, both the EDF and CDF estimates are conditional on the response variable being greater than the smallest left-truncation threshold in the sample.

Figure 28.8 EDF and CDF Estimates for the Truncated and Censored Data



When you specify the PLOTS=CDFPERDIST option, PROC SEVERITY prepares a plot that compares the nonparametric EDF estimates with the parametric CDF estimates for each distribution. These plots for lognormal and Weibull distributions are shown in Figure 28.9. These plots also contain the lower and upper confidence limits of EDF for the specified confidence level. Because no confidence level is specified in the EDFALPHA= option in the PROC SEVERITY statement, a default confidence level of 95% is used, which is equivalent to specifying EDFALPHA=0.05. If the CDF estimates lie entirely within the EDF confidence interval, then you can be 95% confident that the parametric and nonparametric estimates are in agreement.

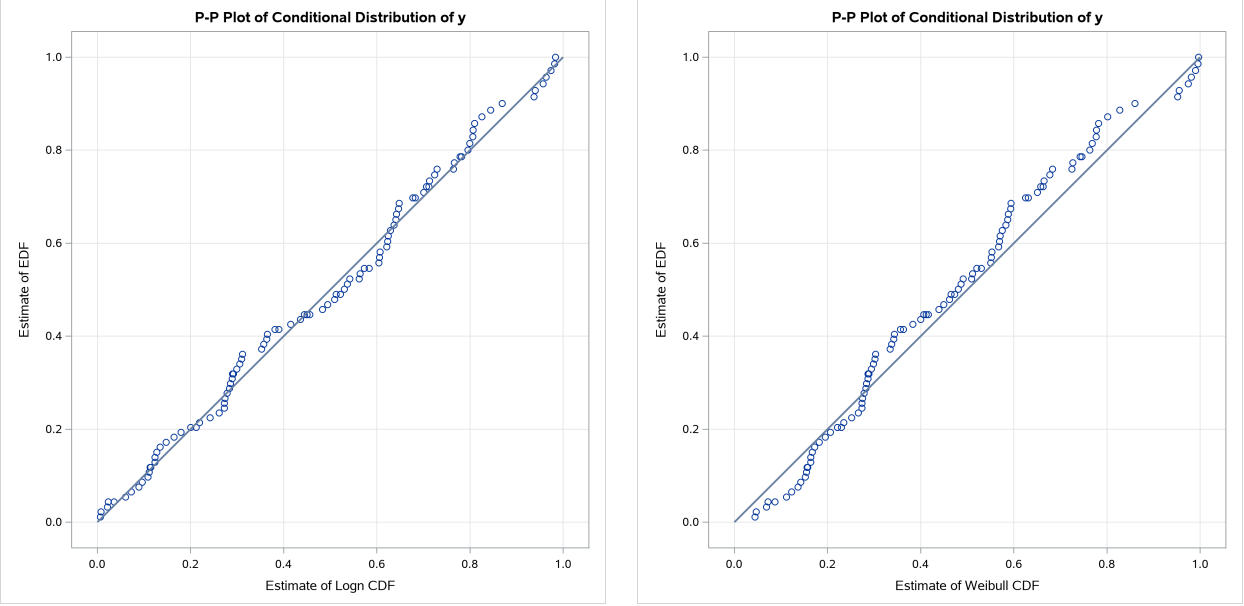
Figure 28.9 Comparing EDF and CDF Estimates for Lognormal and Weibull Models Fitted to Truncated and Censored Data



There are two additional ways to compare nonparametric (empirical) and parametric estimates for each model that has not failed to converge:

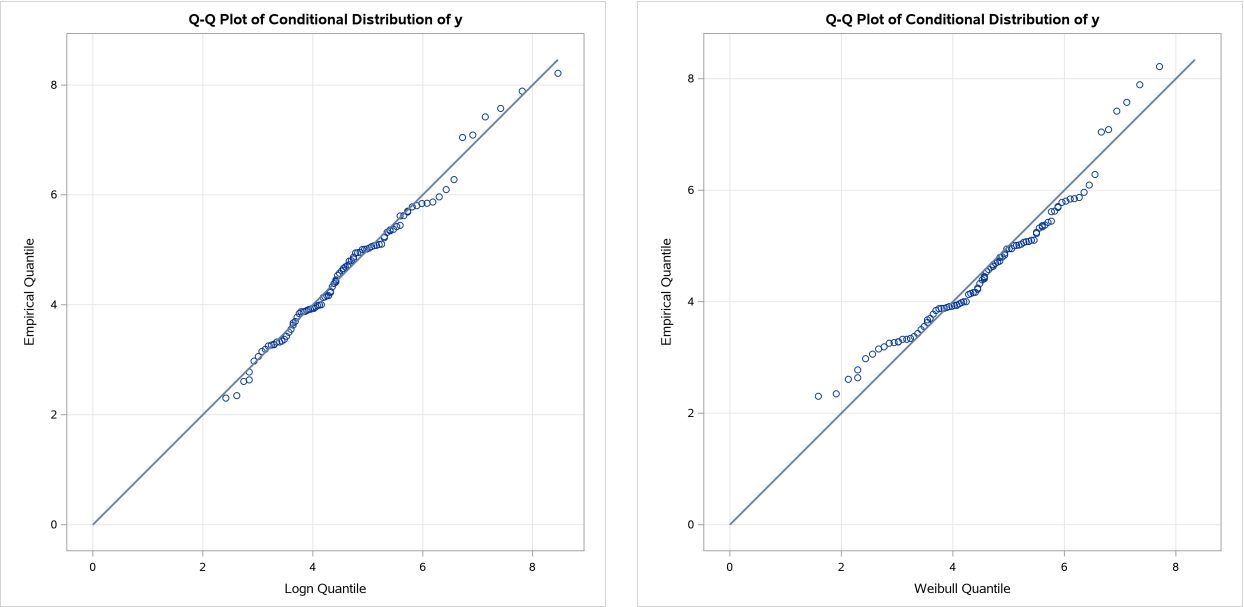
- A P-P plot is a scatter plot of the EDF and the CDF estimates. The model for which the points are scattered closer to the unit-slope reference line is a better fit. The P-P plot for the lognormal distribution is shown in Figure 28.10. It indicates that the EDF and the CDF match very closely. In contrast, the P-P plot for the Weibull distribution, also shown in Figure 28.10, indicates a poor fit.

Figure 28.10 P-P Plots for Lognormal and Weibull Models Fitted to Truncated and Censored Data



- A Q-Q plot is a scatter plot of empirical quantiles and the quantiles of a parametric distribution. Like the P-P plot, points scattered closer to the unit-slope reference line indicate a better fit. The Q-Q plots of lognormal and Weibull distributions are shown in Figure 28.11, which confirm the conclusions arrived at by comparing the P-P plots.

Figure 28.11 Q-Q Plots for Lognormal and Weibull Models Fitted to Truncated and Censored Data



Specifying Initial Values for Parameters

All the predefined distributions have parameter initialization functions built into them. For the current example, Figure 28.12 shows the initial values that are obtained by the predefined method for the Burr distribution. It also shows the summary of the optimization process and the final parameter estimates.

Figure 28.12 Burr Model Summary for the Truncated and Censored Data

Initial Parameter Values and Bounds

Parameter	Initial Value	Lower Bound	Upper Bound
Theta	4.78102	1.05367E-8	Infty
Alpha	2.00000	1.05367E-8	Infty
Gamma	2.00000	1.05367E-8	Infty

Optimization Summary

Optimization Technique	Trust Region
Iterations	8
Function Calls	23
Log Likelihood	-148.20614

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Theta	1	4.76980	0.62492	7.63	<.0001
Alpha	1	1.16363	0.58859	1.98	0.0509
Gamma	1	5.94081	1.05004	5.66	<.0001

You can specify a different set of initial values if estimates are available from fitting the distribution to similar

data. For this example, the parameters of the Burr distribution can be initialized with the final parameter estimates of the Burr distribution that were obtained in the first example (shown in Figure 28.5). One of the ways in which you can specify the initial values is as follows:

```
/*------ Specifying initial values using INIT= option -------*/
proc severity data=test_sev2 crit=aicc print=all plots=none;
   loss y / lt=threshold rc=limit;

   dist burr(init=(theta=4.62348 alpha=1.15706 gamma=6.41227));
run;
```

The names of the parameters that are specified in the INIT option must match the parameter names in the definition of the distribution. The results obtained with these initial values are shown in Figure 28.13. These results indicate that new set of initial values causes the optimizer to reach the same solution with fewer iterations and function evaluations as compared to the default initialization.

An Example of Modeling Regression Effects

Consider a scenario in which the magnitude of the response variable might be affected by some regressor (exogenous or independent) variables. The SEVERITY procedure enables you to model the effect of such variables on the distribution of the response variable via an exponential link function. In particular, if you have k random regressor variables denoted by x_j $(j = 1, \ldots, k)$, then the distribution of the response variable Y is assumed to have the form

$$Y \sim \exp(\sum_{j=1}^{k} \beta_j x_j) \cdot \mathcal{F}(\Theta)$$

where $\mathcal{F}$ denotes the distribution of Y with parameters Θ and $\beta_j (j = 1, \ldots, k)$ denote the regression parameters (coefficients). For the effective distribution of Y to be a valid distribution from the same parametric family as $\mathcal{F}$, it is necessary for $\mathcal{F}$ to have a scale parameter. The effective distribution of Y can be

written as

$$Y \sim \mathcal{F}(\theta, \Omega)$$

where θ denotes the scale parameter and Ω denotes the set of nonscale parameters. The scale θ is affected by the regressors as

$$\theta = \theta_0 \cdot \exp(\sum_{j=1}^{k} \beta_j x_j)$$

where θ_0 denotes a *base* value of the scale parameter.

Given this form of the model, PROC SEVERITY allows a distribution to be a candidate for modeling regression effects only if it has an untransformed or a log-transformed scale parameter.

All the predefined distributions, except the lognormal distribution, have a direct scale parameter (that is, a parameter that is a scale parameter without any transformation). For the lognormal distribution, the parameter μ is a log-transformed scale parameter. This can be verified by replacing μ with a parameter $\theta = e^{\mu}$, which results in the following expressions for the PDF f and the CDF F in terms of θ and σ, respectively, where Φ denotes the CDF of the standard normal distribution:

$$f(x;\theta,\sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\log(x)-\log(\theta)}{\sigma}\right)^2} \quad \text{and} \quad F(x;\theta,\sigma) = \Phi\left(\frac{\log(x)-\log(\theta)}{\sigma}\right)$$

With this parameterization, the PDF satisfies the $f(x;\theta,\sigma) = \frac{1}{\theta} f(\frac{x}{\theta};1,\sigma)$ condition and the CDF satisfies the $F(x;\theta,\sigma) = F(\frac{x}{\theta};1,\sigma)$ condition. This makes θ a scale parameter. Hence, $\mu = \log(\theta)$ is a log-transformed scale parameter and the lognormal distribution is eligible for modeling regression effects.

The following DATA step simulates a lognormal sample whose scale is decided by the values of the three regressors X1, X2, and X3 as follows:

$$\mu = \log(\theta) = 1 + 0.75\ \mathrm{X1} - \mathrm{X2} + 0.25\ \mathrm{X3}$$

```
/*----------- Lognormal Model with Regressors ------------*/
data test_sev3(keep=y x1-x3
               label='A Lognormal Sample Affected by Regressors');
   array x{*} x1-x3;
   array b{4} _TEMPORARY_ (1 0.75 -1 0.25);
   call streaminit(45678);
   label y='Response Influenced by Regressors';
   Sigma = 0.25;
   do n = 1 to 100;
      Mu = b(1); /* log of base value of scale */
      do i = 1 to dim(x);
         x(i) = rand('UNIFORM');
         Mu = Mu + b(i+1) * x(i);
      end;
      y = exp(Mu) * rand('LOGNORMAL')**Sigma;
      output;
   end;
run;
```

The following PROC SEVERITY step fits the lognormal, Burr, and gamma distribution models to these data. The regressors are specified in the SCALEMODEL statement. The DFMIXTURE= option in the SCALEMODEL statement specifies the method of computing the CDF estimates that are used to compute the EDF-based statistics of fit.

```
proc severity data=test_sev3 crit=aicc print=all;
   loss y;
   scalemodel x1-x3 / dfmixture=full;

   dist logn burr gamma;
run;
```

Some of the key results prepared by PROC SEVERITY are shown in Figure 28.14 through Figure 28.18. The descriptive statistics of all the variables are shown in Figure 28.14.

Figure 28.14 Summary Results for the Regression Example

The SEVERITY Procedure

Input Data Set	
Name	WORK.TEST_SEV3
Label	A Lognormal Sample Affected by Regressors

The final parameter estimates of the lognormal model are shown in Figure 28.17. All the estimates are significantly different from 0. The estimate that is reported for the parameter *Mu* is the base value for the log-transformed scale parameter μ. Let $x_i (1 \leq i \leq 3)$ denote the observed value for regressor X*i*. If the lognormal distribution is chosen to model Y, then the effective value of the parameter μ varies with the observed values of regressors as

$$\mu = 1.04047 + 0.65221\, x_1 - 0.91116\, x_2 + 0.16243\, x_3$$

These estimated coefficients are reasonably close to the population parameters (that is, within one or two standard errors).

Figure 28.17 Parameter Estimates for the Lognormal Model with Regressors

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|

x3	1	0.16243	0.07782	2.09	0.0395

The estimates of the gamma distribution model, which is the best model according to a majority of the EDF-based statistics, are shown in Figure 28.18. The estimate that is reported for the parameter *Theta* is the base value for the scale parameter θ. If the gamma distribution is chosen to model Y, then the effective value of the scale parameter is $\theta = 0.14293 \exp(0.64562\, x_1 - 0.89831\, x_2 + 0.14901\, x_3)$.

Specifies that distributions be validated without estimating any models that use them	DIST	VALIDATEONLY

PROC SEVERITY Statement

PROC SEVERITY *options* **;**

The PROC SEVERITY statement invokes the procedure. You can specify two types of *options* in the PROC SEVERITY statement. One set of *options* controls input and output. The other set of *options* controls the model estimation and selection process.

The following *options* control the input data sets used by PROC SEVERITY and various forms of output generated by PROC SEVERITY. The *options* are listed in alphabetical order.

COVOUT

specifies that the OUTEST= data set contain the estimate of the covariance structure of the parameters. This option has no effect if you do not specify the OUTEST= option. For more information about how the covariance is reported in the OUTEST= data set, see the section "OUTEST= Data Set" on page 2150.

DATA=*SAS-data-set*

names the input data set. If you do not specify the DATA= option, then the most recently created SAS data set is used.

EDFALPHA=*confidence-level*

specifies the confidence level in the (0,1) range that is used for computing the confidence intervals for the EDF estimates. The lower and upper confidence limits that correspond to this level are reported in the OUTCDF= data set, if specified, and are displayed in the plot that is created when you specify the PLOTS=CDFPERDIST option.

If you do not specify the EDFALPHA= option, then PROC SEVERITY uses a default value of 0.05.

INEST=*SAS-data-set*
names the input data set that contains the initial values of the parameter estimates to start the optimization process. The initial values that you specify in the INIT= option in the DIST statement take precedence over any initial values that you specify in the INEST= data set. For more information about the variables in this data set, see the section "INEST= Data Set" on page 2147.

If you specify the SCALEMODEL statement, then PROC SEVERITY reads the INEST= data set only if the SCALEMODEL statement contains singleton continuous effects. For more generic regression effects, you should save the estimates by specifying the OUTSTORE= item store in a step and then use the INSTORE= option to read those estimates. The INSTORE= option is the newer and more flexible method of specifying initial values for distribution and regression parameters.

INITSAMPLE (*initsample-option***)**

INITSAMPLE (*initsample-option . . . initsample-option***)**
specifies that a sample of the input data be used for initializing the distribution parameters. If you specify more than one *initsample-option*, then separate them with spaces.

When you do not specify initial values for the distribution parameters, PROC SEVERITY needs to compute the empirical distribution function (EDF) estimates as part of the default method for parameter initialization. The EDF estimation process can be expensive, especially when you specify censoring or truncation effects for the loss variable. Furthermore, it is not amenable to parallelism due to the sequential nature of the algorithm for truncation effects. You can use the INITSAMPLE option to specify that only a fraction of the input data be used in order to reduce the time taken to compute the EDF estimates. PROC SEVERITY uses the uniform random sampling method to select the sample, the size and randomness of which are controlled by the following *initsample-options*:

FRACTION=*number*
specifies the fraction, between 0 and 1, of the input data to be used for sampling.

SEED=*number*
specifies the seed to be used for the uniform random number generator. This option enables you to select the same sample from the same input data across different runs of PROC SEVERITY, which can be useful for replicating the results across different runs. If you do not specify the seed value, PROC SEVERITY generates a seed that is based on the system clock.

SIZE=*number*
specifies the size of the sample. If the data are distributed across different nodes, then this size applies to the sample that is prepared at each node. For example, let the input data set of size 100,000 observations be distributed across 10 nodes such that each node has 10,000 observations. If you specify SIZE=1000, then each node computes a local EDF estimate by using a sample of size 1,000 selected randomly from its 10,000 observations. If you specify both of the SIZE= and FRACTION= options, then the value that you specify in the SIZE= option is used and the FRACTION= option is ignored.

If you do not specify the INITSAMPLE option, then PROC SEVERITY computes the EDF estimates by using all valid observations in the DATA= data set, or by using all valid observations in the current BY group if you specify a BY statement.

INSTORE=*store-name*

names the item store that contains the context and results of the severity model estimation process. An item store has a binary file format that cannot be modified. You must specify an item store that you have created in another PROC SEVERITY step by using the OUTSTORE= option.

The *store-name* is a usual one- or two-level SAS name, as for SAS data sets. If you specify a one-level name, then PROC SEVERITY reads the item store from the WORK library. If you specify a two-level name of the form *libname.membername*, then PROC SEVERITY reads the item store from the *libname* library.

This option is more flexible than the INEST= option, because it can read estimates of any type of scale regression model; the INEST= option can read only scale regression models that contain singleton continuous effects.

For more information about how the input item store is used for parameter initialization, see the sections "Parameter Initialization" on page 2092 and "Parameter Initialization for Regression Models" on page 2094.

NAMELEN=*number*

specifies the length to which long regression effect names are shortened. The default and minimum value is 20.

This option does not apply to the names of singleton continuous effects if you have not specified any CLASS variables.

NOCLPRINT<=*number***>**

suppresses the display of the "Class Level Information" table if you do not specify *number*. If you specify *number*, the values of the classification variables are displayed for only those variables whose number of levels is less than *number*. Specifying a *number* helps to reduce the size of the "Class Level Information" table if some classification variables have a large number of levels. This option has no effect if you do not specify the CLASS statement.

NOPRINT

turns off all displayed and graphical output. If you specify this option, then any value that you specify for the PRINT= and PLOTS= options is ignored.

OUTCDF=*SAS-data-set*

names the output data set to contain estimates of the cumulative distribution function (CDF) value at each of the observations. The information is output for each specified model whose parameter estimation process converges. The data set also contains the estimates of the empirical distribution function (EDF). For more information about the variables in this data set, see the section "OUTCDF= Data Set" on page 2149.

OUTEST=*SAS-data-set*

names the output data set to contain estimates of the parameter values and their standard errors for each model whose parameter estimation process converges. For more information about the variables in this data set, see the section "OUTEST= Data Set" on page 2150.

If you specify the SCALEMODEL statement such that it contains at least one effect that is not a singleton continuous effect, then the OUTEST= data set that this option creates cannot be used as an INEST= data set in a subsequent PROC SEVERITY step. In such cases, it is recommended that you use the newer OUTSTORE= option to save the estimates and specify those estimates in a subsequent PROC SEVERITY step by using the INSTORE= option.

OUTMODELINFO=*SAS-data-set*
names the output data set to contain the information about each candidate distribution. For more information about the variables in this data set, see the section "OUTMODELINFO= Data Set" on page 2152.

OUTSTAT=*SAS-data-set*
names the output data set to contain the values of statistics of fit for each model whose parameter estimation process converges. For more information about the variables in this data set, see the section "OUTSTAT= Data Set" on page 2152.

OUTSTORE=*store-name*
names the item store to contain the context and results of the severity model estimation process. The resulting item store has a binary file format that cannot be modified. You can specify this item store in a subsequent PROC SEVERITY step by using the INSTORE= option.

The *store-name* is a usual one- or two-level SAS name, as for SAS data sets. If you specify a one-level name, then the item store resides in the WORK library and is deleted at the end of the SAS session. Because item stores are meant to be consumed by a subsequent PROC SEVERITY step for parameter initialization, typical usage specifies a two-level name of the form *libname.membername*.

This option is more useful than the OUTEST= option, especially when you specify a scale regression model that contains interaction effects or effects that have CLASS variables. You can initialize such scale regression models in a subsequent PROC SEVERITY step only by specifying the item store that this option creates as an INSTORE= item store in that step.

PLOTS <(*global-plot-options***)> <=***plot-request-option***>**
PLOTS <(*global-plot-options***)> <=(***plot-request-option . . . plot-request-option***)>**
specifies the desired graphical output. If you specify more than one *global-plot-option*, then separate them with spaces and enclose them in parentheses. If you specify more than one *plot-request-option*, then separate them with spaces and enclose them in parentheses.

You can specify the following *global-plot-options*:

HISTOGRAM
plots the histogram of the response variable on the PDF plots.

KERNEL
plots the kernel estimate of the probability density of the response variable on the PDF plots.

ONLY
turns off the default graphical output and creates only the requested plots.

You can specify the following *plot-request-options*:

ALL
creates all the graphical output.

CDF

creates a plot that compares the cumulative distribution function (CDF) estimates of all the candidate distribution models to the empirical distribution function (EDF) estimate. The plot does not contain CDF estimates for models whose parameter estimation process does not converge.

CDFPERDIST

creates a plot of the CDF estimates of each candidate distribution model. A plot is not created for models whose parameter estimation process does not converge.

CONDITIONALPDF < (*cpdf-options*) >

CONDPDF < (*cpdf-options*) >

creates a plot that compares the conditional PDF estimates of all the candidate distribution models. The plot does not contain conditional PDF estimates for models whose parameter estimation process does not converge.

A conditional PDF of a loss random variable Y in an interval $(Y_l, Y_r]$ is the probability that a specific loss value is observed, given that the loss values belong to that interval. Formally, the conditional PDF of y, denoted by $f^c(y)$, for the $(Y_l, Y_r]$ interval is defined as $f^c(y) = \Pr[Y = y | Y_l < Y \leq Y_r]$. If $f(y)$ and $F(y)$ denote the PDF and CDF at loss value y, respectively, then $f^c(y)$ for the $(Y_l, Y_r]$ interval is computed as $f^c(y) = f(y)/(F(Y_r) - F(Y_l))$. The scaling factor of $1/(F(Y_r) - F(Y_l))$ ensures that the conditional PDF is a true PDF that integrates to 1 in the $(Y_l, Y_r]$ interval.

PROC SEVERITY prepares a conditional PDF comparison plot that contains at most three regions (intervals) of mutually exclusive ranges of the loss variable's value:

- left-tail: $(y_{\min} - \epsilon, L]$
- center: $(L, R]$
- right-tail: $(R, y_{\max}]$

where $y_{\min}$ and $y_{\max}$ denote the smallest and largest values of the loss variable in the DATA= data set, respectively, and ϵ denotes a small machine-precision constant for a double-precision value.

You can specify the following *cpdf-options* to control how the values of L and R are computed and which regions are displayed:

LEFTQ | LEFT | L=*number*

specifies the CDF value, between 0 and 1, to mark the end of the left-tail region. The left-tail region always starts at the minimum loss variable value in the DATA= data set. The value of L, the end of the left-tail region, is determined by the *number* that you specify. Let the *number* be p_l. If you do not specify the QUANTILEBOUNDS option, then PROC SEVERITY sets L equal to the $100p_l$th percentile. If you specify the QUANTILEBOUNDS option, then for a distribution D with an estimated quantile function $\hat{Q}_D$, $L_D = \hat{Q}_D(p_l)$ marks the end of the left-tail region. L_D can be different for each distribution, so the left-tail region ends at different values for different distributions.

RIGHTQ | RIGHT | R=*number*

specifies the CDF value, between 0 and 1, to mark the start of the right-tail region. The right-tail region always ends at the maximum loss variable value in the DATA= data set. The value of R, the start of the right-tail region, is determined by the *number* that you specify. Let the *number* be p_r. If you do not specify the QUANTILEBOUNDS option, then PROC SEVERITY sets R equal to the $100p_r$th percentile. If you specify the QUANTILEBOUNDS option, then for a distribution D with an estimated quantile function $\hat{Q}_D$, $R_D = \hat{Q}_D(p_r)$ marks the start of the right-tail region. R_D can be different for each distribution, so the right-tail region starts at different values for different distributions.

QUANTILEBOUNDS

specifies that the region boundaries be computed by using the estimated quantile functions of individual distributions. If you do not specify this option, then the boundaries are computed by using the percentiles, which are quantiles from the empirical distribution.

When you specify this option, the left-tail region of different distributions can end at different values and the right-tail region of different distributions can start at different values, because the quantile function of different distributions can produce different values for the same CDF value.

SHOWREGION | SHOW=*region-option*

SHOWREGION | SHOW=(*region-options***)**

specifies the regions to display in the plot. You can specify any combination of the following *region-options*:

CENTER | C

specifies that the center region of the plot, which is the region between the end of the left-tail region and the beginning of the right-tail region, be shown. If you specify this option, you must also specify valid values for both the LEFTQ= and RIGHTQ= options.

LEFT | L

specifies that the left-tail region of the plot be shown. If you specify this option, you must also specify a valid value for the LEFTQ= option.

RIGHT | R

specifies that the right-tail region of the plot be shown. If you specify this option, you must also specify a valid value for the RIGHTQ= option.

If you do not specify the SHOWREGION option, then PROC SEVERITY determines the default displayed regions as follows:

- If you do not specify either the LEFTQ= or RIGHTQ= option, then this is equivalent to specifying (LEFTQ=0.25 RIGHTQ=0.75), and PROC SEVERITY displays all three regions (left-tail, center, and right-tail).
- If you specify valid values for both the LEFTQ= and RIGHTQ= options, then PROC SEVERITY displays all three regions (left-tail, center, and right-tail).
- If you specify a valid value for the LEFTQ= option but do not specify the RIGHTQ= option, then PROC SEVERITY displays two regions: left-tail and the remaining region that combines the center and right-tail regions.

- If you specify a valid value for the RIGHTQ= option but do not specify the LEFTQ= option, then PROC SEVERITY displays two regions: right-tail and the remaining region that combines the center and left-tail regions.

Whether you specify the SHOWREGION option or not, PROC SEVERITY does not display a region if the region contains fewer than five observations, and it issues a corresponding warning in the SAS log.

For an illustration of the CONDITIONALPDF option, see "Example 28.3: Defining a Model for Mixed-Tail Distributions" on page 2169.

CONDITIONALPDFPERDIST <(*cpdf-options*)>

CONDPDFDIST <(*cpdf-options*)>

creates a plot of the conditional PDF estimates of each candidate distribution model. A plot is not created for models whose parameter estimation process does not converge.

The *cpdf-options* are identical to those listed for the CONDITIONALPDF plot option, except that they are interpreted in the context of each candidate distribution individually. You can specify a different set of values for the *cpdf-options* in the CONDITIONALPDFPERDIST option than you specify in the CONDITIONALPDF option.

For an illustration of the CONDITIONALPDFPERDIST option, see "Example 28.4: Estimating Parameters Using the Cramér–von Mises Estimator" on page 2178.

NONE

creates none of the graphical output. If you specify this option, then it overrides all the other *plot-request-options*. The default graphical output is also suppressed.

PDF

creates a plot that compares the probability density function (PDF) estimates of all the candidate distribution models. The plot does not contain PDF estimates for models whose parameter estimation process does not converge.

PDFPERDIST

creates a plot of the PDF estimates of each candidate distribution model. A plot is not created for models whose parameter estimation process does not converge.

PP

creates the probability-probability plot (known as the P-P plot), which compares the CDF estimate of each candidate distribution model to the empirical distribution function (EDF). The data that are shown in this plot are used for computing the EDF-based statistics of fit.

QQ

creates the quantile-quantile plot (known as the Q-Q plot), which compares the empirical quantiles to the quantiles of each candidate distribution model.

If you do not specify the PLOTS= option or if you do not specify the ONLY *global-plot-option*, then the default graphical output is equivalent to specifying PLOTS(HISTOGRAM KERNEL)=(CDF PDF).

PRINT <(*global-display-option***)> <=***display-option***>**

PRINT <(*global-display-option***)> <= (***display-option . . . display-option***) >**

specifies the desired displayed output. If you specify more than one *display-option*, then separate them with spaces and enclose them in parentheses.

You can specify the following *global-display-option*:

ONLY
turns off the default displayed output and displays only the requested output.

You can specify the following *display-options*:

ALL
displays all the output.

ALLFITSTATS
displays the comparison of all the statistics of fit for all the models in one table. The table does not include the models whose parameter estimation process does not converge.

CONVSTATUS
displays the convergence status of the parameter estimation process.

DESCSTATS
displays the descriptive statistics for the response variable. If you specify the SCALEMODEL statement, then this option also displays the descriptive statistics for the regression effects that do not contain a CLASS variable.

DISTINFO
displays the information about each specified distribution. For each distribution, the information includes the name, description, validity status, and number of distribution parameters.

ESTIMATES | PARMEST
displays the final estimates of parameters. The estimates are not displayed for models whose parameter estimation process does not converge.

INITIALVALUES
displays the initial values and bounds used for estimating each model.

NLOHISTORY
displays the iteration history of the nonlinear optimization process used for estimating the parameters.

NLOSUMMARY
displays the summary of the nonlinear optimization process used for estimating the parameters.

NONE
displays none of the output. If you specify this option, then it overrides all other display options. The default displayed output is also suppressed.

SELECTION | SELECT
displays the model selection table.

STATISTICS | FITSTATS
displays the statistics of fit for each model. The statistics of fit are not displayed for models whose parameter estimation process does not converge.

If you do not specify the PRINT= option or if you do not specify the ONLY *global-display-option*, then the default displayed output is equivalent to specifying PRINT=(SELECTION CONVSTATUS NLOSUMMARY STATISTICS ESTIMATES).

VARDEF=DF | N
specifies the denominator to use for computing the covariance estimates. You can specify one of the following values:

DF specifies that the number of nonmissing observations minus the model degrees of freedom (number of parameters) be used.

N specifies that the number of nonmissing observations be used.

For more information about the covariance estimation, see the section "Estimating Covariance and Standard Errors" on page 2092.

The following *options* control the model estimation and selection process:

CRITERION | CRITERIA | CRIT=*criterion-option*
specifies the model selection criterion.

If you specify two or more candidate models for estimation, then the one with the best value for the selection criterion is chosen as the best model. If you specify the OUTSTAT= data set, then the best model's observation has a value of 1 for the _SELECTED_ variable.

You can specify one of the following *criterion-options*:

AD
specifies the Anderson-Darling (AD) statistic value, which is computed by using the empirical distribution function (EDF) estimate, as the selection criterion. A lower value is deemed better.

AIC
specifies Akaike's information criterion (AIC) as the selection criterion. A lower value is deemed better.

AICC
specifies the finite-sample corrected Akaike's information criterion (AICC) as the selection criterion. A lower value is deemed better.

BIC
specifies the Schwarz Bayesian information criterion (BIC) as the selection criterion. A lower value is deemed better.

CUSTOM
specifies the custom objective function as the selection criterion. You can specify this only if you also specify the OBJECTIVE= option. A lower value is deemed better.

CVM
specifies the Cramér–von Mises (CvM) statistic value, which is computed by using the empirical distribution function (EDF) estimate, as the selection criterion. A lower value is deemed better.

KS
specifies the Kolmogorov-Smirnov (KS) statistic value, which is computed by using the empirical distribution function (EDF) estimate, as the selection criterion. A lower value is deemed better.

LOGLIKELIHOOD | LL
specifies $-2 * \log(L)$ as the selection criterion, where L is the likelihood of the data. A lower value is deemed better. This is the default.

For more information about these *criterion-options*, see the section "Statistics of Fit" on page 2114.

EMPIRICALCDF | EDF=*method*
specifies the method to use for computing the nonparametric or empirical estimate of the cumulative distribution function of the data. You can specify one of the following values for *method*:

AUTOMATIC | AUTO
specifies that the method be chosen automatically based on the data specification. This option is the default.

If you do not specify any censoring or truncation, then the standard empirical estimation method (STANDARD) is chosen. If you specify both right-censoring and left-censoring, then Turnbull's estimation method (TURNBULL) is chosen. For all other combinations of censoring and truncation, the Kaplan-Meier method (KAPLANMEIER) is chosen.

KAPLANMEIER | KM
specifies that the product limit estimator proposed by Kaplan and Meier (1958) be used. Specification of this method has no effect when you specify both right-censoring and left-censoring.

MODIFIEDKM | MKM <(*options***)>**
specifies that the modified product limit estimator be used. Specification of this method has no effect when you specify both right-censoring and left-censoring.

This method allows Kaplan-Meier's product limit estimates to be more robust by ignoring the contributions to the estimate due to small risk-set sizes. The risk set is the set of observations at the risk of failing, where an observation is said to fail if it has not been processed yet and might experience censoring or truncation. You can specify the minimum risk-set size that makes it eligible to be included in the estimation either as an absolute lower bound on the size (RSLB= option) or a relative lower bound determined by the formula cn^{α} proposed by Lai and Ying (1991). You can specify the values of c and α by using the C= and ALPHA= options, respectively. By default, the relative lower bound is used with values of $c = 1$ and $\alpha = 0.5$. However, you can modify the default by using the following *options*:

ALPHA | A=*number*
specifies the value to use for α when the lower bound on the risk set size is defined as cn^{α}. This value must satisfy $0 < \alpha < 1$.

C=*number*
specifies the value to use for c when the lower bound on the risk set size is defined as cn^{α}. This value must satisfy $c > 0$.

RSLB=*number*
specifies the absolute lower bound on the risk set size to be included in the estimate.

STANDARD | STD
specifies that the standard empirical estimation method be used. If you specify both right-censoring and left-censoring, then the specification of this method has no effect. If you specify any other combination of censoring or truncation effects, then this method ignores such effects, and can thus result in estimates that are more biased than those obtained with other methods that are more suitable for censored or truncated data.

TURNBULL | EM <(*options***)>**
specifies that the Turnbull's method be used. This method is used when you specify both right-censoring and left-censoring. An iterative expectation-maximization (EM) algorithm proposed by Turnbull (1976) is used to compute the empirical estimates. If you also specify truncation, then the modification suggested by Frydman (1994) is used. You can modify the default behavior of the EM algorithm by using the following *options*:

ENSUREMLE
specifies that the final EDF estimates be maximum likelihood estimates. The Kuhn-Tucker conditions are computed for the likelihood maximization problem and checked to ensure that EM algorithm converges to maximum likelihood estimates. The method generalizes the method proposed by Gentleman and Geyer (1994) by taking into account any truncation information that you might specify.

EPS=*number*
specifies the maximum relative error to be allowed between estimates of two consecutive iterations. This criterion is used to check the convergence of the algorithm. If you do not specify this option, then PROC SEVERITY uses a default value of 1.0E–8.

MAXITER=*number*
specifies the maximum number of iterations to attempt to find the empirical estimates. If you do not specify this option, then PROC SEVERITY uses a default value of 500.

ZEROPROB=*number*
specifies the threshold below which an empirical estimate of the probability is considered zero. This option is used to decide if the final estimate is a maximum likelihood estimate. This option does not have an effect if you do not specify the ENSUREMLE option. If you specify the ENSUREMLE option, but do not specify this option, then PROC SEVERITY uses a default value of 1.0E–8.

For more information about each of the methods, see the section "Empirical Distribution Function Estimation Methods" on page 2108.

OBJECTIVE=*symbol-name*

names the symbol that represents the objective function in the SAS programming statements that you specify. For each model to be estimated, PROC SEVERITY executes the programming statements to compute the value of this symbol for each observation. The values are added across all observations to obtain the value of the objective function. The optimization algorithm estimates the model parameters such that the objective function value is *minimized*. A separate optimization problem is solved for each candidate distribution. If you specify a BY statement, then a separate optimization problem is solved for each candidate distribution within each BY group.

For more information about writing SAS programming statements to define your own objective function, see the section "Custom Objective Functions" on page 2143.

BY Statement

BY *variable-list* **;**

A BY statement can be used in the SEVERITY procedure to process the input data set in groups of observations defined by the BY variables.

If you specify the BY statement, then PROC SEVERITY expects the input data set to be sorted in the order of the BY variables unless you specify the NOTSORTED option.

CLASS Statement

CLASS *variable* < *(options)* > . . . < *variable* < *(options)* > > < / *global-options* > **;**

The CLASS statement names the classification variables to be used in the scale regression model. These variables enter the analysis not through their values, but through levels to which the unique values are mapped. For more information about these mappings, see the section "Levelization of Classification Variables" on page 2099.

If you specify a CLASS statement, then it must precede the SCALEMODEL statement.

You can specify options either as individual variable *options* or as *global-options*. You can specify *options* for each variable by enclosing the options in parentheses after the variable name. You can also specify *global-options* for the CLASS statement by placing them after a slash (/). *Global-options* are applied to all the variables that you specify in the CLASS statement. If you specify more than one CLASS statement, the *global-options* that are specified in any one CLASS statement apply to all CLASS statements. However, individual CLASS variable *options* override the *global-options*.

You can specify the following values for either an *option* or a *global-option*:

DESCENDING

DESC

reverses the sort order of the classification variable. If you specify both the DESCENDING and ORDER= options, the SEVERITY procedure orders the levels of classification variables according to the ORDER= option and then reverses that order.

ORDER=DATA | FORMATTED | INTERNAL

ORDER=FREQ | FREQDATA | FREQFORMATTED | FREQINTERNAL

specifies the sort order for the levels of classification variables. This order is used by the parameterization method to create the parameters in the model. By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. When ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

Table 28.2 shows how the SEVERITY procedure interprets values of the ORDER= option.

Table 28.2 Interpretation of ORDER= Option Values

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted values, except for numeric variables that have no explicit format, which are sorted by their unformatted (internal) values
FREQ	Descending frequency count (levels that have more observations come earlier in the order)
FREQDATA	Order of descending frequency count, and within counts by order of appearance in the input data set when counts are tied
FREQFORMATTED	Order of descending frequency count, and within counts by formatted value when counts are tied
FREQINTERNAL	Order of descending frequency count, and within counts by unformatted (internal) value when counts are tied
INTERNAL	Unformatted value

For more information about sort order, see the chapter about the SORT procedure in *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Programmers Guide: Essentials*.

REF=*'level'* | *keyword*

REFERENCE=*'level'* | *keyword*

specifies the reference level that is used when you specify PARAM=REFERENCE. For an individual (but not a global) variable REF= *option*, you can specify the *level* of the variable to use as the reference level. Specify the formatted value of the variable if a format is assigned. For a REF= *option* or *global-option*, you can use one of the following *keywords*:

FIRST designates the first-ordered level as reference.

LAST designates the last-ordered level as reference.

By default, REF=LAST.

If you choose a reference level for any CLASS variable, all variables are parameterized in the reference parameterization for computational efficiency. In other words, the SEVERITY procedure applies a single parameterization method to all classification variables.

Suppose that the variable temp has three levels (`'hot'`, `'warm'`, and `'cold'`) and that the variable gender has two levels (`'M'` and `'F'`). The following statements fit a scale regression model:

```
proc severity;
   loss y;
   class gender(ref='F') temp;
   scalemodel gender*temp gender;
run;
```

Both CLASS variables are in reference parameterization in this model. The reference levels are `'F'` for the variable gender and `'warm'` for the variable temp, because the statements are equivalent to the following statements:

```
proc severity;
   loss y;
   class gender(ref='F') temp(ref=last);
   scalemodel gender*temp gender;
run;
```

You can specify the following *global-options*:

MISSING
treats missing values (“.”, “.A”, . . . , “.Z” for numeric variables and blanks for character variables) as valid values for the CLASS variable.

If you do not specify the MISSING option, observations that have missing values for CLASS variables are removed from the analysis, even if the CLASS variables are not used in the model formulation.

PARAM=*keyword*
specifies the parameterization method for the classification variable or variables. You can specify the following *keywords*:

GLM specifies a less-than-full-rank reference cell coding.

REFERENCE specifies a reference cell encoding. You can choose the reference value by specifying an option for a specific *variable* or set of *variables* in the CLASS statement, or you can designate the first- or last-ordered value by specifying a *global-option*. By default, REFERENCE=LAST.

The GLM parameterization is the default. For more information about how parameterization of classification variables affects the construction and interpretation of model effects, see the section “Specification and Parameterization of Model Effects” on page 2101.

TRUNCATE<=*n***>**
specifies the truncation width of formatted values of CLASS variables when the optional *n* is specified.

If *n* is not specified, the TRUNCATE option requests that classification levels be determined by using no more than the first 16 characters of the formatted values of CLASS variables.

DIST Statement

DIST *distribution-name-or-keyword* < *(distribution-option)* < *distribution-name-or-keyword* < *(distribution-option)* > > . . . > < / *preprocess-options* > **;**

The DIST statement specifies candidate distributions to be estimated by the SEVERITY procedure. You can specify multiple DIST statements, and each statement can contain one or more distribution specifications.

For your convenience, PROC SEVERITY provides the following 10 different predefined distributions (the name in parentheses is the name to use in the DIST statement): Burr (BURR), exponential (EXP), gamma (GAMMA), generalized Pareto (GPD), inverse Gaussian or Wald (IGAUSS), lognormal (LOGN), Pareto (PARETO), Tweedie (TWEEDIE), scaled Tweedie (STWEEDIE), and Weibull (WEIBULL). These are described in detail in the section "Predefined Distributions" on page 2079.

You can specify any of the predefined distributions or any distribution that you have defined. If a distribution that you specify is not a predefined distribution, then you must submit the CMPLIB= system option with appropriate libraries before you submit the PROC SEVERITY step to enable the procedure to find the functions associated with your distribution. The predefined distributions are defined in the Sashelp.Svrtdist library. However, you are not required to specify this library in the CMPLIB= system option. For more information about defining your own distributions, see the section "Defining a Severity Distribution Model with the FCMP Procedure" on page 2119.

As a convenience, you can also use a shortcut keyword to indicate a list of distributions. You can specify one or more of the following keywords:

ALL
specifies all the predefined distributions and the distributions that you have defined in the libraries that you specify in the CMPLIB= system option. In addition to the eight predefined distributions included by the _PREDEFINED_ keyword, this list also includes the Tweedie and scaled Tweedie distributions that are defined in the Sashelp.Svrtdist library.

PREDEFINED
specifies the list of eight predefined distributions: BURR, EXP, GAMMA, GPD, IGAUSS, LOGN, PARETO, and WEIBULL. Although the TWEEDIE and STWEEDIE distributions are available in the Sashelp.Svrtdist library along with these eight distributions, they are not included by this keyword. If you want to fit the TWEEDIE and STWEEDIE distributions, then you must specify them explicitly or use the _ALL_ keyword.

USER
specifies the list of all the distributions that you have defined in the libraries that you specify in the CMPLIB= system option. This list does not include the distributions defined in the Sashelp.Svrtdist library, even if you specify the Sashelp.Svrtdist library in the CMPLIB= option.

The use of these keywords, especially _ALL_, can result in a large list of distributions, which might take a longer time to estimate. A warning is printed to the SAS log if the number of total distribution models to estimate exceeds 10.

If you specify the OUTCDF= option or request a CDF plot and you do not specify any DIST statement, then PROC SEVERITY does not fit any distributions and produces the empirical estimates of the cumulative distribution function.

The following *distribution-option* values can be used in the DIST statement for a distribution name that is not a shortcut keyword:

INIT=*(name=value . . . name=value)*
specifies the initial values to be used for the distribution parameters to start the parameter estimation process. You must specify the values by parameter names, and the parameter names must match the names used in the model definition. For example, let a model M's definition contain an M_PDF function with the following signature:

```
function M_PDF(x, alpha, beta);
```

For this model, the names **alpha** and **beta** must be used for the INIT option. The names are case-insensitive. If you do not specify initial values for some parameters in the INIT statement, then a default value of 0.001 is assumed for those parameters. If you specify an incorrect parameter, PROC SEVERITY prints a warning to the SAS log and does not fit the model. All specified values must be nonmissing.

If you are modeling regression effects, then the initial value of the first distribution parameter (**alpha** in the preceding example) should be the initial *base* value of the scale parameter or log-transformed scale parameter. For more information, see the section "Estimating Regression Effects" on page 2093.

The use of INIT= option is one of the three methods available for initializing the parameters. For more information, see the section "Parameter Initialization" on page 2092. If none of the initialization methods is used, then PROC SEVERITY initializes all parameters to 0.001.

You can specify the following *preprocess-options* in the DIST statement:

LISTONLY
specifies that the list of all candidate distributions be printed to the SAS log without doing any further processing on them. This option is especially useful when you use a shortcut keyword to include a list of distributions. It enables you to find out which distributions are included by the keyword.

VALIDATEONLY
specifies that all candidate distributions be checked for validity without doing any further processing on them. If a distribution is invalid, the reason for invalidity is written to the SAS log. If all distributions are valid, then the distribution information is written to the SAS log. The information includes name, description, validity status (valid or invalid), and number of distribution parameters. The information is not written to the SAS log if you specify an OUTMODELINFO= data set or the PRINT=DISTINFO or PRINT=ALL option in the PROC SEVERITY statement. This option is especially useful when you specify your own distributions or when you specify the _USER_ or _ALL_ keywords in the DIST statement. It enables you to check whether your custom distribution definitions satisfy PROC SEVERITY's requirements for the specified modeling task. It is recommended that you specify the SCALEMODEL statement if you intend to fit a model with regression effects, because the SCALEMODEL statement instructs PROC SEVERITY to perform additional checks to validate whether regression effects can be modeled on each candidate distribution.

LOSS Statement

LOSS < *response-variable-name* > < / *censoring-truncation-options* > **;**

The LOSS statement specifies the name of the response or loss variable whose distribution needs to be modeled. You can also specify additional options to indicate any truncation or censoring of the response. The specification of response variable is optional if you specify at least one type of censoring. You must specify a response variable if you do not specify any censoring. If you specify more than one LOSS statement, then the first statement is used.

All the analysis variables that you specify in this statement must be present in the input data set that you specify by using the DATA= option in the PROC SEVERITY statement. The response variable is expected to have nonmissing values. If the variable has a missing value in an observation, then a warning is written to the SAS log and that observation is ignored.

The following *censoring-truncation-options* can be used in the LOSS statement:

LEFTCENSORED | LC=*variable-name*

LEFTCENSORED | LC=*number*

specifies the left-censoring variable or a global left-censoring limit.

You can use the *variable-name* argument to specify a data set variable that contains the left-censoring limit. If the value of this variable is missing, then PROC SEVERITY assumes that such observations are not left-censored.

Alternatively, you can use the *number* argument to specify a left-censoring limit value that applies to all the observations in the data set. This limit must be a nonzero positive number.

By the definition of left-censoring, an exact value of the response is not known when it is less than or equal to the left-censoring limit. If you specify the response variable and the value of that variable is less than or equal to the value of the left-censoring limit for some observations, then PROC SEVERITY treats such observations as left-censored and the value of the response variable is ignored. If you specify the response variable and the value of that variable is greater than the value of the left-censoring limit for some observations, then PROC SEVERITY assumes that such observations are not left-censored and the value of the left-censoring limit is ignored.

If you specify both right-censoring and left-censoring limits, then the left-censoring limit must be greater than or equal to the right-censoring limit. If both limits are identical, then the observation is assumed to be uncensored.

For more information about left-censoring, see the section "Censoring and Truncation" on page 2088.

LEFTTRUNCATED | LT=*variable-name* < *(left-truncation-option)* >

LEFTTRUNCATED | LT=*number* < *(left-truncation-option)* >

specifies the left-truncation variable or a global left-truncation threshold.

You can use the *variable-name* argument to specify a data set variable that contains the left-truncation threshold. If the value of this variable is missing or 0 for some observations, then PROC SEVERITY assumes that such observations are not left-truncated.

Alternatively, you can use the *number* argument to specify a left-truncation threshold that applies to all the observations in the data set. This threshold must be a nonzero positive number.

It is assumed that the response variable contains the observed values. By the definition of left-truncation, you can observe only a value that is greater than the left-truncation threshold. If a response variable value is less than or equal to the left-truncation threshold, a warning is printed to the SAS log, and the observation is ignored. For more information about left-truncation, see the section "Censoring and Truncation" on page 2088.

You can specify the following *left-truncation-option* for an alternative interpretation of the left-truncation threshold:

PROBOBSERVED | POBS=*number*

specifies the probability of observability, which is defined as the probability that the underlying severity event is observed (and recorded) for the specified left-threshold value.

The specified *number* must lie in the (0.0, 1.0] interval. A value of 1.0 is equivalent to specifying that there is no left-truncation, because it means that no severity events can occur with a value less than or equal to the threshold. If you specify value of 1.0, PROC SEVERITY prints a warning to the SAS log and proceeds by assuming that LEFTTRUNCATED= option is not specified.

For more information, see the section "Probability of Observability" on page 2089.

RIGHTCENSORED | RC=*variable-name*

RIGHTCENSORED | RC=*number*

specifies the right-censoring variable or a global right-censoring limit.

You can use the *variable-name* argument to specify a data set variable that contains the right-censoring limit. If the value of this variable is missing, then PROC SEVERITY assumes that such observations are not right-censored.

Alternatively, you can use the *number* argument to specify a right-censoring limit value that applies to all the observations in the data set. This limit must be a nonzero positive number.

By the definition of right-censoring, an exact value of the response is not known when it is greater than or equal to the right-censoring limit. If you specify the response variable and the value of that variable is greater than or equal to the value of the right-censoring limit for some observations, then PROC SEVERITY treats such observations as right-censored and the value of the response variable is ignored. If you specify the response variable and the value of that variable is less than the value of the right-censoring limit for some observations, then PROC SEVERITY assumes that such observations are not right-censored and the value of the right-censoring limit is ignored.

If you specify both right-censoring and left-censoring limits, then the left-censoring limit must be greater than or equal to the right-censoring limit. If both limits are identical, then the observation is assumed to be uncensored.

For more information about right-censoring, see the section "Censoring and Truncation" on page 2088.

RIGHTTRUNCATED | RT=*variable-name*

RIGHTTRUNCATED | RT=*number*

specifies the right-truncation variable or a global right-truncation threshold.

You can use the *variable-name* argument to specify a data set variable that contains the right-truncation threshold. If the value of this variable is missing for some observations, then PROC SEVERITY assumes that such observations are not right-truncated.

Alternatively, you can use the *number* argument to specify a right-truncation threshold that applies to all the observations in the data set. This threshold must be a nonzero positive number.

It is assumed that the response variable contains the observed values. By the definition of right-truncation, you can observe only a value that is less than or equal to the right-truncation threshold. If a response variable value is greater than the right-truncation threshold, a warning is printed to the SAS log, and the observation is ignored. For more information about right-truncation, see the section "Censoring and Truncation" on page 2088.

NLOPTIONS Statement

NLOPTIONS *options* **;**

The SEVERITY procedure uses the nonlinear optimization (NLO) subsystem to perform the nonlinear optimization of the likelihood function to obtain the estimates of distribution and regression parameters. You can use the NLOPTIONS statement to control different aspects of this optimization process. For most problems, the default settings of the optimization process are adequate. However, in some cases it might be useful to change the optimization technique or to change the maximum number of iterations. The following statement uses the MAXITER= option to set the maximum number of iterations to 200 and uses the TECH= option to change the optimization technique to the double-dogleg optimization (DBLDOG) rather than the default technique, the trust region optimization (TRUREG), that is used in the SEVERITY procedure:

```
nloptions tech=dbldog maxiter=200;
```

A discussion of the full range of *options* that can be used in the NLOPTIONS statement is given in Chapter 6, "Nonlinear Optimization Methods." The SEVERITY procedure supports all those options except the options that are related to displaying the optimization information. You can use the PRINT= option in the PROC SEVERITY statement to request the optimization summary and iteration history. If you specify more than one NLOPTIONS statement, then the first statement is used.

OUTPUT Statement

OUTPUT < **OUT**=*SAS-data-set*> *output-options* **;**

The OUTPUT statement specifies the data set to write the estimates of scoring functions and quantiles to. To specify the name of the output data set, use the following option:

OUT=*SAS-data-set*
specifies the name of the output data set. If you do not specify this option, then PROC SEVERITY names the output data set by using the DATA*n* convention.

To control the contents of the OUT= data set, specify the following *output-options*:

COPYVARS=*variable-list*
specifies the names of the variables that you want to copy from the input DATA= data set to the OUT= data set. If you want to specify more than one name, then separate them by spaces.

If you specify the BY statement, then the BY variables are not automatically copied to the OUT= data set, so you must specify the BY variables in the COPYVARS= option.

FUNCTIONS=(*function*<**(***arg*)><**=***variable*> < *function*<**(***arg*)><**=***variable*>> **...)**

specifies the scoring functions that you want to estimate. For each scoring function that you want to estimate, specify the suffix of the scoring function as the *function*. For each *function* that you specify in this option and for each distribution *D* that you specify in the DIST statement, the FCMP function *D_function* must be defined in the search path that you specify by using the CMPLIB= system option.

If you want to evaluate the scoring function at a specific value of the response variable, then specify a number *arg*, which is enclosed in parentheses immediately after the *function*. If you do not specify *arg* or if you specify a missing value as *arg*, then for each observation in the DATA= data set, PROC SEVERITY computes the value v by using the following table and evaluates the scoring function at v, where y, r, and l denote the values of the response variable, right-censoring limit, and left-censoring limit, respectively:

Right-Censored	Left-Censored	v
No	No	y
No	Yes	l
Yes	No	r
Yes	Yes	$(l + r)/2$

You can specify the suffix of the variable that contains the estimate of the scoring function by specifying a valid SAS name as a *variable*. If you do not specify a *variable*, then PROC SEVERITY uses *function* as the suffix of the variable name.

To illustrate the FUNCTIONS= option with an example, assume that you specify the following DIST and OUTPUT statements:

```
dist exp logn;
output out=score functions=(cdf pdf(1000)=f1000 mean);
```

Let both exponential (EXP) and lognormal (LOGN) distributions converge. If $\hat{\theta}$ is the final estimate of the scale parameter of the exponential distribution, then PROC SEVERITY creates the following three scoring function variables for the exponential (EXP) distribution in the Work.Score data set:

EXP_CDF contains the CDF estimate $F_{\text{exp}}(v, \hat{\theta})$, where F_{exp} denotes the CDF of the exponential distribution and v is the value that is determined by the preceding table.

EXP_F1000 contains the PDF estimate $f_{\text{exp}}(1000, \hat{\theta})$, where f_{exp} denotes the PDF of the exponential distribution.

EXP_MEAN contains the mean of the exponential distribution for the scale parameter $\hat{\theta}$.

Similarly, if $\hat{\mu}$ and $\hat{\sigma}$ are the final estimates of the log-scale and shape parameters of the lognormal distribution, respectively, then PROC SEVERITY creates the following three scoring function variables for the lognormal (LOGN) distribution in the Work.Score data set:

LOGN_CDF contains the CDF estimate $F_{\text{logn}}(v, \hat{\mu}, \hat{\sigma})$, where F_{logn} denotes the CDF of the lognormal distribution and v is the value that is determined by the preceding table.

LOGN_F1000 contains the probability density function (PDF) estimate $f_{\text{logn}}(1000, \hat{\mu}, \hat{\sigma})$, where f_{logn} denotes the PDF of the lognormal distribution.

LOGN_MEAN contains the mean of the lognormal distribution for the parameters $\hat{\mu}$ and $\hat{\sigma}$.

If you specify the SCALEMODEL statement, then the value of the scale parameter of a distribution depends on the values of the regression parameters. So it might be different for different observations. In this example, the values of $\hat{\theta}$ and $\hat{\mu}$ might vary by observation, which might cause the values of the EXP_F1000, EXP_MEAN, LOGN_F1000, and LOGN_MEAN variables to vary by observation. The values of the EXP_CDF and LOGN_CDF variables might vary not only because of the varying values of v but also because of the varying values of $\hat{\theta}$ and $\hat{\mu}$.

If you do not specify the SCALEMODEL statement, then the values of scoring functions for which you specify a nonmissing argument *arg* and scoring functions that do not depend on the response variable value do not vary by observation. In this example, the values of the EXP_F1000, EXP_MEAN, LOGN_F1000, and LOGN_MEAN variables do not vary by observation.

If a distribution does not converge, then the scoring function variables for that distribution contain missing values in all observations.

For more information about scoring functions, see the section "Scoring Functions" on page 2136.

QUANTILES=*quantile-options*

specifies the quantiles that you want to estimate. To use this option, for each distribution that you specify in the DIST statement, the FCMP function *D_QUANTILE* must be defined in the search path that you specify by using the CMPLIB= system option.

You can specify the following *quantile-options*:

CDF=*CDF-values*

POINTS=*CDF-values*

specifies the CDF values at which you want to estimate the quantiles. *CDF-values* can be one or more numbers, separated by spaces. Each number must be in the interval (0,1).

NAMES=*variable-names*

specifies the suffixes of the names of the variables for each of the quantile estimates. If you specify n ($n \geq 0$) names in the *variable-names* option and k values in the CDF= option, and if $n < k$, then PROC SEVERITY uses the n names to name the variables that correspond to the first n CDF values. For each of the remaining $k - n$ CDF values, p_i ($n < i \leq k$), PROC SEVERITY creates a variable name P*t*, where *t* is the text representation of $100p_i$ that is formed by retaining at most NDECIMAL= digits after the decimal point and replacing the decimal point with an underscore ('_').

NDECIMAL=*number*

specifies the number of digits to keep after the decimal point when PROC SEVERITY creates the name of the quantile estimate variable. If you do not specify this option, then the default value is 3.

For example, assume that you specify the following DIST and OUTPUT statements:

```
dist burr;
output out=score quantiles=(cdf=0.9 0.975 0.995 names=ninety var);
```

PROC SEVERITY creates three quantile estimate variables, BURR_NINETY, BURR_VAR, and BURR_P99_5, in the Work.Score data set for the Burr distribution. These variables contain the estimates of $Q_{\text{Burr}}(p, \hat{\theta}, \hat{\alpha}, \hat{\gamma})$, for $p = 0.9$, 0.975, and 0.995, respectively, where Q_{Burr} denotes the quantile function and $\hat{\theta}$, $\hat{\alpha}$, and $\hat{\gamma}$ denote the parameter estimates of the Burr distribution.

If you specify the SCALEMODEL statement, then the quantile estimate might vary by observation, because the scale parameter of a distribution depends on the values of the regression parameters.

If you do not specify the SCALEMODEL statement, then the quantile estimates do not vary by observation, and if you do not specify any scoring functions in the FUNCTIONS= option whose estimates vary by observation, then the OUT= data set contains only one observation per BY group.

If a distribution does not converge, then the quantile estimate variables for that distribution contain missing values for all observations.

For more information about the variables and observations in the OUT= data set, see the section "OUT= Data Set" on page 2149.

OUTSCORELIB Statement

OUTSCORELIB < **OUTLIB**=> *fcmp-library-name options* **;**

The OUTSCORELIB statement specifies the library to write scoring functions to. Scoring functions enable you to easily compute a distribution function on the fitted parameters of the distribution without going through a potentially complex process of extracting the fitted parameter estimates from other output such as the OUTEST= data set that is created by PROC SEVERITY.

If you specify the SCALEMODEL statement and if you specify interaction or classification effects, then PROC SEVERITY ignores the OUTSCORELIB statement and does not generate scoring functions. In other words, if you specify the SCALEMODEL statement, then PROC SEVERITY generates scoring functions if you specify only singleton continuous effects in the SCALEMODEL statement.

You must specify the following option as the first option in the statement:

OUTLIB=*fcmp-library-name*

names the FCMP library to contain the scoring functions. PROC SEVERITY writes the scoring functions to the FCMP library named *fcmp-library-name*. If a library or data set named *fcmp-library-name* already exists, PROC SEVERITY deletes it before proceeding.

This option is similar to the OUTLIB= option that you would specify in a PROC FCMP statement, except that *fcmp-library-name* must be a two-level name whereas the OUTLIB= option in the PROC FCMP statement requires a three-level name. The third level of a three-level name specifies the package to which the functions belong. You do not need to specify the package name in the *fcmp-library-name*, because PROC SEVERITY automatically creates the package for you. By default, a separate package is created for each distribution that has not failed to converge. Each package is named for a distribution.

For example, if you define and fit a distribution named *mydist*, and if *mydist* does not fail to converge, then PROC SEVERITY creates a package named *mydist* in the OUTLIB= library that you specify. Further, let the definition of the *mydist* distribution contain three distribution functions, *mydist_PDF(x,Parm1,Parm2)*, *mydist_LOGCDF(x,Parm1,Parm2)*, and *mydist_XYZ(x,Parm1,Parm2)*. If you specify the OUTSCORELIB statement

```
outscorelib outlib=sasuser.scorefunc;
```

then the Sasuser.Scorefunc library contains the following three functions in a package named *mydist*: *SEV_PDF(x)*, *SEV_LOGCDF(x)*, and *SEV_XYZ(x)*.

The key feature of scoring functions is that they do not require the parameter arguments (*Parm1* and *Parm2* in this example). The fitted parameter estimates are encoded inside the scoring function so that you can compute or score the value of each function for a given value of the loss variable without having to know or extract the parameter estimates through some other means.

For convenience, you can omit the OUTLIB= portion of the specification and just specify the name, as in the following example:

```
outscorelib sasuser.scorefunc;
```

When the SEVERITY procedure runs successfully, the *fcmp-library-name* is appended to the CMPLIB system option, so you can immediately start using the scoring functions in a DATA step or PROC FCMP step.

You can specify the following *options* in the OUTSCORELIB statement:

COMMONPACKAGE

ONEPACKAGE

requests that only one common package be created to contain all the scoring functions.

If you specify this option, then all the scoring functions are created in a package called *sevfit*. For each distribution function that has the name *distribution_suffix*, the name of the corresponding scoring function is formed as *SEV_suffix_distribution*. For example, the scoring function of the distribution function 'MYDIST_BAR' is named 'SEV_BAR_MYDIST'.

If you do not specify this option, then all scoring functions for a distribution are created in a package that has the same name as the distribution, and for each distribution function that has the name *distribution_suffix*, the name of the corresponding scoring function is formed as *SEV_suffix*. For example, the scoring function of the distribution function 'MYDIST_BAR' is named 'SEV_BAR'.

OUTBYID=*SAS-data-set*

names the output data set to contain the unique identifier for each BY group. This unique identifier is used as part of the name of the package or scoring function for each distribution. This is a required option when you specify a BY statement in PROC SEVERITY.

The OUTBYID= data set contains one observation per BY group and a variable named _ID_ in addition to the BY variables that you specify in the BY statement. The _ID_ variable contains the unique identifier for each BY group. The identifier of the BY group is the decimal representation of the sequence number of the BY group. The first BY group has an identifier of 1, the second BY group has an identifier of 2, the tenth BY group has an identifier of 10, and so on.

If you do not specify the COMMONPACKAGE option in the OUTSCORELIB statement, then for each distribution, PROC SEVERITY creates as many packages as the number of BY groups. The unique BY-group identifier is used as a suffix for the package name. For example, if your DATA= data set has three BY groups and if you specify the OUTSCORELIB statement

```
outscorelib outlib=sasuser.byscorefunc outbyid=sasuser.byid;
```

then for the distribution 'MYDIST', the Sasuser.Byscorefunc library contains the three packages 'MYDIST1', 'MYDIST2', and 'MYDIST3', and each package contains one scoring function named 'SEV_BAR' for each distribution function named 'MYDIST_BAR'.

If you specify the COMMONPACKAGE option in the OUTSCORELIB statement, PROC SEVERITY creates as many versions of the distribution function as the number of BY groups. The unique BY-group identifier is used as a suffix for the function name. Extending the previous example, if you specify the OUTSCORELIB statement with the COMMONPACKAGE option,

```
outscorelib outlib=sasuser.byscorefunc outbyid=sasuser.byid commonpackage;
```

then for the distribution function 'MYDIST_BAR' of the distribution 'MYDIST', the Sasuser.Byscorefunc library contains the following three scoring functions: 'SEV_BAR_MYDIST1', 'SEV_BAR_MYDIST2', and 'SEV_BAR_MYDIST3'. All the scoring functions are created in one common package named *sevfit*.

For both the preceding examples, the Sasuser.Byid data set contains three observations, one for each BY group. The value of the _ID_ variable is 1 for the first BY group, 2 for the second BY group, and 3 for the third BY group.

For more information about scoring functions, see the section "Scoring Functions" on page 2136.

SCALEMODEL Statement

SCALEMODEL *regression-effect-list* < / *scalemodel-options* > **;**

The SCALEMODEL statement specifies regression effects. A regression effect is formed from one or more regressor variables according to effect construction rules. Each regression effect forms one element of $\mathbf{X}$ in the linear model structure $\mathbf{X}\boldsymbol{\beta}$ that affects the scale parameter of the distribution. The SCALEMODEL statement in conjunction with the CLASS statement supports a rich set of effects. Effects are specified by a special notation that uses regressor variable names and operators. There are two types of regressor variables: classification (or CLASS) variables and continuous variables. Classification variables can be either numeric or character and are specified in a CLASS statement. To include CLASS variables in regression effects, you must specify the CLASS statement so that it appears before the SCALEMODEL statement. A regressor variable that is not declared in the CLASS statement is assumed to be continuous. For more information about effect construction rules, see the section "Specification and Parameterization of Model Effects" on page 2101.

All the regressor variables must be present in the input data set that you specify by using the DATA= option in the PROC SEVERITY statement. The scale parameter of each candidate distribution is linked to the linear predictor $\mathbf{X}\boldsymbol{\beta}$ that includes an intercept. If a distribution does not have a scale parameter, then a model based on that distribution is not estimated. If you specify more than one SCALEMODEL statement, then the first statement is used.

The regressor variables are expected to have nonmissing values. If any of the variables has a missing value in an observation, then a warning is written to the SAS log and that observation is ignored.

For more information about modeling regression effects, see the section "Estimating Regression Effects" on page 2093.

You can specify the following *scalemodel-options* in the SCALEMODEL statement:

DFMIXTURE=*method-name* < *(method-options)* >
specifies the method for computing representative estimates of the cumulative distribution function (CDF) and the probability density function (PDF).

When you specify regression effects, the scale of the distribution depends on the values of the regressors. For a given distribution family, each observation in the input data set implies a different scaled version of the distribution. To compute estimates of CDF and PDF that are comparable across different distribution families, PROC SEVERITY needs to construct a single representative distribution from all such distributions. You can specify one of the following *method-name* values to specify the method that is used to construct the representative distribution. For more information about each of the methods, see the section "CDF and PDF Estimates with Regression Effects" on page 2097.

FULL
specifies that the representative distribution be the mixture of N distributions such that each distribution has a scale value that is implied by each of the N observations that are used for estimation. This method is the slowest.

MEAN
specifies that the representative distribution be the one-point mixture of the distribution whose scale value is computed by using the mean of the N values of the linear predictor that are implied by the N observations that are used for estimation. If you do not specify the DFMIXTURE= option, then this method is used by default. This is also the fastest method.

QUANTILE < (K=*q***) >**
specifies that the representative distribution be the mixture of a fixed number of distributions whose scale values are computed by using the quantiles from the sample of N values of the linear predictor that are implied by the N observations that are used for estimation.

You can use the K= option to specify the number of distributions in the mixture. If you specify K=q, then the mixture contains $(q-1)$ distributions such that each distribution has as its scale one of the $(q-1)$-quantiles.

If you do not specify the K= option, then PROC SEVERITY uses the default of 2, which implies the use of a one-point mixture with a distribution whose scale value is the median of all scale values.

RANDOM < (*random-method-options***) >**
specifies that the representative distribution be the mixture of a fixed number of distributions whose scale values are computed by using the values of the linear predictor that are implied by a randomly chosen subset of the set of all observations that are used for estimation. The same subset of observations is used for each distribution family.

You can specify the following *random-method-options* to specify how the subset is chosen:

K=*r*
specifies the number of distributions to include in the mixture. If you do not specify this option, then PROC SEVERITY uses the default of 15.

SEED=*number*
specifies the seed that is used to generate the uniform random sample of observation indices. If you do not specify this option, then PROC SEVERITY generates a seed internally that is based on the current value of the system clock.

OFFSET=*offset-variable-name*
specifies the name of the offset variable in the scale regression model. An offset variable is a regressor variable whose regression coefficient is known to be 1. For more information, see the section "Offset Variable" on page 2094.

WEIGHT Statement

WEIGHT *variable-name* **;**

The WEIGHT statement specifies the name of a variable whose values represent the weight of each observation. PROC SEVERITY associates a weight of w to each observation, where w is the value of the WEIGHT variable for the observation. If the weight value is missing or less than or equal to 0, then the observation is ignored and a warning is written to the SAS log. When you do not specify the WEIGHT statement, each observation is assigned a weight of 1. If you specify more than one WEIGHT statement, then the last statement is used.

The weights are normalized so that they add up to the actual sample size. In particular, the weight of each observation is multiplied by $\frac{N}{\sum_{i=1}^{N} w_i}$, where N is the sample size. All computations, including the computations of the EDF-based statistics of fit, use normalized weights.

Programming Statements

You can use a series of programming statements that use variables in the input data set that you specify in the DATA= option in the PROC SEVERITY statement to assign a value to an objective function symbol. You must specify the objective function symbol by using the OBJECTIVE= option in the PROC SEVERITY statement. If you do not specify the OBJECTIVE= option in the PROC SEVERITY statement, then the programming statements are ignored and models are estimated using the maximum likelihood method.

You can use most DATA step statements and functions in your program. Any additional functions, restrictions, and differences are listed in the section "Custom Objective Functions" on page 2143.

Details: SEVERITY Procedure

Predefined Distributions

For the response variable Y, PROC SEVERITY assumes the model

$$Y \sim \mathcal{F}(\Theta)$$

where $\mathcal{F}$ is a continuous probability distribution with parameters Θ. The model hypothesizes that the observed response is generated from a stochastic process that is governed by the distribution $\mathcal{F}$. This model is usually referred to as the error model. Given a representative input sample of response variable values, PROC SEVERITY estimates the model parameters for any distribution $\mathcal{F}$ and computes the statistics of fit for each model. This enables you to find the distribution that is most likely to generate the observed sample.

A set of predefined distributions is provided with the SEVERITY procedure. A summary of the distributions is provided in Table 28.3. For each distribution, the table lists the name of the distribution that should be used in the DIST statement, the parameters of the distribution along with their bounds, and the mathematical expressions for the probability density function (PDF) and cumulative distribution function (CDF) of the distribution.

All the predefined distributions, except LOGN and TWEEDIE, are parameterized such that their first parameter is the scale parameter. For LOGN, the first parameter μ is a log-transformed scale parameter. TWEEDIE does not have a scale parameter. The presence of scale parameter or a log-transformed scale parameter enables you to use all of the predefined distributions, except TWEEDIE, as a candidate for estimating regression effects.

A distribution model is associated with each predefined distribution. You can also define your own distribution model, which is a set of functions and subroutines that you define by using the FCMP procedure. For more information, see the section "Defining a Severity Distribution Model with the FCMP Procedure" on page 2119.

Table 28.3 Predefined PROC SEVERITY Distributions

TheadName	**Distribution**	**Parameters**	**PDF (f) and CDF (F)**
BURR	Burr (Type XII)	$\theta > 0, \alpha > 0,$ $\gamma > 0$	$f(x) = \frac{\alpha\gamma z^{\gamma}}{x(1+z^{\gamma})^{(\alpha+1)}}$ $F(x) = 1 - \left(\frac{1}{1+z^{\gamma}}\right)^{\alpha}$
EXP	Exponential	$\theta > 0$	$f(x) = \frac{1}{\theta}e^{-z}$ $F(x) = 1 - e^{-z}$
GAMMA	Gamma	$\theta > 0, \alpha > 0$	$f(x) = \frac{z^{\alpha}e^{-z}}{x\Gamma(\alpha)}$ $F(x) = \frac{\gamma(\alpha,z)}{\Gamma(\alpha)}$
GPD	Generalized Pareto	$\theta > 0, \xi > 0$	$f(x) = \frac{1}{\theta}(1+\xi z)^{-1-1/\xi}$ $F(x) = 1 - (1+\xi z)^{-1/\xi}$

Table 28.3 *continued*

Name	Distribution	Parameters	PDF (f) and CDF (F)
IGAUSS	Inverse Gaussian (Wald)	$\theta > 0, \alpha > 0$	$f(x) = \frac{1}{\theta}\sqrt{\frac{\alpha}{2\pi z^3}}\, e^{\frac{-\alpha(z-1)^2}{2z}}$ $F(x) = \Phi\left((z-1)\sqrt{\frac{\alpha}{z}}\right) + \Phi\left(-(z+1)\sqrt{\frac{\alpha}{z}}\right) e^{2\alpha}$
LOGN	Lognormal	μ (no bounds), $\sigma > 0$	$f(x) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\log(x)-\mu}{\sigma}\right)^2}$ $F(x) = \Phi\left(\frac{\log(x)-\mu}{\sigma}\right)$
PARETO	Pareto (Type II)	$\theta > 0, \alpha > 0$	$f(x) = \frac{\alpha\theta^\alpha}{(x+\theta)^{\alpha+1}}$ $F(x) = 1 - \left(\frac{\theta}{x+\theta}\right)^\alpha$
TWEEDIE	Tweedie**	$p > 1, \mu > 0,$ $\phi > 0$	$f(x) = a(x,\phi)\exp\left[\frac{1}{\phi}\left(\frac{x\mu^{1-p}}{1-p} - \kappa(\mu,p)\right)\right]$ $F(x) = \int_0^x f(t)dt$
STWEEDIE	Scaled Tweedie**	$\theta > 0, \lambda > 0,$ $1 < p < 2$	$f(x) = a(x,\theta,\lambda,p)\exp\left(-\frac{x}{\theta} - \lambda\right)$ $F(x) = \int_0^x f(t)dt$
WEIBULL	Weibull	$\theta > 0, \tau > 0$	$f(x) = \frac{1}{x}\tau z^\tau e^{-z^\tau}$ $F(x) = 1 - e^{-z^\tau}$

**For more information, see the section "Tweedie Distributions" on page 2080.

Notes:

1. $z = x/\theta$, wherever z is used.
2. θ denotes the scale parameter for all the distributions. For LOGN, $\log(\theta) = \mu$.
3. Parameters are listed in the order in which they are defined in the distribution model.
4. $\gamma(a,b) = \int_0^b t^{a-1}e^{-t}dt$ is the lower incomplete gamma function.
5. $\Phi(y) = \frac{1}{2}\left(1 + \text{erf}\left(\frac{y}{\sqrt{2}}\right)\right)$ is the standard normal CDF.

Tweedie Distributions

Tweedie distributions are a special case of the exponential dispersion family (Jørgensen 1987) with a property that the variance of the distribution is equal to $\phi\mu^p$, where μ is the mean of the distribution, ϕ is a dispersion parameter, and p is an index parameter as discovered by Tweedie (1984). The distribution is defined for all values of p except for values of p in the open interval $(0, 1)$. Many important known distributions are a special case of Tweedie distributions including normal (p=0), Poisson (p=1), gamma (p=2), and the inverse Gaussian (p=3). Apart from these special cases, the probability density function (PDF) of the Tweedie distribution does not have an analytic expression. For $p > 1$, it has the form (Dunn and Smyth 2005),

$$f(x;\mu,\phi,p) = a(x,\phi)\exp\left[\frac{1}{\phi}\left(\frac{x\mu^{1-p}}{1-p} - \kappa(\mu,p)\right)\right]$$

where $\kappa(\mu, p) = \mu^{2-p}/(2-p)$ for $p \neq 2$ and $\kappa(\mu, p) = \log(\mu)$ for $p = 2$. The function $a(x, \phi)$ does not have an analytical expression. It is typically evaluated using series expansion methods described in Dunn and Smyth (2005).

For $1 < p < 2$, the Tweedie distribution is a compound Poisson-gamma mixture distribution, which is the distribution of S defined as

$$S = \sum_{i=1}^{N} X_i$$

where $N \sim \text{Poisson}(\lambda)$ and $X_i \sim \text{gamma}(\alpha, \theta)$ are independent and identically distributed gamma random variables with shape parameter α and scale parameter θ. At $X = 0$, the density is a probability mass that is governed by the Poisson distribution, and for values of $X > 0$, it is a mixture of gamma variates with Poisson mixing probability. The parameters λ, α, and θ are related to the natural parameters μ, ϕ, and p of the Tweedie distribution as

$$\begin{aligned}
\lambda &= \frac{\mu^{2-p}}{\phi(2-p)} \\
\alpha &= \frac{2-p}{p-1} \\
\theta &= \phi(p-1)\mu^{p-1}
\end{aligned}$$

The mean of a Tweedie distribution is positive for $p > 1$.

Two predefined versions of the Tweedie distribution are provided with the SEVERITY procedure. The first version, named TWEEDIE and defined for $p > 1$, has the natural parameterization with parameters μ, ϕ, and p. The second version, named STWEEDIE and defined for $1 < p < 2$, is the version with a scale parameter. It corresponds to the compound Poisson-gamma distribution with gamma scale parameter θ, Poisson mean parameter λ, and the index parameter p. The index parameter decides the shape parameter α of the gamma distribution as

$$\alpha = \frac{2-p}{p-1}$$

The parameters θ and λ of the STWEEDIE distribution are related to the parameters μ and ϕ of the TWEEDIE distribution as

$$\begin{aligned}
\mu &= \lambda\theta\alpha \\
\phi &= \frac{(\lambda\theta\alpha)^{2-p}}{\lambda(2-p)} = \frac{\theta}{(p-1)(\lambda\theta\alpha)^{p-1}}
\end{aligned}$$

You can fit either version when there are no regression variables. Each version has its own merits. If you fit the TWEEDIE version, you have the direct estimate of the overall mean of the distribution. If you are interested in the most practical range of the index parameter $1 < p < 2$, then you can fit the STWEEDIE version, which provides you direct estimates of the Poisson and gamma components that comprise the distribution (an estimate of the gamma shape parameter α is easily obtained from the estimate of p).

If you want to estimate the effect of exogenous (regression) variables on the distribution, then you must use the STWEEDIE version, because PROC SEVERITY requires a distribution to have a scale parameter in order to estimate regression effects. For more information, see the section "Estimating Regression Effects" on page 2093. The gamma scale parameter θ is the scale parameter of the STWEEDIE distribution. If you

are interested in determining the effect of regression variables on the mean of the distribution, you can do so by first fitting the STWEEDIE distribution to determine the effect of the regression variables on the scale parameter θ. Then, you can easily estimate how the mean of the distribution μ is affected by the regression variables using the relationship $\mu = c\theta$, where $c = \lambda\alpha = \lambda(2-p)/(p-1)$. The estimates of the regression parameters remain the same, whereas the estimate of the intercept parameter is adjusted by the estimates of the λ and p parameters.

Parameter Initialization for Predefined Distributions

The parameters are initialized by using the method of moments for all the distributions, except for the gamma and the Weibull distributions. For the gamma distribution, approximate maximum likelihood estimates are used. For the Weibull distribution, the method of percentile matching is used.

Given n observations of the severity value y_i $(1 \leq i \leq n)$, the estimate of kth raw moment is denoted by m_k and computed as

$$m_k = \frac{1}{n}\sum_{i=1}^{n} y_i^k$$

The $100p$th percentile is denoted by π_p $(0 \leq p \leq 1)$. By definition, π_p satisfies

$$F(\pi_p-) \leq p \leq F(\pi_p)$$

where $F(\pi_p-) = \lim_{h\downarrow 0} F(\pi_p - h)$. PROC SEVERITY uses the following practical method of computing π_p. Let $\hat{F}_n(y)$ denote the empirical distribution function (EDF) estimate at a severity value y. Let y_p^- and y_p^+ denote two consecutive values in the ascending sequence of y values such that $\hat{F}_n(y_p^-) < p$ and $\hat{F}_n(y_p^+) \geq p$. Then, the estimate $\hat{\pi}_p$ is computed as

$$\hat{\pi}_p = y_p^- + \frac{p - \hat{F}_n(y_p^-)}{\hat{F}_n(y_p^+) - \hat{F}_n(y_p^-)}(y_p^+ - y_p^-)$$

Let ϵ denote the smallest double-precision floating-point number such that $1 + \epsilon > 1$. This machine precision constant can be obtained by using the CONSTANT function in Base SAS software.

The details of how parameters are initialized for each predefined distribution are as follows:

BURR Burr proposed 12 types of families of continuous distributions (Burr 1942; Rodriguez 2006). The predefined BURR distribution in PROC SEVERITY implements Burr's Type XII distribution. The parameters are initialized by using the method of moments. The kth raw moment of the Burr distribution of Type XII is

$$E[X^k] = \frac{\theta^k \Gamma(1 + k/\gamma)\Gamma(\alpha - k/\gamma)}{\Gamma(\alpha)}, \quad -\gamma < k < \alpha\gamma$$

Three moment equations $E[X^k] = m_k$ $(k = 1, 2, 3)$ need to be solved for initializing the three parameters of the distribution. In order to get an approximate closed form solution, the second shape parameter $\hat{\gamma}$ is initialized to a value of 2. If $2m_3 - 3m_1m_2 > 0$, then simplifying and solving the moment equations yields the following feasible set of initial values:

$$\hat{\theta} = \sqrt{\frac{m_2 m_3}{2m_3 - 3m_1m_2}}, \quad \hat{\alpha} = 1 + \frac{m_3}{2m_3 - 3m_1m_2}, \quad \hat{\gamma} = 2$$

If $2m_3 - 3m_1m_2 < \epsilon$, then the parameters are initialized as follows:

$$\hat{\theta} = \sqrt{m_2}, \quad \hat{\alpha} = 2, \quad \hat{\gamma} = 2$$

EXP The parameters are initialized by using the method of moments. The kth raw moment of the exponential distribution is

$$E[X^k] = \theta^k \Gamma(k+1), \quad k > -1$$

Solving $E[X] = m_1$ yields the initial value of $\hat{\theta} = m_1$.

GAMMA The parameter α is initialized by using its *approximate* maximum likelihood (ML) estimate. For a set of n independent and identically distributed observations y_i $(1 \leq i \leq n)$ drawn from a gamma distribution, the log likelihood l is defined as follows:

$$\begin{aligned} l &= \sum_{i=1}^{n} \log\left(y_i^{\alpha-1} \frac{e^{-y_i/\theta}}{\theta^\alpha \Gamma(\alpha)}\right) \\ &= (\alpha - 1)\sum_{i=1}^{n} \log(y_i) - \frac{1}{\theta}\sum_{i=1}^{n} y_i - n\alpha \log(\theta) - n\log(\Gamma(\alpha)) \end{aligned}$$

Using a shorter notation of $\sum$ to denote $\sum_{i=1}^{n}$ and solving the equation $\partial l/\partial\theta = 0$ yields the following ML estimate of θ:

$$\hat{\theta} = \frac{\sum y_i}{n\alpha} = \frac{m_1}{\alpha}$$

Substituting this estimate in the expression of l and simplifying gives

$$l = (\alpha - 1)\sum \log(y_i) - n\alpha - n\alpha \log(m_1) + n\alpha \log(\alpha) - n\log(\Gamma(\alpha))$$

Let d be defined as follows:

$$d = \log(m_1) - \frac{1}{n}\sum \log(y_i)$$

Solving the equation $\partial l/\partial\alpha = 0$ yields the following expression in terms of the digamma function, $\psi(\alpha)$:

$$\log(\alpha) - \psi(\alpha) = d$$

The digamma function can be approximated as follows:

$$\hat{\psi}(\alpha) \approx \log(\alpha) - \frac{1}{\alpha}\left(0.5 + \frac{1}{12\alpha + 2}\right)$$

This approximation is within 1.4% of the true value for all the values of $\alpha > 0$ except when α is arbitrarily close to the positive root of the digamma function (which is approximately 1.461632). Even for the values of α that are close to the positive root, the absolute error between true and approximate values is still acceptable ($|\hat{\psi}(\alpha) - \psi(\alpha)| < 0.005$ for $\alpha > 1.07$). Solving the equation that arises from this approximation yields the following estimate of α:

$$\hat{\alpha} = \frac{3 - d + \sqrt{(d-3)^2 + 24d}}{12d}$$

If this approximate ML estimate is infeasible, then the method of moments is used. The kth raw moment of the gamma distribution is

$$E[X^k] = \theta^k \frac{\Gamma(\alpha + k)}{\Gamma(\alpha)}, \quad k > -\alpha$$

Solving $E[X] = m_1$ and $E[X^2] = m_2$ yields the following initial value for α:

$$\hat{\alpha} = \frac{m_1^2}{m_2 - m_1^2}$$

If $m_2 - m_1^2 < \epsilon$ (almost zero sample variance), then α is initialized as follows:

$$\hat{\alpha} = 1$$

After computing the estimate of α, the estimate of θ is computed as follows:

$$\hat{\theta} = \frac{m_1}{\hat{\alpha}}$$

Both the maximum likelihood method and the method of moments arrive at the same relationship between $\hat{\alpha}$ and $\hat{\theta}$.

GPD

The parameters are initialized by using the method of moments. Notice that for $\xi > 0$, the CDF of the generalized Pareto distribution (GPD) is:

$$\begin{aligned} F(x) &= 1 - \left(1 + \frac{\xi x}{\theta}\right)^{-1/\xi} \\ &= 1 - \left(\frac{\theta/\xi}{x + \theta/\xi}\right)^{1/\xi} \end{aligned}$$

This is equivalent to a Pareto distribution with scale parameter $\theta_1 = \theta/\xi$ and shape parameter $\alpha = 1/\xi$. Using this relationship, the parameter initialization method used for the PARETO distribution is used to get the following initial values for the parameters of the GPD distribution:

$$\hat{\theta} = \frac{m_1 m_2}{2(m_2 - m_1^2)}, \quad \hat{\xi} = \frac{m_2 - 2m_1^2}{2(m_2 - m_1^2)}$$

If $m_2 - m_1^2 < \epsilon$ (almost zero sample variance) or $m_2 - 2m_1^2 < \epsilon$, then the parameters are initialized as follows:

$$\hat{\theta} = \frac{m_1}{2}, \quad \hat{\xi} = \frac{1}{2}$$

IGAUSS

The parameters are initialized by using the method of moments. The standard parameterization of the inverse Gaussian distribution (also known as the Wald distribution), in terms of the location parameter μ and shape parameter λ, is as follows (Klugman, Panjer, and Willmot 1998, p. 583):

$$f(x) = \sqrt{\frac{\lambda}{2\pi x^3}} \exp\left(\frac{-\lambda(x-\mu)^2}{2\mu^2 x}\right)$$

$$F(x) = \Phi\left(\left(\frac{x}{\mu} - 1\right)\sqrt{\frac{\lambda}{x}}\right) + \Phi\left(-\left(\frac{x}{\mu} + 1\right)\sqrt{\frac{\lambda}{x}}\right) \exp\left(\frac{2\lambda}{\mu}\right)$$

For this parameterization, it is known that the mean is $E[X] = \mu$ and the variance is $\mathrm{Var}[X] = \mu^3/\lambda$, which yields the second raw moment as $E[X^2] = \mu^2(1 + \mu/\lambda)$ (computed by using $E[X^2] = \mathrm{Var}[X] + (E[X])^2$).

The predefined IGAUSS distribution in PROC SEVERITY uses the following alternate parameterization to allow the distribution to have a scale parameter, θ:

$$f(x) = \sqrt{\frac{\alpha\theta}{2\pi x^3}}\ \exp\left(\frac{-\alpha(x-\theta)^2}{2x\theta}\right)$$

$$F(x) = \Phi\left(\left(\frac{x}{\theta} - 1\right)\sqrt{\frac{\alpha\theta}{x}}\right) + \Phi\left(-\left(\frac{x}{\theta} + 1\right)\sqrt{\frac{\alpha\theta}{x}}\right)\ \exp(2\alpha)$$

The parameters θ (scale) and α (shape) of this alternate form are related to the parameters μ and λ of the preceding form such that $\theta = \mu$ and $\alpha = \lambda/\mu$. Using this relationship, the first and second raw moments of the IGAUSS distribution are

$$E[X] = \theta$$

$$E[X^2] = \theta^2\left(1 + \frac{1}{\alpha}\right)$$

Solving $E[X] = m_1$ and $E[X^2] = m_2$ yields the following initial values:

$$\hat{\theta} = m_1, \quad \hat{\alpha} = \frac{m_1^2}{m_2 - m_1^2}$$

If $m_2 - m_1^2 < \epsilon$ (almost zero sample variance), then the parameters are initialized as follows:

$$\hat{\theta} = m_1, \quad \hat{\alpha} = 1$$

LOGN

The parameters are initialized by using the method of moments. The *k*th raw moment of the lognormal distribution is

$$E[X^k] = \exp\left(k\mu + \frac{k^2\sigma^2}{2}\right)$$

Solving $E[X] = m_1$ and $E[X^2] = m_2$ yields the following initial values:

$$\hat{\mu} = 2\log(m1) - \frac{\log(m2)}{2}, \quad \hat{\sigma} = \sqrt{\log(m2) - 2\log(m1)}$$

PARETO

The predefined PARETO distribution in PROC SEVERITY implements the Type II Pareto distribution with the location parameter set to 0. This predefined PARETO distribution is also known as the Lomax distribution. The parameters are initialized by using the method of moments. The *k*th raw moment of the Pareto distribution is

$$E[X^k] = \frac{\theta^k\Gamma(k+1)\Gamma(\alpha-k)}{\Gamma(\alpha)}, -1 < k < \alpha$$

Solving $E[X] = m_1$ and $E[X^2] = m_2$ yields the following initial values:

$$\hat{\theta} = \frac{m_1 m_2}{m_2 - 2m_1^2}, \quad \hat{\alpha} = \frac{2(m_2 - m_1^2)}{m_2 - 2m_1^2}$$

If $m_2 - m_1^2 < \epsilon$ (almost zero sample variance) or $m_2 - 2m_1^2 < \epsilon$, then the parameters are initialized as follows:

$$\hat{\theta} = m_1, \quad \hat{\alpha} = 2$$

TWEEDIE The parameter p is initialized by assuming that the sample is generated from a gamma distribution with shape parameter α and by computing $\hat{p} = \frac{\hat{\alpha}+2}{\hat{\alpha}+1}$. The initial value $\hat{\alpha}$ is obtained from using the method previously described for the GAMMA distribution. The parameter μ is the mean of the distribution. Hence, it is initialized to the sample mean as

$$\hat{\mu} = m_1$$

Variance of a Tweedie distribution is equal to $\phi\mu^p$. Thus, the sample variance is used to initialize the value of ϕ as

$$\hat{\phi} = \frac{m_2 - m_1^2}{\hat{\mu}^{\hat{p}}}$$

STWEEDIE STWEEDIE is a compound Poisson-gamma mixture distribution with mean $\mu = \lambda\theta\alpha$, where α is the shape parameter of the gamma random variables in the mixture and the parameter p is determined solely by α. First, the parameter p is initialized by assuming that the sample is generated from a gamma distribution with shape parameter α and by computing $\hat{p} = \frac{\hat{\alpha}+2}{\hat{\alpha}+1}$. The initial value $\hat{\alpha}$ is obtained from using the method previously described for the GAMMA distribution. As done for initializing the parameters of the TWEEDIE distribution, the sample mean and variance are used to compute the values $\hat{\mu}$ and $\hat{\phi}$ as

$$\hat{\mu} = m_1$$
$$\hat{\phi} = \frac{m_2 - m_1^2}{\hat{\mu}^{\hat{p}}}$$

Based on the relationship between the parameters of TWEEDIE and STWEEDIE distributions described in the section "Tweedie Distributions" on page 2080, values of θ and λ are initialized as

$$\hat{\theta} = \hat{\phi}(\hat{p} - 1)\hat{\mu}^{p-1}$$
$$\hat{\lambda} = \frac{\hat{\mu}}{\hat{\theta}\hat{\alpha}}$$

WEIBULL The parameters are initialized by using the percentile matching method. Let $q1$ and $q3$ denote the estimates of the 25th and 75th percentiles, respectively. Using the formula for the CDF of Weibull distribution, they can be written as

$$1 - \exp(-(q1/\theta)^{\tau}) = 0.25$$
$$1 - \exp(-(q3/\theta)^{\tau}) = 0.75$$

Simplifying and solving these two equations yields the following initial values,

$$\hat{\theta} = \exp\left(\frac{r\log(q1) - \log(q3)}{r-1}\right), \quad \hat{\tau} = \frac{\log(\log(4))}{\log(q3) - \log(\hat{\theta})}$$

where $r = \log(\log(4))/\log(\log(4/3))$. These initial values agree with those suggested in Klugman, Panjer, and Willmot (1998).

A summary of the initial values of all the parameters for all the predefined distributions is given in Table 28.4. The table also provides the names of the parameters to use in the INIT= option in the DIST statement if you want to provide a different initial value.

Table 28.4 Parameter Initialization for Predefined Distributions

Distribution	Parameter	Name for INIT Option	Default Initial Value
BURR	θ	theta	$\sqrt{\frac{m_2 m_3}{2m_3 - 3m_1 m_2}}$
	α	alpha	$1 + \frac{m_3}{2m_3 - 3m_1 m_2}$
	γ	gamma	2
EXP	θ	theta	m_1
GAMMA	θ	theta	m_1/α
	α	alpha	$\frac{3-d+\sqrt{(d-3)^2+24d}}{12d}$
GPD	θ	theta	$m_1 m_2/(2(m_2 - m_1^2))$
	ξ	xi	$(m_2 - 2m_1^2)/(2(m_2 - m_1^2))$
IGAUSS	θ	theta	m_1
	α	alpha	$m_1^2/(m_2 - m_1^2)$
LOGN	μ	mu	$2\log(m1) - \log(m2)/2$
	σ	sigma	$\sqrt{\log(m2) - 2\log(m1)}$
PARETO	θ	theta	$m_1 m_2/(m_2 - 2m_1^2)$
	α	alpha	$2(m_2 - m_1^2)/(m_2 - 2m_1^2)$
TWEEDIE	μ	mu	m_1
	ϕ	phi	$(m_2 - m_1^2)/m_1^p$
	p	p	$(\alpha + 2)/(\alpha + 1)$ where $\alpha = \frac{3-d+\sqrt{(d-3)^2+24d}}{12d}$
STWEEDIE	θ	theta	$(m_2 - m_1^2)(p-1)/m_1$
	λ	lambda	$m_1^2/(\alpha(m_2 - m_1^2)(p-1))$
	p	p	$(\alpha + 2)/(\alpha + 1)$ where $\alpha = \frac{3-d+\sqrt{(d-3)^2+24d}}{12d}$
WEIBULL	θ	theta	$\exp\left(\frac{r\log(q1)-\log(q3)}{r-1}\right)$
	τ	tau	$\log(\log(4))/(\log(q3) - \log(\hat{\theta}))$

Notes:
1. m_k denotes the kth raw moment.
2. $d = \log(m_1) - (\sum \log(y_i))/n$
3. $q1$ and $q3$ denote the 25th and 75th percentiles, respectively.
4. $r = \log(\log(4))/\log(\log(4/3))$

Censoring and Truncation

One of the key features of PROC SEVERITY is that it enables you to specify whether the severity event's magnitude is observable and if it is observable, then whether the exact value of the magnitude is known. If an event is unobservable when the magnitude is in certain intervals, then it is referred to as a truncation effect. If the exact magnitude of the event is not known, but it is known to have a value in a certain interval, then it is referred to as a censoring effect.

PROC SEVERITY allows a severity event to be subject to any combination of the following four censoring and truncation effects:

- Left-truncation: An event is said to be left-truncated if it is observed only when $Y > T^l$, where Y denotes the random variable for the magnitude and T^l denotes a random variable for the truncation threshold. You can specify left-truncation using the LEFTTRUNCATED= option in the LOSS statement.
- Right-truncation: An event is said to be right-truncated if it is observed only when $Y \leq T^r$, where Y denotes the random variable for the magnitude and T^r denotes a random variable for the truncation threshold. You can specify right-truncation using the RIGHTTRUNCATED= option in the LOSS statement.
- Left-censoring: An event is said to be left-censored if it is known that the magnitude is $Y \leq C^l$, but the exact value of Y is not known. C^l is a random variable for the censoring limit. You can specify left-censoring using the LEFTCENSORED= option in the LOSS statement.
- Right-censoring: An event is said to be right-censored if it is known that the magnitude is $Y > C^r$, but the exact value of Y is not known. C^r is a random variable for the censoring limit. You can specify right-censoring using the RIGHTCENSORED= option in the LOSS statement.

For each effect, you can specify a different threshold or limit for each observation or specify a single threshold or limit that applies to all the observations.

If all four types of effects are present on an event, then the following relationship holds: $T^l < C^r \leq C^l \leq T^r$. PROC SEVERITY checks these relationships and writes a warning to the SAS log if any relationship is violated.

If you specify the response variable in the LOSS statement, then PROC SEVERITY also checks whether each observation satisfies the definitions of the specified censoring and truncation effects. If you specify left-truncation, then PROC SEVERITY ignores observations where $Y \leq T^l$, because such observations are not observable by definition. Similarly, if you specify right-truncation, then PROC SEVERITY ignores observations where $Y > T^r$. If you specify left-censoring, then PROC SEVERITY treats an observation with $Y > C^l$ as uncensored and ignores the value of C^l. The observations with $Y \leq C^l$ are considered as left-censored, and the value of Y is ignored. If you specify right-censoring, then PROC SEVERITY treats an observation with $Y \leq C^r$ as uncensored and ignores the value of C^r. The observations with $Y > C^r$ are considered as right-censored, and the value of Y is ignored. If you specify both left-censoring and right-censoring, it is referred to as interval-censoring. If $C^r < C^l$ is satisfied for an observation, then it is considered as interval-censored and the value of the response variable is ignored. If $C^r = C^l$ for an observation, then PROC SEVERITY assumes that observation to be uncensored. If all the observations in a data set are censored in some form, then the specification of the response variable in the LOSS statement is

optional, because the actual value of the response variable is not required for the purposes of estimating a model.

Specification of censoring and truncation affects the likelihood of the data (see the section "Likelihood Function" on page 2090) and how the empirical distribution function (EDF) is estimated (see the section "Empirical Distribution Function Estimation Methods" on page 2108).

Probability of Observability

For left-truncated data, PROC SEVERITY also enables you to provide additional information in the form of *probability of observability* by using the PROBOBSERVED= option. It is defined as the probability that the underlying severity event gets observed (and recorded) for the specified left-truncation threshold value. For example, if you specify a value of 0.75, then for every 75 observations recorded above a specified threshold, 25 more events have happened with a severity value less than or equal to the specified threshold. Although the exact severity value of those 25 events is not known, PROC SEVERITY can use the information about the number of those events.

In particular, for each left-truncated observation, PROC SEVERITY assumes a presence of $(1 - p)/p$ additional observations with $y_i = t_i$. These additional observations are then used for computing the likelihood (see the section "Probability of Observability and Likelihood" on page 2091) and an unconditional estimate of the empirical distribution function (see the section "EDF Estimates and Truncation" on page 2113).

Truncation and Conditional CDF Estimates

If you specify left-truncation without the probability of observability or if you specify right-truncation, then the EDF estimates that are computed by all methods except the STANDARD method are conditional on the truncation information. For more information, see the section "EDF Estimates and Truncation" on page 2113. In such cases, PROC SEVERITY uses conditional estimates of the CDF whenever they are used for computational or visual comparison with the EDF estimates.

Let $t^l_{\min} = \min_i \{t^l_i\}$ be the smallest value of the left-truncation threshold (t^l_i is the left-truncation threshold for observation i) and $t^r_{\max} = \max_i \{t^r_i\}$ be the largest value of the right-truncation threshold (t^r_i is the right-truncation threshold for observation i). If $\hat{F}(y)$ denotes the unconditional estimate of the CDF at y, then the conditional estimate $\hat{F}^c(y)$ is computed as follows:

- If you do not specify the probability of observability, then the EDF estimates are conditional on the left-truncation information. If an observation is both left-truncated and right-truncated, then

$$\hat{F}^c(y) = \frac{\hat{F}(y) - \hat{F}(t^l_{\min})}{\hat{F}(t^r_{\max}) - \hat{F}(t^l_{\min})}$$

  If an observation is left-truncated but not right-truncated, then

$$\hat{F}^c(y) = \frac{\hat{F}(y) - \hat{F}(t^l_{\min})}{1 - \hat{F}(t^l_{\min})}$$

  If an observation is right-truncated but not left-truncated, then

$$\hat{F}^c(y) = \frac{\hat{F}(y)}{\hat{F}(t^r_{\max})}$$

- If you specify the probability of observability, then EDF estimates are not conditional on the left-truncation information. If an observation is not right-truncated, then the conditional estimate is the same as the unconditional estimate. If an observation is right-truncated, then the conditional estimate is computed as

$$\hat{F}^c(y) = \frac{\hat{F}(y)}{\hat{F}(t^r_{\max})}$$

If you specify regression effects, then $\hat{F}(y)$, $\hat{F}(t^l_{\min})$, and $\hat{F}(t^r_{\max})$ are all computed from a mixture distribution, as described in the section "CDF and PDF Estimates with Regression Effects" on page 2097.

Parameter Estimation Method

If you do not specify a custom objective function by specifying programming statements and the OBJECTIVE= option in the PROC SEVERITY statement, then PROC SEVERITY uses the maximum likelihood (ML) method to estimate the parameters of each model. A nonlinear optimization process is used to maximize the log of the likelihood function. If you specify a custom objective function, then PROC SEVERITY uses a nonlinear optimization algorithm to estimate the parameters of each model that minimize the value of your specified objective function. For more information, see the section "Custom Objective Functions" on page 2143.

Likelihood Function

Let $f_\Theta(x)$ and $F_\Theta(x)$ denote the PDF and CDF, respectively, evaluated at x for a set of parameter values Θ. Let Y denote the random response variable, and let y denote its value recorded in an observation in the input data set. Let T^l and T^r denote the random variables for the left-truncation and right-truncation threshold, respectively, and let t^l and t^r denote their values for an observation, respectively. If there is no left-truncation, then $t^l = \tau^l$, where τ^l is the smallest value in the support of the distribution; so $F(t^l) = 0$. If there is no right-truncation, then $t^r = \tau_h$, where τ_h is the largest value in the support of the distribution; so $F(t^r) = 1$. Let C^l and C^r denote the random variables for the left-censoring and right-censoring limit, respectively, and let c^l and c^r denote their values for an observation, respectively. If there is no left-censoring, then $c^l = \tau_h$; so $F(c^l) = 1$. If there is no right-censoring, then $c^r = \tau^l$; so $F(c^r) = 0$.

The set of input observations can be categorized into the following four subsets within each BY group:

- E is the set of uncensored and untruncated observations. The likelihood of an observation in E is

$$l_E = \Pr(Y = y) = f_\Theta(y)$$

- E_t is the set of uncensored observations that are truncated. The likelihood of an observation in E_t is

$$l_{E_t} = \Pr(Y = y | t^l < Y \le t^r) = \frac{f_\Theta(y)}{F_\Theta(t^r) - F_\Theta(t^l)}$$

- C is the set of censored observations that are not truncated. The likelihood of an observation C is

$$l_C = \Pr(c^r < Y \le c^l) = F_\Theta(c^l) - F_\Theta(c^r)$$

- C_t is the set of censored observations that are truncated. The likelihood of an observation C_t is

$$l_{C_t} = \Pr(c^r < Y \leq c^l | t^l < Y \leq t^r) = \frac{F_\Theta(c^l) - F_\Theta(c^r)}{F_\Theta(t^r) - F_\Theta(t^l)}$$

Note that $(E \cup E_t) \cap (C \cup C_t) = \emptyset$. Also, the sets E_t and C_t are empty when you do not specify truncation, and the sets C and C_t are empty when you do not specify censoring.

Given this, the likelihood of the data L is as follows:

$$L = \prod_E f_\Theta(y) \prod_{E_t} \frac{f_\Theta(y)}{F_\Theta(t^r) - F_\Theta(t^l)} \prod_C F_\Theta(c^l) - F_\Theta(c^r) \prod_{C_t} \frac{F_\Theta(c^l) - F_\Theta(c^r)}{F_\Theta(t^r) - F_\Theta(t^l)}$$

The maximum likelihood procedure used by PROC SEVERITY finds an optimal set of parameter values $\hat{\Theta}$ that maximizes $\log(L)$ subject to the boundary constraints on parameter values. For a distribution *dist*, you can specify such boundary constraints by using the *dist*_LOWERBOUNDS and *dist*_UPPERBOUNDS subroutines. For more information, see the section "Defining a Severity Distribution Model with the FCMP Procedure" on page 2119. Some aspects of the optimization process can be controlled by using the NLOPTIONS statement.

Probability of Observability and Likelihood

If you specify the probability of observability for the left-truncation, then PROC SEVERITY uses a modified likelihood function for each truncated observation. If the probability of observability is $p \in (0.0, 1.0]$, then for each left-truncated observation with truncation threshold t^l, there exist $(1-p)/p$ observations with a response variable value less than or equal to t^l. Each such observation has a probability of $\Pr(Y \leq t^l) = F_\Theta(t^l)$. The right-truncation and censoring information does not apply to these added observations. Thus, following the notation of the section "Likelihood Function" on page 2090, the likelihood of the data is as follows:

$$\begin{aligned} L = & \prod_E f_\Theta(y) \prod_{E_t, t^l = \tau^l} \frac{f_\Theta(y)}{F_\Theta(t^r)} \prod_{E_t, t^l > \tau^l} \frac{f_\Theta(y)}{F_\Theta(t^r)} F_\Theta(t^l)^{\frac{1-p}{p}} \\ & \prod_C F_\Theta(c^l) - F_\Theta(c^r) \prod_{C_t, t^l = \tau^l} \frac{F_\Theta(c^l) - F_\Theta(c^r)}{F_\Theta(t^r)} \prod_{C_t, t^l > \tau^l} \frac{F_\Theta(c^l) - F_\Theta(c^r)}{F_\Theta(t^r)} F_\Theta(t^l)^{\frac{1-p}{p}} \end{aligned}$$

Note that the likelihood of the observations that are not left-truncated (observations in sets E and C, and observations in sets E_t and C_t for which $t^l = \tau^l$) is not affected.

If you specify a custom objective function, then PROC SEVERITY accounts for the probability of observability only while computing the empirical distribution function estimate. The parameter estimates are affected only by your custom objective function.

Estimating Covariance and Standard Errors

PROC SEVERITY computes an estimate of the covariance matrix of the parameters by using the asymptotic theory of the maximum likelihood estimators (MLE). If N denotes the number of observations used for estimating a parameter vector $\boldsymbol{\theta}$, then the theory states that as $N \rightarrow \infty$, the distribution of $\hat{\boldsymbol{\theta}}$, the estimate of $\boldsymbol{\theta}$, converges to a normal distribution with mean $\boldsymbol{\theta}$ and covariance $\hat{\mathbf{C}}$ such that $\mathbf{I}(\boldsymbol{\theta}) \cdot \hat{\mathbf{C}} \rightarrow 1$, where $\mathbf{I}(\boldsymbol{\theta}) = -E\left[\nabla^2 \log(L(\boldsymbol{\theta}))\right]$ is the information matrix for the likelihood of the data, $L(\boldsymbol{\theta})$. The covariance estimate is obtained by using the inverse of the information matrix.

In particular, if $\mathbf{G} = \nabla^2(-\log(L(\boldsymbol{\theta})))$ denotes the Hessian matrix of the negative of log likelihood, then the covariance estimate is computed as

$$\hat{\mathbf{C}} = \frac{N}{d}\mathbf{G}^{-1}$$

where d is a denominator that is determined by the VARDEF= option. If VARDEF=N, then $d = N$, which yields the asymptotic covariance estimate. If VARDEF=DF, then $d = N - k$, where k is number of parameters (the model's degrees of freedom). The VARDEF=DF option is the default, because it attempts to correct the potential bias introduced by the finite sample.

The standard error s_i of the parameter θ_i is computed as the square root of the ith diagonal element of the estimated covariance matrix; that is, $s_i = \sqrt{\hat{C}_{ii}}$.

If you specify a custom objective function, then the covariance matrix of the parameters is still computed by inverting the information matrix, except that the Hessian matrix $\mathbf{G}$ is computed as $\mathbf{G} = \nabla^2 \log(U(\boldsymbol{\theta}))$, where U denotes your custom objective function that is minimized by the optimizer.

Covariance and standard error estimates might not be available if the Hessian matrix is found to be singular at the end of the optimization process. This can especially happen if the optimization process stops without converging.

Parameter Initialization

PROC SEVERITY enables you to initialize parameters of a model in different ways. A model can have two kinds of parameters: distribution parameters and regression parameters.

The distribution parameters can be initialized by using one of the following three methods:

INIT= option	You can use the INIT= option in the DIST statement.
INEST= or INSTORE= option	You can use either the INEST= data set or the INSTORE= item store, but not both.
PARMINIT subroutine	You can define a *dist*_PARMINIT subroutine in the distribution model. For more information, see the section "Defining a Severity Distribution Model with the FCMP Procedure" on page 2119.

Note that only one of the initialization methods is used. You cannot combine them. They are used in the following order:

- The method that uses the INIT= option takes the highest precedence. If you use the INIT= option to provide an initial value for at least one parameter, then other initialization methods (INEST=,

INSTORE=, or PARMINIT) are not used. If you specify initial values for some but not all the parameters by using the INIT= option, then the uninitialized parameters are initialized to the default value of 0.001.

If you use this option and if you specify the regression effects, then the value of the first distribution parameter must be related to the initial value for the *base* value of the scale or log-transformed scale parameter. For more information, see the section "Estimating Regression Effects" on page 2093.

- The method that uses the INEST= data set or INSTORE= item store takes second precedence. If the INEST= data set or INSTORE= item store contains a nonmissing value for even one distribution parameter, then the PARMINIT method is not used and any uninitialized parameters are initialized to the default value of 0.001.
- If none of the distribution parameters are initialized by using the INIT= option, the INEST= data set, or the INSTORE= item store, but the distribution model defines a PARMINIT subroutine, then PROC SEVERITY invokes that subroutine with appropriate inputs to initialize the parameters. If the PARMINIT subroutine returns missing values for some parameters, then those parameters are initialized to the default value of 0.001.
- If none of the initialization methods are used, each distribution parameter is initialized to the default value of 0.001.

For more information about regression models and initialization of regression parameters, see the section "Estimating Regression Effects" on page 2093.

Estimating Regression Effects

The SEVERITY procedure enables you to estimate the influence of regression (exogenous) effects while fitting a distribution if the distribution has a scale parameter or a log-transformed scale parameter.

Let x_j, $j = 1, \ldots, k$, denote the k regression effects. Let β_j denote the regression parameter that corresponds to the effect x_j. If you do not specify regression effects, then the model for the response variable Y is of the form

$$Y \sim \mathcal{F}(\Theta)$$

where $\mathcal{F}$ is the distribution of Y with parameters Θ. This model is usually referred to as the error model. The regression effects are modeled by extending the error model to the following form:

$$Y \sim \exp(\sum_{j=1}^{k} \beta_j x_j) \cdot \mathcal{F}(\Theta)$$

Under this model, the distribution of Y is valid and belongs to the same parametric family as $\mathcal{F}$ if and only if $\mathcal{F}$ has a scale parameter. Let θ denote the scale parameter and Ω denote the set of nonscale distribution parameters of $\mathcal{F}$. Then the model can be rewritten as

$$Y \sim \mathcal{F}(\theta, \Omega)$$

such that θ is modeled by the regression effects as

$$\theta = \theta_0 \cdot \exp(\sum_{j=1}^{k} \beta_j x_j)$$

where θ_0 is the *base* value of the scale parameter. Thus, the scale regression model consists of the following parameters: θ_0, Ω, and $\beta_j (j = 1, \ldots, k)$.

Given this form of the model, distributions without a scale parameter cannot be considered when regression effects are to be modeled. If a distribution does not have a direct scale parameter, then PROC SEVERITY accepts it only if it has a log-transformed scale parameter—that is, if it has a parameter $p = \log(\theta)$.

Offset Variable

You can specify that an offset variable be included in the scale regression model by specifying it in the OFFSET= option of the SCALEMODEL statement. The offset variable is a regressor whose regression coefficient is known to be 1. If x_o denotes the offset variable, then the scale regression model becomes

$$\theta = \theta_0 \cdot \exp(x_o + \sum_{j=1}^{k} \beta_j x_j)$$

The regression coefficient of the offset variable is fixed at 1 and not estimated, so it is not reported in the ParameterEstimates ODS table. However, if you specify the OUTEST= data set, then the regression coefficient is added as a variable to that data set. The value of the offset variable in OUTEST= data set is equal to 1 for the estimates row (_TYPE_='EST') and is equal to a special missing value (.F) for the standard error (_TYPE_='STDERR') and covariance (_TYPE_='COV') rows.

An offset variable is useful to model the scale parameter per unit of some measure of exposure. For example, in the automobile insurance context, measure of exposure can be the number of car-years insured or the total number of miles driven by a fleet of cars at a rental car company. For worker's compensation insurance, if you want to model the expected loss per enterprise, then you can use the number of employees or total employee salary as the measure of exposure. For epidemiological data, measure of exposure can be the number of people who are exposed to a certain pathogen when you are modeling the loss associated with an epidemic. In general, if e denotes the value of the exposure measure and if you specify $x_o = \log(e)$ as the offset variable, then you are modeling the influence of other regression effects (x_j) on the size of the scale of the distribution *per unit of exposure*.

Another use for an offset variable is when you have a priori knowledge of the influence of some exogenous variables that cannot be included in the SCALEMODEL statement. You can model the combined influence of such variables as an offset variable in order to correct for the omitted variable bias.

Parameter Initialization for Regression Models

The regression parameters are initialized either by using the values that you specify or by the default method.

- If you provide initial values for the regression parameters, then you must provide valid, nonmissing initial values for θ_0 and β_j parameters for all j.

  You can specify the initial value for θ_0 by using either the INEST= data set, the INSTORE= item store, or the INIT= option in the DIST statement. If the distribution has a direct scale parameter (no

transformation), then the initial value for the first parameter of the distribution is used as an initial value for θ_0. If the distribution has a log-transformed scale parameter, then the initial value for the first parameter of the distribution is used as an initial value for $\log(\theta_0)$.

You can use only the INEST= data set or the INSTORE= item store, but not both, to specify the initial values for β_j. The requirements for each option are as follows:

- If you use the INEST= data set, then it must contain nonmissing initial values for all the regressors that you specify in the SCALEMODEL statement. The only missing value that is allowed is the special missing value .R, which indicates that the regressor is linearly dependent on other regressors. If you specify .R for a regressor for one distribution in a BY group, you must specify it the same way for all the distributions in that BY group.

  Note that you cannot specify INEST= data set if the regression model contains effects that have CLASS variables or interaction effects.
- The parameter estimates in the INSTORE= item store are used to initialize the parameters of a model if the item store contains a model specification that matches the model specification in the current PROC SEVERITY step according to the following rules:
  - The distribution name and the number and names of the distribution parameters must match.
  - The model in the item store must include a scale regression model whose regression parameters match as follows:
    - If the regression model in the item store does not contain any redundant parameters, then at least one regression parameter must match. Initial values of the parameters that match are set equal to the estimates that are read from the item store, and initial values of the other regression parameters are set equal to the default value of 0.001.
    - If the regression model in the item store contains any redundant parameters, then all the regression parameters must match, and the initial values of all parameters are set equal to the estimates that are read from the item store.

    Note that a regression parameter is defined by the variables that form the underlying regression effect and by the levels of the CLASS variables if the effect contains any CLASS variables.

- If you do not specify valid initial values for θ_0 or β_j parameters for all j, then PROC SEVERITY initializes those parameters by using the following method:

  Let a random variable Y be distributed as $\mathcal{F}(\theta, \Omega)$, where θ is the scale parameter. By the definition of the scale parameter, a random variable $W = Y/\theta$ is distributed as $\mathcal{G}(\Omega)$ such that $\mathcal{G}(\Omega) = \mathcal{F}(1, \Omega)$. Given a random error term e that is generated from a distribution $\mathcal{G}(\Omega)$, a value y from the distribution of Y can be generated as

  $$y = \theta \cdot e$$

  Taking the logarithm of both sides and using the relationship of θ with the regression effects yields

  $$\log(y) = \log(\theta_0) + \sum_{j=1}^{k} \beta_j x_j + \log(e)$$

  PROC SEVERITY makes use of the preceding relationship to initialize parameters of a regression model with distribution *dist* as follows:

1. The following linear regression problem is solved to obtain initial estimates of β_0 and β_j:

$$\log(y) = \beta_0 + \sum_{j=1}^{k} \beta_j x_j$$

   The estimates of $\beta_j (j = 1, \ldots, k)$ in the solution of this regression problem are used to initialize the respective regression parameters of the model. The estimate of β_0 is later used to initialize the value of θ_0.

   The results of this regression are also used to detect whether any regression parameters are linearly dependent on the other regression parameters. If any such parameters are found, then a warning is written to the SAS log and the corresponding parameter is eliminated from further analysis. The estimates for linearly dependent parameters are denoted by a special missing value of .R in the OUTEST= data set and in any displayed output.

2. Let s_0 denote the initial value of the scale parameter.

   If the distribution model of *dist* does not contain the *dist*_PARMINIT subroutine, then s_0 and all the nonscale distribution parameters are initialized to the default value of 0.001.

   However, it is strongly recommended that each distribution's model contain the *dist*_PARMINIT subroutine. For more information, see the section "Defining a Severity Distribution Model with the FCMP Procedure" on page 2119. If that subroutine is defined, then s_0 is initialized as follows:

   Each input value y_i of the response variable is transformed to its scale-normalized version w_i as

$$w_i = \frac{y_i}{\exp(\beta_0 + \sum_{j=1}^{k} \beta_j x_{ij})}$$

   where x_{ij} denotes the value of *j*th regression effect in the *i*th input observation. These w_i values are used to compute the input arguments for the *dist*_PARMINIT subroutine. The values that are computed by the subroutine for nonscale parameters are used as their respective initial values. If the distribution has an untransformed scale parameter, then s_0 is set to the value of the scale parameter that is computed by the subroutine. If the distribution has a log-transformed scale parameter P, then s_0 is computed as $s_0 = \exp(l_0)$, where l_0 is the value of P computed by the subroutine.

3. The value of θ_0 is initialized as

$$\theta_0 = s_0 \cdot \exp(\beta_0)$$

Reporting Estimates of Regression Parameters

When you request estimates to be written to the output (either ODS displayed output or in the OUTEST= data set), the estimate of the base value of the first distribution parameter is reported. If the first parameter is the log-transformed scale parameter, then the estimate of $\log(\theta_0)$ is reported; otherwise, the estimate of θ_0 is reported. The transform of the first parameter of a distribution *dist* is controlled by the *dist*_SCALETRANSFORM function that is defined for it.

CDF and PDF Estimates with Regression Effects

When regression effects are estimated, the estimate of the scale parameter depends on the values of the regressors and the estimates of the regression parameters. This dependency results in a potentially different distribution for each observation. To make estimates of the cumulative distribution function (CDF) and probability density function (PDF) comparable across distributions and comparable to the empirical distribution function (EDF), PROC SEVERITY computes and reports the CDF and PDF estimates from a representative distribution. The *representative distribution* is a mixture of a certain number of distributions, where each distribution differs only in the value of the scale parameter. You can specify the number of distributions in the mixture and how their scale values are chosen by using the DFMIXTURE= option in the SCALEMODEL statement.

Let N denote the number of observations that are used for estimation, K denote the number of components in the mixture distribution, s_k denote the scale parameter of the kth mixture component, and d_k denote the weight associated with kth mixture component.

Let $f(y; s_k, \hat{\Omega})$ and $F(y; s_k, \hat{\Omega})$ denote the PDF and CDF, respectively, of the kth component distribution, where $\hat{\Omega}$ denotes the set of estimates of all parameters of the distribution other than the scale parameter. Then, the PDF and CDF estimates, $f^*(y)$ and $F^*(y)$, respectively, of the mixture distribution at y are computed as

$$f^*(y) = \frac{1}{D}\sum_{k=1}^{K} d_k f(y; s_k, \hat{\Omega})$$

$$F^*(y) = \frac{1}{D}\sum_{k=1}^{K} d_k F(y; s_k, \hat{\Omega})$$

where D is the normalization factor ($D = \sum_{k=1}^{K} d_k$).

PROC SEVERITY uses the $F^*(y)$ values to compute the EDF-based statistics of fit and to create the OUTCDF= data set and the CDF plots. The PDF estimates that is plots in PDF plots are the $f^*(y)$ values.

The scale values s_k for the K mixture components are derived from the set $\{\hat{\lambda}_i\}$ ($i = 1, \ldots, N$) of N linear predictor values, where $\hat{\lambda}_i$ denotes the estimate of the linear predictor due to observation i. It is computed as

$$\hat{\lambda}_i = \log(\hat{\theta}_0) + \sum_{j=1}^{k} \hat{\beta}_j x_{ij}$$

where $\hat{\theta}_0$ is an estimate of the base value of the scale parameter, $\hat{\beta}_j$ are the estimates of regression coefficients, and x_{ij} is the value of jth regression effect in observation i.

Let w_i denote the weight of observation i. If you specify the WEIGHT statement, then the weight is equal to the value of the specified weight variable for the corresponding observation in the DATA= data set; otherwise, the weight is set to 1.

You can specify one of the following *method-names* in the DFMIXTURE= option in the SCALEMODEL statement to specify the method of choosing K and the corresponding s_k and d_k values:

FULL
: In this method, there are as many mixture components as the number of observations that are used for estimation. In other words, $K = N$, $s_k = \hat{\theta}_k$, and $d_k = w_k$ ($k = 1, \ldots, N$). This is the slowest method, because it requires $O(N)$ computations to compute the mixture CDF $F^*(y_i)$ or the mixture PDF $f^*(y_i)$ of one observation. For N observations,

the computational complexity in terms of number of CDF or PDF evaluations is $O(N^2)$. Even for moderately large values of N, the time that is taken to compute the mixture CDF and PDF can significantly exceed the time that is taken to estimate the model parameters. So it is recommended that you use the FULL method only for small data sets.

MEAN

In this method, the mixture contains only one distribution, whose scale value is determined by the mean of the linear predictor values that are implied by all the observations. In other words, s_1 is computed as

$$s_1 = \exp\left(\frac{1}{N}\sum_{i=1}^{N}\hat{\lambda}_i\right)$$

The component's weight d_1 is set to 1.

This method is the fastest because it requires only one CDF or PDF evaluation per observation. The computational complexity is $O(N)$ for N observations.

If you do not specify the DFMIXTURE= option in the SCALEMODEL statement, then this is the default method.

QUANTILE

In this method, a certain number of quantiles are chosen from the set of all linear predictor values. If you specify a value of q for the K= option when specifying this method, then $K = q - 1$ and s_k $(k = 1, \ldots, K)$ is computed as $s_k = \exp(\hat{\lambda}_k)$, where $\hat{\lambda}_k$ is the kth q-quantile from the set $\{\hat{\lambda}_i\}$ $(i = 1, \ldots, N)$. The weight of each of the components (d_k) is assumed to be 1 for this method.

The default value of q is 2, which implies a one-point mixture that has a distribution whose scale value is equal to the median scale value.

For this method, PROC SEVERITY needs to sort the N linear predictor values in the set $\{\hat{\lambda}_i\}$; the sorting requires $O(N\log(N))$ computations. Then, computing the mixture estimate of one observation requires $(q - 1)$ CDF or PDF evaluations. Hence, the computational complexity of this method is $O(qN) + O(N\log(N))$ for computing a mixture CDF or PDF of N observations. For $q << N$, the QUANTILE method is significantly faster than the FULL method.

RANDOM

In this method, a uniform random sample of observations is chosen, and the mixture contains the distributions that are implied by those observations. If you specify a value of r for the K= option when specifying this method, then the size of the sample is r. Hence, $K = r$. If l_j denotes the index of jth observation in the sample $(j = 1, \ldots, r)$, such that $1 \le l_j \le N$, then the scale of kth component distribution in the mixture is $s_k = \exp(\hat{\lambda}_{l_k})$. The weight of each of the components (d_k) is assumed to be 1 for this method.

You can also specify the seed to be used for generating the random sample by using the SEED= option for this method. The same sample of observations is used for all models.

Computing a mixture estimate of one observation requires r CDF or PDF evaluations. Hence, the computational complexity of this method is $O(rN)$ for computing a mixture CDF or PDF of N observations. For $r << N$, the RANDOM method is significantly faster than the FULL method.

Levelization of Classification Variables

A classification variable enters the statistical analysis or model not through its values but through its levels. The process of associating values of a variable with levels is called *levelization*.

During the process of levelization, observations that share the same value are assigned to the same level. The manner in which values are grouped can be affected by the inclusion of formats. You can determine the sort order of the levels by specifying the ORDER= option in the CLASS statement. You can also control the sort order separately for each variable in the CLASS statement.

Consider the data on nine observations in Table 28.5. The variable A is integer-valued, and the variable X is a continuous variable that has a missing value for the fourth observation. The fourth and fifth columns of Table 28.5 apply two different formats to the variable X.

Table 28.5 Example Data for Levelization

Obs	A	X	FORMAT X 3.0	FORMAT X 3.1
1	2	1.09	1	1.1
2	2	1.13	1	1.1
3	2	1.27	1	1.3
4	3	.	.	.
5	3	2.26	2	2.3
6	3	2.48	2	2.5
7	4	3.34	3	3.3
8	4	3.34	3	3.3
9	4	3.14	3	3.1

By default, levelization of the variables groups the observations by the formatted value of the variable, except for numerical variables for which no explicit format is provided. Those numerical variables are sorted by their internal value. The levelization of the four columns in Table 28.5 leads to the level assignment in Table 28.6.

Table 28.6 Values and Levels

	A		X		FORMAT X 3.0		FORMAT X 3.1	
Obs	Value	Level	Value	Level	Value	Level	Value	Level
1	2	1	1.09	1	1	1	1.1	1
2	2	1	1.13	2	1	1	1.1	1
3	2	1	1.27	3	1	1	1.3	2
4	3	2	.	.	.	.	.	.
5	3	2	2.26	4	2	2	2.3	3
6	3	2	2.48	5	2	2	2.5	4
7	4	3	3.34	7	3	3	3.3	6
8	4	3	3.34	7	3	3	3.3	6
9	4	3	3.14	6	3	3	3.1	5

You can specify the sort order for the levels of CLASS variables in the ORDER= option in the CLASS statement.

When ORDER=FORMATTED (which is the default) is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values. To order numeric class levels that have no explicit format by their BEST12. formatted values, you can specify the BEST12. format explicitly for the CLASS variables.

Table 28.7 shows how values of the ORDER= option are interpreted.

Table 28.7 Interpretation of Values of ORDER= Option

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables that have no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count (levels that have the most observations come first in the order)
INTERNAL	Unformatted value
FREQDATA	Order of descending frequency count, and within counts by order of appearance in the input data set when counts are tied
FREQFORMATTED	Order of descending frequency count, and within counts by formatted value when counts are tied
FREQINTERNAL	Order of descending frequency count, and within counts by unformatted (internal) value when counts are tied

For FORMATTED, FREQFORMATTED, FREQINTERNAL, and INTERNAL values, the sort order is machine-dependent. For more information about sort order, see the chapter about the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Programmers Guide: Essentials*.

When you specify the MISSING option in the CLASS statement, the missing values ('.' for a numeric variable and blanks for a character variable) are included in the levelization and are assigned a level. Table 28.8 displays the results of levelizing the values in Table 28.5 when the MISSING option is in effect.

Table 28.8 Values and Levels with the MISSING Option

	A		X		FORMAT x 3.0		FORMAT x 3.1	
Obs	Value	Level	Value	Level	Value	Level	Value	Level
1	2	1	1.09	2	1	2	1.1	2
2	2	1	1.13	3	1	2	1.1	2
3	2	1	1.27	4	1	2	1.3	3
4	3	2	.	1	.	1	.	1

Table 28.8 *continued*

	A		X		FORMAT x 3.0		FORMAT x 3.1	
Obs	Value	Level	Value	Level	Value	Level	Value	Level
5	3	2	2.26	5	2	3	2.3	4
6	3	2	2.48	6	2	3	2.5	5
7	4	3	3.34	8	3	4	3.3	7
8	4	3	3.34	8	3	4	3.3	7
9	4	3	3.14	7	3	4	3.1	6

When you do not specify the MISSING option, it is important to understand the implications of missing values for your statistical analysis. When PROC SEVERITY levelizes the CLASS variables, any observations for which a CLASS variable has a missing value are excluded from the analysis. This is true regardless of whether the variable is used to form the statistical model. For example, consider the case in which some observations contain missing values for variable A but the records for these observations are otherwise complete with respect to all other variables in the model. The analysis results that come from the following statements do not include any observations for which variable A contains missing values, even though A is not specified in the SCALEMODEL statement:

```
class A B;
scalemodel B x B*x;
```

You can request PROC SEVERITY to print the "Descriptive Statistics" table, which shows the number of observations that are read from the data set and the number of observations that are used in the analysis. Pay careful attention to this table—especially when your data set contains missing values—to ensure that no observations are unintentionally excluded from the analysis.

Specification and Parameterization of Model Effects

PROC SEVERITY supports formation of regression effects in the SCALEMODEL statement. A *regression effect* is formed from one or more regressor variables according to effect construction rules (*parameterization*). Each regression effect forms one element of $\mathbf{X}$ in the linear model structure $\mathbf{X}\boldsymbol{\beta}$ that affects the scale parameter. The SCALEMODEL statement in conjunction with the CLASS statement supports a rich set of effects. In order to correctly interpret the results, you need to understand the specification and parameterization of effects that are discussed in this section.

Effects are specified by a special notation that uses variable names and operators. There are two types of regressor variables: classification (or CLASS) variables and continuous variables. *Classification variables* can be either numeric or character and are specified in a CLASS statement. For more information, see the section "Levelization of Classification Variables" on page 2099. A regressor variable that is not declared in the CLASS statement is assumed to be *continuous*.

Two primary operators (crossing and nesting) are used for combining the variables, and several additional operators are used to simplify effect specification. Operators are discussed in the section "Effect Operators" on page 2102.

If you specify the CLASS statement, then PROC SEVERITY supports a general linear model (GLM) parameterization and a reference parameterization for the classification variables. The GLM parameterization

is the default. For more information, see the sections "GLM Parameterization of Classification Variables and Effects" on page 2104 and "Reference Parameterization" on page 2108.

Effect Operators

Table 28.9 summarizes the operators that are available for selecting and constructing effects. These operators are discussed in the following sections.

Table 28.9 Available Effect Operators

Operator	Example	Description
Interaction	A*B	Crosses the levels of the effects
Nesting	A(B)	Nests A levels within B levels
Bar operator	A | B | C	Specifies all interactions
At sign operator	A | B | C@2	Reduces interactions in bar effects
Dash operator	A1-A10	Specifies sequentially numbered variables
Colon operator	A:	Specifies variables that have a common prefix
Double dash operator	A- -C	Specifies sequential variables in data set order

Bar and At Sign Operators

You can shorten the specification of a large factorial model by using the bar operator. For example, two ways of writing the model for a full three-way factorial model follow:

```
scalemodel A B C   A*B A*C B*C   A*B*C;

scalemodel A|B|C;
```

When you use the bar (|), the right and left sides become effects, and the cross of them becomes an effect. Multiple bars are permitted. The expressions are expanded from left to right, using rules 2–4 from Searle (1971, p. 390).

- Multiple bars are evaluated from left to right. For example, A | B | C is evaluated as follows:

$$\begin{aligned} \text{A | B | C} &\rightarrow \{\,\text{A | B}\,\}\,\text{| C} \\ &\rightarrow \{\,\text{A B A*B}\,\}\,\text{| C} \\ &\rightarrow \text{A B A*B C A*C B*C A*B*C} \end{aligned}$$

- Crossed and nested groups of variables are combined. For example, A(B) | C(D) generates A*C(B D), among other terms.
- Duplicate variables are removed. For example, A(C) | B(C) generates A*B(C C), among other terms, and the extra C is removed.
- Effects are discarded if a variable occurs on both the crossed and nested parts of an effect. For example, A(B) | B(D E) generates A*B(B D E), but this effect is eliminated immediately.

You can also specify the maximum number of variables involved in any effect that results from bar evaluation by specifying that maximum number, preceded by an at sign (@), at the end of the bar effect. For example, the following specification selects only those effects that contain two or fewer variables:

```
scalemodel A|B|C@2;
```

The preceding example is equivalent to the following SCALEMODEL statement:

```
scalemodel A B C   A*B A*C B*C;
```

More examples of using the bar and at sign operators follow:

A | C(B)	is equivalent to	A C(B) A*C(B)
A(B) | C(B)	is equivalent to	A(B) C(B) A*C(B)
A(B) | B(D E)	is equivalent to	A(B) B(D E)
A | B(A) | C	is equivalent to	A B(A) C A*C B*C(A)
A | B(A) | C@2	is equivalent to	A B(A) C A*C
A | B | C | D@2	is equivalent to	A B A*B C A*C B*C D A*D B*D C*D
A*B(C*D)	is equivalent to	A*B(C D)

NOTE: The preceding examples assume the following CLASS statement specification:

```
class A B C D;
```

Colon, Dash, and Double Dash Operators

You can simplify the specification of a large model when some of your variables have a common prefix by using the colon (:) operator and the dash (-) operator. The colon operator selects all variables that have a particular prefix, and the dash operator enables you to list variables that are numbered sequentially. For example, if your data set contains the variables X1 through X9, the following SCALEMODEL statements are equivalent:

```
scalemodel X1 X2 X3 X4 X5 X6 X7 X8 X9;

scalemodel X1-X9;

scalemodel X:;
```

If your data set contains only the three covariates X1, X2, and X9, then the colon operator selects all three variables:

```
scalemodel X:;
```

However, the following specification returns an error because X3 through X8 are not in the data set:

```
scalemodel X1-X9;
```

The double dash (--) operator enables you to select variables that are stored sequentially in the SAS data set, whether or not they have a common prefix. You can use the CONTENTS procedure (see *Base SAS Procedures Guide*) to determine your variable ordering. For example, if you replace the dash in the preceding SCALEMODEL statement with a double dash, as follows, then all three variables are selected:

```
scalemodel X1--X9;
```

If your data set contains the variables A, B, and C, then you can use the double dash operator to select these variables by specifying the following:

```
scalemodel A--C;
```

GLM Parameterization of Classification Variables and Effects

Table 28.10 shows the types of effects that are available in the SEVERITY procedure; they are discussed in more detail in the following sections. Let A, B, and C represent classification variables, and let X and Z represent continuous variables.

Table 28.10 Available Types of Effects

Effect	Example	Description
Singleton continuous	X Z	Continuous variables
Polynomial continuous	X*Z	Interaction of continuous variables
Main	A B	CLASS variables
Interaction	A*B	Crossing of CLASS variables
Nested	A(B)	Main effect A nested within CLASS effect B
Continuous-by-class	X*A	Crossing of continuous and CLASS variables
Continuous-nesting-class	X(A)	Continuous variable X nested within CLASS variable A
General	X*Z*A(B)	Combinations of different types of effects

Continuous Effects

Continuous variables or polynomial terms that involve them can be included in the model as continuous effects. An effect that contains a single continuous variable is referred to as a *singleton continuous* effect, and an effect that contains an interaction of only continuous variables is referred to as a *polynomial continuous* effect. The actual values of such terms are included as columns of the relevant model matrices. You can use the bar operator along with a continuous variable to generate polynomial effects. For example, X | X | X expands to X X*X X*X*X, which is a cubic model.

Main Effects

If a classification variable has m levels, the GLM parameterization generates m columns for its main effect in the model matrix. Each column is an indicator variable for a given level. The order of the columns is the sort order of the values of their levels and can be controlled by the ORDER= option in the CLASS statement.

Table 28.11 is an example where β_0 denotes the intercept and A and B are classification variables that have two and three levels, respectively.

Table 28.11 Example of Main Effects

Data		I	A		B		
A	B	β_0	A1	A2	B1	B2	B3
1	1	1	1	0	1	0	0

Table 28.11 *continued*

Data		I	A		B		
1	2	1	1	0	0	1	0
1	3	1	1	0	0	0	1
2	1	1	0	1	1	0	0
2	2	1	0	1	0	1	0
2	3	1	0	1	0	0	1

There are usually more columns for these effects than there are degrees of freedom to estimate them. In other words, the GLM parameterization of main effects is *singular*.

Interaction Effects

Often a regression model includes interaction (crossed) effects to account for how the effect of a variable changes along with the values of other variables. In an interaction, the terms are first reordered to correspond to the order of the variables in the CLASS statement. Thus, B*A becomes A*B if A precedes B in the CLASS statement. Then, the GLM parameterization generates columns for all combinations of levels that occur in the data. The order of the columns is such that the rightmost variables in the interaction change faster than the leftmost variables, as illustrated in Table 28.12.

Table 28.12 Example of Interaction Effects

Data		I	A		B			A*B					
A	B	β_0	A1	A2	B1	B2	B3	A1B1	A1B2	A1B3	A2B1	A2B2	A2B3
1	1	1	1	0	1	0	0	1	0	0	0	0	0
1	2	1	1	0	0	1	0	0	1	0	0	0	0
1	3	1	1	0	0	0	1	0	0	1	0	0	0
2	1	1	0	1	1	0	0	0	0	0	1	0	0
2	2	1	0	1	0	1	0	0	0	0	0	1	0
2	3	1	0	1	0	0	1	0	0	0	0	0	1

In the matrix in Table 28.12, main-effects columns are not linearly independent of crossed-effects columns. In fact, the column space for the crossed effects contains the space of the main effect.

When your regression model contains many interaction effects, you might be able to code them more parsimoniously by using the bar operator (|). The bar operator generates all possible interaction effects. For example, A | B | C expands to A B A*B C A*C B*C A*B*C. To eliminate higher-order interaction effects, use the at sign (@) in conjunction with the bar operator. For example, A | B | C | D@2 expands to A B A*B C A*C B*C D A*D B*D C*D.

Nested Effects

Nested effects are generated in the same manner as crossed effects. Hence, the design columns that are generated by the following two statements are the same (but the ordering of the columns is different):

```
scalemodel A B(A);

scalemodel A A*B;
```

The nesting operator in PROC SEVERITY is more of a notational convenience than an operation that is distinct from crossing. Nested effects are usually characterized by the property that the nested variables do not appear as main effects. The order of the variables within nesting parentheses is made to correspond to the order of these variables in the CLASS statement. The order of the columns is such that variables outside the parentheses index faster than those inside the parentheses, and the rightmost nested variables index faster than the leftmost variables, as illustrated in Table 28.13.

Table 28.13 Example of Nested Effects

Data		I	A		B(A)					
A	B	β_0	A1	A2	B1A1	B2A1	B3A1	B1A2	B2A2	B3A2
1	1	1	1	0	1	0	0	0	0	0
1	2	1	1	0	0	1	0	0	0	0
1	3	1	1	0	0	0	1	0	0	0
2	1	1	0	1	0	0	0	1	0	0
2	2	1	0	1	0	0	0	0	1	0
2	3	1	0	1	0	0	0	0	0	1

Continuous-Nesting-Class Effects

When a continuous variable nests or crosses with a classification variable, the design columns are constructed by multiplying the continuous values into the design columns for the classification effect, as illustrated in Table 28.14.

Table 28.14 Example of Continuous-Nesting-Class Effects

Data		I	A		X(A)	
X	A	β_0	A1	A2	X(A1)	X(A2)
21	1	1	1	0	21	0
24	1	1	1	0	24	0
22	1	1	1	0	22	0
28	2	1	0	1	0	28
19	2	1	0	1	0	19
23	2	1	0	1	0	23

Continuous-by-Class Effects

Continuous-by-class effects generate the same design columns as continuous-nesting-class effects. Table 28.15 shows the construction of the X*A effect. The two columns for this effect are the same as the columns for the X(A) effect in Table 28.14.

Table 28.15 Example of Continuous-by-Class Effects

Data		I	X	A		X*A	
X	A	β_0	X	A1	A2	X*A1	X*A2
21	1	1	21	1	0	21	0
24	1	1	24	1	0	24	0
22	1	1	22	1	0	22	0
28	2	1	28	0	1	0	28
19	2	1	19	0	1	0	19
23	2	1	23	0	1	0	23

General Effects

An example that combines all the effects is X1*X2*A*B*C(D E). The continuous list comes first, followed by the crossed list, followed by the nested list in parentheses. PROC SEVERITY might rename effects to correspond to ordering rules. For example, B*A(E D) might be renamed A*B(D E) to satisfy the following:

- Classification variables that occur outside parentheses (crossed effects) are sorted in the order in which they appear in the CLASS statement.
- Variables within parentheses (nested effects) are sorted in the order in which they appear in the CLASS statement.

The sequencing of the parameters that are generated by an effect is determined by the variables whose levels are indexed faster:

- Variables in the crossed list index faster than variables in the nested list.
- Within a crossed or nested list, variables to the right index faster than variables to the left.

For example, suppose a model includes four effects—A, B, C, and D—each of which has two levels, 1 and 2. Assume the CLASS statement is

```
class A B C D;
```

Then the order of the parameters for the effect B*A(C D), which is renamed A*B(C D), is

$$\begin{array}{llll} A_1B_1C_1D_1 \rightarrow & A_1B_2C_1D_1 \rightarrow & A_2B_1C_1D_1 \rightarrow & A_2B_2C_1D_1 \rightarrow \\ A_1B_1C_1D_2 \rightarrow & A_1B_2C_1D_2 \rightarrow & A_2B_1C_1D_2 \rightarrow & A_2B_2C_1D_2 \rightarrow \\ A_1B_1C_2D_1 \rightarrow & A_1B_2C_2D_1 \rightarrow & A_2B_1C_2D_1 \rightarrow & A_2B_2C_2D_1 \rightarrow \\ A_1B_1C_2D_2 \rightarrow & A_1B_2C_2D_2 \rightarrow & A_2B_1C_2D_2 \rightarrow & A_2B_2C_2D_2 \end{array}$$

Note that first the crossed effects B and A are sorted in the order in which they appear in the CLASS statement so that A precedes B in the parameter list. Then, for each combination of the nested effects in turn, combinations of A and B appear. The B effect changes fastest because it is rightmost in the cross list. Then A changes next fastest, and D changes next fastest after that. The C effect changes most slowly because it is leftmost in the nested list.

Reference Parameterization

Classification variables can be represented in the reference parameterization. Consider the classification variable A that has four values, 1, 2, 5, and 7. The reference parameterization generates three columns (one less than the number of variable levels). The columns indicate group membership of the nonreference levels. For the reference level, the three dummy variables have a value of 0. If the reference level is 7 (REF='7'), the design columns for variable A are as shown in Table 28.16.

Table 28.16 Reference Coding

	Design Matrix		
A	**A1**	**A2**	**A5**
1	1	0	0
2	0	1	0
5	0	0	1
7	0	0	0

Parameter estimates of CLASS main effects that use the reference coding scheme estimate the difference in the effect of each nonreference level compared to the effect of the reference level.

Empirical Distribution Function Estimation Methods

The empirical distribution function (EDF) is a nonparametric estimate of the cumulative distribution function (CDF) of the distribution. PROC SEVERITY computes EDF estimates for two purposes: to send the estimates to a distribution's PARMINIT subroutine in order to initialize the distribution parameters, and to compute the EDF-based statistics of fit.

To reduce the time that it takes to compute the EDF estimates, you can use the INITSAMPLE option to specify that only a fraction of the input data be used. If you do not specify the INITSAMPLE option, then PROC SEVERITY computes the EDF estimates by using all valid observations in the DATA= data set, or by using all valid observations in the current BY group if you specify a BY statement.

This section describes the methods that are used for computing EDF estimates.

Notation

Let there be a set of N observations, each containing a quintuplet of values $(y_i, t_i^l, t_i^r, c_i^r, c_i^l), i = 1, \ldots, N$, where y_i is the value of the response variable, t_i^l is the value of the left-truncation threshold, t_i^r is the value of the right-truncation threshold, c_i^r is the value of the right-censoring limit, and c_i^l is the value of the left-censoring limit.

If an observation is not left-truncated, then $t_i^l = \tau^l$, where τ^l is the smallest value in the support of the distribution; so $F(t_i^l) = 0$. If an observation is not right-truncated, then $t_i^r = \tau_h$, where τ_h is the largest value in the support of the distribution; so $F(t_i^r) = 1$. If an observation is not right-censored, then $c_i^r = \tau^l$; so $F(c_i^r) = 0$. If an observation is not left-censored, then $c_i^l = \tau_h$; so $F(c_i^l) = 1$.

Let w_i denote the weight associated with ith observation. If you specify the WEIGHT statement, then w_i is the normalized value of the weight variable; otherwise, it is set to 1. The weights are normalized such that they sum up to N.

An indicator function $I[e]$ takes a value of 1 or 0 if the expression e is true or false, respectively.

Estimation Methods

If the response variable is subject to both left-censoring and right-censoring effects, then PROC SEVERITY uses the Turnbull's method. This section describes methods other than Turnbull's method. For Turnbull's method, see the next section "Turnbull's EDF Estimation Method" on page 2111.

The method descriptions assume that all observations are either uncensored or right-censored; that is, each observation is of the form $(y_i, t_i^l, t_i^r, \tau^l, \tau_h)$ or $(y_i, t_i^l, t_i^r, c_i^r, \tau_h)$.

If all observations are either uncensored or left-censored, then each observation is of the form $(y_i, t_i^l, t_i^r, \tau_l, c_i^l)$. It is converted to an observation $(-y_i, -t_i^r, -t_i^l, -c_i^l, \tau_h)$; that is, the signs of all the response variable values are reversed, the new left-truncation threshold is equal to the negative of the original right-truncation threshold, the new right-truncation threshold is equal to the negative of the original left-truncation threshold, and the negative of the original left-censoring limit becomes the new right-censoring limit. With this transformation, each observation is either uncensored or right-censored. The methods described for handling uncensored or right-censored data are now applicable. After the EDF estimates are computed, the observations are transformed back to the original form and EDF estimates are adjusted such $F_n(y_i) = 1 - F_n(-y_i-)$, where $F_n(-y_i-)$ denotes the EDF estimate of the value slightly less than the transformed value $-y_i$.

Further, a set of uncensored or right-censored observations can be converted to a set of observations of the form $(y_i, t_i^l, t_i^r, \delta_i)$, where δ_i is the indicator of right-censoring. $\delta_i = 0$ indicates a right-censored observation, in which case y_i is assumed to record the right-censoring limit c_i^r. $\delta_i = 1$ indicates an uncensored observation, and y_i records the exact observed value. In other words, $\delta_i = I[Y \le C^r]$ and $y_i = \min(y_i, c_i^r)$.

Given this notation, the EDF is estimated as

$$F_n(y) = \begin{cases} 0 & \text{if } y < y^{(1)} \\ \hat{F}_n(y^{(k)}) & \text{if } y^{(k)} \le y < y^{(k+1)}, k = 1, \ldots, N-1 \\ \hat{F}_n(y^{(N)}) & \text{if } y^{(N)} \le y \end{cases}$$

where $y^{(k)}$ denotes the kth-order statistic of the set $\{y_i\}$ and $\hat{F}_n(y^{(k)})$ is the estimate computed at that value. The definition of $\hat{F}_n$ depends on the estimation method. You can specify a particular method or let PROC SEVERITY choose an appropriate method by using the EMPIRICALCDF= option in the PROC SEVERITY statement. Each method computes $\hat{F}_n$ as follows:

STANDARD — This method is the standard way of computing EDF. The EDF estimate at observation i is computed as follows:

$$\hat{F}_n(y_i) = \frac{1}{N} \sum_{j=1}^{N} w_j \cdot I[y_j \le y_i]$$

If you do not specify any censoring or truncation information, then this method is chosen. If you explicitly specify this method, then PROC SEVERITY ignores any censoring and truncation information that you specify in the LOSS statement.

The standard error of $\hat{F}_n(y_i)$ is computed by using the normal approximation method:

$$\hat{\sigma}_n(y_i) = \sqrt{\hat{F}_n(y_i)(1 - \hat{F}_n(y_i))/N}$$

KAPLANMEIER

The Kaplan-Meier (KM) estimator, also known as the product-limit estimator, was first introduced by Kaplan and Meier (1958) for censored data. Lynden-Bell (1971) derived a similar estimator for left-truncated data. PROC SEVERITY uses the definition that combines both censoring and truncation information (Klein and Moeschberger 1997; Lai and Ying 1991).

The EDF estimate at observation i is computed as

$$\hat{F}_n(y_i) = 1 - \prod_{\tau \le y_i} \left(1 - \frac{n(\tau)}{R_n(\tau)}\right)$$

where $n(\tau)$ and $R_n(\tau)$ are defined as follows:

- $n(\tau) = \sum_{k=1}^{N} w_k \cdot I[y_k = \tau \text{ and } \tau \le t_k^r \text{ and } \delta_k = 1]$, which is the number of uncensored observations ($\delta_k = 1$) for which the response variable value is equal to τ and τ is observable according to the right-truncation threshold of that observation ($\tau \le t_k^r$).
- $R_n(\tau) = \sum_{k=1}^{N} w_k \cdot I[y_k \ge \tau > t_k^l]$, which is the size (cardinality) of the risk set at τ. The term *risk set* has its origins in survival analysis; it contains the events that are at risk of failure at a given time, τ. In other words, it contains the events that have survived up to time τ and might fail at or after τ. For PROC SEVERITY, *time* is equivalent to the magnitude of the event and *failure* is equivalent to an uncensored and observable event, where observable means it satisfies the truncation thresholds.

This method is chosen when you specify at least one form of censoring or truncation.

The standard error of $\hat{F}_n(y_i)$ is computed by using Greenwood's formula (Greenwood 1926):

$$\hat{\sigma}_n(y_i) = \sqrt{(1 - \hat{F}_n(y_i))^2 \cdot \sum_{\tau \le y_i} \left(\frac{n(\tau)}{R_n(\tau)(R_n(\tau) - n(\tau))}\right)}$$

MODIFIEDKM

The product-limit estimator used by the KAPLANMEIER method does not work well if the risk set size becomes very small. For right-censored data, the size can become small towards the right tail. For left-truncated data, the size can become small at the left tail and can remain so for the entire range of data. This was demonstrated by Lai and Ying (1991). They proposed a modification to the estimator that ignores the effects due to small risk set sizes.

The EDF estimate at observation i is computed as

$$\hat{F}_n(y_i) = 1 - \prod_{\tau \le y_i} \left(1 - \frac{n(\tau)}{R_n(\tau)} \cdot I[R_n(\tau) \ge cN^{\alpha}]\right)$$

where the definitions of $n(\tau)$ and $R_n(\tau)$ are identical to those used for the KAPLAN-MEIER method described previously.

You can specify the values of c and α by using the C= and ALPHA= options. If you do not specify a value for c, the default value used is $c = 1$. If you do not specify a value for α, the default value used is $\alpha = 0.5$.

As an alternative, you can also specify an absolute lower bound, say L, on the risk set size by using the RSLB= option, in which case $I[R_n(\tau) \geq cN^{\alpha}]$ is replaced by $I[R_n(\tau) \geq L]$ in the definition.

The standard error of $\hat{F}_n(y_i)$ is computed by using Greenwood's formula (Greenwood 1926):

$$\hat{\sigma}_n(y_i) = \sqrt{(1 - \hat{F}_n(y_i))^2 \cdot \sum_{\tau \leq y_i} \left(\frac{n(\tau)}{R_n(\tau)(R_n(\tau) - n(\tau))} \cdot I[R_n(\tau) \geq cN^{\alpha}] \right)}$$

Turnbull's EDF Estimation Method

If the response variable is subject to both left-censoring and right-censoring effects, then the SEVERITY procedure uses a method proposed by Turnbull (1976) to compute the nonparametric estimates of the cumulative distribution function. The original Turnbull's method is modified using the suggestions made by Frydman (1994) when truncation effects are present.

Let the input data consist of N observations in the form of quintuplets of values $(y_i, t_i^l, t_i^r, c_i^r, c_i^l), i = 1, \ldots, N$ with notation described in the section "Notation" on page 2108. For each observation, let $A_i = (c_i^r, c_i^l]$ be the censoring interval; that is, the response variable value is known to lie in the interval A_i, but the exact value is not known. If an observation is uncensored, then $A_i = (y_i - \epsilon, y_i]$ for any arbitrarily small value of $\epsilon > 0$. If an observation is censored, then the value y_i is ignored. Similarly, for each observation, let $B_i = (t_i^l, t_i^r]$ be the truncation interval; that is, the observation is drawn from a truncated (conditional) distribution $F(y, B_i) = P(Y \leq y | Y \in B_i)$.

Two sets, L and R, are formed using A_i and B_i as follows:

$$L = \{c_i^r, 1 \leq i \leq N\} \cup \{t_i^r, 1 \leq i \leq N\}$$
$$R = \{c_i^l, 1 \leq i \leq N\} \cup \{t_i^l, 1 \leq i \leq N\}$$

The sets L and R represent the left endpoints and right endpoints, respectively. A set of disjoint intervals $C_j = [q_j, p_j], 1 \leq j \leq M$ is formed such that $q_j \in L$ and $p_j \in R$ and $q_j \leq p_j$ and $p_j < q_{j+1}$. The value of M is dependent on the nature of censoring and truncation intervals in the input data. Turnbull (1976) showed that the maximum likelihood estimate (MLE) of the EDF can increase only inside intervals C_j. In other words, the MLE estimate is constant in the interval (p_j, q_{j+1}). The likelihood is independent of the behavior of F_n inside any of the intervals C_j. Let s_j denote the increase in F_n inside an interval C_j. Then, the EDF estimate is as follows:

$$F_n(y) = \begin{cases} 0 & \text{if } y < q_1 \\ \sum_{k=1}^{j} s_k & \text{if } p_j < y < q_{j+1}, 1 \leq j \leq M-1 \\ 1 & \text{if } y > p_M \end{cases}$$

PROC SEVERITY computes the estimates $F_n(p_j+) = F_n(q_{j+1}-) = \sum_{k=1}^{j} s_k$ at points p_j and q_{j+1} and computes $F_n(q_1-) = 0$ at point q_1, where $F_n(x+)$ denotes the limiting estimate at a point that is infinitesimally larger than x when approaching x from values larger than x and where $F_n(x-)$ denotes the

limiting estimate at a point that is infinitesimally smaller than x when approaching x from values smaller than x.

PROC SEVERITY uses the expectation-maximization (EM) algorithm proposed by Turnbull (1976), who referred to the algorithm as the self-consistency algorithm. By default, the algorithm runs until one of the following criteria is met:

- Relative-error criterion: The maximum relative error between the two consecutive estimates of s_j falls below a threshold ϵ. If l indicates an index of the current iteration, then this can be formally stated as

$$\arg \max_{1 \le j \le M} \left\{ \frac{|s_j^l - s_j^{l-1}|}{s_j^{l-1}} \right\} \le \epsilon$$

  You can control the value of ϵ by specifying the EPS= suboption of the EDF=TURNBULL option in the PROC SEVERITY statement. The default value is 1.0E–8.

- Maximum-iteration criterion: The number of iterations exceeds an upper limit that you specify for the MAXITER= suboption of the EDF=TURNBULL option in the PROC SEVERITY statement. The default number of maximum iterations is 500.

The self-consistent estimates obtained in this manner might not be maximum likelihood estimates. Gentleman and Geyer (1994) suggested the use of the Kuhn-Tucker conditions for the maximum likelihood problem to ensure that the estimates are MLE. If you specify the ENSUREMLE suboption of the EDF=TURNBULL option in the PROC SEVERITY statement, then PROC SEVERITY computes the Kuhn-Tucker conditions at the end of each iteration to determine whether the estimates $\{s_j\}$ are MLE. If you do not specify any truncation effects, then the Kuhn-Tucker conditions derived by Gentleman and Geyer (1994) are used. If you specify any truncation effects, then PROC SEVERITY uses modified Kuhn-Tucker conditions that account for the truncation effects. An integral part of checking the conditions is to determine whether an estimate s_j is zero or whether an estimate of the Lagrange multiplier or the reduced gradient associated with the estimate s_j is zero. PROC SEVERITY declares these values to be zero if they are less than or equal to a threshold δ. You can control the value of δ by specifying the ZEROPROB= suboption of the EDF=TURNBULL option in the PROC SEVERITY statement. The default value is 1.0E–8. The algorithm continues until the Kuhn-Tucker conditions are satisfied or the number of iterations exceeds the upper limit. The relative-error criterion stated previously is not used when you specify the ENSUREMLE option.

The standard errors for Turnbull's EDF estimates are computed by using the asymptotic theory of the maximum likelihood estimators (MLE), even though the final estimates might not be MLE. Turnbull's estimator essentially attempts to maximize the likelihood L, which depends on the parameters s_j ($j = 1, \ldots, M$). Let $\boldsymbol{s} = \{s_j\}$ denote the set of these parameters. If $\mathbf{G}(\boldsymbol{s}) = \nabla^2(-\log(L(\boldsymbol{s})))$ denotes the Hessian matrix of the negative of log likelihood, then the variance-covariance matrix of $\boldsymbol{s}$ is estimated as $\hat{\mathbf{C}}(\boldsymbol{s}) = \mathbf{G}^{-1}(\boldsymbol{s})$. Given this matrix, the standard error of $F_n(y)$ is computed as

$$\sigma_n(y) = \sqrt{\sum_{k=1}^{j} \left(\hat{C}_{kk} + 2 \cdot \sum_{l=1}^{k-1} \hat{C}_{kl} \right)}, \text{ if } p_j < y < q_{j+1}, 1 \le j \le M-1$$

The standard error is undefined outside of these intervals.

EDF Estimates and Truncation

If you specify truncation, then the estimate $\hat{F}_n(y)$ that is computed by any method other than the STANDARD method is a *conditional* estimate. In other words, $\hat{F}_n(y) = \Pr(Y \le y | \tau_G < Y \le \tau_H)$, where G and H denote the (unknown) distribution functions of the left-truncation threshold variable T^l and the right-truncation threshold variable T^r, respectively, τ_G denotes the smallest left-truncation threshold with a nonzero cumulative probability, and τ_H denotes the largest right-truncation threshold with a nonzero cumulative probability. Formally, $\tau_G = \inf\{s : G(s) > 0\}$ and $\tau_H = \sup\{s : H(s) > 0\}$. For computational purposes, PROC SEVERITY estimates τ_G and τ_H by $t^l_{\min}$ and $t^r_{\max}$, respectively, defined as

$$t^l_{\min} = \min\{t^l_k : 1 \le k \le N\}$$
$$t^r_{\max} = \max\{t^r_k : 1 \le k \le N\}$$

These estimates of $t^l_{\min}$ and $t^r_{\max}$ are used to compute the conditional estimates of the CDF as described in the section "Truncation and Conditional CDF Estimates" on page 2089.

If you specify left-truncation *with* the probability of observability p, then PROC SEVERITY uses the additional information provided by p to compute an estimate of the EDF that is not conditional on the left-truncation information. In particular, for each left-truncated observation i with response variable value y_i and truncation threshold t^l_i, an observation j is added with *weight* $w_j = (1-p)/p$ and $y_j = t^l_j$. Each added observation is assumed to be uncensored and untruncated. Then, your specified EDF method is used by assuming no left-truncation. The EDF estimate that is obtained using this method is not conditional on the left-truncation information. For the KAPLANMEIER and MODIFIEDKM methods with uncensored or right-censored data, definitions of $n(\tau)$ and $R_n(\tau)$ are modified to account for the added observations. If N^a denotes the total number of observations including the added observations, then $n(\tau)$ is defined as $n(\tau) = \sum_{k=1}^{N^a} w_k I[y_k = \tau \text{ and } \tau \le t^r_k \text{ and } \delta_k = 1]$, and $R_n(\tau)$ is defined as $R_n(\tau) = \sum_{k=1}^{N^a} w_k I[y_k \ge \tau]$. In the definition of $R_n(\tau)$, the left-truncation information is not used, because it was used along with p to add the observations.

If the original data are a combination of left- and right-censored data, then Turnbull's method is applied to the appended set that contains no left-truncated observations.

Supplying EDF Estimates to Functions and Subroutines

The parameter initialization subroutines in distribution models and some predefined utility functions require EDF estimates. For more information, see the sections "Defining a Severity Distribution Model with the FCMP Procedure" on page 2119 and "Predefined Utility Functions" on page 2131.

PROC SEVERITY supplies the EDF estimates to these subroutines and functions by using two arrays, `x` and `F`, the dimension of each array, and a type of the EDF estimates. The type identifies how the EDF estimates are computed and stored. They are as follows:

Type 1 specifies that EDF estimates are computed using the STANDARD method; that is, the data that are used for estimation are neither censored nor truncated.

Type 2 specifies that EDF estimates are computed using either the KAPLANMEIER or the MODIFIEDKM method; that is, the data that are used for estimation are subject to truncation and one type of censoring (left or right, but not both).

Type 3 specifies that EDF estimates are computed using the TURNBULL method; that is, the data that are used for estimation are subject to both left- and right-censoring. The data might or might not be truncated.

For Types 1 and 2, the EDF estimates are stored in arrays x and F of dimension N such that the following holds,

$$F_n(y) = \begin{cases} 0 & \text{if } y < x[1] \\ F[k] & \text{if } x[k] \le y < x[k+1], k = 1, \ldots, N-1 \\ F[N] & \text{if } x[N] \le y \end{cases}$$

where $[k]$ denotes kth element of the array ($[1]$ denotes the first element of the array).

For Type 3, the EDF estimates are stored in arrays x and F of dimension N such that the following holds:

$$F_n(y) = \begin{cases} 0 & \text{if } y < x[1] \\ \text{undefined} & \text{if } x[2k-1] \le y < x[2k], k = 1, \ldots, (N-1)/2 \\ F[2k] = F[2k+1] & \text{if } x[2k] \le y < x[2k+1], k = 1, \ldots, (N-1)/2 \\ F[N] & \text{if } x[N] \le y \end{cases}$$

Although the behavior of EDF is theoretically undefined for the interval $[x[2k-1], x[2k])$, for computational purposes, all predefined functions and subroutines assume that the EDF increases linearly from $F[2k-1]$ to $F[2k]$ in that interval if $x[2k-1] < x[2k]$. If $x[2k-1] = x[2k]$, which can happen when the EDF is estimated from a combination of uncensored and interval-censored data, the predefined functions and subroutines assume that $F_n(x[2k-1]) = F_n(x[2k]) = F[2k]$.

Statistics of Fit

PROC SEVERITY computes and reports various statistics of fit to indicate how well the estimated model fits the data. The statistics belong to two categories: likelihood-based statistics and EDF-based statistics. Neg2LogLike, AIC, AICC, and BIC are likelihood-based statistics, and KS, AD, and CvM are EDF-based statistics. The following subsections provide definitions of each.

Likelihood-Based Statistics of Fit

Let $y_i, i = 1, \ldots, N$, denote the response variable values. Let L be the likelihood as defined in the section "Likelihood Function" on page 2090. Let p denote the number of model parameters that are estimated. Note that $p = p_d + (k - k_r)$, where p_d is the number of distribution parameters, k is the number of all regression parameters, and k_r is the number of regression parameters that are found to be linearly dependent (redundant) on other regression parameters. Given this notation, the likelihood-based statistics are defined as follows:

Neg2LogLike The log likelihood is reported as

$$\text{Neg2LogLike} = -2\log(L)$$

The multiplying factor -2 makes it easy to compare it to the other likelihood-based statistics. A model that has a smaller value of Neg2LogLike is deemed better.

AIC Akaike's information criterion (AIC) is defined as

$$\text{AIC} = -2\log(L) + 2p$$

A model that has a smaller AIC value is deemed better.

AICC

The corrected Akaike's information criterion (AICC) is defined as

$$\text{AICC} = -2\log(L) + \frac{2Np}{N-p-1}$$

A model that has a smaller AICC value is deemed better. It corrects the finite-sample bias that AIC has when N is small compared to p. AICC is related to AIC as

$$\text{AICC} = \text{AIC} + \frac{2p(p+1)}{N-p-1}$$

As N becomes large compared to p, AICC converges to AIC. AICC is usually recommended over AIC as a model selection criterion.

BIC

The Schwarz Bayesian information criterion (BIC) is defined as

$$\text{BIC} = -2\log(L) + p\log(N)$$

A model that has a smaller BIC value is deemed better.

EDF-Based Statistics

This class of statistics is based on the difference between the estimate of the cumulative distribution function (CDF) and the estimate of the empirical distribution function (EDF). A model that has a smaller value of the chosen EDF-based statistic is deemed better.

Let $y_i, i = 1, \ldots, N$, denote the sample of N values of the response variable. Let w_i denote the normalized weight of the ith observation. If w_i^o denotes the original, unnormalized weight of the ith observation, then $w_i = N w_i^o / (\sum_{i=1}^{N} w_i^o)$. Let N_u denote the number of observations with unique (nonduplicate) values of the response variable. Let $W_i = \sum_{j=1}^{N} w_j I[y_j = y_i]$ denote the total weight of observations with a value y_i, where I is an indicator function. Let $r_i = \sum_{j=1}^{N} w_j I[y_j \le y_i]$ denote the total weight of observations with a value less than or equal to y_i. Let $W = \sum_{i=1}^{N_u} W_i$ denote the total weight of all observations. Use of normalized weights implies that $W = N$.

Let $F_n(y_i)$ denote the EDF estimate that is computed by using the method that you specify in the EMPIRICALCDF= option. Let $Z_i = \hat{F}(y_i)$ denote the estimate of the CDF. Let $F_n(Z_i)$ denote the EDF estimate of Z_i values that are computed using the same method that is used to compute the EDF of y_i values. Using the probability integral transformation, if $F(y)$ is the true distribution of the random variable Y, then the random variable $Z = F(y)$ is uniformly distributed between 0 and 1 (D'Agostino and Stephens 1986, Ch. 4). Thus, comparing $F_n(y_i)$ with $\hat{F}(y_i)$ is equivalent to comparing $F_n(Z_i)$ with $\hat{F}(Z_i) = Z_i$ (uniform distribution).

Note the following two points regarding which CDF estimates are used for computing the test statistics:

- If you specify regression effects, then the CDF estimates Z_i that are used for computing the EDF test statistics are from a mixture distribution. For more information, see the section "CDF and PDF Estimates with Regression Effects" on page 2097.
- If the EDF estimates are conditional because of the truncation information, then each unconditional estimate Z_i is converted to a conditional estimate using the method described in the section "Truncation and Conditional CDF Estimates" on page 2089.

In the following, it is assumed that Z_i denotes an appropriate estimate of the CDF if you specify any truncation or regression effects. Given this, the EDF-based statistics of fit are defined as follows:

KS The Kolmogorov-Smirnov (KS) statistic computes the largest vertical distance between the CDF and the EDF. It is formally defined as follows:

$$\text{KS} = \sup_y |F_n(y) - F(y)|$$

If the STANDARD method is used to compute the EDF, then the following formula is used:

$$D^+ = \max_i(\frac{r_i}{W} - Z_i)$$
$$D^- = \max_i(Z_i - \frac{r_{i-1}}{W})$$
$$\text{KS} = \sqrt{W}\ \max(D^+, D^-) + \frac{0.19}{\sqrt{W}}$$

Note that r_0 is assumed to be 0.

If the method used to compute the EDF is any method other than the STANDARD method, then the following formula is used:

$$D^+ = \max_i(F_n(Z_i) - Z_i),\ \text{if } F_n(Z_i) \geq Z_i$$
$$D^- = \max_i(Z_i - F_n(Z_i)),\ \text{if } F_n(Z_i) < Z_i$$
$$\text{KS} = \sqrt{W}\ \max(D^+, D^-) + \frac{0.19}{\sqrt{W}}$$

AD The Anderson-Darling (AD) statistic is a quadratic EDF statistic that is proportional to the expected value of the weighted squared difference between the EDF and CDF. It is formally defined as follows:

$$\text{AD} = N \int_{-\infty}^{\infty} \frac{(F_n(y) - F(y))^2}{F(y)(1 - F(y))} dF(y)$$

If the STANDARD method is used to compute the EDF, then PROC SEVERITY uses the following formula:

$$\text{AD} = -W - \frac{1}{W} \sum_{i=1}^{N_u} W_i\ [(2r_i - 1)\log(Z_i) + (2W + 1 - 2r_i)\log(1 - Z_i)]$$

If the method used to compute the EDF is any method other than the STANDARD method, then the statistic can be computed by using the following two pieces of information:

- If the EDF estimates are computed using the KAPLANMEIER or MODIFIEDKM methods, then EDF is a step function such that the estimate $F_n(z)$ is a constant equal to $F_n(Z_{i-1})$ in interval $[Z_{i-1}, Z_i]$. If the EDF estimates are computed using the TURNBULL method, then there are two types of intervals: one in which the EDF curve is constant and the other in which the EDF curve is theoretically undefined. For computational purposes, it is assumed that the EDF curve is linear for the latter type of the interval. For each method, the EDF estimate $F_n(y)$ at y can be written as

  $$F_n(z) = F_n(Z_{i-1}) + S_i(z - Z_{i-1}),\ \text{for } z \in [Z_{i-1}, Z_i]$$

  where S_i is the slope of the line defined as

  $$S_i = \frac{F_n(Z_i) - F_n(Z_{i-1})}{Z_i - Z_{i-1}}$$

  For the KAPLANMEIER or MODIFIEDKM method, $S_i = 0$ in each interval.

- Using the probability integral transform $z = F(y)$, the formula simplifies to

$$\text{AD} = N \int_{-\infty}^{\infty} \frac{(F_n(z) - z)^2}{z(1-z)} dz$$

The computation formula can then be derived from the approximation,

$$\begin{aligned}
\text{AD} &= N \sum_{i=1}^{K+1} \int_{Z_{i-1}}^{Z_i} \frac{(F_n(z) - z)^2}{z(1-z)} dz \\
&= N \sum_{i=1}^{K+1} \int_{Z_{i-1}}^{Z_i} \frac{(F_n(Z_{i-1}) + S_i(z - Z_{i-1}) - z)^2}{z(1-z)} dz \\
&= N \sum_{i=1}^{K+1} \int_{Z_{i-1}}^{Z_i} \frac{(P_i - Q_i z)^2}{z(1-z)} dz
\end{aligned}$$

where $P_i = F_n(Z_{i-1}) - S_i Z_{i-1}$, $Q_i = 1 - S_i$, and K is the number of points at which the EDF estimate are computed. For the TURNBULL method, $K = 2k$ for some k.

Assuming $Z_0 = 0$, $Z_{K+1} = 1$, $F_n(0) = 0$, and $F_n(Z_K) = 1$ yields the computation formula,

$$\begin{aligned}
\text{AD} = &- N(Z_1 + \log(1 - Z_1) + \log(Z_K) + (1 - Z_K)) \\
&+ N \sum_{i=2}^{K} \left[P_i^2 A_i - (Q_i - P_i)^2 B_i - Q_i^2 C_i \right]
\end{aligned}$$

where $A_i = \log(Z_i) - \log(Z_{i-1})$, $B_i = \log(1 - Z_i) - \log(1 - Z_{i-1})$, and $C_i = Z_i - Z_{i-1}$.

If EDF estimates are computed using the KAPLANMEIER or MODIFIEDKM method, then $P_i = F_n(Z_{i-1})$ and $Q_i = 1$, which simplifies the formula as

$$\begin{aligned}
\text{AD} = &- N(1 + \log(1 - Z_1) + \log(Z_K)) \\
&+ N \sum_{i=2}^{K} \left[F_n(Z_{i-1})^2 A_i - (1 - F_n(Z_{i-1}))^2 B_i \right]
\end{aligned}$$

CvM The Cramér–von Mises (CvM) statistic is a quadratic EDF statistic that is proportional to the expected value of the squared difference between the EDF and CDF. It is formally defined as follows:

$$\text{CvM} = N \int_{-\infty}^{\infty} (F_n(y) - F(y))^2 dF(y)$$

If the STANDARD method is used to compute the EDF, then the following formula is used:

$$\text{CvM} = \frac{1}{12W} + \sum_{i=1}^{N_u} W_i \left(Z_i - \frac{(2r_i - 1)}{2W} \right)^2$$

If the method used to compute the EDF is any method other than the STANDARD method, then the statistic can be computed by using the following two pieces of information:

- As described previously for the AD statistic, the EDF estimates are assumed to be piecewise linear such that the estimate $F_n(y)$ at y is

$$F_n(z) = F_n(Z_{i-1}) + S_i(z - Z_{i-1}), \text{ for } z \in [Z_{i-1}, Z_i]$$

  where S_i is the slope of the line defined as

$$S_i = \frac{F_n(Z_i) - F_n(Z_{i-1})}{Z_i - Z_{i-1}}$$

  For the KAPLANMEIER or MODIFIEDKM method, $S_i = 0$ in each interval.

- Using the probability integral transform $z = F(y)$, the formula simplifies to

$$\text{CvM} = N \int_{-\infty}^{\infty} (F_n(z) - z)^2 dz$$

The computation formula can then be derived from the following approximation,

$$\begin{aligned}
\text{CvM} &= N \sum_{i=1}^{K+1} \int_{Z_{i-1}}^{Z_i} (F_n(z) - z)^2 dz \\
&= N \sum_{i=1}^{K+1} \int_{Z_{i-1}}^{Z_i} (F_n(Z_{i-1}) + S_i(z - Z_{i-1}) - z)^2 dz \\
&= N \sum_{i=1}^{K+1} \int_{Z_{i-1}}^{Z_i} (P_i - Q_i z)^2 dz
\end{aligned}$$

where $P_i = F_n(Z_{i-1}) - S_i Z_{i-1}$, $Q_i = 1 - S_i$, and K is the number of points at which the EDF estimate are computed. For the TURNBULL method, $K = 2k$ for some k.

Assuming $Z_0 = 0$, $Z_{K+1} = 1$, and $F_n(0) = 0$ yields the following computation formula,

$$\text{CvM} = N \frac{Z_1^3}{3} + N \sum_{i=2}^{K+1} \left[P_i^2 A_i - P_i Q_i B_i - \frac{Q_i^2}{3} C_i \right]$$

where $A_i = Z_i - Z_{i-1}$, $B_i = Z_i^2 - Z_{i-1}^2$, and $C_i = Z_i^3 - Z_{i-1}^3$.

If EDF estimates are computed using the KAPLANMEIER or MODIFIEDKM method, then $P_i = F_n(Z_{i-1})$ and $Q_i = 1$, which simplifies the formula as

$$\text{CvM} = \frac{N}{3} + N \sum_{i=2}^{K+1} \left[F_n(Z_{i-1})^2 (Z_i - Z_{i-1}) - F_n(Z_{i-1})(Z_i^2 - Z_{i-1}^2) \right]$$

which is similar to the formula proposed by Koziol and Green (1976).

Defining a Severity Distribution Model with the FCMP Procedure

A *severity distribution model* consists of a set of functions and subroutines that are defined using the FCMP procedure. The FCMP procedure is part of Base SAS software. Each function or subroutine must be named as <*distribution-name*>_<*keyword*>, where *distribution-name* is the identifying short name of the distribution and *keyword* identifies one of the functions or subroutines. The total length of the name should not exceed 32. Each function or subroutine must have a specific signature, which consists of the number of arguments, sequence and types of arguments, and return value type. The summary of all the recognized function and subroutine names and their expected behavior is given in Table 28.17.

Consider the following points when you define a distribution model:

- When you define a function or subroutine requiring parameter arguments, the names and order of those arguments must be the same. Arguments other than the parameter arguments can have any name, but they must satisfy the requirements on their type and order.
- When the SEVERITY procedure invokes any function or subroutine, it provides the necessary input values according to the specified signature, and expects the function or subroutine to prepare the output and return it according to the specification of the return values in the signature.
- You can use most of the SAS programming statements and SAS functions that you can use in a DATA step for defining the FCMP functions and subroutines. However, there are a few differences in the capabilities of the DATA step and the FCMP procedure. To learn more, see the documentation of the FCMP procedure in the *Base SAS Procedures Guide*.
- You must specify either the PDF or the LOGPDF function. Similarly, you must specify either the CDF or the LOGCDF function. All other functions are optional, except when necessary for correct definition of the distribution. It is strongly recommended that you define the PARMINIT subroutine to provide a good set of initial values for the parameters. The information that PROC SEVERITY provides to the PARMINIT subroutine enables you to use popular initialization approaches based on the method of moments and the method of percentile matching, but you can implement any algorithm to initialize the parameters by using the values of the response variable and the estimate of its empirical distribution function.
- The LOWERBOUNDS subroutines should be defined if the lower bound on at least one distribution parameter is different from the default lower bound of 0. If you define a LOWERBOUNDS subroutine but do not set a lower bound for some parameter inside the subroutine, then that parameter is assumed to have no lower bound (or a lower bound of $-\infty$). Hence, it is recommended that you explicitly return the lower bound for each parameter when you define the LOWERBOUNDS subroutine.
- The UPPERBOUNDS subroutines should be defined if the upper bound on at least one distribution parameter is different from the default upper bound of ∞. If you define an UPPERBOUNDS subroutine but do not set an upper bound for some parameter inside the subroutine, then that parameter is assumed to have no upper bound (or a upper bound of ∞). Hence, it is recommended that you explicitly return the upper bound for each parameter when you define the UPPERBOUNDS subroutine.
- If you want to use the distribution in a model with regression effects, then make sure that the first parameter of the distribution is the scale parameter itself or a log-transformed scale parameter. If the first parameter is a log-transformed scale parameter, then you must define the SCALETRANSFORM function.

- In general, it is not necessary to define the gradient and Hessian functions, because the SEVERITY procedure uses an internal system to evaluate the required derivatives. The internal system typically computes the derivatives analytically. But it might not be able to do so if your function definitions use other functions that it cannot differentiate analytically. In such cases, derivatives are approximated using a finite difference method and a note is written to the SAS log to indicate the components that are differentiated using such approximations. PROC SEVERITY does reasonably well with these finite difference approximations. But, if you know of a way to compute the derivatives of such components analytically, then you should define the gradient and Hessian functions.

In order to use your distribution with PROC SEVERITY, you need to record the FCMP library that contains the functions and subroutines for your distribution and other FCMP libraries that contain FCMP functions or subroutines used within your distribution's functions and subroutines. Specify all those libraries in the CMPLIB= system option by using the OPTIONS global statement. For more information about the OPTIONS statement, see *SAS Global Statements: Reference*. For more information about the CMPLIB= system option, see *SAS System Options: Reference*.

Each predefined distribution mentioned in the section "Predefined Distributions" on page 2079 has a distribution model associated with it. The functions and subroutines of all those models are available in the Sashelp.Svrtdist library. The order of the parameters in the signatures of the functions and subroutines is the same as listed in Table 28.3. You do not need to use the CMPLIB= option in order to use the predefined distributions with PROC SEVERITY. However, if you need to use the functions or subroutines of the predefined distributions in SAS statements other than the PROC SEVERITY step (such as in a DATA step), then specify the Sashelp.Svrtdist library in the CMPLIB= system option by using the OPTIONS global statement prior to using them.

Table 28.17 shows functions and subroutines that define a distribution model, and subsections after the table provide more detail. The functions are listed in alphabetical order of the keyword suffix.

Table 28.17 List of Functions and Subroutines That Define a Distribution Model

Name	Type	Required	Expected to Return
*dist*_CDF	Function	YES[1]	Cumulative distribution function value
*dist*_CDFGRADIENT	Subroutine	NO	Gradient of the CDF
*dist*_CDFHESSIAN	Subroutine	NO	Hessian of the CDF
*dist*_CONSTANTPARM	Subroutine	NO	Constant parameters
*dist*_DESCRIPTION	Function	NO	Description of the distribution
*dist*_LOGCDF	Function	YES[1]	Log of cumulative distribution function value
*dist*_LOGCDFGRADIENT	Subroutine	NO	Gradient of the LOGCDF
*dist*_LOGCDFHESSIAN	Subroutine	NO	Hessian of the LOGCDF
*dist*_LOGPDF	Function	YES[2]	Log of probability density function value
*dist*_LOGPDFGRADIENT	Subroutine	NO	Gradient of the LOGPDF
*dist*_LOGPDFHESSIAN	Subroutine	NO	Hessian of the LOGPDF
*dist*_LOGSDF	Function	NO	Log of survival function value

Table 28.17 *continued*

Name	Type	Required	Expected to Return
*dist*_LOGSDFGRADIENT	Subroutine	NO	Gradient of the LOGSDF
*dist*_LOGSDFHESSIAN	Subroutine	NO	Hessian of the LOGSDF
*dist*_LOWERBOUNDS	Subroutine	NO	Lower bounds on parameters
*dist*_PARMINIT	Subroutine	NO	Initial values for parameters
*dist*_PDF	Function	YES[2]	Probability density function value
*dist*_PDFGRADIENT	Subroutine	NO	Gradient of the PDF
*dist*_PDFHESSIAN	Subroutine	NO	Hessian of the PDF
*dist*_QUANTILE	Function	NO	Quantile for a given CDF value
*dist*_SCALETRANSFORM	Function	NO	Type of relationship between the first distribution parameter and the scale parameter
*dist*_SDF	Function	NO	Survival function value
*dist*_SDFGRADIENT	Subroutine	NO	Gradient of the SDF
*dist*_SDFHESSIAN	Subroutine	NO	Hessian of the SDF
*dist*_UPPERBOUNDS	Subroutine	NO	Upper bounds on parameters

Notes:
1. Either the *dist*_CDF or the *dist*_LOGCDF function must be defined.
2. Either the *dist*_PDF or the *dist*_LOGPDF function must be defined.

The signature syntax and semantics of each function or subroutine are as follows:

*dist*_**CDF**
defines a function that returns the value of the cumulative distribution function (CDF) of the distribution at the specified values of the random variable and distribution parameters.

- *Type*: Function
- *Required*: YES
- *Number of arguments*: $m + 1$, where m is the number of distribution parameters
- *Sequence and type of arguments*:

  x Numeric value of the random variable at which the CDF value should be evaluated

  p1 Numeric value of the first parameter

  p2 Numeric value of the second parameter

  ...

  p*m* Numeric value of the *m*th parameter

- *Return value*: Numeric value that contains the CDF value $F(x; p_1, p_2, \ldots, p_m)$

If you want to consider this distribution as a candidate distribution when you estimate a response variable model with regression effects, then the first parameter of this distribution must be a scale

parameter or log-transformed scale parameter. In other words, if the distribution has a scale parameter, then the following equation must be satisfied:

$$F(x; p_1, p_2, \ldots, p_m) = F(\frac{x}{p_1}; 1, p_2, \ldots, p_m)$$

If the distribution has a log-transformed scale parameter, then the following equation must be satisfied:

$$F(x; p_1, p_2, \ldots, p_m) = F(\frac{x}{\exp(p_1)}; 0, p_2, \ldots, p_m)$$

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_CDF(x, P1, P2);
    /* Code to compute CDF by using x, P1, and P2 */

    F = <computed CDF>;
    return (F);
endsub;
```

*dist*_CONSTANTPARM

defines a subroutine that specifies constant parameters. A parameter is *constant* if it is required for defining a distribution but is not subject to optimization in PROC SEVERITY. Constant parameters are required to be part of the model in order to compute the PDF or the CDF of the distribution. Typically, values of these parameters are known a priori or estimated using some means other than the maximum likelihood method used by PROC SEVERITY. You can estimate them inside the *dist*_PARMINIT subroutine. Once initialized, the parameters remain constant in the context of PROC SEVERITY; that is, they retain their initial value. PROC SEVERITY estimates only the nonconstant parameters.

- *Type*: Subroutine
- *Required*: NO
- *Number of arguments*: *k*, where *k* is the number of constant parameters
- *Sequence and type of arguments*:

  constant parameter 1 Name of the first constant parameter
  ...
  constant parameter *k* Name of the *k*th constant parameter

- *Return value*: None

Here is a sample structure of the subroutine for a distribution named 'FOO' that has P3 and P5 as its constant parameters, assuming that distribution has at least three parameters:

```
subroutine FOO_CONSTANTPARM(p5, p3);
endsub;
```

Note the following points when you specify the constant parameters:

- At least one distribution parameter must be free to be optimized; that is, if a distribution has total *m* parameters, then *k* must be strictly less than *m*.

- If you want to use this distribution for modeling regression effects, then the first parameter must not be a constant parameter.
- The order of arguments in the signature of this subroutine does not matter as long as each argument's name matches the name of one of the parameters that are defined in the signature of the *dist*_PDF function.
- The constant parameters must be specified in signatures of all the functions and subroutines that accept distribution parameters as their arguments.
- You must provide a nonmissing initial value for each constant parameter by using one of the supported parameter initialization methods.

***dist*_DESCRIPTION**

defines a function that returns a description of the distribution.

- *Type*: Function
- *Required*: NO
- *Number of arguments*: None
- *Sequence and type of arguments*: Not applicable
- *Return value*: Character value containing a description of the distribution

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_DESCRIPTION() $48;
    length desc $48;
    desc = "A model for a continuous distribution named foo";
    return (desc);
endsub;
```

There is no restriction on the length of the description (the length of 48 used in the previous example is for illustration purposes only). However, if the length is greater than 256, then only the first 256 characters appear in the displayed output and in the _DESCRIPTION_ variable of the OUTMODELINFO= data set. Hence, the recommended length of the description is less than or equal to 256.

dist*_LOG*core

defines a function that returns the natural logarithm of the specified *core* function of the distribution at the specified values of the random variable and distribution parameters. The *core* keyword can be PDF, CDF, or SDF.

- *Type*: Function
- *Required*: YES only if *core* is PDF or CDF and you have not defined that *core* function; otherwise, NO
- *Number of arguments*: $m + 1$, where m is the number of distribution parameters
- *Sequence and type of arguments*:

  x Numeric value of the random variable at which the natural logarithm of the *core* function should be evaluated

  p1 Numeric value of the first parameter

p2 Numeric value of the second parameter
...
p*m* Numeric value of the *m*th parameter

- *Return value*: Numeric value that contains the natural logarithm of the *core* function

Here is a sample structure of the function for the core function PDF of a distribution named 'FOO':

```
function FOO_LOGPDF(x, P1, P2);
    /* Code to compute LOGPDF by using x, P1, and P2 */

    l = <computed LOGPDF>;
    return (l);
endsub;
```

*dist*_LOWERBOUNDS

defines a subroutine that returns lower bounds for the parameters of the distribution. If this subroutine is not defined for a given distribution, then the SEVERITY procedure assumes a lower bound of 0 for each parameter. If a lower bound of l_i is returned for a parameter p_i, then the SEVERITY procedure assumes that $l_i < p_i$ (strict inequality). If a missing value is returned for some parameter, then the SEVERITY procedure assumes that there is no lower bound for that parameter (equivalent to a lower bound of $-\infty$).

- *Type*: Subroutine
- *Required*: NO
- *Number of arguments*: *m*, where *m* is the number of distribution parameters
- *Sequence and type of arguments*:

  p1 Output argument that returns the lower bound on the first parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.

  p2 Output argument that returns the lower bound on the second parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.
  ...

  p*m* Output argument that returns the lower bound on the *m*th parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.

- *Return value*: The results, lower bounds on parameter values, should be returned in the parameter arguments of the subroutine.

Here is a sample structure of the subroutine for a distribution named 'FOO':

```
subroutine FOO_LOWERBOUNDS(p1, p2);
    outargs p1, p2;

    p1 = <lower bound for P1>;
    p2 = <lower bound for P2>;
endsub;
```

***dist*_PARMINIT**

defines a subroutine that returns the initial values for the distribution's parameters given an empirical distribution function (EDF) estimate.

- *Type*: Subroutine
- *Required*: NO
- *Number of arguments*: $m + 4$, where m is the number of distribution parameters
- *Sequence and type of arguments*:

dim	Input numeric value that contains the dimension of the x, nx, and F array arguments.
x{*}	Input numeric array of dimension *dim* that contains values of the random variables at which the EDF estimate is available. It can be assumed that x contains values in an increasing order. In other words, if $i < j$, then x[i] < x[j].
nx{*}	Input numeric array of dimension *dim*. Each nx[i] contains the number of observations in the original data that have the value x[i].
F{*}	Input numeric array of dimension *dim*. Each F[i] contains the EDF estimate for x[i]. This estimate is computed by the SEVERITY procedure based on the options that you specify in the LOSS statement and the EMPIRICALCDF= option.
Ftype	Input numeric value that contains the type of the EDF estimate that is stored in x and F. For definitions of types, see the section "Supplying EDF Estimates to Functions and Subroutines" on page 2113.
p1	Output argument that returns the initial value of the first parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.
p2	Output argument that returns the initial value of the second parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.
...	
p*m*	Output argument that returns the initial value of the *m*th parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.

- *Return value*: The results, initial values of the parameters, should be returned in the parameter arguments of the subroutine.

Here is a sample structure of the subroutine for a distribution named 'FOO':

```
subroutine FOO_PARMINIT(dim, x{*}, nx{*}, F{*}, Ftype, p1, p2);
    outargs p1, p2;

    /* Code to initialize values of P1 and P2 by using
       dim, x, nx, and F */

    p1 = <initial value for p1>;
    p2 = <initial value for p2>;
endsub;
```

*dist*_**PDF**

defines a function that returns the value of the probability density function (PDF) of the distribution at the specified values of the random variable and distribution parameters.

- *Type*: Function
- *Required*: YES
- *Number of arguments*: $m + 1$, where m is the number of distribution parameters
- *Sequence and type of arguments*:

  x Numeric value of the random variable at which the PDF value should be evaluated

  p1 Numeric value of the first parameter

  p2 Numeric value of the second parameter

  ...

  pm Numeric value of the mth parameter

- *Return value*: Numeric value that contains the PDF value $f(x; p_1, p_2, \ldots, p_m)$

If you want to consider this distribution as a candidate distribution when you estimate a response variable model with regression effects, then the first parameter of this distribution must be a scale parameter or log-transformed scale parameter. In other words, if the distribution has a scale parameter, then the following equation must be satisfied:

$$f(x; p_1, p_2, \ldots, p_m) = \frac{1}{p_1} f(\frac{x}{p_1}; 1, p_2, \ldots, p_m)$$

If the distribution has a log-transformed scale parameter, then the following equation must be satisfied:

$$f(x; p_1, p_2, \ldots, p_m) = \frac{1}{\exp(p_1)} f(\frac{x}{\exp(p_1)}; 0, p_2, \ldots, p_m)$$

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_PDF(x, P1, P2);
    /* Code to compute PDF by using x, P1, and P2 */

    f = <computed PDF>;
    return (f);
endsub;
```

*dist*_**QUANTILE**

defines a function that returns the quantile of the distribution at the specified value of the CDF for the specified values of distribution parameters.

- *Type*: Function
- *Required*: NO
- *Number of arguments*: $m + 1$, where m is the number of distribution parameters
- *Sequence and type of arguments*:

cdf Numeric value of the cumulative distribution function (CDF) for which the quantile should be evaluated

p1 Numeric value of the first parameter

p2 Numeric value of the second parameter

...

p*m* Numeric value of the *m*th parameter

- *Return value*: Numeric value that contains the quantile $F^{-1}(\text{cdf}; p_1, p_2, \ldots, p_m)$

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_QUANTILE(c, P1, P2);
    /* Code to compute quantile by using c, P1, and P2 */

    Q = <computed quantile>;
    return (Q);
endsub;
```

*dist*_SCALETRANSFORM

defines a function that returns a keyword to identify the transform that needs to be applied to the scale parameter to convert it to the first parameter of the distribution.

If you want to use this distribution for modeling regression effects, then the first parameter of this distribution must be a scale parameter. However, for some distributions, a typical or convenient parameterization might not have a scale parameter, but one of the parameters can be a simple transform of the scale parameter. As an example, consider a typical parameterization of the lognormal distribution with two parameters, location μ and shape σ, for which the PDF is defined as follows:

$$f(x;\mu,\sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\log(x)-\mu}{\sigma}\right)^2}$$

You can reparameterize this distribution to contain a parameter θ instead of the parameter μ such that $\mu = \log(\theta)$. The parameter θ would then be a scale parameter. However, if you want to specify the distribution in terms of μ and σ (which is a more recognized form of the lognormal distribution) and still allow it as a candidate distribution for estimating regression effects, then instead of writing another distribution with parameters θ and σ, you can simply define the distribution with μ as the first parameter and specify that it is the logarithm of the scale parameter.

- *Type*: Function
- *Required*: NO
- *Number of arguments*: None
- *Sequence and type of arguments*: Not applicable
- *Return value*: Character value that contains one of the following keywords:

LOG	specifies that the first parameter is the logarithm of the scale parameter.
IDENTITY	specifies that the first parameter is a scale parameter without any transformation.

If you do not specify this function, then the IDENTITY transform is assumed.

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_SCALETRANSFORM() $8;
    length xform $8;
    xform = "IDENTITY";
    return (xform);
endsub;
```

*dist*_**SDF**

defines a function that returns the value of the survival distribution function (SDF) of the distribution at the specified values of the random variable and distribution parameters.

- *Type*: Function
- *Required*: NO
- *Number of arguments*: $m + 1$, where m is the number of distribution parameters
- *Sequence and type of arguments*:

  x Numeric value of the random variable at which the SDF value should be evaluated

  p1 Numeric value of the first parameter

  p2 Numeric value of the second parameter

  ...

  p*m* Numeric value of the *m*th parameter

- *Return value*: Numeric value that contains the SDF value $S(x; p_1, p_2, \ldots, p_m)$

If you want to consider this distribution as a candidate distribution when estimating a response variable model with regression effects, then the first parameter of this distribution must be a scale parameter or log-transformed scale parameter. In other words, if the distribution has a scale parameter, then the following equation must be satisfied:

$$S(x; p_1, p_2, \ldots, p_m) = S(\frac{x}{p_1}; 1, p_2, \ldots, p_m)$$

If the distribution has a log-transformed scale parameter, then the following equation must be satisfied:

$$S(x; p_1, p_2, \ldots, p_m) = S(\frac{x}{\exp(p_1)}; 0, p_2, \ldots, p_m)$$

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_SDF(x, P1, P2);
    /* Code to compute SDF by using x, P1, and P2 */

    S = <computed SDF>;
    return (S);
endsub;
```

*dist*_UPPERBOUNDS

defines a subroutine that returns upper bounds for the parameters of the distribution. If this subroutine is not defined for a given distribution, then the SEVERITY procedure assumes that there is no upper bound for any of the parameters. If an upper bound of u_i is returned for a parameter p_i, then the SEVERITY procedure assumes that $p_i < u_i$ (strict inequality). If a missing value is returned for some parameter, then the SEVERITY procedure assumes that there is no upper bound for that parameter (equivalent to an upper bound of ∞).

- *Type*: Subroutine
- *Required*: NO
- *Number of arguments*: *m*, where *m* is the number of distribution parameters
- *Sequence and type of arguments*:

  p1 — Output argument that returns the upper bound on the first parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.

  p2 — Output argument that returns the upper bound on the second parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.

  . . .

  p*m* — Output argument that returns the upper bound on the *m*th parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.

- *Return value*: The results, upper bounds on parameter values, should be returned in the parameter arguments of the subroutine.

Here is a sample structure of the subroutine for a distribution named 'FOO':

```
subroutine FOO_UPPERBOUNDS(p1, p2);
    outargs p1, p2;

    p1 = <upper bound for P1>;
    p2 = <upper bound for P2>;
endsub;
```

*dist_core*GRADIENT

defines a subroutine that returns the gradient vector of the specified *core* function of the distribution at the specified values of the random variable and distribution parameters. The *core* keyword can be PDF, CDF, SDF, LOGPDF, LOGCDF, or LOGSDF.

- *Type*: Subroutine
- *Required*: NO

- *Number of arguments*: $m + 2$, where m is the number of distribution parameters
- *Sequence and type of arguments*:

x	Numeric value of the random variable at which the gradient should be evaluated
p1	Numeric value of the first parameter
p2	Numeric value of the second parameter
	...
p*m*	Numeric value of the *m*th parameter
grad{*}	Output numeric array of size m that contains the gradient vector evaluated at the specified values. If h denotes the value of the *core* function, then the expected order of the values in the array is as follows: $\frac{\partial h}{\partial p_1}\ \frac{\partial h}{\partial p_2} \cdots \frac{\partial h}{\partial p_m}$

- *Return value*: Numeric array that contains the gradient evaluated at x for the parameter values $(p_1, p_2, \ldots, p_m)$

Here is a sample structure of the function for the core function CDF of a distribution named 'FOO':

```
subroutine FOO_CDFGRADIENT(x, P1, P2, grad{*});
    outargs grad;

    /* Code to compute gradient by using x, P1, and P2 */
    grad[1] = <partial derivative of CDF w.r.t. P1
               evaluated at x, P1, P2>;
    grad[2] = <partial derivative of CDF w.r.t. P2
               evaluated at x, P1, P2>;
endsub;
```

*dist_core*__HESSIAN__

defines a subroutine that returns the Hessian matrix of the specified *core* function of the distribution at the specified values of the random variable and distribution parameters. The *core* keyword can be PDF, CDF, SDF, LOGPDF, LOGCDF, or LOGSDF.

- *Type*: Subroutine
- *Required*: NO
- *Number of arguments*: $m + 2$, where m is the number of distribution parameters
- *Sequence and type of arguments*:

x	Numeric value of the random variable at which the Hessian matrix should be evaluated
p1	Numeric value of the first parameter
p2	Numeric value of the second parameter
	...
p*m*	Numeric value of the *m*th parameter
hess{*}	Output numeric array of size $m(m+1)/2$ that contains the lower triangular portion of the Hessian matrix in a packed vector form, evaluated at the specified values. If h denotes the value of the *core* function, then the expected order of the values in the array is as follows: $\frac{\partial^2 h}{\partial p_1^2} \mid \frac{\partial^2 h}{\partial p_1 \partial p_2}\ \frac{\partial^2 h}{\partial p_2^2} \mid \cdots \mid \frac{\partial^2 h}{\partial p_1 \partial p_m}\ \frac{\partial^2 h}{\partial p_2 \partial p_m} \cdots \frac{\partial^2 h}{\partial p_m^2}$

- *Return value*: Numeric array that contains the lower triangular portion of the Hessian matrix evaluated at x for the parameter values $(p_1, p_2, \ldots, p_m)$

Here is a sample structure of the subroutine for the core function LOGSDF of a distribution named 'FOO':

```
subroutine FOO_LOGSDFHESSIAN(x, P1, P2, hess{*});
    outargs hess;

    /* Code to compute Hessian by using x, P1, and P2 */
    hess[1] = <second order partial derivative of LOGSDF
               w.r.t. P1 evaluated at x, P1, P2>;
    hess[2] = <second order partial derivative of LOGSDF
               w.r.t. P1 and P2 evaluated at x, P1, P2>;
    hess[3] = <second order partial derivative of LOGSDF
               w.r.t. P2 evaluated at x, P1, P2>;
endsub;
```

Predefined Utility Functions

The following predefined utility functions are provided with the SEVERITY procedure and are available in the Sashelp.Svrtdist library:

SVRTUTIL_EDF

This function computes the empirical distribution function (EDF) estimate at the specified value of the random variable given the EDF estimate for a sample.

- *Type*: Function
- *Signature*: SVRTUTIL_EDF(y, n, x{*}, F{*}, Ftype)
- *Argument description*:

y	Value of the random variable at which the EDF estimate is desired
n	Dimension of the x and F input arrays
x{*}	Input numeric array of dimension n that contains values of the random variable observed in the sample. These values are sorted in nondecreasing order.
F{*}	Input numeric array of dimension n in which each F[i] contains the EDF estimate for x[i]. These values must be sorted in nondecreasing order.
Ftype	Type of the empirical estimate that is stored in the x and F arrays. For definitions of types, see the section "Supplying EDF Estimates to Functions and Subroutines" on page 2113.

- *Return value*: The EDF estimate at y

The type of the sample EDF estimate determines how the EDF estimate at y is computed. For more information, see the section "Supplying EDF Estimates to Functions and Subroutines" on page 2113.

SVRTUTIL_EMPLIMMOMENT

This function computes the empirical estimate of the limited moment of specified order for the specified upper limit, given the EDF estimate for a sample.

- *Type*: Function
- *Signature*: SVRTUTIL_EMPLIMMOMENT(k, u, n, x{*}, F{*}, Ftype)
- *Argument description*:

  k — Order of the desired empirical limited moment

  u — Upper limit on the value of the random variable to be used in the computation of the desired empirical limited moment

  n — Dimension of the *x* and *F* input arrays

  x{*} — Input numeric array of dimension *n* that contains values of the random variable observed in the sample. These values are sorted in nondecreasing order.

  F{*} — Input numeric array of dimension *n* in which each F[*i*] contains the EDF estimate for x[*i*]. These values must be sorted in nondecreasing order.

  Ftype — Type of the empirical estimate that is stored in the *x* and *F* arrays. For definitions of types, see the section "Supplying EDF Estimates to Functions and Subroutines" on page 2113.

- *Return value*: The desired empirical limited moment

The empirical limited moment is computed by using the empirical estimate of the CDF. If $F_n(x)$ denotes the EDF at x, then the empirical limited moment of order k with upper limit u is defined as

$$E_n[(X \wedge u)^k] = k \int_0^u (1 - F_n(x)) x^{k-1} dx$$

The SVRTUTIL_EMPLIMMOMENT function uses the piecewise linear nature of $F_n(x)$ as described in the section "Supplying EDF Estimates to Functions and Subroutines" on page 2113 to compute the integration.

SVRTUTIL_HILLCUTOFF

This function computes an estimate of the value where the right tail of a distribution is expected to begin. The function implements the algorithm described in Danielsson et al. 2001. The description of the algorithm uses the following notation:

n — Number of observations in the original sample

B — Number of bootstrap samples to draw

m_1 — Size of the bootstrap sample in the first step of the algorithm ($m_1 < n$)

$x_{(i)}^{j,m}$ — ith order statistic of jth bootstrap sample of size m ($1 \leq i \leq m, 1 \leq j \leq B$)

$x_{(i)}$ — ith order statistic of the original sample ($1 \leq i \leq n$)

Given the input sample x and values of B and m_1, the steps of the algorithm are as follows:

1. Take B bootstrap samples of size m_1 from the original sample.

2. Find the integer k_1 that minimizes the bootstrap estimate of the mean squared error:

$$k_1 = \arg \min_{1 \le k < m_1} Q(m_1, k)$$

3. Take B bootstrap samples of size $m_2 = m_1^2/n$ from the original sample.
4. Find the integer k_2 that minimizes the bootstrap estimate of the mean squared error:

$$k_2 = \arg \min_{1 \le k < m_2} Q(m_2, k)$$

5. Compute the integer k_{opt}, which is used for computing the cutoff point:

$$k_{\text{opt}} = \frac{k_1^2}{k_2} \left(\frac{\log(k_1)}{2\log(m_1) - \log(k_1)} \right)^{2-2\log(k_1)/\log(m_1)}$$

6. Set the cutoff point equal to $x_{(k_{\text{opt}}+1)}$.

The bootstrap estimate of the mean squared error is computed as

$$Q(m,k) = \frac{1}{B} \sum_{j=1}^{B} \text{MSE}_j(m,k)$$

The mean squared error of jth bootstrap sample is computed as

$$\text{MSE}_j(m,k) = (M_j(m,k) - 2(\gamma_j(m,k))^2)^2$$

where $M_j(m,k)$ is a control variate proposed by Danielsson et al. 2001,

$$M_j(m,k) = \frac{1}{k} \sum_{i=1}^{k} \left(\log(x^{j,m}_{(m-i+1)}) - \log(x^{j,m}_{(m-k)}) \right)^2$$

and $\gamma_j(m,k)$ is the Hill's estimator of the tail index (Hill 1975),

$$\gamma_j(m,k) = \frac{1}{k} \sum_{i=1}^{k} \log(x^{j,m}_{(m-i+1)}) - \log(x^{j,m}_{(m-k)})$$

This algorithm has two tuning parameters, B and m_1. The number of bootstrap samples B is chosen based on the availability of computational resources. The optimal value of m_1 is chosen such that the following ratio, $R(m_1)$, is minimized:

$$R(m_1) = \frac{(Q(m_1, k_1))^2}{Q(m_2, k_2)}$$

The SVRTUTIL_HILLCUTOFF utility function implements the preceding algorithm. It uses the grid search method to compute the optimal value of m_1.

- *Type*: Function
- *Signature*: SVRTUTIL_HILLCUTOFF(n, x{*}, b, s, status)
- *Argument description*:

n — Dimension of the array *x*

x{*} — Input numeric array of dimension *n* that contains the sample

b — Number of bootstrap samples used to estimate the mean squared error. If *b* is less than 10, then a default value of 50 is used.

s — Approximate number of steps used to search the optimal value of m_1 in the range $[n^{0.75}, n-1]$. If *s* is less than or equal to 1, then a default value of 10 is used.

status — Output argument that contains the status of the algorithm. If the algorithm succeeds in computing a valid cutoff point, then *status* is set to 0. If the algorithm fails, then *status* is set to 1.

- *Return value*: The cutoff value where the right tail is estimated to start. If the size of the input sample is inadequate ($n \leq 5$), then a missing value is returned and *status* is set to a missing value. If the algorithm fails to estimate a valid cutoff value (*status* = 1), then the fifth-largest value in the input sample is returned.

SVRTUTIL_PERCENTILE

This function computes the specified empirical percentile given the EDF estimates.

- *Type*: Function
- *Signature*: SVRTUTIL_PERCENTILE(p, n, x{*}, F{*}, Ftype)
- *Argument description*:

p — Desired percentile. The value must be in the interval (0,1). The function returns the 100*p*th percentile.

n — Dimension of the *x* and *F* input arrays

x{*} — Input numeric array of dimension *n* that contains values of the random variable observed in the sample. These values are sorted in nondecreasing order.

F{*} — Input numeric array of dimension *n* in which each F[*i*] contains the EDF estimate for x[*i*]. These values must be sorted in nondecreasing order.

Ftype — Type of the empirical estimate that is stored in the *x* and *F* arrays. For definitions of types, see the section "Supplying EDF Estimates to Functions and Subroutines" on page 2113.

- *Return value*: The 100*p*th percentile of the input sample

The method used to compute the percentile depends on the type of the EDF estimate (Ftype argument).

Ftype = 1 — Smoothed empirical estimates are computed using the method described in Klugman, Panjer, and Willmot (1998). Let $\lfloor x \rfloor$ denote the greatest integer less than or equal to x. Define $g = \lfloor p(n+1) \rfloor$ and $h = p(n+1) - g$. Then the empirical percentile $\hat{\pi}_p$ is defined as

$$\hat{\pi}_p = (1-h)x[g] + hx[g+1]$$

This method does not work if $p < 1/(n+1)$ or $p > n/(n+1)$. If $p < 1/(n+1)$, then the function returns $\hat{\pi}_p = x[1]/2$, which assumes that the EDF is 0 in the interval $[0, x[1])$. If $p > n/(n+1)$, then $\hat{\pi}_p = x[n]$.

Ftype = 2 If $p < F[1]$, then $\hat{\pi}_p = x[1]/2$, which assumes that the EDF is 0 in the interval $[0, x[1])$. If $|p - F[i]| < \epsilon$ for some value of i and $i < n$, then $\hat{\pi}_p$ is computed as

$$\hat{\pi}_p = \frac{x[i] + x[i+1]}{2}$$

where ϵ is a machine-precision constant as returned by the SAS function CONSTANT('MACEPS'). If $F[i-1] < p < F[i]$, then $\hat{\pi}_p$ is computed as

$$\hat{\pi}_p = x[i]$$

If $p \geq F[n]$, then $\hat{\pi}_p = x[n]$.

Ftype = 3 If $p < F[1]$, then $\hat{\pi}_p = x[1]/2$, which assumes that the EDF is 0 in the interval $[0, x[1])$. If $|p - F[i]| < \epsilon$ for some value of i and $i < n$, then $\hat{\pi}_p$ is computed as

$$\hat{\pi}_p = \frac{x[i] + x[i+1]}{2}$$

where ϵ is a machine-precision constant as returned by the SAS function CONSTANT('MACEPS'). If $F[i-1] < p < F[i]$, then $\hat{\pi}_p$ is computed as

$$\hat{\pi}_p = x[i-1] + (p - F[i-1])\frac{x[i] - x[i-1]}{F[i] - F[i-1]}$$

If $p \geq F[n]$, then $\hat{\pi}_p = x[n]$.

SVRTUTIL_RAWMOMENTS

This subroutine computes the raw moments of a sample.

- *Type*: Subroutine
- *Signature*: SVRTUTIL_RAWMOMENTS(n, x{*}, nx{*}, nRaw, raw{*})
- *Argument description*:

  n Dimension of the *x* and *nx* input arrays

  x{*} Input numeric array of dimension *n* that contains distinct values of the random variable that are observed in the sample

  nx{*} Input numeric array of dimension *n* in which each *nx*[*i*] contains the number of observations in the sample that have the value x[*i*]

  nRaw Desired number of raw moments. The output array *raw* contains the first *nRaw* raw moments.

  raw{*} Output array of raw moments. The *k*th element in the array (raw{*k*}) contains the *k*th raw moment, where $1 \leq k \leq$ nRaw.

- *Return value*: Numeric array *raw* that contains the first *nRaw* raw moments. The array contains missing values if the sample has no observations (that is, if all the values in the *nx* array add up to zero).

SVRTUTIL_SORT

This function sorts the given array of numeric values in an ascending or descending order.

- *Type*: Subroutine
- *Signature*: SVRTUTIL_SORT(n, x{*}, flag)
- *Argument description*:

n — Dimension of the input array *x*

x{*} — Numeric array that contains the values to be sorted at input. The subroutine uses the same array to return the sorted values.

flag — A numeric value that controls the sort order. If *flag* is 0, then the values are sorted in an ascending order. If *flag* has any value other than 0, then the values are sorted in descending order.

- *Return value*: Numeric array *x*, which is sorted in place (that is, the sorted array is stored in the same storage area occupied by the input array *x*)

You can use the following predefined functions when you use the FCMP procedure to define functions and subroutines. They are summarized here for your information. For more information, see the FCMP procedure documentation in *Base SAS Procedures Guide*.

INVCDF
: This function computes the quantile from any continuous probability distribution by numerically inverting the CDF of that distribution. You need to specify the CDF function of the distribution, the values of its parameters, and the cumulative probability to compute the quantile.

LIMMOMENT
: This function computes the limited moment of order k with upper limit u for any continuous probability distribution. The limited moment is defined as

$$E[(X \wedge u)^k] = \int_0^u x^k f(x)dx + \int_u^\infty u^k f(x)dx$$
$$= \int_0^u x^k f(x)dx + u^k(1 - F(u))$$

where $f(x)$ and $F(x)$ denote the PDF and the CDF of the distribution, respectively. The LIMMOMENT function uses the following alternate definition, which can be derived using integration-by-parts:

$$E[(X \wedge u)^k] = k \int_0^u (1 - F(x))x^{k-1}dx$$

You need to specify the CDF function of the distribution, the values of its parameters, and the values of k and u to compute the limited moment.

Scoring Functions

Scoring refers to the act of evaluating a distribution function, such as LOGPDF, SDF, or QUANTILE, on an observation by using the fitted parameter estimates of that distribution. You can do scoring in a DATA step by using the OUTEST= data set that you create with PROC SEVERITY. However, that approach requires some cumbersome programming. In order to simplify the scoring process, you can specify that PROC SEVERITY create scoring functions for each fitted distribution.

As an example, assume that you have fitted the Pareto distribution by using PROC SEVERITY and that it converges. Further assume that you want to use the fitted distribution to evaluate the probability of observing a loss value greater than some set of regulatory limits {L} that are encoded in a data set. You can simplify this scoring process as follows. First, in the PROC SEVERITY step that fits your distributions, you create the scoring functions library by specifying the OUTSCORELIB statement as illustrated in the following steps:

```
proc severity data=input;
   loss lossclaim;
   dist pareto;
   outscorelib outlib=sasuser.fitdist;
run;
```

Upon successful completion, if the Pareto distribution model has converged, then the Sasuser.Fitdist library contains the *SEV_SDF* scoring function in addition to other scoring functions, such as *SEV_PDF*, *SEV_LOGPDF*, and so on. Further, PROC SEVERITY also sets the CMPLIB system option to include the Sasuser.Fitdist library. If the set of limits {L} is recorded in the variable Limit in the scoring data set Work.Limits, then you can submit the following DATA step to compute the probability of seeing a loss greater than each limit:

```
data prob;
   set work.limits;
   exceedance_probability = sev_sdf(limit);
run;
```

Without the use of scoring functions, you can still perform this scoring task, but the DATA step that you need to write to accomplish it becomes more complicated and less flexible. For example, you would need to read the parameter estimates from some output created by PROC SEVERITY. To do that, you would need to know the parameter names, which are different for different distributions; this in turn would require you to write a specific DATA step for each distribution or to write a SAS macro. With the use of scoring functions, you can accomplish that task much more easily.

If you fit multiple distributions, then you can specify the COMMONPACKAGE option in the OUTSCORELIB statement as follows:

```
proc severity data=input;
   loss lossclaim;
   dist exp pareto weibull;
   outscorelib outlib=sasuser.fitdist commonpackage;
run;
```

The preceding step creates scoring functions such as *SEV_SDF_Exp*, *SEV_SDF_Pareto*, and *SEV_SDF_Weibull*. You can use them to compare the probabilities of exceeding the limit for different distributions by using the following DATA step:

```
data prob;
   set work.limits;
   exceedance_exp = sev_sdf_exp(limit);
   exceedance_pareto = sev_sdf_pareto(limit);
   exceedance_weibull = sev_sdf_weibull(limit);
run;
```

Formal Description

PROC SEVERITY creates a scoring function for each distribution function. A distribution function is defined as any function named *dist_suffix*, where *dist* is the name of a distribution that you specify in the DIST statement and the function's signature is identical to the signature of the required distribution function such as *dist*_CDF or *dist*_LOGCDF. For example, for the function 'FOO_BAR' to be a distribution function, you

must specify the distribution 'FOO' in the DIST statement and you must define 'FOO_BAR' in the following manner if the distribution 'FOO' has parameters named 'P1' and 'P2':

```
function FOO_BAR(y, P1, P2);
   /* Code to compute BAR by using y, P1, and P2 */
   R = <computed BAR>;
   return (R);
endsub;
```

For more information about the signature that defines a distribution function, see the description of the *dist*_CDF function in the section "Defining a Severity Distribution Model with the FCMP Procedure" on page 2119.

The name and package of the scoring function of a distribution function depend on whether you specify the COMMONPACKAGE option in the OUTSCORELIB statement.

When you do not specify the COMMONPACKAGE option, the scoring function that corresponds to the distribution function *dist_suffix* is named *SEV_suffix*, where *SEV_* is the standard prefix of all scoring functions. The scoring function is created in a package named *dist*. Each scoring function accepts only one argument, the value of the loss variable, and returns the same value as the value returned by the corresponding distribution function for the final estimates of the distribution's parameters. For example, for the preceding 'FOO_BAR' distribution function, the scoring function named 'SEV_BAR' is created in the package named 'FOO' and 'SEV_BAR' has the following signature:

```
function SEV_BAR(y);
   /* returns value of FOO_BAR for the supplied value
      of y and fitted values of P1, P2 */
endsub;
```

If you specify the COMMONPACKAGE option in the OUTSCORELIB statement, then the scoring function that corresponds to the distribution function *dist_suffix* is named *SEV_suffix_dist*, where *SEV_* is the standard prefix of all scoring functions. The scoring function is created in a package named *sevfit*. For example, for the preceding 'FOO_BAR' distribution function, if you specify the COMMONPACKAGE option, the scoring function named 'SEV_BAR_FOO' is created in the *sevfit* package and 'SEV_BAR_FOO' has the following signature:

```
function SEV_BAR_FOO(y);
   /* returns value of FOO_BAR for the supplied value
      of y and fitted values of P1, P2 */
endsub;
```

Scoring Functions for the Scale Regression Model

If you use the SCALEMODEL statement to specify a scale regression model, then PROC SEVERITY generates the scoring functions when you specify only singleton continuous effects. If you specify interaction or classification effects, then scoring functions are not generated.

For a scale regression model, the estimate of the scale parameter or the log-transformed scale parameter of the distribution depends on the values of the regressors. So PROC SEVERITY creates a scoring function that has the following signature, where *x{*}* represents the array of regressors:

```
function SEV_BAR(y, x{*});
   /* returns value of FOO_BAR for the supplied value of x and fitted values of P1, P2 */
endsub;
```

As an illustration of using this form, assume that you submit the following PROC SEVERITY step to create the scoring library Sasuser.Scalescore:

```
proc severity data=input;
   loss lossclaim;
   scalemodel x1-x3;
   dist pareto;
   outscorelib outlib=sasuser.scalescore;
run;
```

Your scoring data set must contain all the regressors that you specify in the SCALEMODEL statement. You can submit the following DATA step to score observations by using the scale regression model:

```
data prob;
   array regvals{*} x1-x3;
   set work.limits;
   exceedance_probability = sev_sdf(limit, regvals);
run;
```

PROC SEVERITY creates two utility functions, SEV_NUMREG and SEV_REGNAME, in the OUTLIB= library that return the number of regressors and name of a given regressor, respectively. They are described in detail in the next section. These utility functions are useful when you do not have easy access to the regressor names in the SCALEMODEL statement. You can use the utility functions as follows:

```
data prob;
   array regvals{10} _temporary_;
   set work.limits;
   do i = 1 to sev_numreg();
      regvals(i) = input(vvaluex(sev_regname(i)), best12.);
   end;
   exceedance_probability = sev_sdf(limit, regvals);
run;
```

The dimension of the regressor values array that you supply to the scoring function must be equal to $K + L$, where K is the number of regressors that you specify in the SCALEMODEL statement irrespective of whether PROC SEVERITY deems any of those regressors to be redundant. L is 1 if you specify an OFFSET= variable in the SCALEMODEL statement, and 0 otherwise.

Utility Functions and Subroutines in the OUTLIB= Library

In addition to creating the scoring functions for all distribution functions, PROC SEVERITY creates the following utility functions and subroutines in the OUTLIB= library.

SEV_NUMPARM | SEV_NUMPARM_*dist*
is a function that returns the number of distribution parameters and has the following signature:

- *Type*: Function
- *Number of arguments*: 0
- *Sequence and type of arguments*: Not applicable

- *Return value*: Numeric value that contains the number of distribution parameters

If you do not specify the COMMONPACKAGE option in the OUTSCORELIB statement, then a function named SEV_NUMPARM is created in the package of each distribution. Here is a sample structure of the code that PROC SEVERITY uses to define the function:

```
function SEV_NUMPARM();
    n = <number of distribution parameters>;
    return (n);
endsub;
```

If you specify the COMMONPACKAGE option in the OUTSCORELIB statement, then for each distribution *dist*, the function named SEV_NUMPARM_*dist* is created in the *sevfit* package. SEV_NUMPARM_*dist* has the same structure as the SEV_NUMPARM function that is described previously.

SEV_PARMEST | SEV_PARMEST_*dist*
is a subroutine that returns the estimate and standard error of a specified distribution parameter and has the following signature:

- *Type*: Subroutine
- *Number of arguments*: 3
- *Sequence and type of arguments*:

  index specifies the numeric value of the index of the distribution parameter for which you want the information. The value of *index* must be in the interval [1,*m*], where *m* is the number of parameters in the distribution to which this subroutine belongs.

  est specifies the output argument that returns the estimate of the requested parameter.

  stderr specifies the output argument that returns the standard error of the requested parameter.

- *Return value*: Estimate and standard error of the requested distribution parameter that are returned in the output arguments *est* and *stderr*, respectively

If you do not specify the COMMONPACKAGE option in the OUTSCORELIB statement, then a subroutine named SEV_PARMEST is created in the package of each distribution. Here is a sample structure of the code that PROC SEVERITY uses to define the subroutine:

```
subroutine SEV_PARMEST(index, est, stderr);
    outargs est, stderr;
    est = <value of the estimate for the distribution parameter
           at position 'index'>;
    stderr =  <value of the standard error for distribution parameter
               at position 'index'>;
endsub;
```

If you specify the COMMONPACKAGE option in the OUTSCORELIB statement, then for each distribution *dist*, the subroutine named SEV_PARMEST_*dist* is created in the *sevfit* package. SEV_PARMEST_*dist* has the same structure as the SEV_PARMEST subroutine that is described previously.

If you use the SCALEMODEL statement to specify a scale regression model, and if you specify only singleton continuous effects, then for *index*=1, the returned estimates are of θ_0, the base value of the scale parameter, or $\log(\theta_0)$ if the distribution has a log-scale parameter. For more information about θ_0, see the section "Estimating Regression Effects" on page 2093.

SEV_PARMNAME | SEV_PARMNAME_*dist*
is a function that returns the name of a specified distribution parameter and has the following signature:

- *Type*: Function
- *Number of arguments*: 1
- *Sequence and type of arguments*:

  index specifies the numeric value of the index of the distribution parameter for which you want the information. The value of *index* must be in the interval [1,*m*], where *m* is the number of parameters in the distribution to which this function belongs.

- *Return value*: Character value that contains the name of the distribution parameter that appears at the position *index* in the distribution's definition

If you do not specify the COMMONPACKAGE option in the OUTSCORELIB statement, then a function named SEV_PARMNAME is created in the package of each distribution. Here is a sample structure of the code that PROC SEVERITY uses to define the function:

```
function SEV_PARMNAME(index) $32;
    name = <name of the distribution parameter at position 'index'>;
    return (name);
endsub;
```

If you specify the COMMONPACKAGE option in the OUTSCORELIB statement, then for each distribution *dist*, a function named SEV_PARMNAME_*dist* is created in the *sevfit* package. SEV_PARMNAME_*dist* has the same structure as the SEV_PARMNAME function that is described previously.

If you use the SCALEMODEL statement to specify a scale regression model, and if you specify only singleton continuous effects, then the following helper functions and subroutines are also created in the OUTLIB= library.

SEV_NUMREG
is a function that returns the number of regressors and has the following signature:

- *Type*: Function
- *Number of arguments*: 0
- *Sequence and type of arguments*: Not applicable
- *Return value*: Numeric value that contains the number of regressors that you specify in the SCALEMODEL statement. If you specify an OFFSET= variable in the SCALEMODEL statement, then the returned value is equal to 1 plus the number of regressors that you specify in the SCALEMODEL statement.

Here is a sample structure of the code that PROC SEVERITY uses to define the function:

```
function SEV_NUMREG();
    m = <number of regressors>;
    if (<offset variable is specified>) then m = m + 1;
    return (m);
endsub;
```

This function does not depend on any distribution, so it is always created in the *sevfit* package.

SEV_REGEST | SEV_REGEST_*dist*

is a subroutine that returns the estimate and standard error of a specified regression parameter and has the following signature:

- *Type*: Subroutine
- *Number of arguments*: 3
- *Sequence and type of arguments*:

  index specifies the numeric value of the index of the regression parameter for which you want the information. The value of *index* must be in the interval [1,*K*], where *K* is the number of regressors as returned by the SEV_NUMREG function. If you specify an OFFSET= variable in the SCALEMODEL statement, then an *index* value of *K* corresponds to the offset variable.

  est specifies the output argument that returns the estimate of the requested regression parameter.

  stderr specifies the output argument that returns the standard error of the requested regression parameter.

- *Return value*: Estimate and standard error of the requested regression parameter that are returned in the output arguments *est* and *stderr*, respectively

If you do not specify the COMMONPACKAGE option in the OUTSCORELIB statement, then a subroutine named SEV_REGEST is created in the package of each distribution. Here is a sample structure of the code that PROC SEVERITY uses to define the subroutine:

```
subroutine SEV_REGEST(index, est, stderr);
    outargs est, stderr;
    est = <value of the estimate for the regression parameter
           at position 'index'>;
    stderr =  <value of the standard error for regression parameter
               at position 'index'>;
endsub;
```

If you specify the COMMONPACKAGE option in the OUTSCORELIB statement, then for each distribution *dist*, the subroutine named SEV_REGEST_*dist* is created in the *sevfit* package. SEV_REGEST_*dist* has the same structure as the SEV_REGEST subroutine that is described previously.

If the regressor that corresponds to the specified *index* value is a redundant regressor, the returned values of both *est* and *stderr* are equal to the special missing value of .R. If you specify an OFFSET=

variable in the SCALEMODEL statement and if the *index* value corresponds to the offset variable—that is, it is equal to the value that the SEV_NUMREG function returns—then the returned value of *est* is equal to 1 and the returned value of *stderr* is equal to the special missing value of .F.

SEV_REGNAME

is a function that returns the name of a specified regressor and has the following signature:

- *Type*: Function
- *Number of arguments*: 1
- *Sequence and type of arguments*:

  index specifies the numeric value of the index of the regressor for which you want the name. The value of *index* must be in the interval [1,*K*], where *K* is the number of regressors as returned by the SEV_NUMREG function. If you specify an OFFSET= variable in the SCALEMODEL statement, then an *index* value of *K* corresponds to the offset variable.

- *Return value*: Character value that contains the name of the regressor that appears at the position *index* in the SCALEMODEL statement. If you specify an OFFSET= variable in the SCALEMODEL statement, then for an *index* value of *K*, the returned value contains the name of the offset variable.

Here is a sample structure of the code that PROC SEVERITY uses to define the function:

```
function SEV_REGNAME(index) $32;
    name = <name of regressor at position 'index'>;
    return (name);
endsub;
```

This function does not depend on any distribution, so it is always created in the *sevfit* package.

Custom Objective Functions

You can use a series of programming statements that use variables in the DATA= data set to assign a value to an objective function symbol. You must specify the objective function symbol by using the OBJECTIVE= option in the PROC SEVERITY statement.

The objective function can be programmed such that it is applicable to any distribution that is used in the model. For that purpose, PROC SEVERITY recognizes the following *keyword* functions in the programming statements:

PDF(x) returns the probability density function (PDF) of a distribution evaluated at the current value of a data set variable x.

CDF(x) returns the cumulative distribution function (CDF) of a distribution evaluated at the current value of a data set variable x.

SDF(x) returns the survival distribution function (SDF) of a distribution evaluated at the current value of a data set variable x.

LOGPDF(x) returns the natural logarithm of the PDF of a distribution evaluated at the current value of a data set variable x.

LOGCDF(x) returns the natural logarithm of the CDF of a distribution evaluated at the current value of a data set variable x.

LOGSDF(x) returns the natural logarithm of the SDF of a distribution evaluated at the current value of a data set variable x.

EDF(x) returns the empirical distribution function (EDF) estimate evaluated at the current value of a data set variable x. Internally, PROC SEVERITY computes the estimate using the SVRTUTIL_EDF function as described in the section "Predefined Utility Functions" on page 2131. The EDF estimate that is required by the SVRTUTIL_EDF function is computed by using the response variable values in the current BY group or in the entire input data set if you do not specify the BY statement.

EMPLIMMOMENT(k, u) returns the empirical limited moment of order *k* evaluated at the current value of a data set variable u that represents the upper limit of the limited moment. The order *k* can also be a data set variable. Internally, PROC SEVERITY computes the moment using the SVRTUTIL_EMPLIMMOMENT function as described in the section "Predefined Utility Functions" on page 2131. The EDF estimate that is required by the SVRTUTIL_EMPLIMMOMENT function is computed by using the response variable values in the current BY group or in the entire input data set if you do not specify the BY statement.

LIMMOMENT(k, u) returns the limited moment of order *k* evaluated at the current value of a data set variable u that represents the upper limit of the limited moment. The order *k* can be a data set variable or a constant. Internally, for each candidate distribution, PROC SEVERITY computes the moment using the LIMMOMENT function as described in the section "Predefined Utility Functions" on page 2131.

All the preceding functions are right-hand side functions. They act as placeholders for distribution-specific functions, with the exception of _EDF_ and _EMPLIMMOMENT_ functions.

As an example, let the data set Work.Test contain a response variable Y and a left-truncation threshold variable T. The following statements use the values in this data set to fit a model with distribution D such that the parameters of the model minimize the value of the objective function symbol MYOBJ:

```
options cmplib=(work.mydist);
proc severity data=work.test objective=myobj;
    loss y / lt=t;

    myobj = -_LOGPDF_(y);
    if (not(missing(t))) then
        myobj = myobj + log(1-_CDF_(t));

    dist d;
run;
```

The symbol MYOBJ is designated as an objective function symbol by using the OBJECTIVE= option in the PROC SEVERITY statement. The response variable Y and left-truncation variable T are specified in the LOSS statement. The distribution D is specified in the DIST statement. The remaining statements constitute a program that computes the value of the MYOBJ symbol.

Let the distribution D have parameters P1 and P2. In order to estimate the model for this distribution, PROC SEVERITY internally converts the generic program to the following program specific to distribution D:

```
myobj = -D_LOGPDF(y, p1, p2);
if (not(missing(t))) then
    myobj = myobj + log(1-D_CDF(t, p1, p2));
```

Note that the generic keyword functions _LOGPDF_ and _CDF_ have been replaced with distribution-specific functions D_LOGPDF and D_CDF, respectively, with appropriate distribution parameters. The D_LOGPDF and D_CDF functions must have been defined previously and are assumed to be available in the Work.Mydist library that you specify in the CMPLIB= option.

The program is executed for each observation in Work.Test to compute the value of MYOBJ by using the values of variables Y and T in that observation and internally computed values of the model parameters P1 and P2. The values of MYOBJ are then added over all the observations of the data set or over all the observations of the current BY group if you specify the BY statement. The resulting aggregate value is the value of the objective function, and it is supplied to the optimizer. If the optimizer requires derivatives of the objective function, then PROC SEVERITY automatically differentiates MYOBJ with respect to the parameters P1 and P2. The optimizer iterates over various combinations of the values of parameters P1 and P2, each time computing a new value of the objective function and the needed derivatives of it, until it finds a combination that minimizes the objective function.

Note the following points when you define your own program to compute the custom objective function:

- The value of the objective function is always minimized by PROC SEVERITY. If you want to maximize the value of a certain objective, then add a statement that assigns the negated value of the maximization objective to the objective function symbol that you specify in the OBJECTIVE= option. Minimization of the negated objective is equivalent to the maximization of the original objective.
- The contributions of individual observations are always added to compute the overall objective function in a given iteration of the optimizer. If you specify the WEIGHT statement, then the contribution of each observation is weighted by multiplying it with the normalized value of the weight variable for that observation.
- If you are fitting multiple distributions in one PROC SEVERITY step and use any of the keyword functions in your program, then it is recommended that you do not explicitly use the parameters of any of the specified distributions in your programming statements.
- If you use a specific keyword function in your programming statements, then the corresponding distribution functions must be defined in a library that you specify in the CMPLIB= system option or in Sashelp.Svrtdist, the predefined functions library. In the preceding example, it is assumed that the functions D_LOGPDF and D_CDF are defined in the Work.Mydist library that is specified in the CMPLIB= option.
- You can use most DATA step statements and functions in your program. The DATA step file and the data set I/O statements (for example, INPUT, FILE, SET, and MERGE) are not available. However, some functionality of the PUT statement is supported. For more information, see the section "PROC FCMP and DATA Step Differences" in *Base SAS Procedures Guide*. In addition to the differences listed in that section, the following differences exist:
  - Only numeric-valued variables can be used in PROC SEVERITY programming statements. This restriction also implies that you cannot use SAS functions or call routines that require

character-valued arguments, unless you pass those arguments as constant (literal) strings or characters.

  - You cannot use functions that create lagged versions of a variable in PROC SEVERITY programming statements. If you need lagged versions, then you can use a DATA step prior to the PROC SEVERITY step to add those versions to the input data set.

- When coding your programming statements, avoid defining variables that begin with an underscore (_), because they might conflict with internal variables created by PROC SEVERITY.

Custom Objective Functions and Regression Effects

If you specify regression effects by using the SCALEMODEL statement, then PROC SEVERITY automatically adds a statement prior to your programming statements to compute the value of the scale parameter or the log-transformed scale parameter of the distribution using the values of the regression variables and internally created regression parameters. For example, if your specification of the SCALEMODEL statement results in three regression effects x1, x2, and x3, then for a model that contains the distribution D with scale parameter S, PROC SEVERITY adds a statement that is equivalent to the following statement to the beginning of your program:

```
S = _SEVTHETA0 * exp(_SEVBETA1 * x1 + _SEVBETA2 * x2 + _SEVBETA3 * x3);
```

If a model contains a distribution D1 with a log-transformed scale parameter M, PROC SEVERITY adds a statement that is equivalent to the following statement to the beginning of your program:

```
M = _SEVTHETA0 + _SEVBETA1 * x1 + _SEVBETA2 * x2 + _SEVBETA3 * x3;
```

The _SEVTHETA0, _SEVBETA1, _SEVBETA2, and _SEVBETA3 are the internal regression parameters associated with the intercept and the regression effects x1, x2, and x3, respectively.

Since the names of the internal regression parameters start with a prefix _SEV, if you use a variable in your program with a name that begins with _SEV, then PROC SEVERITY writes an error message to the SAS log and stops processing.

Multithreaded Computation

PROC SEVERITY attempts to use all the computational resources of the machine where SAS is running in order to complete the estimation tasks as fast as possible. This section describes the options that control the use of multithreading by PROC SEVERITY.

Threading refers to the organization of computational work into multiple tasks (processing units that can be scheduled by the operating system). A task is associated with a thread. Multithreading refers to the concurrent execution of threads. When multithreading is possible, substantial performance gains can be realized compared to sequential (single-threaded) execution.

The number of threads spawned by the SEVERITY procedure is determined by the number of CPUs on a machine. You can control the number of threads by specifying either the CPUCOUNT= or the NOTHREADS SAS system option.

- You can specify the CPU count with the CPUCOUNT= SAS system option. For example, if you specify the following statement, then PROC SEVERITY schedules threads as if it executed on a system with four CPUs, regardless of the actual CPU count:

  ```
  options cpucount=4;
  ```

  On most systems, the default value of the CPUCOUNT= system option is set to the number of actual CPU cores available for processing.

- If you do not want PROC SEVERITY to use multithreading, then you can turn off the THREADS SAS system option by specifying the following statement:

  ```
  options nothreads;
  ```

  On most systems, the THREADS option is turned on by default.

You can examine the current settings of these system options in the SAS log by submitting the following PROC OPTIONS step:

```
proc options option=(threads cpucount);
run;
```

Input Data Sets

PROC SEVERITY accepts DATA= and INEST= data sets as input data sets. This section details the information they are expected to contain.

DATA= Data Set

The DATA= data set is expected to contain the values of the analysis variables that you specify in the LOSS statement and the SCALEMODEL statement.

If you specify the BY statement, then the DATA= data set must contain all the BY variables that you specify in the BY statement and the data set must be sorted by the BY variables unless you specify the NOTSORTED option in the BY statement.

INEST= Data Set

The INEST= data set is expected to contain the initial values of the parameters for the parameter estimation process.

If you specify the SCALEMODEL statement, then you can use the INEST= data set only if the SCALEMODEL statement contains singleton continuous effects.

If you specify the BY statement, then the INEST= data set must contain all the BY variables that you specify in the BY statement. If you do not specify the NOTSORTED option in the BY statement, then the INEST= data set must be sorted by the BY variables. However, it is not required to contain all the BY groups present in the DATA= data set. For the BY groups that are not present in the INEST= data set, the default parameter

initialization method is used. If you specify the NOTSORTED option in the BY statement, then the INEST= data set must contain all the BY groups that are present in the DATA= data set and they must appear in the same order as they appear in the DATA= data set.

In addition to any variables that you specify in the BY statement, the data set must contain the following variables:

MODEL identifying name of the distribution for which the estimates are provided.

TYPE type of the estimate. The value of this variable must be EST for an observation to be valid.

<Parameter 1> . . . <Parameter M>
M variables, named after the parameters of all candidate distributions, that contain initial values of the respective parameters. *M* is the cardinality of the union of parameter name sets from all candidate distributions. In an observation, estimates are read only from variables for parameters that correspond to the distribution that is indicated by the _MODEL_ variable.

If you specify a missing value for some parameters, then default initial values are used unless the parameter is initialized by using the INIT= option in the DIST statement. If you want to use the *dist*_PARMINIT subroutine for initializing the parameters of a model, then you should either not specify the model in the INEST= data set or specify missing values for all the distribution parameters in the INEST= data set and not use the INIT= option in the DIST statement.

If you specify regressors, then the initial value that you provide for the first parameter of each distribution must be the base value of the scale or log-transformed scale parameter. For more information, see the section "Estimating Regression Effects" on page 2093.

<Regressor 1> . . . <Regressor K>
If you specify *K* regressors in the SCALEMODEL statement, then the INEST= data set must contain *K* variables that are named for each regressor. The variables contain initial values of the respective regression coefficients. If a regressor is linearly dependent on other regressors for a given BY group, then you can indicate this by providing a special missing value of .R for the respective variable. In a given BY group, if you mark a variable as linearly dependent for one model, then you must mark that variable as linearly dependent for all the models. Similarly, in a given BY group, if you do not mark a variable as linearly dependent for one model, then you must not mark that variable as linearly dependent for all the models.

Output Data Sets

PROC SEVERITY writes the OUTCDF=, OUTEST=, OUTMODELINFO=, and OUTSTAT= data sets when requested by their respective options in the PROC SEVERITY statement. It also writes the OUT= data set when you specify the OUTPUT statement. The data sets and their contents are described in the following sections.

OUT= Data Set

The OUT= data set that you specify in the OUTPUT statement records the estimates of the scoring functions and quantiles that you specify in the OUTPUT statement.

For each distribution that you specify in the DIST statement, the OUT= data set contains one variable for each scoring function that you specify in the FUNCTIONS= option and one variable for each quantile that you specify in the QUANTILES= option. The prefix of the variable's name is <distribution-name>_, whereas the suffix of the variable's name is determined by the information that you specify in the respective option or by the default method that PROC SEVERITY uses. For more information about variable names, see the description of the OUTPUT statement.

The OUT= data set also contains the variables that you specify in the COPYVARS= option. If you specify the BY statement and if you want PROC SEVERITY to copy the BY variables from the DATA= data set to the OUT= data set, then you must specify them in the COPYVARS= option.

The number of observations in the OUT= data set depends on the options that you specify in the OUTPUT statement and whether or not you specify the SCALEMODEL statement.

If either of the following conditions is met, then the number of observations in the OUT= data set is equal to the number of observations in the DATA= data set:

- You specify the SCALEMODEL statement.
- You specify the FUNCTIONS= option in the OUTPUT statement such that at least one scoring function does not have a constant, nonmissing argument.

If neither of the preceding conditions is met, then the number of observations in the OUT= data set is equal to the number of BY groups, which is equal to 1 if you do not specify the BY statement.

OUTCDF= Data Set

The OUTCDF= data set records the estimates of the cumulative distribution function (CDF) of each of the specified model distributions and an estimate of the empirical distribution function (EDF).

If you specify BY variables, then the data are organized in BY groups and the data set contains variables that you specify in the BY statement. In addition, the data set contains the following variables:

<response variable>
: value of the response variable. The values are sorted. If there are multiple BY groups, the values are sorted within each BY group.

OBSNUM
: observation number in the DATA= data set. This is a sequence number that indicates the order in which the procedure accesses the observation; it does not necessarily reflect the actual observation number in the data set.

EDF estimate of the empirical distribution function (EDF). This estimate is computed by using the EMPIRICALCDF= option that you specify in the PROC SEVERITY statement.

_EDF_STD estimate of the standard error of EDF. This estimate is computed by using a method that is appropriate for the EMPIRICALCDF= option that you specify in the PROC SEVERITY statement.

_EDF_LOWER estimate of the lower confidence limit of EDF for a pointwise $100(1-\alpha)\%$ confidence interval, where α is the value of the EDFALPHA= option that you specify in the PROC SEVERITY statement (default is $\alpha = 0.05$). For an EDF estimate F_n that has standard error σ_n, it is computed as $\text{MAX}(0, F_n - z_{(1-\alpha/2)}\sigma_n)$, where z_p is the pth quantile from the standard normal distribution.

_EDF_UPPER estimate of the upper confidence limit of EDF for a pointwise $100(1-\alpha)\%$ confidence interval, where α is the value of the EDFALPHA= option that you specify in the PROC SEVERITY statement (default is $\alpha = 0.05$). For an EDF estimate F_n that has standard error σ_n, it is computed as $\text{MIN}(1, F_n + z_{(1-\alpha/2)}\sigma_n)$, where z_p is the pth quantile from the standard normal distribution.

<distribution1>_CDF ... <distribution*D*>_CDF
estimate of the cumulative distribution function (CDF) for each of the D candidate distributions, computed by using the final parameter estimates for that distribution. This value is missing if the parameter estimation process does not converge for the given distribution.

If you specify regression effects, then the reported estimates are from a mixture distribution. For more information, see the section "CDF and PDF Estimates with Regression Effects" on page 2097.

If you specify truncation, then the data set contains the following additional variables:

<distribution1>_COND_CDF ... <distribution*D*>_COND_CDF
estimate of the conditional CDF for each of the D candidate distributions, computed by using the final parameter estimates for that distribution. This value is missing if the parameter estimation process does not converge for the distribution. The conditional estimates are computed by using the method that is described in the section "Truncation and Conditional CDF Estimates" on page 2089.

OUTEST= Data Set

The OUTEST= data set records the estimates of the model parameters. It also contains estimates of their standard errors and optionally their covariance structure. If you specify BY variables, then the data are organized in BY groups and the data set contains variables that you specify in the BY statement.

If you do not specify the COVOUT option, then the data set contains the following variables:

MODEL identifying name of the distribution model. The observation contains information about this distribution.

TYPE type of the estimates reported in this observation. It can take one of the following two values:

EST	point estimates of model parameters
STDERR	standard error estimates of model parameters

STATUS status of the reported estimates. The possible values are listed in the section "_STATUS_ Variable Values" on page 2153.

<Parameter 1> . . . <Parameter M>
M variables, named after the parameters of all candidate distributions, that contain estimates of the respective parameters. *M* is the cardinality of the union of parameter name sets from all candidate distributions. In an observation, estimates are populated only for parameters that correspond to the distribution that is indicated by the _MODEL_ variable. If _TYPE_ is EST, then the estimates are missing if the model does not converge. If _TYPE_ is STDERR, then the estimates are missing if covariance estimates cannot be obtained.

If you specify regression effects, then the estimate that is reported for the first parameter of each distribution is the estimate of the base value of the scale or log-transformed scale parameter. For more information, see the section "Estimating Regression Effects" on page 2093.

<Regression Effect 1> . . . <Regression Effect K>
If your effect specification in the SCALEMODEL statement results in *K* regression effects, then the OUTEST= data set contains *K* regression variables. The name of each variable is formed by using the name of the effect and the names of the levels of the CLASS variables that the effect might contain. If the effect name or level names are too long, then the variable name is constructed by using partial effect name and integer identifiers for BY groups and CLASS variable levels. The label of the variable is more descriptive than the name of the variable. The variables contain estimates for their respective regression coefficients. If an effect is deemed to be linearly dependent on other effects for a given BY group, then a warning message is written to the SAS log and a special missing value of .R is written in the respective variable. If _TYPE_ is EST, then the estimates are missing if the model does not converge. If _TYPE_ is STDERR, then the estimates are missing if covariance estimates cannot be obtained.

<Offset Variable>
If you specify an OFFSET= variable in the SCALEMODEL statement, then the OUTEST= data set contains a variable that is named after the offset variable. If _TYPE_ is EST, then the value of this variable is 1. If _TYPE_ is STDERR, then the value of this variable is a special missing value of .F.

If you specify the COVOUT option in the PROC SEVERITY statement, then the OUTEST= data set contains additional observations that contain the estimates of the covariance structure. Given the symmetric nature of the covariance structure, only the lower triangular portion is reported. In addition to the variables listed and described previously, the data set contains the following variables that are either new or have a modified description:

TYPE type of the estimates reported in this observation. For observations that contain rows of the covariance structure, the value is COV.

STATUS status of the reported estimates. For observations that contain rows of the covariance structure, the status is 0 if covariance estimation was successful. If estimation fails, the

status is 1 and a single observation is reported with _TYPE_=COV and missing values for all the parameter variables.

NAME name of the parameter for the row of covariance matrix that is reported in the current observation.

OUTMODELINFO= Data Set

The OUTMODELINFO= data set records the information about each candidate distribution that you specify in the DIST statement. It contains the following variables:

MODEL identifying name of the distribution model. The observation contains information about this distribution.

DEPVAR name of the loss variable.

DESCRIPTION descriptive name of the model. This has a nonmissing value only if the DESCRIPTION function has been defined for this model.

VALID validity of the distribution definition. This has a value of 1 for valid definitions and a value of 0 for invalid definitions. If the definition is invalid, then PROC SEVERITY writes the reason for invalidity to the SAS log.

_PARMNAME1 ... _PARMNAME*M*
M variables that contain names of parameters of the distribution model, where *M* is the maximum number of parameters across all the specified distribution models. For a given distribution with *m* parameters, values of variables _PARMNAME*j* ($j > m$) are missing.

OUTSTAT= Data Set

The OUTSTAT= data set records statistics of fit and model selection information. If you specify BY variables, then the data are organized in BY groups and the data set contains variables that you specify in the BY statement. The data set contains the following variables:

MODEL identifying name of the distribution model. The observation contains information about this distribution.

NMODELPARM number of parameters in the distribution.

NESTPARM number of estimated parameters. This includes the regression parameters, if you specify any regression effects.

NOBS number of nonmissing observations used for parameter estimation.

STATUS status of the parameter estimation process for this model. The possible values are listed in the section "_STATUS_ Variable Values" on page 2153.

SELECTED indicator of the best distribution model. If the value is 1, then this model is the best model for the current BY group according to the specified model selection criterion. This value is missing if the parameter estimation process does not converge for this model.

Neg2LogLike	value of the log likelihood, multiplied by –2, that is attained at the end of the parameter estimation process. This value is missing if the parameter estimation process does not converge for this model.
AIC	value of the Akaike's information criterion (AIC) that is attained at the end of the parameter estimation process. This value is missing if the parameter estimation process does not converge for this model.
AICC	value of the corrected Akaike's information criterion (AICC) that is attained at the end of the parameter estimation process. This value is missing if the parameter estimation process does not converge for this model.
BIC	value of the Schwarz Bayesian information criterion (BIC) that is attained at the end of the parameter estimation process. This value is missing if the parameter estimation process does not converge for this model.
KS	value of the Kolmogorov-Smirnov (KS) statistic that is attained at the end of the parameter estimation process. This value is missing if the parameter estimation process does not converge for this model.
AD	value of the Anderson-Darling (AD) statistic that is attained at the end of the parameter estimation process. This value is missing if the parameter estimation process does not converge for this model.
CVM	value of the Cramér–von Mises (CvM) statistic that is attained at the end of the parameter estimation process. This value is missing if the parameter estimation process does not converge for this model.

STATUS Variable Values

The _STATUS_ variable in the OUTEST= and OUTSTAT= data sets contains a value that indicates the status of the parameter estimation process for the respective distribution model. The variable can take the following values in the OUTEST= data set for _TYPE_=EST observations and in the OUTSTAT= data set:

0 The parameter estimation process converged for this model.

301 The parameter estimation process might not have converged for this model because there is no improvement in the objective function value. This might indicate that the initial values of the parameters are optimal, or you can try different convergence criteria in the NLOPTIONS statement.

302 The parameter estimation process might not have converged for this model because the number of iterations exceeded the maximum allowed value. You can try setting a larger value for the MAXITER= options in the NLOPTIONS statement.

303 The parameter estimation process might not have converged for this model because the number of objective function evaluations exceeded the maximum allowed value. You can try setting a larger value for the MAXFUNC= options in the NLOPTIONS statement.

304 The parameter estimation process might not have converged for this model because the time taken by the process exceeded the maximum allowed value. You can try setting a larger value for the MAXTIME= option in the NLOPTIONS statement.

400 The parameter estimation process did not converge for this model.

The _STATUS_ variable can take the following values in the OUTEST= data set for _TYPE_=STDERR and _TYPE_=COV observations:

0 The covariance and standard error estimates are available and valid.

1 The covariance and standard error estimates are not available, because the process of computing covariance estimates failed.

Displayed Output

The SEVERITY procedure optionally produces displayed output by using the Output Delivery System (ODS). All output is controlled by the PRINT= option in the PROC SEVERITY statement. Table 28.18 relates the ODS tables to PRINT= options.

Table 28.18 ODS Tables Produced in PROC SEVERITY

ODS Table Name	Description	Option
AllFitStatistics	Statistics of fit for all the distribution models	PRINT=ALLFITSTATS
ConvergenceStatus	Convergence status of parameter estimation process	PRINT=CONVSTATUS
DescStats	Descriptive statistics for the response variable	PRINT=DESCSTATS
DistributionInfo	Distribution information	PRINT=DISTINFO
InitialValues	Initial parameter values and bounds	PRINT=INITIALVALUES
IterationHistory	Optimization iteration history	PRINT=NLOHISTORY
ModelSelection	Model selection summary	PRINT=SELECTION
OptimizationSummary	Optimization summary	PRINT=NLOSUMMARY
ParameterEstimates	Final parameter estimates	PRINT=ESTIMATES
RegDescStats	Descriptive statistics for the regression effects that do not contain a CLASS variable	PRINT=DESCSTATS
StatisticsOfFit	Statistics of fit	PRINT=STATISTICS
Timing	Timing information for various computational stages of the procedure	PRINT=ALL
TurnbullSummary	Turnbull EDF estimation summary	PRINT=ALL

If you do not specify the PRINT= option, then by default PROC SEVERITY produces ModelSelection, ConvergenceStatus, OptimizationSummary, StatisticsOfFit, and ParameterEstimates ODS tables.

The following describes the content that is displayed in each table:

AllFitStatistics (PRINT=ALLFITSTATS)
displays the comparison of all the statistics of fit for all the models in one table. The table does not include the models whose parameter estimation process does not converge. If all the models fail to converge, then this table is not produced. If the table contains more than one model, then the best model according to each statistic is indicated with an asterisk (*) in that statistic's column.

ConvergenceStatus (PRINT=CONVSTATUS)
displays the convergence status of the parameter estimation process.

DescStats (PRINT=DESCSTATS)
displays the descriptive statistics for the response variable.

DistributionInfo (PRINT=DISTINFO)
displays the information about all the candidate distribution. It includes the name, the description, the number of distribution parameters, and whether the distribution is valid for the specified modeling task.

InitialValues (PRINT=INITIALVALUES)
displays the initial values and bounds used for estimating each model.

IterationHistory (PRINT=NLOHISTORY)
displays the iteration history of the nonlinear optimization process used for estimating the parameters.

ModelSelection (PRINT=SELECTION)
displays the model selection table. The table shows the convergence status of each candidate model, and the value of the selection criterion along with an indication of the selected model.

OptimizationSummary (PRINT=NLOSUMMARY)
displays the summary of the nonlinear optimization process used for estimating the parameters.

ParameterEstimates (PRINT=ESTIMATES)
displays the final estimates of parameters. The estimates are not displayed for models whose parameter estimation process does not converge.

RegDescStats (PRINT=DESCSTATS)
displays the descriptive statistics for the regression effects in the SCALEMODEL statement that do not contain a CLASS variable.

StatisticsOfFit (PRINT=STATISTICS)
displays the statistics of fit for each model. The statistics of fit are not displayed for models whose parameter estimation process does not converge.

Timing (PRINT=ALL)
displays elapsed times (absolute and relative) for the main tasks of the procedure.

TurnbullSummary (PRINT=ALL)
displays the summary of Turnbull's estimation process if Turnbull's method is used for computing EDF estimates. The summary includes whether the nonlinear optimization converged, the number of iterations, the maximum absolute relative error, the maximum absolute reduced gradient, and whether the final estimates are maximum likelihood estimates. This table is produced only if you specify PRINT=ALL and Turnbull's method is used for computing EDF estimates.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

This section describes the use of ODS for creating graphics with the SEVERITY procedure.

ODS Graph Names

PROC SEVERITY assigns a name to each graph that it creates by using ODS. You can use these names to selectively reference the graphs. The names are listed in Table 28.19.

Table 28.19 ODS Graphics Produced by PROC SEVERITY

ODS Graph Name	Plot Description	PLOTS= Option
CDFPlot	Comparative CDF plot	CDF
CDFDistPlot	CDF plot per distribution	CDFPERDIST
PDFPlot	Comparative PDF plot	PDF
PDFDistPlot	PDF plot per distribution	PDFPERDIST
PPPlot	P-P plot of CDF and EDF	PP
QQPlot	Q-Q plot	QQ

Comparative CDF Plot

The comparative CDF plot helps you visually compare the cumulative distribution function (CDF) estimates of all the candidate distribution models and the empirical distribution function (EDF) estimate. The plot does not contain CDF estimates for models whose parameter estimation process does not converge. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the CDF or EDF estimates.

If you specify truncation, then conditional CDF estimates are plotted. Otherwise, unconditional CDF estimates are plotted. The conditional estimates are computed by using the method that is described in the section "Truncation and Conditional CDF Estimates" on page 2089.

If you specify regression effects, then the plotted CDF estimates are from a mixture distribution. For more information, see the section "CDF and PDF Estimates with Regression Effects" on page 2097.

CDF Plot per Distribution

The CDF plot per distribution shows the CDF estimates of each candidate distribution model unless that model's parameter estimation process does not converge. The plot also contains estimates of the EDF. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the CDF or EDF estimates.

This plot shows the lower and upper pointwise confidence limits for the EDF estimates. For an EDF estimate F_n with standard error σ_n, they are computed as MAX(0, $F_n - z_{(1-\alpha/2)}\sigma_n$) and MIN(1, $F_n + z_{(1-\alpha/2)}\sigma_n$), respectively, where z_p is the pth quantile from the standard normal distribution and α denotes the confidence level that you specify in the EDFALPHA= option (the default is $\alpha = 0.05$).

If you specify truncation, then conditional CDF estimates are plotted. Otherwise, unconditional CDF estimates are plotted. The conditional estimates are computed by using the method that is described in the section "Truncation and Conditional CDF Estimates" on page 2089.

If you specify regression effects, then the plotted CDF estimates are from a mixture distribution. For more information, see the section "CDF and PDF Estimates with Regression Effects" on page 2097.

Comparative PDF Plot

The comparative PDF plot helps you visually compare the probability density function (PDF) estimates of all the candidate distribution models. The plot does not contain PDF estimates for models whose parameter estimation process does not converge. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the PDF estimates.

If you specify the HISTOGRAM option, then the plot also contains the histogram of response variable values. If you specify the KERNEL option, then the plot also contains the kernel density estimate of the response variable values.

If you specify regression effects, then the plotted PDF estimates are from a mixture distribution. For more information, see the section "CDF and PDF Estimates with Regression Effects" on page 2097.

PDF Plot per Distribution

The PDF plot per distribution shows the PDF estimates of each candidate distribution model unless that model's parameter estimation process does not converge. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the PDF estimates.

If you specify the HISTOGRAM option, then the plot also contains the histogram of response variable values. If you specify the KERNEL option, then the plot also contains the kernel density estimate of the response variable values.

If you specify regression effects, then the plotted PDF estimates are from a mixture distribution. For more information, see the section "CDF and PDF Estimates with Regression Effects" on page 2097.

P-P Plot of CDF and EDF

The P-P plot of CDF and EDF is the probability-probability plot that compares the CDF estimates of a distribution to the EDF estimates. A plot is not prepared for models whose parameter estimation process does not converge. The horizontal axis represents the CDF estimates of a candidate distribution, and the vertical axis represents the EDF estimates.

This plot can be interpreted as displaying the data that are used for computing the EDF-based statistics of fit for the given candidate distribution. As described in the section "EDF-Based Statistics" on page 2115, these statistics are computed by comparing the EDF, denoted by $F_n(y)$, to the CDF, denoted by $F(y)$, at each of the response variable values y. Using the probability inverse transform $z = F(y)$, this is equivalent to comparing the EDF of the z, denoted by $F_n(z)$, to the CDF of z, denoted by $F(z)$ (D'Agostino and Stephens 1986, Ch. 4). Because the CDF of z is a uniform distribution ($F(z) = z$), the EDF-based statistics can be computed by comparing the EDF estimate of z to the estimate of z. The horizontal axis of the plot represents the estimated CDF $\hat{z} = \hat{F}(y)$. The vertical axis represents the estimated EDF of z, $\hat{F}_n(z)$. The plot contains a scatter plot of $(\hat{z}, \hat{F}_n(z))$ points and a reference line $F_n(z) = z$ that represents the expected uniform distribution of z. Points that are scattered closer to the reference line indicate a better fit than the points that are scattered farther away from the reference line.

If you specify truncation, then the EDF estimates are conditional, as described in the section "EDF Estimates and Truncation" on page 2113. So conditional estimates of CDF are displayed, which are computed by using the method that is described in the section "Truncation and Conditional CDF Estimates" on page 2089.

If you specify regression effects, then the displayed CDF estimates, both unconditional and conditional, are from a mixture distribution. For more information, see the section "CDF and PDF Estimates with Regression Effects" on page 2097.

Q-Q Plot

The Q-Q plot is a quantile-quantile scatter plot that compares the empirical quantiles to the quantiles from a candidate distribution. A plot is not prepared for models whose parameter estimation process does not converge. The horizontal axis represents the quantiles from a candidate distribution, and the vertical axis represents the empirical quantiles.

Each point in the plot corresponds to a specific value of the EDF estimate, F_n. The Y coordinate is the value of the response variable for which F_n is computed. The X coordinate is computed by using one of the two following methods for a candidate distribution named *dist*:

- If you have defined the *dist*_QUANTILE function that satisfies the requirements listed in the section "*dist*_QUANTILE" on page 2126, then that function is invoked by using F_n and estimated distribution parameters as arguments. The QUANTILE function is defined in the Sashelp.Svrtdist library for all the predefined distributions.
- If the *dist*_QUANTILE function is not defined, then PROC SEVERITY numerically inverts the *dist*_CDF function at the CDF value of F_n for the estimated distribution parameters. If the *dist*_CDF function is not defined, then the exp(*dist*_LOGCDF) function is inverted. If the inversion fails, the corresponding point is not plotted in the Q-Q plot.

If you specify truncation, then the EDF estimates are conditional, as described in the section "EDF Estimates and Truncation" on page 2113. The CDF inversion process, whether done numerically or by evaluating the

*dist*_QUANTILE function, needs to accept an unconditional CDF value. So the F_n value is first transformed to an unconditional estimate F_n^u as

$$F_n^u = F_n \cdot (\hat{F}(t_{\max}^r) - \hat{F}(t_{\min}^l)) + \hat{F}(t_{\min}^l)$$

where $\hat{F}(t_{\max}^r)$ and $\hat{F}(t_{\min}^l)$ are as defined in the section "Truncation and Conditional CDF Estimates" on page 2089.

If you specify regression effects, then the value of the first distribution parameter is determined by using the DFMIXTURE=MEAN method that is described in the section "CDF and PDF Estimates with Regression Effects" on page 2097.

Examples: SEVERITY Procedure

Example 28.1: Defining a Model for Gaussian Distribution

Suppose you want to fit a distribution model other than one of the predefined ones available to you. Suppose you want to define a model for the Gaussian distribution with the following typical parameterization of the PDF (f) and CDF (F):

$$f(x;\mu,\sigma) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$$
$$F(x;\mu,\sigma) = \frac{1}{2}\left(1 + \operatorname{erf}\left(\frac{x-\mu}{\sigma\sqrt{2}}\right)\right)$$

For PROC SEVERITY, a *distribution model* consists of a set of functions and subroutines that are defined with the FCMP procedure. Each function and subroutine should be written following certain rules. For more information, see the section "Defining a Severity Distribution Model with the FCMP Procedure" on page 2119.

NOTE: The Gaussian distribution is not a commonly used severity distribution. It is used in this example primarily to illustrate the process of defining your own distribution models. Although the distribution has a support over the entire real line, you can fit the distribution with PROC SEVERITY only if the input sample contains nonnegative values.

The following SAS statements define a distribution model named NORMAL for the Gaussian distribution. The OUTLIB= option in the PROC FCMP statement stores the compiled versions of the functions and subroutines in the 'models' package of the Work.Sevexmpl library. The LIBRARY= option in the PROC FCMP statement enables this PROC FCMP step to use the SVRTUTIL_RAWMOMENTS utility subroutine that is available in the Sashelp.Svrtdist library. The subroutine is described in the section "Predefined Utility Functions" on page 2131.

```
/*-------- Define Normal Distribution with PROC FCMP  ----------*/
proc fcmp library=sashelp.svrtdist outlib=work.sevexmpl.models;
   function normal_pdf(x,Mu,Sigma);
      /* Mu    : Location */
      /* Sigma : Standard Deviation */
```

```
      return ( exp(-(x-Mu)**2/(2 * Sigma**2)) /
             (Sigma * sqrt(2*constant('PI'))) );
   endsub;

   function normal_cdf(x,Mu,Sigma);
      /* Mu    : Location */
      /* Sigma : Standard Deviation */
      z = (x-Mu)/Sigma;
      return (0.5 + 0.5*erf(z/sqrt(2)));
   endsub;

   subroutine normal_parminit(dim, x[*], nx[*], F[*], Ftype, Mu, Sigma);
      outargs Mu, Sigma;
      array m[2] / nosymbols;

      /* Compute estimates by using method of moments */
      call svrtutil_rawmoments(dim, x, nx, 2, m);
      Mu    = m[1];
      Sigma = sqrt(m[2] - m[1]**2);
   endsub;

   subroutine normal_lowerbounds(Mu, Sigma);
      outargs Mu, Sigma;
      Mu = .;   /* Mu has no lower bound */
      Sigma = 0; /* Sigma > 0 */
   endsub;
quit;
```

The statements define the two functions required of any distribution model (NORMAL_PDF and NORMAL_CDF) and two optional subroutines (NORMAL_PARMINIT and NORMAL_LOWERBOUNDS). The name of each function or subroutine must follow a specific structure. It should start with the model's short or identifying name, which is 'NORMAL' in this case, followed by an underscore '_', followed by a keyword suffix such as 'PDF'. Each function or subroutine has a specific purpose. For more information about all the functions and subroutines that you can define for a distribution model, see the section "Defining a Severity Distribution Model with the FCMP Procedure" on page 2119. Following is the description of each function and subroutine defined in this example:

- The PDF and CDF suffixes define functions that return the probability density function and cumulative distribution function values, respectively, given the values of the random variable and the distribution parameters.
- The PARMINIT suffix defines a subroutine that returns the initial values for the parameters by using the sample data or the empirical distribution function (EDF) estimate computed from it. In this example, the parameters are initialized by using the method of moments. Hence, you do not need to use the EDF estimates, which are available in the F array. The first two raw moments of the Gaussian distribution are as follows:

  $$E[x] = \mu,\ E[x^2] = \mu^2 + \sigma^2$$

  Given the sample estimates, m_1 and m_2, of these two raw moments, you can solve the equations $E[x] = m_1$ and $E[x^2] = m_2$ to get the following estimates for the parameters: $\hat{\mu} = m_1$ and

$\hat{\sigma} = \sqrt{m_2 - m_1^2}$. The NORMAL_PARMINIT subroutine implements this solution. It uses the SVRTUTIL_RAWMOMENTS utility subroutine to compute the first two raw moments.

- The LOWERBOUNDS suffix defines a subroutine that returns the lower bounds on the parameters. PROC SEVERITY assumes a default lower bound of 0 for all the parameters when a LOWERBOUNDS subroutine is not defined. For the parameter μ (*Mu*), there is no lower bound, so you need to define the NORMAL_LOWERBOUNDS subroutine. It is recommended that you assign bounds for all the parameters when you define the LOWERBOUNDS subroutine or its counterpart, the UPPERBOUNDS subroutine. Any unassigned value is returned as a missing value, which PROC SEVERITY interprets to mean that the parameter is unbounded, and that might not be what you want.

You can now use this distribution model with PROC SEVERITY. Let the following DATA step statements simulate a normal sample with $\mu = 10$ and $\sigma = 2.5$:

```
/*-------- Simulate a Normal sample ----------*/
data testnorm(keep=y);
   call streaminit(12345);
   do i=1 to 100;
      y = rand('NORMAL', 10, 2.5);
      output;
   end;
run;
```

Prior to using your distribution with PROC SEVERITY, you must communicate the location of the library that contains the definition of the distribution and the locations of libraries that contain any functions and subroutines used by your distribution model. The following OPTIONS statement sets the CMPLIB= system option to include the FCMP library Work.Sevexmpl in the search path used by PROC SEVERITY to find FCMP functions and subroutines:

```
/*--- Set the search path for functions defined with PROC FCMP ---*/
options cmplib=(work.sevexmpl);
```

Now, you are ready to fit the NORMAL distribution model with PROC SEVERITY. The following statements fit the model to the values of Y in the Work.Testnorm data set:

```
/*--- Fit models with PROC SEVERITY ---*/
proc severity data=testnorm print=all;
   loss y;
   dist Normal;
run;
```

The DIST statement specifies the identifying name of the distribution model, which is 'NORMAL'. Neither the INEST= option nor the INSTORE= option is specified in the PROC SEVERITY statement, and the INIT= option is not specified in the DIST statement. So PROC SEVERITY initializes the parameters by invoking the NORMAL_PARMINIT subroutine.

Some of the results prepared by the preceding PROC SEVERITY step are shown in Output 28.1.1 and Output 28.1.2. The descriptive statistics of variable Y and the "Model Selection" table, which includes just the normal distribution, are shown in Output 28.1.1.

Output 28.1.1 Summary of Results for Fitting the Normal Distribution

The SEVERITY Procedure

Input Data Set	
Name	WORK.TESTNORM

Descriptive Statistics for y	
Observations	100
Observations Used for Estimation	100
Minimum	3.88249
Maximum	16.00864
Mean	10.02059
Standard Deviation	2.37730

Model Selection

Distribution	Converged	-2 Log Likelihood	Selected
Normal	Yes	455.97541	Yes

The initial values for the parameters, the optimization summary, and the final parameter estimates are shown in Output 28.1.2. No iterations are required to arrive at the final parameter estimates, which are identical to the initial values. This confirms the fact that the maximum likelihood estimates for the Gaussian distribution are identical to the estimates obtained by the method of moments that was used to initialize the parameters in the NORMAL_PARMINIT subroutine.

Output 28.1.2 Details of the Fitted Normal Distribution Model

The SEVERITY Procedure
Normal Distribution

Distribution Information

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Mu	1	10.02059	0.23894	41.94	<.0001
Sigma	1	2.36538	0.16896	14.00	<.0001

The NORMAL distribution defined and illustrated here has no scale parameter, because all the following inequalities are true:

$$f(x;\mu,\sigma) \neq \frac{1}{\mu} f(\frac{x}{\mu};1,\sigma)$$
$$f(x;\mu,\sigma) \neq \frac{1}{\sigma} f(\frac{x}{\sigma};\mu,1)$$
$$F(x;\mu,\sigma) \neq F(\frac{x}{\mu};1,\sigma)$$
$$F(x;\mu,\sigma) \neq F(\frac{x}{\sigma};\mu,1)$$

This implies that you cannot estimate the influence of regression effects on a model for the response variable based on this distribution.

Example 28.2: Defining a Model for the Gaussian Distribution with a Scale Parameter

If you want to estimate the influence of regression effects, then the model needs to be parameterized to have a scale parameter. Although this might not be always possible, it is possible for the Gaussian distribution by replacing the location parameter μ with another parameter, $\alpha = \mu/\sigma$, and defining the PDF (f) and the CDF (F) as follows:

$$f(x;\sigma,\alpha) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{1}{2}\left(\frac{x}{\sigma}-\alpha\right)^2\right)$$
$$F(x;\sigma,\alpha) = \frac{1}{2}\left(1+\operatorname{erf}\left(\frac{1}{\sqrt{2}}\left(\frac{x}{\sigma}-\alpha\right)\right)\right)$$

You can verify that σ is the scale parameter, because both of the following equalities are true:

$$f(x;\sigma,\alpha) = \frac{1}{\sigma} f(\frac{x}{\sigma};1,\alpha)$$
$$F(x;\sigma,\alpha) = F(\frac{x}{\sigma};1,\alpha)$$

NOTE: The Gaussian distribution is not a commonly used severity distribution. It is used in this example primarily to illustrate the concept of parameterizing a distribution such that it has a scale parameter. Although the distribution has a support over the entire real line, you can fit the distribution with PROC SEVERITY only if the input sample contains nonnegative values.

The following statements use the alternate parameterization to define a new model named NORMAL_S. The definition is stored in the Work.Sevexmpl library.

```
/*-------- Define Normal Distribution With Scale Parameter  ----------*/
proc fcmp library=sashelp.svrtdist outlib=work.sevexmpl.models;
   function normal_s_pdf(x, Sigma, Alpha);
      /* Sigma : Scale & Standard Deviation */
      /* Alpha : Scaled mean */
      return ( exp(-(x/Sigma - Alpha)**2/2) /
             (Sigma * sqrt(2*constant('PI'))) );
   endsub;

   function normal_s_cdf(x, Sigma, Alpha);
      /* Sigma : Scale & Standard Deviation */
      /* Alpha : Scaled mean */
      z = x/Sigma - Alpha;
      return (0.5 + 0.5*erf(z/sqrt(2)));
   endsub;

   subroutine normal_s_parminit(dim, x[*], nx[*], F[*], Ftype, Sigma, Alpha);
      outargs Sigma, Alpha;
      array m[2] / nosymbols;

      /* Compute estimates by using method of moments */
      call svrtutil_rawmoments(dim, x, nx, 2, m);
      Sigma = sqrt(m[2] - m[1]**2);
      Alpha = m[1]/Sigma;
   endsub;

   subroutine normal_s_lowerbounds(Sigma, Alpha);
      outargs Sigma, Alpha;
      Alpha = .; /* Alpha has no lower bound */
      Sigma = 0; /* Sigma > 0 */
   endsub;
quit;
```

An important point to note is that the scale parameter *Sigma* is the first distribution parameter (after the 'x' argument) listed in the signatures of NORMAL_S_PDF and NORMAL_S_CDF functions. *Sigma* is also the first distribution parameter listed in the signatures of other subroutines. This is required by PROC SEVERITY, so that it can identify which is the scale parameter. When you specify regression effects, PROC SEVERITY checks whether the first parameter of each candidate distribution is a scale parameter (or a log-transformed scale parameter if *dist*_SCALETRANSFORM subroutine is defined for the distribution with LOG as the transform). If it is not, then an appropriate message is written the SAS log and that distribution is not fitted.

Let the following DATA step statements simulate a sample from the normal distribution where the parameter σ is affected by the regressors as follows:

$$\sigma = \exp(1 + 0.5\ \mathrm{X1} + 0.75\ \mathrm{X3} - 2\ \mathrm{X4} + \mathrm{X5})$$

The sample is simulated such that the regressor X2 is linearly dependent on regressors X1 and X3.

```
/*--- Simulate a Normal sample affected by Regressors ---*/
data testnorm_reg(keep=y x1-x5 Sigma);
   array x{*} x1-x5;
   array b{6} _TEMPORARY_ (1 0.5 . 0.75 -2 1);
   call streaminit(34567);
   label y='Normal Response Influenced by Regressors';

   do n = 1 to 100;
      /* simulate regressors */
      do i = 1 to dim(x);
         x(i) = rand('UNIFORM');
      end;
      /* make x2 linearly dependent on x1 and x3 */
      x(2) = x(1) + 5 * x(3);

      /* compute log of the scale parameter */
      logSigma = b(1);
      do i = 1 to dim(x);
         if (i ne 2) then
            logSigma = logSigma + b(i+1) * x(i);
      end;

      Sigma = exp(logSigma);
      y = rand('NORMAL', 25, Sigma);
      output;
   end;
run;
```

The following statements use PROC SEVERITY to fit the NORMAL_S distribution model along with some of the predefined distributions to the simulated sample:

```
/*--- Set the search path for functions defined with PROC FCMP ---*/
options cmplib=(work.sevexmpl);

/*-------- Fit models with PROC SEVERITY --------*/
proc severity data=testnorm_reg print=all plots=none;
   loss y;
   scalemodel x1-x5;
   dist Normal_s burr logn pareto weibull;
run;
```

The "Model Selection" table in Output 28.2.1 indicates that all the models, except the Burr distribution model, have converged. Also, only three models, Normal_s, Burr, and Weibull, seem to have a good fit for the data. The table that compares all the fit statistics indicates that Normal_s model is the best according to the likelihood-based statistics; however, the Burr model is the best according to the EDF-based statistics.

Output 28.2.1 Summary of Results for Fitting the Normal Distribution with Regressors

Note: The asterisk (*) marks the best model according to each column's criterion.

This prompts you to further evaluate why the model with Burr distribution has not converged. The initial values, convergence status, and the optimization summary for the Burr distribution are shown in Output 28.2.2. The initial values table indicates that the regressor X2 is redundant, which is expected. More importantly, the convergence status indicates that it requires more than 50 iterations. PROC SEVERITY enables you to change several settings of the optimizer by using the NLOPTIONS statement. In this case, you can increase the limit of 50 on the iterations, change the convergence criterion, or change the technique to something other than the default trust-region technique.

Output 28.2.2 Details of the Fitted Burr Distribution Model

The SEVERITY Procedure
Burr Distribution

Distribution Information

Name	Burr
Description	Burr Distribution (Type XII Family)
Distribution Parameters	3

Output 28.2.2 *continued*

Convergence Status
Needs more than 50 iterations.

Optimization Summary	
Optimization Technique	Trust Region
Iterations	50
Function Calls	137
Log Likelihood	-306.40842

The following PROC SEVERITY step uses the NLOPTIONS statement to change the convergence criterion and the limits on the iterations and function evaluations, exclude the lognormal and Pareto distributions that have been confirmed previously to fit the data poorly, and exclude the redundant regressor X2 from the model:

```
/*--- Refit and compare models with higher limit on iterations ---*/
proc severity data=testnorm_reg print=all plots=pp;
   loss y;
   scalemodel x1 x3-x5;
   dist Normal_s burr weibull;
   nloptions absfconv=2.0e-5 maxiter=100 maxfunc=500;
run;
```

The results shown in Output 28.2.3 indicate that the Burr distribution has now converged and that the Burr and Weibull distributions have an almost identical fit for the data. The NORMAL_S distribution is still the best distribution according to the likelihood-based criteria.

Output 28.2.3 Summary of Results after Changing Maximum Number of Iterations

The SEVERITY Procedure

Input Data Set	
Name	WORK.TESTNORM_REG

Model Selection

Distribution	Converged	-2 Log Likelihood	Selected
Normal_s	Yes	603.95786	Yes
Burr	Yes	612.79276	No
Weibull	Yes	612.77496	No

All Fit Statistics

Distribution	-2 Log Likelihood		AIC		AICC		BIC		KS		AD		CvM	
Normal_s	603.95786	*	615.95786	*	616.86108	*	631.58888	*	1.52388		4.00152		0.70769

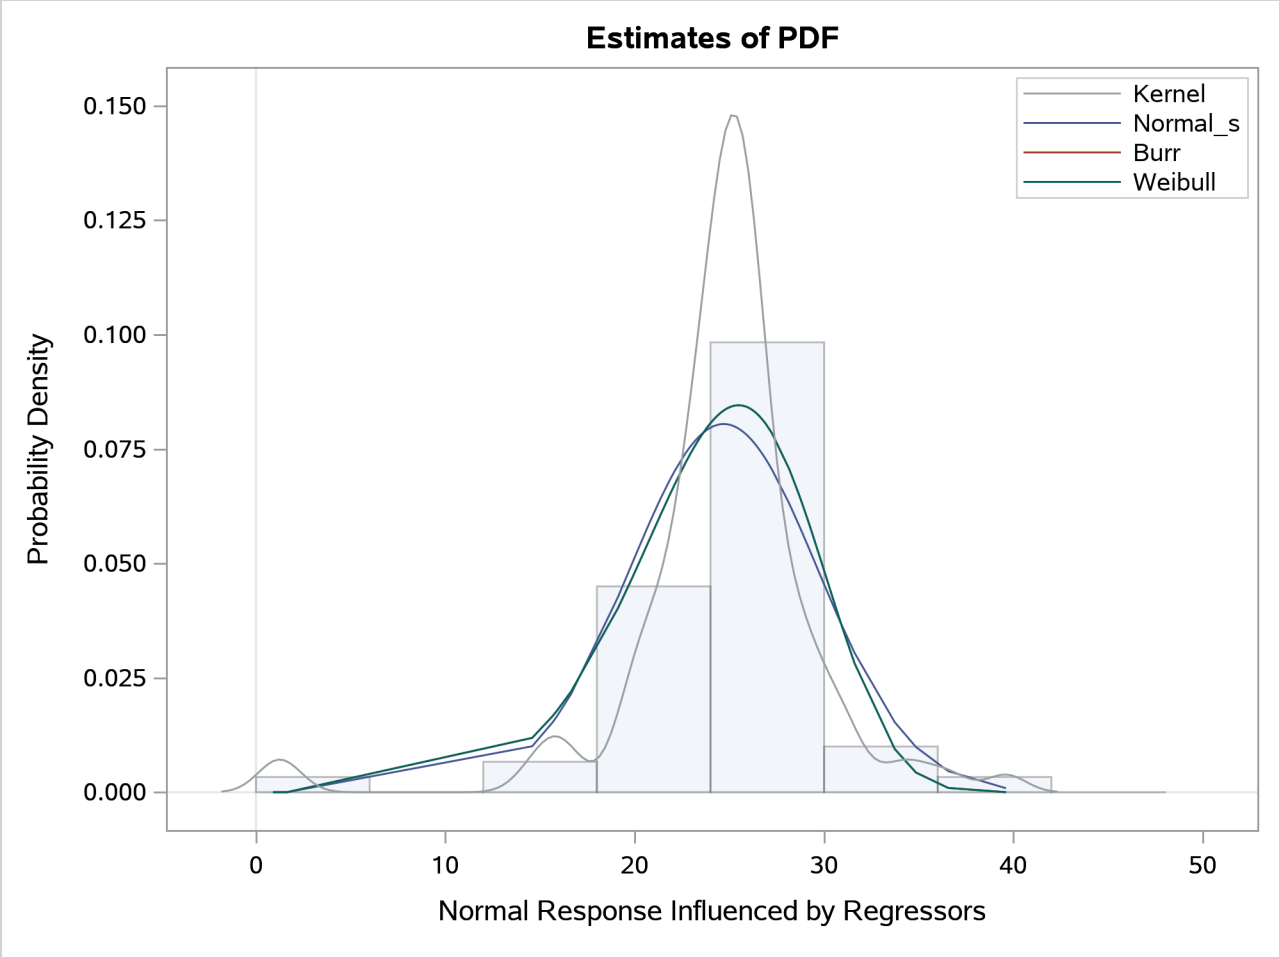
Note: The asterisk (*) marks the best model according to each column's criterion.

The comparison of the PDF estimates of all the candidates is shown in Output 28.2.4. Each plotted PDF estimate is an average computed over the N PDF estimates that are obtained with the scale parameter

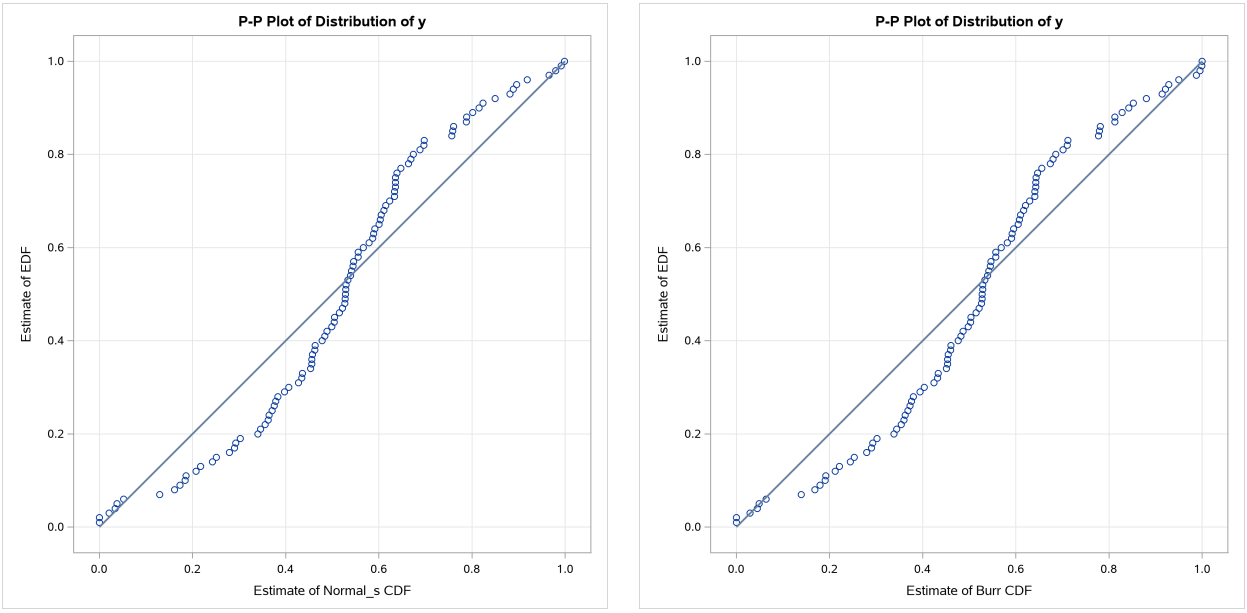
determined by each of the *N* observations in the input data set. The PDF plot shows that the Burr and Weibull models result in almost identical estimates. All the estimates have a slight left skew with the mode closer to Y=25, which is the mean of the simulated sample.

Output 28.2.4 Comparison of EDF and CDF Estimates of the Fitted Models



The P-P plots for the Normal_s and Burr distributions are shown in Output 28.2.5. These plots show how the EDF estimates compare against the CDF estimates. Each plotted CDF estimate is an average computed over the *N* CDF estimates that are obtained with the scale parameter determined by each of the *N* observations in the input data set. Comparing the P-P plots of Normal_s and Burr distributions indicates that both fit the data almost similarly, but the Burr distribution fits the right tail slightly better, which explains why the EDF-based statistics prefer it over the Normal_s distribution.

Output 28.2.5 Comparison of EDF and CDF Estimates of NORMAL_S and BURR Models



Example 28.3: Defining a Model for Mixed-Tail Distributions

In some applications, a few severity values tend to be extreme as compared to the typical values. The extreme values represent the worst case scenarios and cannot be discarded as outliers. Instead, their distribution must be modeled to prepare for their occurrences. In such cases, it is often useful to fit one distribution to the non-extreme values and another distribution to the extreme values. The *mixed-tail* distribution mixes two distributions: one for the *body* region, which contains the non-extreme values, and another for the *tail* region, which contains the extreme values. The tail distribution is usually a generalized Pareto distribution (GPD), because it is good for modeling the conditional excess severity above a threshold. The body distribution can be any distribution. The following definitions are used in describing a generic formulation of a mixed-tail distribution:

$g(x)$	PDF of the body distribution
$G(x)$	CDF of the body distribution
$h(x)$	PDF of the tail distribution
$H(x)$	CDF of the tail distribution
θ	scale parameter for the body distribution
Ω	set of nonscale parameters for the body distribution
ξ	shape parameter for the GPD tail distribution
x_r	normalized value of the response variable at which the tail starts
p_n	mixing probability

Given these notations, the PDF $f(x)$ and the CDF $F(x)$ of the mixed-tail distribution are defined as

$$f(x) = \begin{cases} \frac{p_n}{G(x_b)} g(x) & \text{if } x \le x_b \\ (1 - p_n) h(x - x_b) & \text{if } x > x_b \end{cases}$$

$$F(x) = \begin{cases} \frac{p_n}{G(x_b)} G(x) & \text{if } x \le x_b \\ p_n + (1 - p_n) H(x - x_b) & \text{if } x > x_b \end{cases}$$

where $x_b = \theta x_r$ is the value of the response variable at which the tail starts.

These definitions indicate the following:

- The body distribution is conditional on $X \le x_b$, where X denotes the random response variable.
- The tail distribution is the generalized Pareto distribution of the $(X - x_b)$ values.
- The probability that a response variable value belongs to the body is p_n. Consequently the probability that the value belongs to the tail is $(1 - p_n)$.

The parameters of this distribution are θ, Ω, ξ, x_r, and p_n. The scale of the GPD tail distribution θ_t is computed as

$$\theta_t = \frac{G(x_b; \theta, \Omega)}{g(x_b; \theta, \Omega)} \frac{(1 - p_n)}{p_n} = \theta \frac{G(x_r; \theta = 1, \Omega)}{g(x_r; \theta = 1, \Omega)} \frac{(1 - p_n)}{p_n}$$

The parameter x_r is usually initialized using a tail index estimation algorithm. One such algorithm is Hill's algorithm (Danielsson et al. 2001), which is implemented by the predefined utility function SVRTUTIL_HILLCUTOFF available to you in the Sashelp.Svrtdist library. The algorithm and the utility function are described in detail in the section "Predefined Utility Functions" on page 2131. The function computes an estimate of x_b, which can be used to compute an initial estimate of x_r as $x_r = x_b/\hat{\theta}$, where $\hat{\theta}$ is the estimate of the scale parameter of the body distribution.

The parameter p_n is usually determined by the domain expert based on the fraction of losses that are expected to belong to the tail.

The following SAS statements define the LOGNGPD distribution model for a mixed-tail distribution with the lognormal distribution as the body distribution and GPD as the tail distribution:

```
/*------- Define Lognormal Body-GPD Tail Mixed Distribution -------*/
proc fcmp library=sashelp.svrtdist outlib=work.sevexmpl.models;
   function LOGNGPD_DESCRIPTION() $256;
      length desc $256;
      desc1 = "Lognormal Body-GPD Tail Distribution.";
      desc2 = " Mu, Sigma, Xi, and Xr are free parameters.";
      desc3 = " Pn is a constant parameter.";
      desc = desc1 || desc2 || desc3;
      return(desc);
   endsub;

   function LOGNGPD_SCALETRANSFORM() $3;
      length xform $3;
      xform = "LOG";
      return (xform);
   endsub;

   subroutine LOGNGPD_CONSTANTPARM(Pn);
   endsub;
```

```
function LOGNGPD_PDF(x, Mu,Sigma,Xi,Xr,Pn);
   cutoff = exp(Mu) * Xr;
   p = CDF('LOGN',cutoff, Mu, Sigma);
   if (x < cutoff + constant('MACEPS')) then do;
      return ((Pn/p)*PDF('LOGN', x, Mu, Sigma));
   end;
   else do;
      gpd_scale = p*((1-Pn)/Pn)/PDF('LOGN', cutoff, Mu, Sigma);
      h = (1+Xi*(x-cutoff)/gpd_scale)**(-1-(1/Xi))/gpd_scale;
      return ((1-Pn)*h);
   end;
endsub;

function LOGNGPD_CDF(x, Mu,Sigma,Xi,Xr,Pn);
   cutoff = exp(Mu) * Xr;
   p = CDF('LOGN',cutoff, Mu, Sigma);
   if (x < cutoff + constant('MACEPS')) then do;
      return ((Pn/p)*CDF('LOGN', x, Mu, Sigma));
   end;
   else do;
      gpd_scale = p*((1-Pn)/Pn)/PDF('LOGN', cutoff, Mu, Sigma);
      H = 1 - (1 + Xi*((x-cutoff)/gpd_scale))**(-1/Xi);
      return (Pn + (1-Pn)*H);
   end;
endsub;

subroutine LOGNGPD_PARMINIT(dim,x[*],nx[*],F[*],Ftype,
                     Mu,Sigma,Xi,Xr,Pn);
   outargs Mu,Sigma,Xi,Xr,Pn;
   array xe[1] / nosymbols;
   array nxe[1] / nosymbols;

   eps = constant('MACEPS');

   Pn = 0.8; /* Set mixing probability */
   _status_ = .;
   call streaminit(56789);
   Xb = svrtutil_hillcutoff(dim, x, 100, 25, _status_);
   if (missing(_status_) or _status_ = 1) then
      Xb = svrtutil_percentile(Pn, dim, x, F, Ftype);

   /* Initialize lognormal parameters */
   call logn_parminit(dim, x, nx, F, Ftype, Mu, Sigma);
   if (not(missing(Mu))) then
      Xr = Xb/exp(Mu);
   else
      Xr = .;

   /* prepare arrays for excess values */
   i = 1;
   do while (i <= dim and x[i] < Xb+eps);
      i = i + 1;
   end;
   dime = dim-i+1;
```

```
      if (dime > 0) then do;
         call dynamic_array(xe, dime);
         call dynamic_array(nxe, dime);
         j = 1;
         do while(i <= dim);
            xe[j] = x[i] - Xb;
            nxe[j] = nx[i];
            i = i + 1;
            j = j + 1;
         end;

         /* Initialize GPD's shape parameter using excess values */
         call gpd_parminit(dime, xe, nxe, F, Ftype, theta_gpd, Xi);
      end;
      else do;
         Xi = .;
      end;
   endsub;

   subroutine LOGNGPD_LOWERBOUNDS(Mu,Sigma,Xi,Xr,Pn);
      outargs Mu,Sigma,Xi,Xr,Pn;

      Mu    = .; /* Mu has no lower bound */
      Sigma = 0; /* Sigma > 0 */
      Xi    = 0; /* Xi > 0 */
      Xr    = 0; /* Xr > 0 */
   endsub;
quit;
```

Note the following points about the LOGNGPD definition:

- The parameter p_n is not estimated with the maximum likelihood method used by PROC SEVERITY, so you need to specify it as a *constant* parameter by defining the *dist*_CONSTANTPARM subroutine. The signature of the LOGNGPD_CONSTANTPARM subroutine lists only the constant parameter *Pn*.

- The LOGNGPD_PARMINIT subroutine initializes the parameter x_r by first using the SVRTUTIL_HILLCUTOFF utility function to compute an estimate of the cutoff point $\hat{x}_b$ and then computing $x_r = \hat{x}_b / e^{\hat{\mu}}$. If SVRTUTIL_HILLCUTOFF fails to compute a valid estimate, then the SVRTUTIL_PERCENTILE utility function is used to set $\hat{x}_b$ to the p_nth percentile of the data. The parameter p_n is fixed to 0.8.

- The Sashelp.Svrtdist library is specified with the LIBRARY= option in the PROC FCMP statement to enable the LOGNGPD_PARMINIT subroutine to use the predefined utility functions (SVRTUTIL_HILLCUTOFF and SVRTUTIL_PERCENTILE) and parameter initialization subroutines (LOGN_PARMINIT and GPD_PARMINIT).

- The LOGNGPD_LOWERBOUNDS subroutine defines the lower bounds for all parameters. This subroutine is required because the parameter *Mu* has a non-default lower bound. The bounds for *Sigma*, *Xr*, and *Xi* must be specified. If they are not specified, they are returned as missing values, which PROC SEVERITY interprets as having no lower bound. You do not need to specify any bounds for the constant parameter *Pn*, because it is not subject to optimization.

The following DATA step statements simulate a sample from a mixed-tail distribution with a lognormal body and GPD tail. The parameter p_n is fixed to 0.8, the same value used in the LOGNGPD_PARMINIT subroutine defined previously.

```
/*----- Simulate a sample for the mixed-tail distribution -----*/
data testmixdist(keep=y label='Lognormal Body-GPD Tail Sample');
   call streaminit(45678);
   label y='Response Variable';
   N = 1000;
   Mu = 1.5;
   Sigma = 0.25;
   Xi = 0.7;
   Pn = 0.8;

   /* Generate data comprising the lognormal body */
   Nbody = N*Pn;
   do i=1 to Nbody;
      y = exp(Mu) * rand('LOGNORMAL')**Sigma;
      output;
   end;

   /* Generate data comprising the GPD tail */
   cutoff = quantile('LOGNORMAL', Pn, Mu, Sigma);
   gpd_scale = (1-Pn) / pdf('LOGNORMAL', cutoff, Mu, Sigma);
   do i=Nbody+1 to N;
      y = cutoff + ((1-rand('UNIFORM'))**(-Xi) - 1)*gpd_scale/Xi;
      output;
   end;
run;
```

The following statements use PROC SEVERITY to fit the LOGNGPD distribution model to the simulated sample. They also fit three other predefined distributions (BURR, LOGN, and GPD). The final parameter estimates are written to the Work.Parmest data set.

```
/*--- Set the search path for functions defined with PROC FCMP ---*/
options cmplib=(work.sevexmpl);

/*-------- Fit LOGNGPD model with PROC SEVERITY --------*/
proc severity data=testmixdist print=all outest=parmest
      plots(histogram kernel)=(all conditionalpdf(leftq=0.7 rightq=0.95));
   loss y;
   dist logngpd burr logn gpd;
run;
```

The PLOTS=CONDITIONALPDF option specifies that the PDF plot be split into three regions that are separated by the 70th and 95th percentiles.

Some of the results prepared by PROC SEVERITY are shown in Output 28.3.1 through Output 28.3.5. The "Model Selection" table in Output 28.3.1 indicates that all models converged. The last table in Output 28.3.1 shows that the model with LOGNGPD distribution has the best fit according to all the statistics of fit. The Burr distribution model is the closest contender to the LOGNGPD model, but the GPD distribution model fits the data poorly.

Output 28.3.1 Summary of Fitting Mixed-Tail Distribution

The SEVERITY Procedure

Input Data Set	
Name	WORK.TESTMIXDIST
Label	Lognormal Body-GPD Tail Sample

Model Selection

Distribution	Converged	-2 Log Likelihood	Selected
logngpd	Yes	3640	Yes

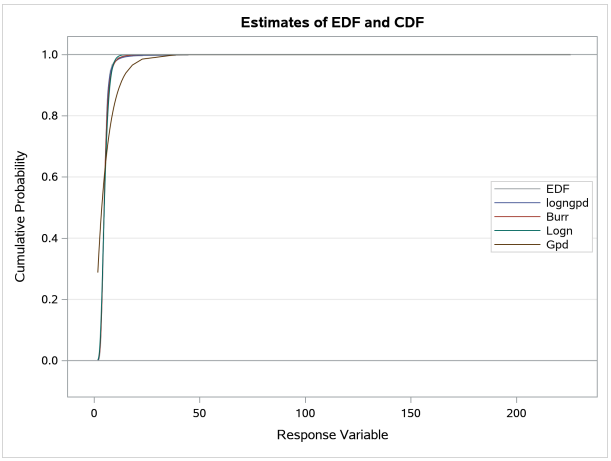
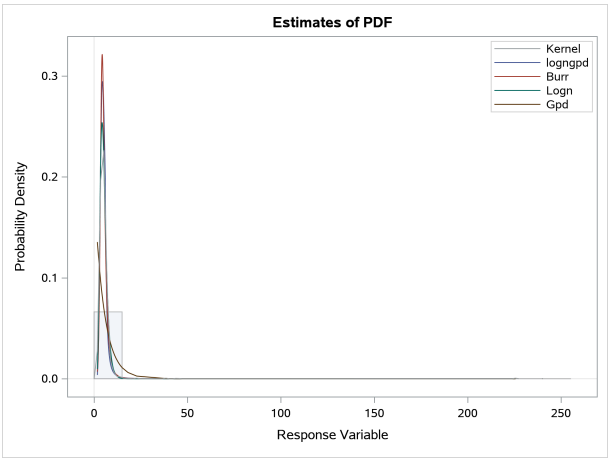
Logn	3862		3866		3866		3875		2.20231		7.31780		0.94769	
Gpd	5344		5348		5348		5358		12.27970		218.30354		44.54186	

Note: The asterisk (*) marks the best model according to each column's criterion.

Output 28.3.2 Comparison of the CDF and PDF Estimates of the Fitted Models



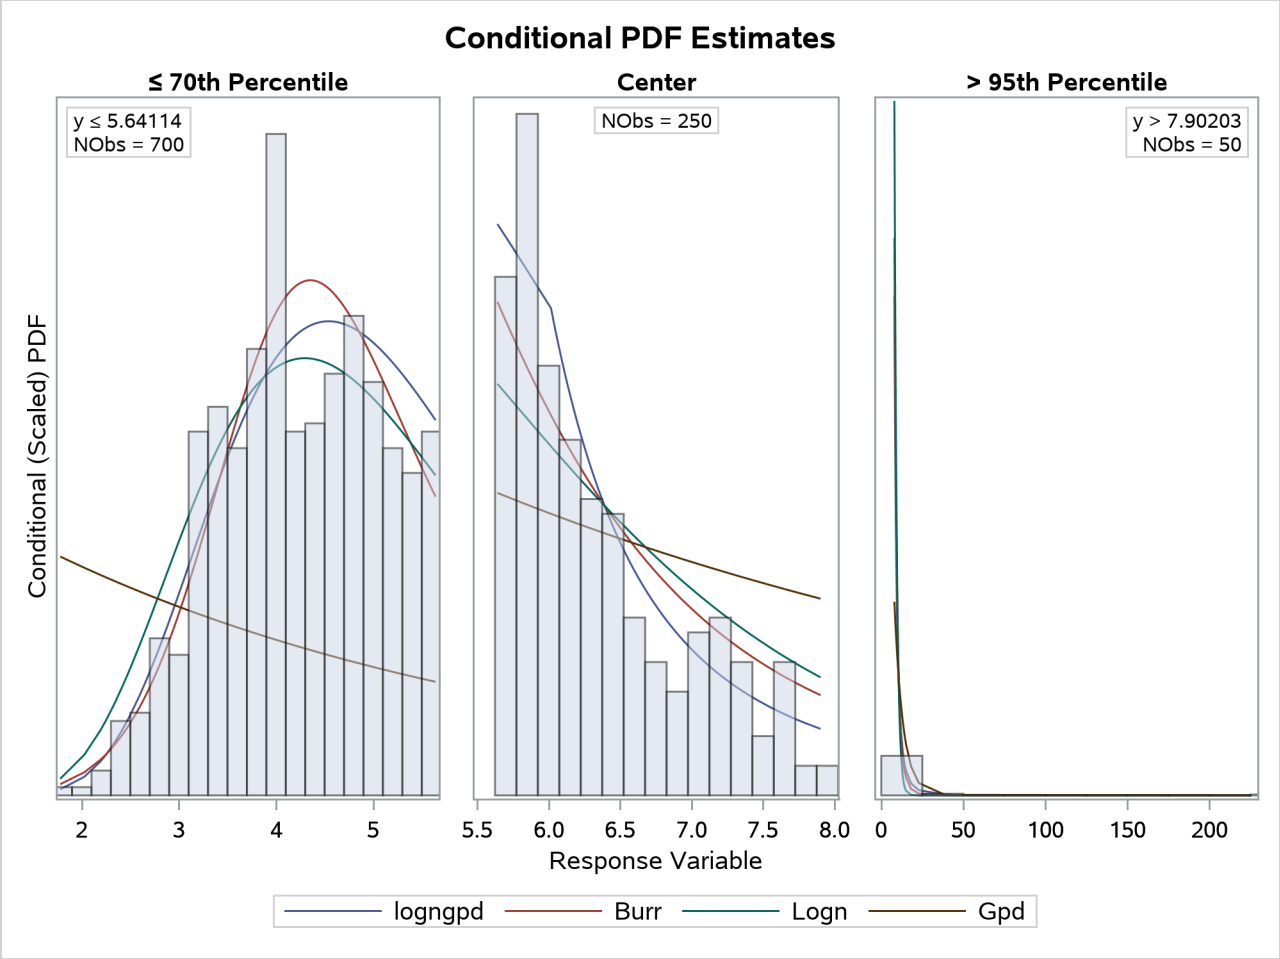


The plots in Output 28.3.2 confirm that the GPD distribution fits the data poorly. It is difficult to compare the other three distributions based on the CDF and PDF comparison plots because of the heaviness of the tail. However, the conditional PDF plot in Output 28.3.3 helps you compare the distributions by zooming in on certain regions of the PDF comparison plot.

The conditional PDF plot of the left region ('$\leq$ 70th Percentile') shows that Burr and lognormal distributions do not fit the data as well as the LOGNGPD distribution in the body portion. The plot of the center region shows that Burr and lognormal distributions also have a poorer fit in the tail portion than the LOGNGPD distribution. The downward dip in the PDF of the LOGNGPD distribution around $y = 6.0$ in the center

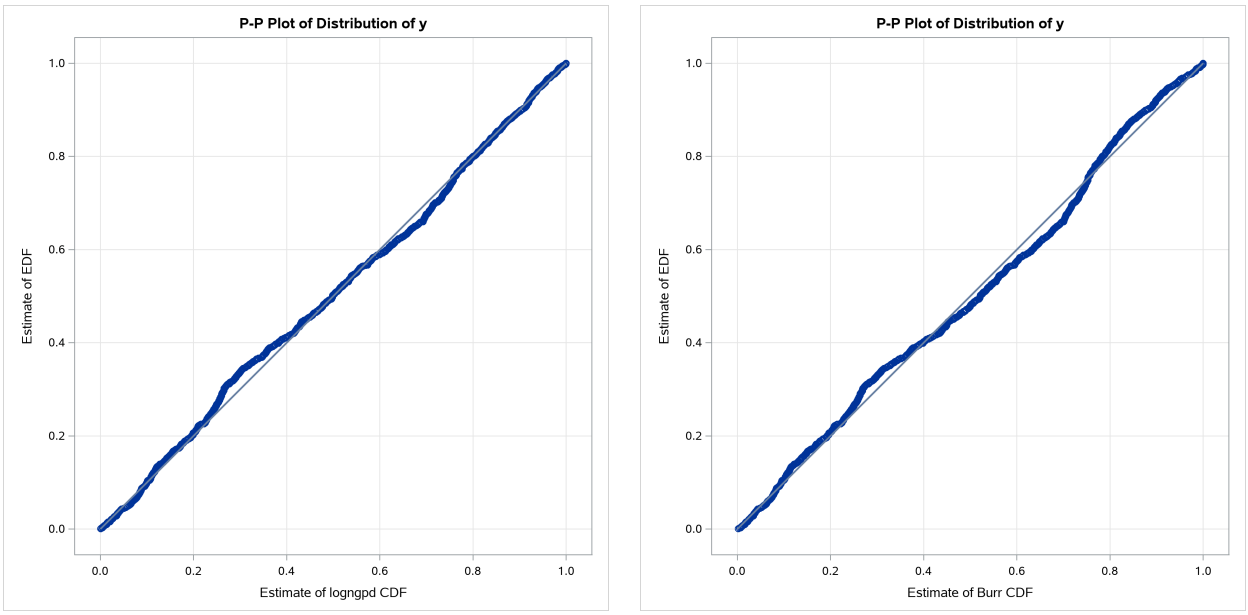
plot shows the approximate location of x_b, where the tail portion of the mixture distribution begins. This illustrates the LOGNGPD distribution's ability to adapt to the tail.

Output 28.3.3 Comparison of the Conditional PDF Estimates of the Fitted Models



The Burr distribution is the closest contender to the LOGNGPD distribution. The P-P plots in Output 28.3.4 provide more visual confirmation that the LOGNGPD distribution fits the tail region better than the Burr distribution.

Output 28.3.4 P-P Plots for the LOGNGPD and BURR Distribution Models



The detailed results for the LOGNGPD distribution are shown in Output 28.3.5. The initial values table shows the fixed value of the *Pn* parameter that the LOGNGPD_PARMINIT subroutine sets. The table uses the bounds columns to indicate that it is a constant parameter. The last table in the figure shows the final parameter estimates. The estimates of all free parameters are significantly different from 0. As expected, the final estimate of the constant parameter *Pn* has not changed from its initial value.

Output 28.3.5 Detailed Results for the LOGNGPD Distribution

Log Likelihood	-1819.8

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Mu	1	1.61374	0.02509	64.31	<.0001
Sigma	1	0.31716	0.01541	20.59	<.0001
Xi	1	0.53177	0.08867	6.00	<.0001
Xr	1	1.19816	0.03925	30.52	<.0001
Pn	1	0.80000	Constant	.	.

The following SAS statements use the parameter estimates to compute the value where the tail region is estimated to start ($x_b = e^{\hat{\mu}}\hat{x_r}$) and the scale of the GPD tail distribution ($\theta_t = \frac{G(x_b)}{g(x_b)}\frac{(1-p_n)}{p_n}$):

```
/*-------- Compute tail cutoff and tail distribution's scale --------*/
data xb_thetat(keep=x_b theta_t);
   set parmest(where=(_MODEL_='logngpd' and _TYPE_='EST'));
   x_b = exp(Mu) * Xr;
   theta_t = (CDF('LOGN',x_b,Mu,Sigma)/PDF('LOGN',x_b,Mu,Sigma)) *
             ((1-Pn)/Pn);
run;

proc print data=xb_thetat noobs;
run;
```

Output 28.3.6 Start of the Tail and Scale of the GPD Tail Distribution

x_b	theta_t
6.01665	1.00677

The computed values of x_b and θ_t are shown as *x_b* and *theta_t* in Output 28.3.6. Equipped with this additional derived information, you can now interpret the results of fitting the mixed-tail distribution as follows:

- The tail starts at $y \approx 6.02$. Optimizing the scale-normalized relative cutoff (x_r) in addition to optimizing the scale of the body region ($\theta = e^{\mu}$) gives you more flexibility in optimizing the absolute cutoff (x_b). If *Xr* is declared as a constant parameter, then x_b is optimized by virtue of optimizing the scale of the body region ($\theta = e^{\mu}$), and you must rely on Hill's tail index estimator to yield an initial estimate of x_b that is close to an optimal estimate. By keeping *Xr* as a free parameter, you account for the possibility that Hill's estimator can yield a suboptimal estimate.
- The values $y \leq 6.02$ follow the lognormal distribution with parameters $\mu \approx 1.61$ and $\sigma \approx 0.32$. These parameter estimates are reasonably close to the parameters of the body distribution that is used

for simulating the sample.

- If X_t denotes the loss random variable for the tail defined as $X_t = X - x_b$, where X is the original loss variable, then for this example, $\Pr[X_t = X - 6.02 | X_t > 0]$ follows the GPD density function with scale $\theta_t \approx 1.01$ and shape $\xi \approx 0.53$.

Example 28.4: Estimating Parameters Using the Cramér–von Mises Estimator

PROC SEVERITY enables you to estimate model parameters by minimizing your own objective function. This example illustrates how you can use PROC SEVERITY to implement the Cramér–von Mises estimator. Let $F(y_i; \Theta)$ denote the estimate of CDF at y_i for a distribution with parameters Θ, and let $F_n(y_i)$ denote the empirical estimate of CDF (EDF) at y_i that is computed from a sample y_i, $1 \leq i \leq N$. Then, the Cramér–von Mises estimator of the parameters is defined as

$$\hat{\Theta} = \arg\min_{\Theta} \sum_{i=1}^{N} (F(y_i; \Theta) - F_n(y_i))^2$$

This estimator belongs to the class of minimum distance estimators. It attempts to estimate the parameters such that the squared distance between the CDF and EDF estimates is minimized.

The following PROC SEVERITY step uses the Cramér–von Mises estimator to fit four candidate distribution models, including the LOGNGPD mixed-tail distribution model that was defined in "Example 28.3: Defining a Model for Mixed-Tail Distributions" on page 2169. The input sample is the same as is used in that example.

```
/*--- Set the search path for functions defined with PROC FCMP ---*/
options cmplib=(work.sevexmpl);

/*-------- Fit LOGNGPD model with PROC SEVERITY by using -------
  -------- the Cramer-von Mises minimum distance estimator -------*/
proc severity data=testmixdist obj=cvmobj print=all outest=est
     plots(histogram)=(pp conditionalpdf(rightq=0.8));
   loss y;
   dist logngpd burr logn gpd;

   * Cramer-von Mises estimator (minimizes the distance *
   * between parametric and nonparametric estimates)    *;
   cvmobj = _cdf_(y);
   cvmobj = (cvmobj -_edf_(y))**2;
run;
```

The OBJ= option in the PROC SEVERITY statement specifies that the objective function cvmobj should be minimized. The programming statements compute the contribution of each observation in the input data set to the objective function cvmobj. The use of the keyword functions _CDF_ and _EDF_ makes the program applicable to all the distributions. In addition to requesting the P-P plot, the PLOTS= option requests the conditional PDF plots of the body and tail regions. The CONDITIONALPDF option with the RIGHTQ=0.8 suboption specifies that the comparative conditional PDF plot be prepared for two regions:

- the body region for loss values that are less than or equal to the 80th percentile

- the right-tail region for loss values that are greater than the 80th percentile

Some of the key results prepared by PROC SEVERITY are shown in Output 28.4.1. The "Model Selection" table indicates that all models converged. When you specify a custom objective function, the default selection criterion is the value of the custom objective function. The "All Fit Statistics" table indicates that LOGNGPD is the best distribution according to all the statistics of fit. Comparing the fit statistics of Output 28.4.1 with those of Output 28.3.1 indicates that the use of the Cramér–von Mises estimator has resulted in smaller values for all the EDF-based statistics of fit for all the models, which is expected from a minimum distance estimator.

Output 28.4.1 Summary of Cramér–von Mises Estimation

The SEVERITY Procedure

Input Data Set	
Name	WORK.TESTMIXDIST
Label	Lognormal Body-GPD Tail Sample

Model Selection

Distribution	Converged	cvmobj	Selected
logngpd	Yes	0.12846	Yes
Burr	Yes	0.22681	No
Logn	Yes	0.16928	No
Gpd	Yes	35.98574	No

All Fit Statistics

Distribution	cvmobj		-2 Log Likelihood		AIC		AICC		BIC		KS		AD		CvM	
logngpd	0.12846	*	3657	*	3667	*	3667	*	3691	*	0.86572	*	1.04025	*	0.12957	*

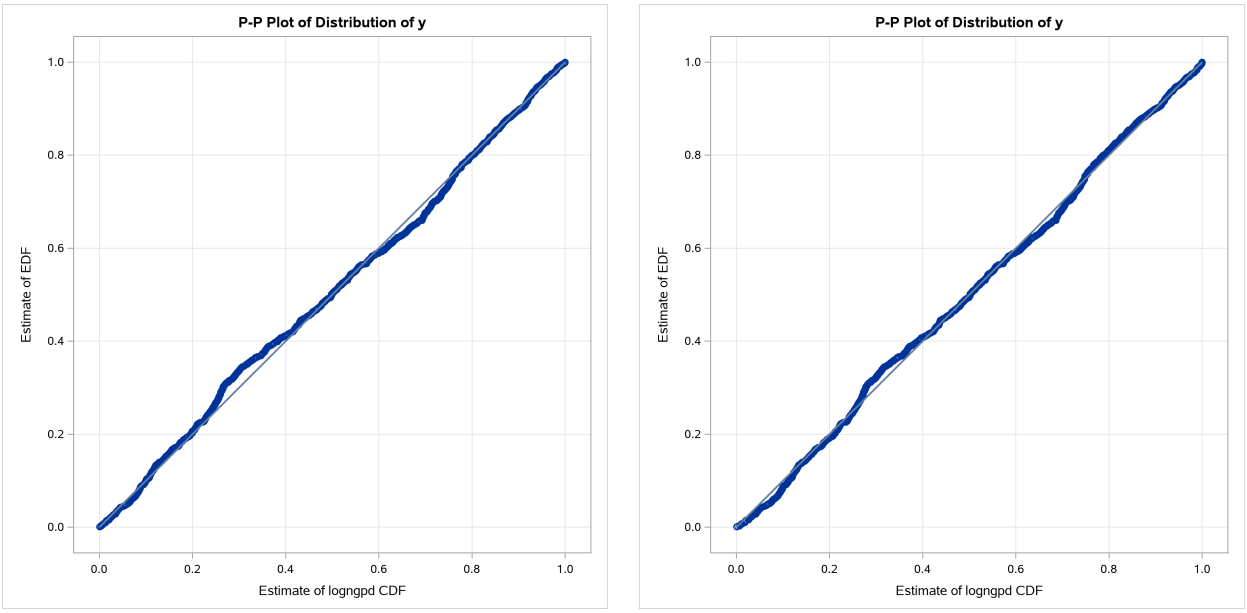
Gpd	35.98574		5401		5405		5405		5415		9.85292		188.93299		35.99968	

Note: The asterisk (*) marks the best model according to each column's criterion.

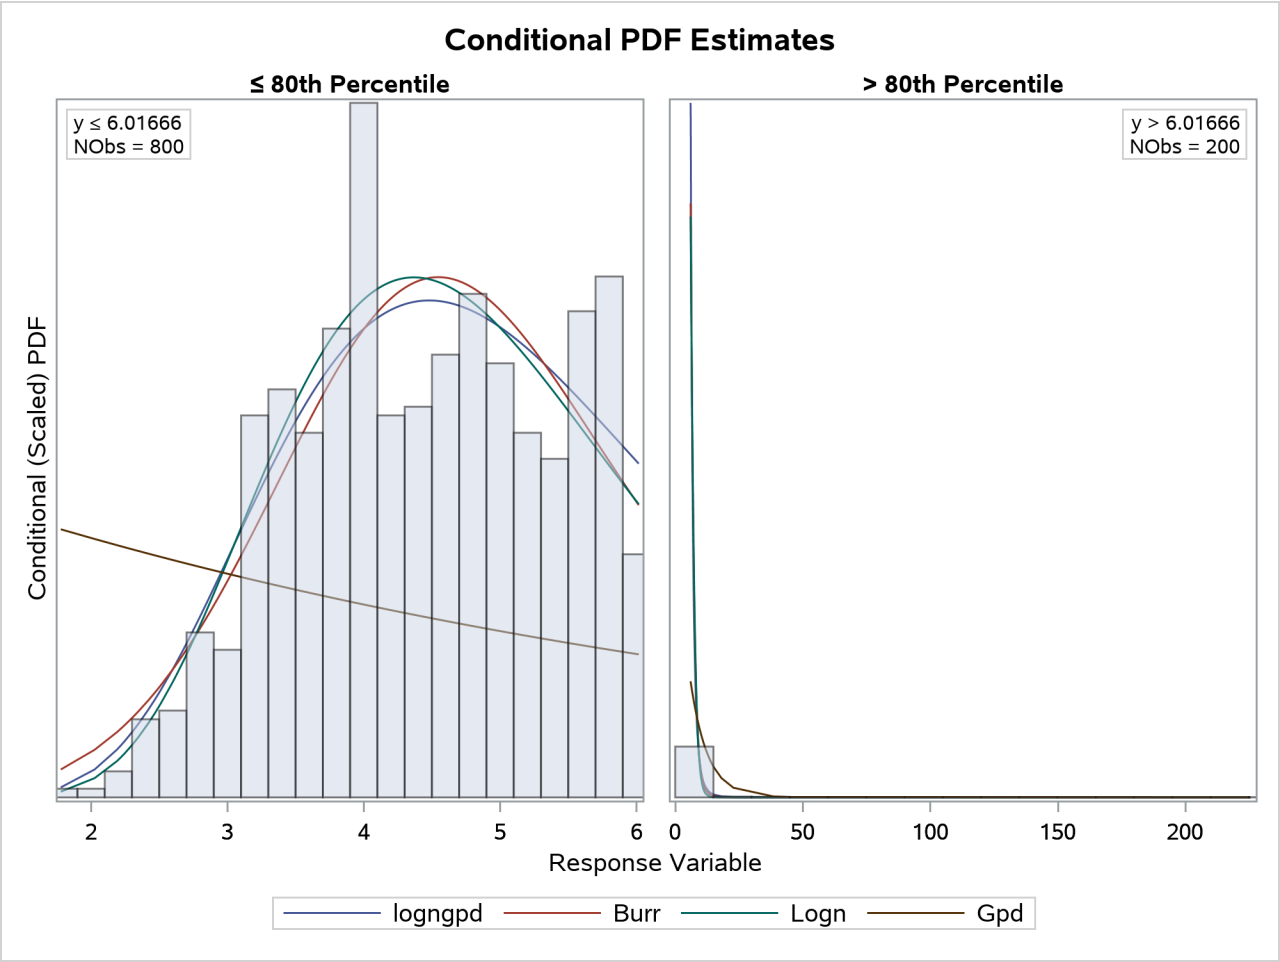
The P-P plots in Output 28.4.2 provide a visual confirmation that the CDF estimates match the EDF estimates more closely when compared to the estimates that are obtained with the maximum likelihood estimator.

Output 28.4.2 P-P Plots for LOGNGPD Model with Maximum Likelihood (Left) and Cramér–von Mises (Right) Estimators



The comparative conditional PDF plot in Output 28.4.3 shows how the scaled density functions of different distributions compare in the body and right-tail regions. The scaling factor of each region reflects the probability that a loss value falls in that region. For the RIGHTQ=0.8 option, in the body region, the PDF values are scaled by a factor of 1.25 ($= 1/0.8$), and in the right-tail region, the PDF values are scaled by a factor of 5 ($= 1/(1 - 0.8)$). Scaling makes the PDF plot in each region a true density function plot.

Output 28.4.3 Comparison of the Conditional PDF Estimates of the Fitted Models



The right-tail plot in Output 28.4.3 shows that the tail is heavy, but it is difficult to see the differences in the distributions because of the wide range of values in the tail. You can zoom in on specific portions of the tail by specifying the appropriate LEFTQ=, RIGHTQ=, and SHOWREGION= options. The following PROC SEVERITY step illustrates this:

```
proc severity data=testmixdist obj=cvmobj print=all inest=est
     plots=(conditionalpdf(leftq=0.75 rightq=0.975)
            conditionalpdfperdist(quantilebounds leftq=0.75 rightq=0.99
                                  showregion=(center right)));
   loss y;
   dist lognpgd burr logn gpd;

   * Cramer-von Mises estimator (minimizes the distance *
   * between parametric and nonparametric estimates)    *;
   cvmobj = _cdf_(y);
   cvmobj = (cvmobj -_edf_(y))**2;
run;
```

The CONDITIONALPDF option specifies that the comparative conditional PDF plots be prepared for three regions: Y <= 75th percentile, 75th percentile < Y <= 97.5th percentile, and Y > 97.5th percentile.

The suboptions of the CONDITIONALPDFPERDIST option specify that conditional PDF plots of individual distributions be prepared as follows:

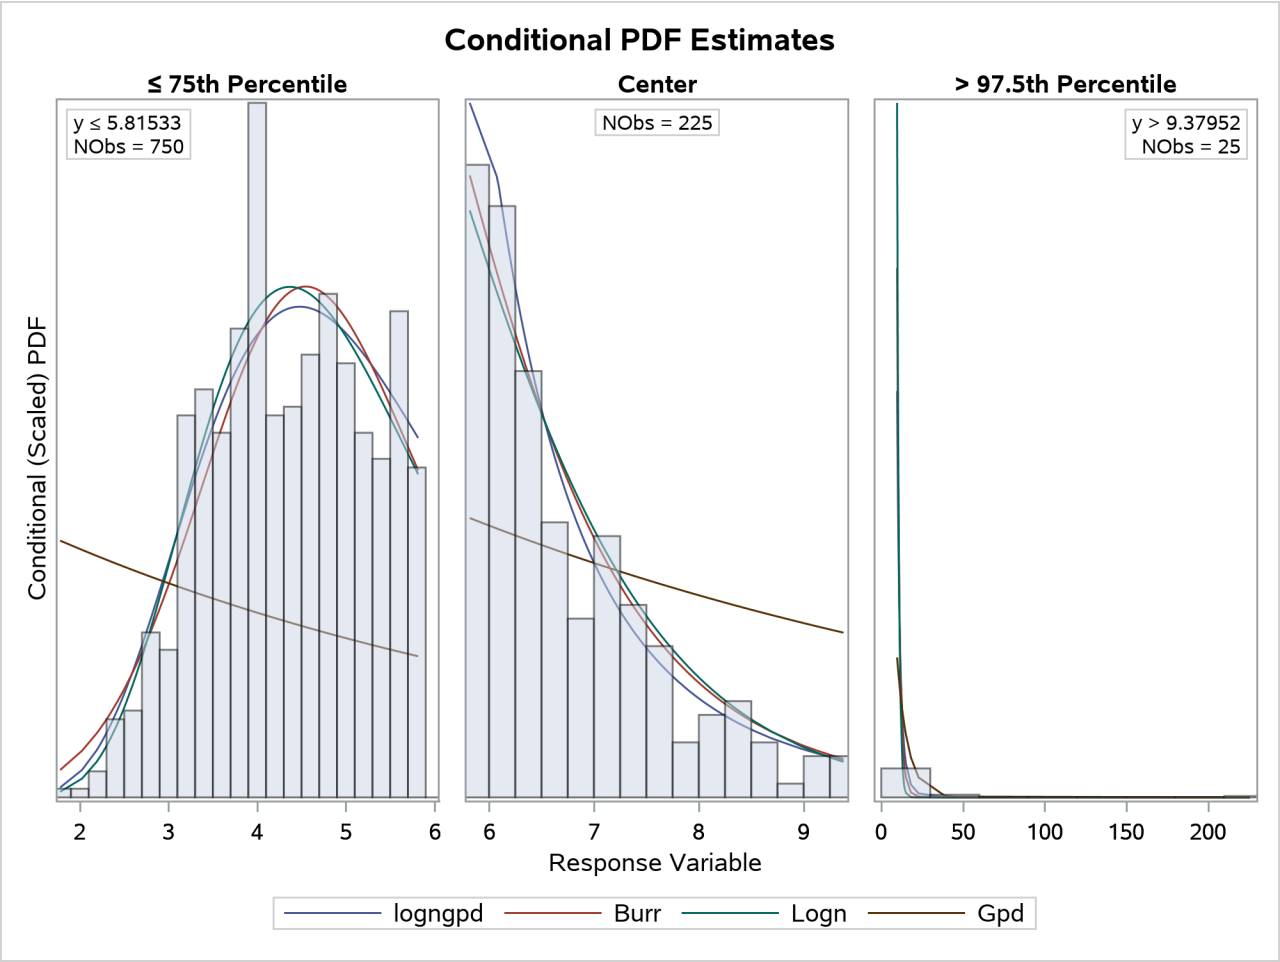
- The QUANTILEBOUNDS option specifies that the region boundaries be computed by using the quantile function of each distribution instead of the default of using percentiles. If you do not specify the QUANTILEBOUNDS option, then by default, PROC SEVERITY computes the region boundaries by using percentiles, which are empirical estimates of the quantile function.
- The LEFTQ= and RIGHTQ= options specify that the plots be prepared for three regions: Y <= Quantile(0.75), Quantile(0.75) < Y <= Quantile(0.99), and Y > Quantile(0.99). Note that the estimated quantile function might produce different values for different distributions, so the regions start and end at different values for different distributions.
- The SHOWREGION= option specifies that only the center and right-tail regions be plotted. The region between the LEFTQ= and RIGHTQ= values defines the center region. So in this example, the SHOW=CENTER option specifies that the region between Quantile(0.75) and Quantile(0.99) be shown. The SHOW=RIGHT option specifies that the right-tail region of values greater than Quantile(0.99) be shown. The example does not use the SHOW=LEFT option, so the left-tail region of values less than or equal to Quantile(0.75) is not shown.

The Work.Est data set is created by specifying the OUTEST= option in the first PROC SEVERITY step of this example. The use of that data set as the INEST= data set helps speed up the parameter initialization and estimation process significantly and enables you to explore different plotting options quickly.

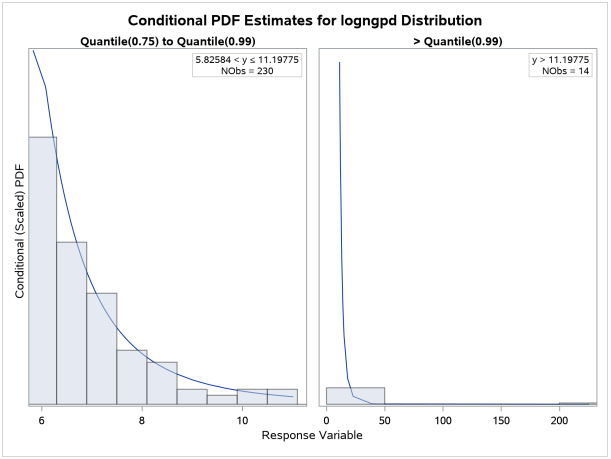
The comparative conditional PDF plot that is prepared by the preceding PROC SEVERITY step is shown in Output 28.4.4. It clearly shows the difference between different distributions in the three regions.

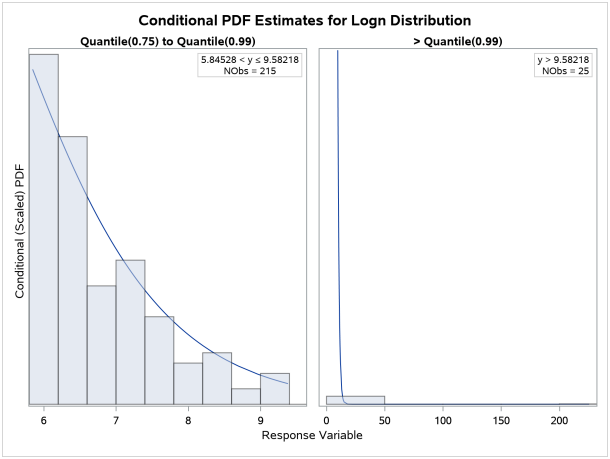
The “All Fit Statistics” table in Output 28.4.1 indicates that lognormal distribution is the best contender to the LOGNGPD distribution according to the EDF-based statistics of fit. The individual conditional PDF plots of the LOGNGPD and lognormal models are shown in Output 28.4.5. Comparing the two plots shows that the LOGNGPD distribution has a better fit than the lognormal distribution in the right-tail region. The information in the insets of each plot indicates that although the Quantile(0.75) values of both distributions are closer to each other, the Quantile(0.99) values are significantly different. The larger Quantile(0.99) value of the LOGNGPD distribution confirms that it has a heavier tail than the lognormal distribution.

Output 28.4.4 Comparative Conditional PDF Plots with Zoomed-In Tail Portions



Output 28.4.5 Conditional PDF Plots for Right-Tail Regions of LOGNGPD (Left) and Lognormal (Right) Models





Example 28.5: Fitting a Scaled Tweedie Model with Regressors

The Tweedie distribution is often used in the insurance industry to explain the influence of regression effects on the distribution of losses. PROC SEVERITY provides a predefined scaled Tweedie distribution (STWEEDIE) that enables you to model the influence of regression effects on the scale parameter. The scale regression model has its own advantages such as the ability to easily account for inflation effects. This example illustrates how that model can be used to evaluate the influence of regression effects on the *mean* of the Tweedie distribution, which is useful in problems such rate-making and pure premium modeling.

Assume a Tweedie process, whose mean μ is affected by k regression effects x_j, $j = 1, \ldots, k$, as follows,

$$\mu = \mu_0 \exp\left(\sum_{j=1}^{k} \beta_j x_j\right)$$

where μ_0 represents the base value of the mean (you can think of μ_0 as $\exp(\beta_0)$, where β_0 is the intercept). This model for the mean is identical to the popular generalized linear model for the mean with a logarithmic link function.

More interestingly, it parallels the model used by PROC SEVERITY for the scale parameter θ,

$$\theta = \theta_0 \exp\left(\sum_{j=1}^{k} \beta_j x_j\right)$$

where θ_0 represents the base value of the scale parameter. As described in the section "Tweedie Distributions" on page 2080, for the parameter range $p \in (1, 2)$, the mean of the Tweedie distribution is given by

$$\mu = \theta\lambda\frac{2-p}{p-1}$$

where λ is the Poisson mean parameter of the scaled Tweedie distribution. This relationship enables you to use the scale regression model to infer the influence of regression effects on the mean of the distribution.

Let the data set Work.Test_Sevtw contain a sample generated from a Tweedie distribution with dispersion parameter $\phi = 0.5$, index parameter $p = 1.75$, and the mean parameter that is affected by three regression variables x1, x2, and x3 as follows:

$$\mu = 5\ \exp(0.25\,\mathrm{x1} - \mathrm{x2} + 3\,\mathrm{x3})$$

Thus, the population values of regression parameters are $\mu_0 = 5$, $\beta_1 = 0.25$, $\beta_2 = -1$, and $\beta_3 = 3$. You can find the code used to generate the sample in the PROC SEVERITY sample program *sevex05.sas*.

The following PROC SEVERITY step uses the sample in Work.Test_Sevtw data set to estimate the parameters of the scale regression model for the predefined scaled Tweedie distribution (STWEEDIE) with the dual quasi-Newton (QUANEW) optimization technique:

```
/*--- Fit the scale parameter version of the Tweedie distribution ---*/
proc severity data=test_sevtw outest=estw covout print=all plots=none;
   loss y;
   scalemodel x1-x3;
```

```
   dist stweedie;
   nloptions tech=quanew;
run;
```

The dual quasi-Newton technique is used because it requires only the first-order derivatives of the objective function, and it is harder to compute reasonably accurate estimates of the second-order derivatives of Tweedie distribution's PDF with respect to the parameters.

Some of the key results prepared by PROC SEVERITY are shown in Output 28.5.1 and Output 28.5.2. The distribution information and the convergence results are shown in Output 28.5.1.

Output 28.5.1 Convergence Results for the STWEEDIE Model with Regressors

The SEVERITY Procedure
stweedie Distribution

Iterations	42
Function Calls	206
Log Likelihood	-1044.3

The final parameter estimates of the STWEEDIE regression model are shown in Output 28.5.2. The estimate that is reported for the parameter Theta is the estimate of the base value θ_0. The estimates of regression coefficients β_1, β_2, and β_3 are indicated by the rows of x1, x2, and x3, respectively.

Output 28.5.2 Parameter Estimates for the STWEEDIE Model with Regressors

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Theta	1	0.82630	0.32594	2.54	0.0118
Lambda	1	16.40981	16.13483	1.02	0.3100
P	1	1.75191	0.25351	6.91	<.0001
x1	1	0.27952	0.09886	2.83	0.0050
x2	1	-0.76718	0.10328	-7.43	<.0001
x3	1	3.03206	0.10151	29.87	<.0001

If your goal is to explain the influence of regression effects on the scale parameter, then the output displayed in Output 28.5.2 is sufficient. But, if you want to compute the influence of regression effects on the mean of the distribution, then you need to do some postprocessing. Using the relationship between μ and θ, μ can be

written in terms of the parameters of the STWEEDIE model as

$$\mu = \theta_0 \exp\left(\sum_{j=1}^{k} \beta_j x_j\right) \lambda \frac{2-p}{p-1}$$

This shows that the parameters β_j are identical for the mean and the scale model, and the base value μ_0 of the mean model is

$$\mu_0 = \theta_0 \lambda \frac{2-p}{p-1}$$

The estimate of μ_0 and the standard error associated with it can be computed by using the property of the functions of maximum likelihood estimators (MLE). If $g(\Omega)$ represents a totally differentiable function of parameters Ω, then the MLE of g has an asymptotic normal distribution with mean $g(\hat{\Omega})$ and covariance $C = (\partial \mathbf{g})' \Sigma (\partial \mathbf{g})$, where $\hat{\Omega}$ is the MLE of Ω, Σ is the estimate of covariance matrix of Ω, and $\partial \mathbf{g}$ is the gradient vector of g with respect to Ω evaluated at $\hat{\Omega}$. For μ_0, the function is $g(\Omega) = \theta_0 \lambda (2-p)/(p-1)$. The gradient vector is

$$\begin{aligned} \partial \mathbf{g} &= \left(\frac{\partial g}{\partial \theta_0} \quad \frac{\partial g}{\partial \lambda} \quad \frac{\partial g}{\partial p} \quad \frac{\partial g}{\partial \beta_1} \cdots \frac{\partial g}{\partial \beta_k}\right) \\ &= \left(\frac{\mu_0}{\theta_0} \quad \frac{\mu_0}{\lambda} \quad \frac{-\mu_0}{(p-1)(2-p)} \quad 0 \ldots 0\right) \end{aligned}$$

You can write a DATA step that implements these computations by using the parameter and covariance estimates prepared by PROC SEVERITY step. The DATA step program is available in the sample program *sevex05.sas*. The estimates of μ_0 prepared by that program are shown in Output 28.5.3. These estimates and the estimates of β_j as shown in Output 28.5.2 are reasonably close (that is, within one or two standard errors) to the parameters of the population from which the sample in Work.Test_Sevtw data set was drawn.

Output 28.5.3 Estimate of the Base Value Mu0 of the Mean Parameter

Parameter	Estimate	Standard Error	t Value	Approx Pr > |t|
Mu0	4.47383	0.42294	10.5779	0

Another outcome of using the scaled Tweedie distribution to model the influence of regression effects is that the regression effects also influence the variance V of the Tweedie distribution. The variance is related to the mean as $V = \phi \mu^p$, where ϕ is the dispersion parameter. Using the relationship between the parameters TWEEDIE and STWEEDIE distributions as described in the section "Tweedie Distributions" on page 2080, the regression model for the dispersion parameter is

$$\begin{aligned} \log(\phi) &= (2-p)\log(\mu) - \log(\lambda(2-p)) \\ &= ((2-p)\log(\mu_0) - \log(\lambda(2-p))) + (2-p)\sum_{j=1}^{k} \beta_j x_j \end{aligned}$$

Subsequently, the regression model for the variance is

$$\begin{aligned}\log(V) &= 2\log(\mu) - \log(\lambda(2-p)) \\ &= (2\log(\mu_0) - \log(\lambda(2-p))) + 2\sum_{j=1}^{k}\beta_j x_j\end{aligned}$$

In summary, PROC SEVERITY enables you to estimate regression effects on various parameters and statistics of the Tweedie model.

Example 28.6: Fitting Distributions to Interval-Censored Data

In some applications, the data available for modeling might not be exact. A commonly encountered scenario is the use of grouped data from an external agency, which for several reasons, including privacy, does not provide information about individual loss events. The losses are grouped into disjoint bins, and you know only the range and number of values in each bin. Each group is essentially interval-censored, because you know that a loss magnitude is in certain interval, but you do not know the exact magnitude. This example illustrates how you can use PROC SEVERITY to model such data.

The following DATA step generates sample grouped data for dental insurance claims, which is taken from Klugman, Panjer, and Willmot (1998):

```
/* Grouped dental insurance claims data
    (Klugman, Panjer, and Willmot, 1998) */
data gdental;
   input lowerbd upperbd count @@;
   datalines;
0 25 30  25 50 31  50 100 57  100 150 42  150 250 65  250 500 84
500 1000 45  1000 1500 10  1500 2500 11  2500 4000 3
;
run;
```

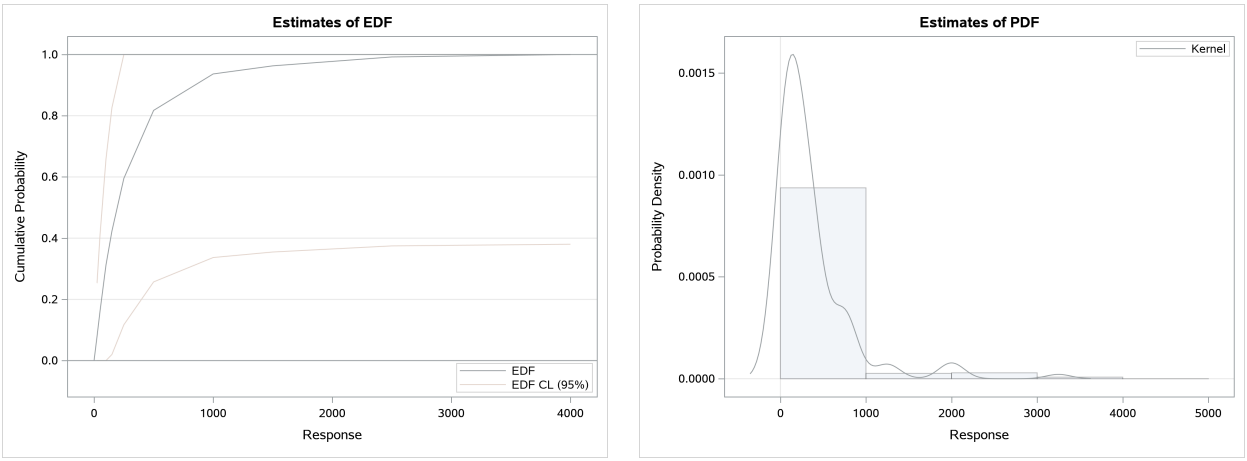
Often, when you do not know the nature of the data, it is recommended that you first explore the nature of the sample distribution by examining the nonparametric estimates of PDF and CDF. The following PROC SEVERITY step prepares the nonparametric estimates, but it does not fit any distribution because there is no DIST statement specified:

```
/* Prepare nonparametric estimates */
proc severity data=gdental print=all plots(histogram kernel)=all;
   loss / rc=lowerbd lc=upperbd;
   weight count;
run;
```

The LOSS statement specifies the left and right boundary of each group as the right-censoring and left-censoring limits, respectively. The variable count records the number of losses in each group and is specified in the WEIGHT statement. Note that there is no response or loss variable specified in the LOSS statement, which is allowed as long as each observation in the input data set is censored. The nonparametric estimates prepared by this step are shown in Output 28.6.1. The histogram, kernel density, and EDF plots all indicate

that the data are heavy-tailed. For interval-censored data, PROC SEVERITY uses Turnbull's algorithm to compute the EDF estimates. The plot of Turnbull's EDF estimates is shown to be linear between the endpoints of a censored group. The linear relationship is chosen for convenient visualization and ease of computation of EDF-based statistics, but you should note that theoretically the behavior of Turnbull's EDF estimates is undefined within a group.

Output 28.6.1 Nonparametric Distribution Estimates for Interval-Censored Data



With the PRINT=ALL option, PROC SEVERITY prints the summary of the Turnbull EDF estimation process as shown in Output 28.6.2. It indicates that the final EDF estimates have converged and are in fact maximum likelihood (ML) estimates. If they were not ML estimates, then you could have used the ENSUREMLE option to force the algorithm to search for ML estimates.

Output 28.6.2 Turnbull EDF Estimation Summary for Interval-Censored Data

Turnbull EDF Estimation Summary	
Technique	EM with Maximum Likelihood Check
Convergence Status	Converged
Iterations	2
Maximum Absolute Relative Error	1.8406E-16
Maximum Absolute Reduced Gradient	1.7764E-15
Estimates	Maximum Likelihood

After exploring the nature of the data, you can now fit a set of heavy-tailed distributions to these data. The following PROC SEVERITY step fits all the predefined distributions to the data in the Work.Gdental data set:

```
/* Fit all predefined distributions */
proc severity data=gdental print=all plots(histogram kernel)=all
              criterion=ad;
   loss / rc=lowerbd lc=upperbd;
   weight count;
   dist _predef_;
run;
```

Some of the key results prepared by PROC SEVERITY are shown in Output 28.6.3 through Output 28.6.4. According to the "Model Selection" table in Output 28.6.3, all distribution models have converged. The "All

Fit Statistics" table in Output 28.6.3 indicates that the exponential distribution (EXP) has the best fit for data according to a majority of the likelihood-based statistics and that the Burr distribution (BURR) has the best fit according to all the EDF-based statistics.

Output 28.6.3 Statistics of Fit for Interval-Censored Data

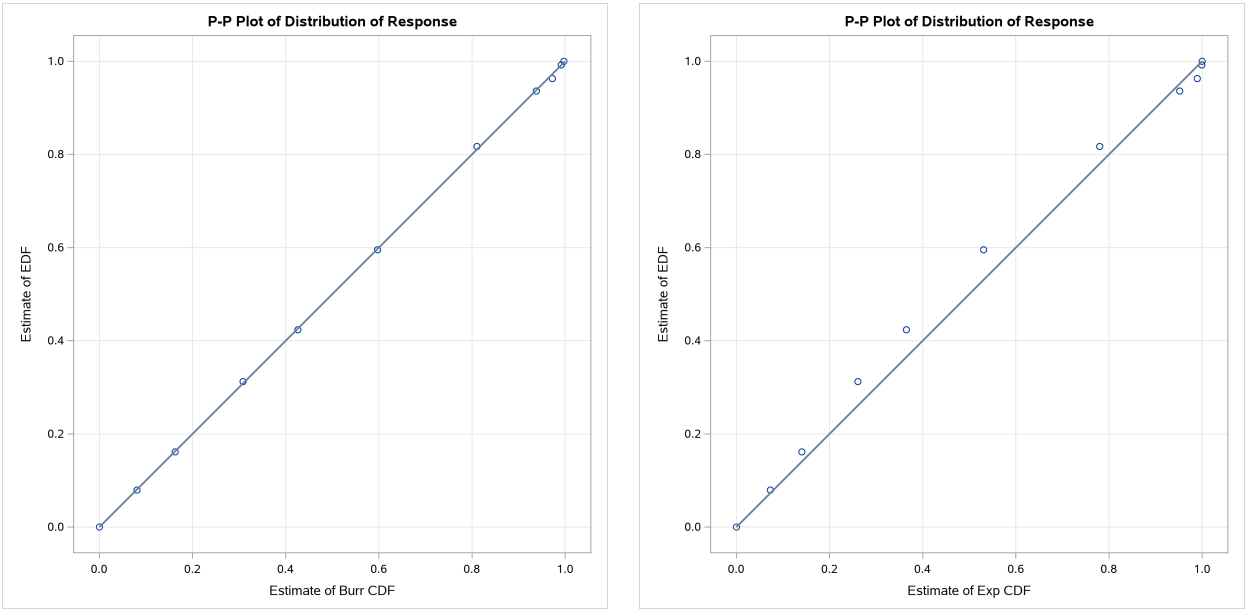
Note: The asterisk (*) marks the best model according to each column's criterion.

The P-P plots in Output 28.6.4 show that the Burr distribution clearly has a better fit between EDF and CDF estimates, confirming the information that is reported by the EDF-based statistics. When the best distributions that are chosen by the likelihood-based and EDF-based statistics are different, you need to decide which fit statistic best represents your objective. In this example, if your objective is to minimize the distance between EDF and CDF values, then you should choose the Burr distribution. On the other hand, if your objective is to maximize the likelihood of the observed data while minimizing the model complexity, then you should choose the exponential distribution. Note that the exponential distribution has worse (lower) raw likelihood than the Burr distribution, but it has better AIC, AICC, and BIC statistics than the Burr distribution because the exponential distribution has only one parameter compared to the three parameters of the Burr distribution. Further, the small sample size of 10 helps accentuate the role of model complexity in the AIC, AICC, and BIC statistics. If the sample size would have been larger, the exponential distribution might not have won according to the likelihood-based statistics.

Output 28.6.4 P-P Plots of Burr and Exponential Distributions for Interval-Censored Data



Example 28.7: Defining a Finite Mixture Model That Has a Scale Parameter

A finite mixture model is a stochastic model that postulates that the probability distribution of the data generation process is a mixture of a finite number of probability distributions. For example, when an insurance company analyzes loss data from multiple policies that are underwritten in different geographic regions, some regions might behave similarly, but the distribution that governs some regions might be different from the distribution that governs other regions. Further, it might not be known which regions behave similarly. Also, the larger amounts of losses might follow a different stochastic process from the stochastic process that governs the smaller amounts of losses. It helps to model all policies together in order to pool the data together and exploit any commonalities among the regions, and the use of a finite mixture model can help capture the differences in distributions across regions and ranges of loss amounts.

Formally, if f_i and F_i denote the PDF and CDF, respectively, of component distribution i and p_i represents the mixing probability that is associated with component i, then the PDF and CDF of the finite mixture of K distribution components are

$$f(x;\Theta,\mathbf{p}) = \sum_{i=1}^{K} p_i\, f_i(x;\Theta_i)$$

$$F(x;\Theta,\mathbf{p}) = \sum_{i=1}^{K} p_i\, F_i(x;\Theta_i)$$

where Θ_i denotes the parameters of component distribution i and Θ denotes the parameters of the mixture distribution, which is a union of all the Θ_i parameters. $\mathbf{p}$ denotes the set of mixing probabilities. All mixing probabilities must add up to 1 ($\sum_{i=1}^{K} p_i = 1$).

You can define the finite mixture of a specific number of components and specific distributions for each of the components by defining the FCMP functions for the PDF and CDF. However, in general, it is not possible

to fit a scale regression model by using any finite mixture distribution unless you take special care to ensure that the mixture distribution has a scale parameter. This example provides a formulation of a two-component finite mixture model that has a scale parameter.

To start with, each component distribution must have either a scale parameter or a log-transformed scale parameter. Let θ_1 and θ_2 denote the scale parameters of the first and second components, respectively. Let $p_1 = p$ be the mixing probability, which makes $p_2 = 1 - p$ by using the constraint on $\mathbf{p}$. The PDF of the mixture of these two distributions can be written as

$$f(x; \theta_1, \theta_2, \Phi, p) = \frac{p}{\theta_1} f_1(\frac{x}{\theta_1}; \Phi_1) + \frac{1-p}{\theta_2} f_2(\frac{x}{\theta_2}; \Phi_2)$$

where Φ_1 and Φ_2 denote the sets of nonscale parameters of the first and second components, respectively, and Φ denotes a union of Φ_1 and Φ_2. For the mixture to have the scale parameter θ, the PDF must be of the form

$$f(x; \theta, \Phi', p) = \frac{1}{\theta}\left(p f_1(\frac{x}{\theta}; \Phi'_1) + (1-p) f_2(\frac{x}{\theta}; \Phi'_2)\right)$$

where Φ', Φ'_1, and Φ'_2 denote the modified sets of nonscale parameters. One simple way to achieve this is to make $\theta_1 = \theta_2 = \theta$ and $\Phi' = \Phi$; that is, you simply equate the scale parameters of both components and keep the set of nonscale parameters unchanged. However, forcing the scale parameters to be equal in both components is restrictive, because the mixture cannot model potential differences in the scales of the two components. A better approach is to tie the scale parameters of the two components by a ratio such that $\theta_1 = \theta$ and $\theta_2 = \rho\theta$. If the ratio parameter ρ is estimated along with the other parameters, then the mixture distribution becomes flexible enough to model the variations across the scale parameters of individual components.

To summarize, the PDF and CDF are of the following form for the two-component mixture that has a scale parameter:

$$f(x; \theta, \rho, \Phi, p) = \frac{1}{\theta}\left(p f_1(\frac{x}{\theta}; \Phi_1) + (1-p) f_2(\frac{x}{\theta}; \rho, \Phi_2)\right)$$
$$F(x; \theta, \rho, \Phi, p) = p F_1(\frac{x}{\theta}; \Phi_1) + (1-p) F_2(\frac{x}{\theta}; \rho, \Phi_2)$$

This can be generalized to a mixture of K components by introducing the $K - 1$ ratio parameters ρ_i that relate the scale parameters of each of the K components to the scale parameter θ of the mixture distribution as follows:

$$\theta_1 = \theta$$
$$\theta_i = \rho_i \theta;\ i \in [2, K]$$

In order to illustrate this approach, define a mixture of two lognormal distributions by using the following PDF function:

$$f(x; \mu, \sigma_1, p_2, \rho_2, \sigma_2) = \frac{(1-p_2)}{\sigma_1 x\sqrt{2\pi}} \exp\left(\frac{-(\log(x)-\mu)^2}{2\sigma_1^2}\right) + \frac{p_2}{\sigma_2 x\sqrt{2\pi}} \exp\left(\frac{-(\log(x)-\mu-\log(\rho_2))^2}{2\sigma_2^2}\right)$$

You can verify that μ serves as the log of the scale parameter θ ($\mu = \log(\theta)$). The following PROC FCMP steps encode this formulation in a distribution named SLOGNMIX2 for use with PROC SEVERITY:

```
/*- Define Mixture of 2 Lognormal Distributions with a Log-Scale Parameter -*/
proc fcmp library=sashelp.svrtdist outlib=work.sevexmpl.models;
   function slognmix2_description() $128;
      return ("Mixture of two lognormals with a log-scale parameter Mu");
   endsub;

   function slognmix2_scaletransform() $8;
      return ("LOG");
   endsub;

   function slognmix2_pdf(x, Mu, Sigma1, p2, Rho2, Sigma2);
      Mu1 = Mu;
      Mu2 = Mu + log(Rho2);
      pdf1 = logn_pdf(x, Mu1, Sigma1);
      pdf2 = logn_pdf(x, Mu2, Sigma2);
      return ((1-p2)*pdf1 + p2*pdf2);
   endsub;

   function slognmix2_cdf(x, Mu, Sigma1, p2, Rho2, Sigma2);
      Mu1 = Mu;
      Mu2 = Mu + log(Rho2);
      cdf1 = logn_cdf(x, Mu1, Sigma1);
      cdf2 = logn_cdf(x, Mu2, Sigma2);
      return ((1-p2)*cdf1 + p2*cdf2);
   endsub;

   subroutine slognmix2_parminit(dim, x[*], nx[*], F[*], Ftype,
                                 Mu, Sigma1, p2, Rho2, Sigma2);
      outargs Mu, Sigma1, p2, Rho2, Sigma2;
      array m[1] / nosymbols;
      p2 = 0.5;
      Rho2 = 0.5;
      median = svrtutil_percentile(0.5, dim, x, F, Ftype);
      Mu = log(2*median/1.5);
      call svrtutil_rawmoments(dim, x, nx, 1, m);
      lm1 = log(m[1]);

      /* Search Rho2 that makes log(sample mean) > Mu */
      do while (lm1 <= Mu and Rho2 < 1);
         Rho2 = Rho2 + 0.01;
         Mu = log(2*median/(1+Rho2));
      end;
      if (Rho2 >= 1) then
         /* If Mu cannot be decreased enough to make it less
            than log(sample mean), then revert to Rho2=0.5.
            That will set Sigma1 and possibly Sigma2 to missing.
            PROC SEVERITY replaces missing initial values with 0.001. */
         Mu = log(2*median/1.5);

      Sigma1 = sqrt(2.0*(log(m[1])-Mu));
      Sigma2 = sqrt(2.0*(log(m[1])-Mu-log(Rho2)));
   endsub;
```

```
   subroutine slognmix2_lowerbounds(Mu, Sigma1, p2, Rho2, Sigma2);
      outargs Mu, Sigma1, p2, Rho2, Sigma2;
      Mu = .; /* Mu has no lower bound */
      Sigma1 = 0; /* Sigma1 > 0 */
      p2 = 0; /* p2 > 0 */
      Rho2 = 0; /* Rho2 > 0 */
      Sigma2 = 0; /* Sigma2 > 0 */
   endsub;

   subroutine slognmix2_upperbounds(Mu, Sigma1, p2, Rho2, Sigma2);
      outargs Mu, Sigma1, p2, Rho2, Sigma2;
      Mu = .; /* Mu has no upper bound */
      Sigma1 = .; /* Sigma1 has no upper bound */
      p2 = 1; /* p2 < 1 */
      Rho2 = 1; /* Rho2 < 1 */
      Sigma2 = .; /* Sigma2 has no upper bound */
   endsub;
quit;
```

As shown in previous examples, an important aspect of defining a distribution for use with PROC SEVERITY is the definition of the PARMINIT subroutine that initializes the parameters. For mixture distributions, in general, the parameter initialization is a nontrivial task. For a two-component mixture, some simplifying assumptions make the problem easier to handle. For the initialization of SLOGNMIX2, the initial values of p_2 and ρ_2 are fixed at 0.5, and the following two simplifying assumptions are made:

- The median of the mixture is the average of the medians of the two components:

  $$F^{-1}(0.5) = (\exp(\mu_1) + \exp(\mu_2))/2 = \exp(\mu)(1 + \rho_2)/2$$

  Solution of this equation yields the value of μ in terms of ρ_2 and the sample median.

- Each component has the same mean, which implies the following:

  $$\exp(\mu + \sigma_1^2/2) = \exp(\mu + \log(\rho_2) + \sigma_2^2/2)$$

  If X_i represents the random variable of component distribution i and X represents the random variable of the mixture distribution, then the following equation holds for the raw moment of any order k:

  $$E[X^k] = \sum_{i=1}^{K} p_i E[X_i^k]$$

  This, in conjunction with the assumption on component means, leads to the equations

  $$\log(m_1) = \mu + \frac{\sigma_1^2}{2}$$
  $$\log(m_1) = \mu + \log(\rho_2) + \frac{\sigma_2^2}{2}$$

  where m_1 denotes the first raw moment of the sample. Solving these equations leads to the following values of σ_1 and σ_2:

  $$\sigma_1^2 = 2(\log(m_1) - \mu)$$
  $$\sigma_2^2 = 2(\log(m_1) - \mu - \log(\rho_2))$$

Note that σ_1 has a valid value only if $\log(m_1) > \mu$. Among the many possible methods of ensuring this condition, the SLOGNMIX2_PARMINIT subroutine uses the method of doing a linear search over ρ_2.

Even when the preceding assumptions are not true for a given problem, they produce reasonable initial values to help guide the nonlinear optimizer to an acceptable optimum if the mixture of two lognormal distributions is indeed a good fit for your input data. This is illustrated by the results of the following steps that fit the SLOGNMIX2 distribution to simulated data, which have different means for the two components (12.18 and 22.76, respectively), and the median of the sample (15.94) is not equal to the average of the medians of the two components (7.39 and 20.09, respectively):

```
/*-------- Simulate a lognormal mixture sample ----------*/
data testlognmix(keep=y);
   call streaminit(12345);
   Mu1 = 2;
   Sigma1 = 1;
   i = 0;
   do j=1 to 2000;
      y = exp(Mu1) * rand('LOGNORMAL')**Sigma1;
      output;
   end;
   Mu2 = 3;
   Sigma2 = 0.5;
   do j=1 to 3000;
      y = exp(Mu2) * rand('LOGNORMAL')**Sigma2;
      output;
   end;
run;

/*-- Fit and compare scale regression models with 2-component  --*/
/*-- lognormal mixture and the standard lognormal distribution --*/
options cmplib=(work.sevexmpl);

proc severity data=testlognmix print=all plots(histogram kernel)=all;
   loss y;
   dist slognmix2 logn;
run;
```

The comparison of the fit statistics of SLOGNMIX2 and LOGN, as shown in Output 28.7.1, confirms that the two-component mixture is certainly a better fit to these data than the single lognormal distribution.

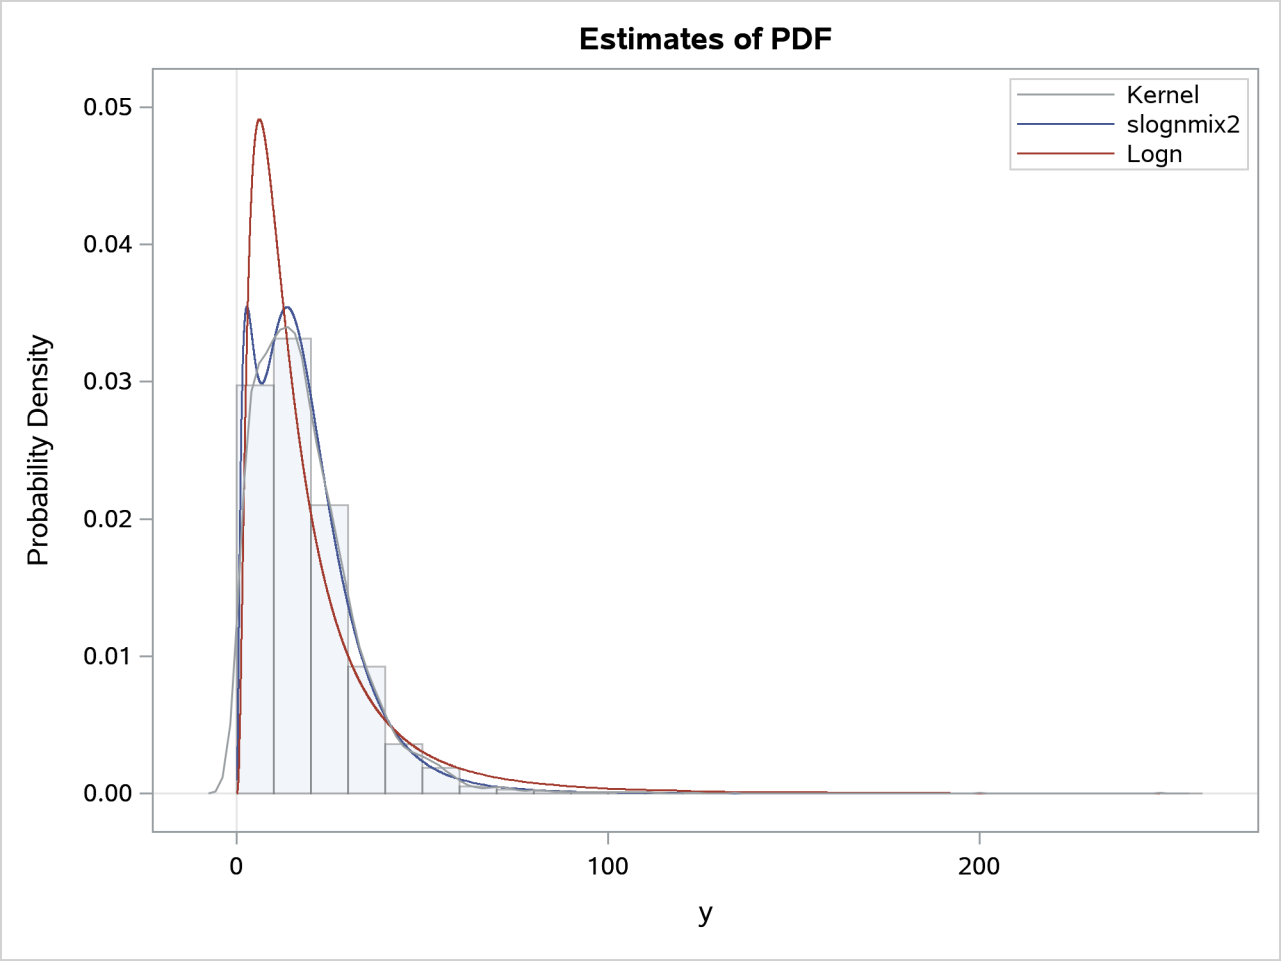
Note: The asterisk (*) marks the best model according to each column's criterion.

The comparative plot of probability densities in Output 28.7.2 shows that the density function of the mixture

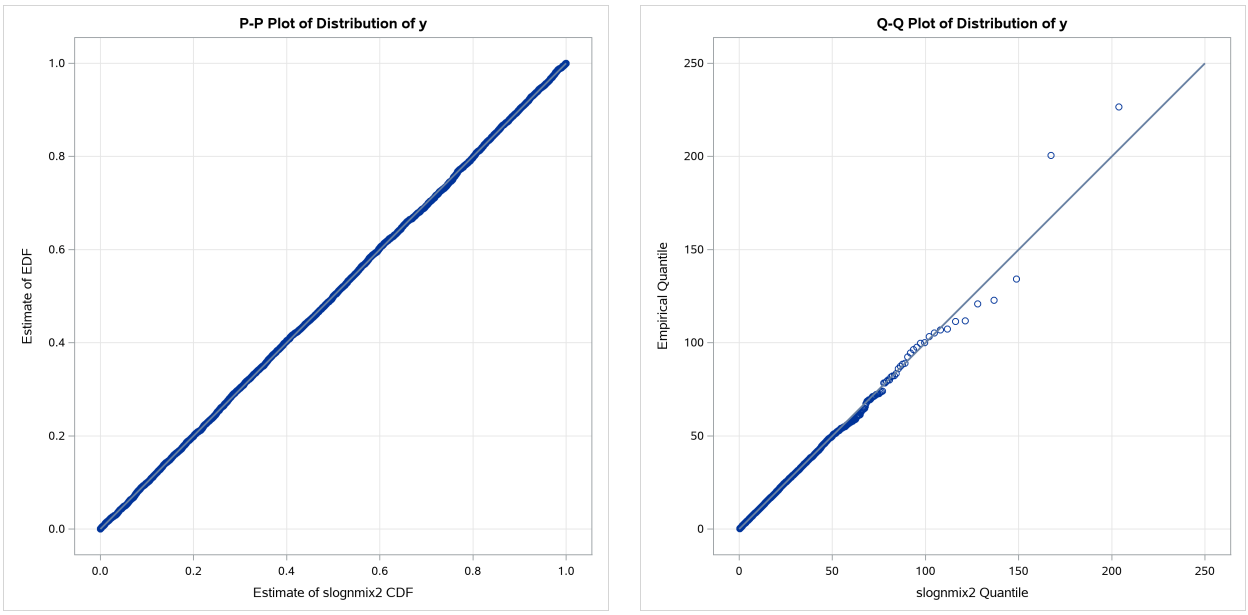
distribution is bimodal. In fact, one of the key motivations for using mixture distributions is to find better-fitting models for multimodal data.

The P-P and Q-Q plots in Output 28.7.3 visually confirm that SLOGNMIX2 fits the data very well.

Output 28.7.2 Comparison of PDF Estimates of the Fitted Models



Output 28.7.3 P-P and Q-Q Plots to Evaluate SLOGNMIX2 Fit



The detailed results for the SLOGNMIX2 distribution are shown in Output 28.7.4. According to the "Initial Parameter Values and Bounds" table, the initial value of ρ_2 is not 0.5, indicating that a linear search was conducted to ensure $\log(m_1) > \mu$.

Output 28.7.4 Detailed Estimation Results for the SLOGNMIX2 Distribution

The SEVERITY Procedure
slognmix2 Distribution

Log Likelihood	-19171.5

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Mu	1	3.00922	0.01554	193.68	<.0001
Sigma1	1	0.49516	0.01451	34.13	<.0001
P2	1	0.40619	0.02600	15.62	<.0001
Rho2	1	0.37212	0.02038	18.26	<.0001
Sigma2	1	1.00019	0.02124	47.09	<.0001

By using the relationship that $\mu_2 = \mu + \log(\rho_2)$, you can see that the final parameter estimates are indeed close to the true parameter values that were used to simulate the input sample.

Example 28.8: Predicting Mean and Value-at-Risk by Using Scoring Functions

If you work in the risk management department of an insurance company or a bank, then one of your primary applications of severity loss distribution models is to predict the value-at-risk (VaR) so that there is a very low probability of experiencing a loss value that is greater than the VaR. The probability level at which VaR is measured is prescribed by industry regulations such as Basel III and Solvency II. The VaR level is usually specified in terms of $(1 - \alpha)$, where $\alpha \in (0, 1)$ is the probability that a loss value exceeds the VaR. Typical VaR levels are 0.95, 0.975, and 0.995.

In addition to predicting the VaR, which is regarded as an estimate of the worst-case loss, businesses are often interested in predicting the average loss by estimating either the mean or median of the distribution.

The estimation of the mean and VaR combined with the scale regression model is very potent tool for analyzing worst-case and average losses for various scenarios. For example, if the regressors that are used in a scale regression model represent some key macroeconomic and operational indicators, which are widely referred to as key risk indicators (KRIs), then you can analyze the VaR and mean loss estimates over various values for the KRIs to get a more comprehensive picture of the risk profile of your organization across various market and internal conditions.

This example illustrates the use of scoring functions to simplify the process of predicting the mean and VaR of scale regression models.

To compute the mean, you need to ensure that the function to compute the mean of a distribution is available in the function library. If you define and fit your own distribution and you want to compute its mean, then you need to use the FCMP procedure to define that function and you need to use the CMPLIB= system option to specify the location of that function. For your convenience, the *dist*_MEAN function (which computes the mean of the *dist* distribution) is already defined in the Sashelp.Svrtdist library for each of the 10 predefined distributions. The following statements display the definitions of MEAN functions of all distributions. Note that the MEAN functions for the Burr, Pareto, and generalized Pareto distributions check the existence of the first moment for specified parameter values.

```
/*--------- Define distribution functions that compute the mean ----------*/
proc fcmp library=sashelp.svrtdist outlib=work.means.scalemod;
   function BURR_MEAN(x, Theta, Alpha, Gamma);
      if not(Alpha * Gamma > 1) then
         return (.); /* first moment does not exist */
      return (Theta*gamma(1 + 1/Gamma)*gamma(Alpha - 1/Gamma)/gamma(Alpha));
   endsub;
   function EXP_MEAN(x, Theta);
      return (Theta);
   endsub;
   function GAMMA_MEAN(x, Theta, Alpha);
      return (Theta*Alpha);
   endsub;
   function GPD_MEAN(x, Theta, Xi);
      if not(Xi < 1) then
         return (.); /* first moment does not exist */
      return (Theta/(1 - Xi));
   endsub;
   function IGAUSS_MEAN(x, Theta, Alpha);
      return (Theta);
   endsub;
   function LOGN_MEAN(x, Mu, Sigma);
      return (exp(Mu + Sigma*Sigma/2.0));
   endsub;

   function PARETO_MEAN(x, Theta, Alpha);
      if not(Alpha > 1) then
         return (.); /* first moment does not exist */
      return (Theta/(Alpha - 1));
   endsub;
   function STWEEDIE_MEAN(x, Theta, Lambda, P);
      return (Theta* Lambda * (2 - P) / (P - 1));
   endsub;
   function TWEEDIE_MEAN(x, P, Mu, Phi);
      return (Mu);
   endsub;
   function WEIBULL_MEAN(x, Theta, Tau);
      return (Theta*gamma(1 + 1/Tau));
   endsub;
quit;
```

For your further convenience, the *dist*_QUANTILE function (which computes the quantile of the *dist* distribution) is also defined in the Sashelp.Svrtdist library for each of the 10 predefined distributions. Because the MEAN and QUANTILE functions satisfy the definition of a distribution function as described in the section "Formal Description" on page 2137, you can submit the following PROC SEVERITY step to fit all regression-friendly predefined distributions and generate the scoring functions for the MEAN, QUANTILE, and other distribution functions:

```
/*----- Fit all distributions and generate scoring functions ------*/
proc severity data=test_sev8 outest=est print=all plots=none;
   loss y;
   scalemodel x1-x5;
```

```
   dist _predefined_ stweedie;
   outscorelib outlib=scorefuncs commonpackage;
run;
```

The SAS statements that simulate the sample in the Work.Test_sev8 data set are available in the PROC SEVERITY sample program *sevex08.sas*. The OUTLIB= option in the OUTSCORELIB statement requests that the scoring functions be written to the Work.Scorefuncs library, and the COMMONPACKAGE option in the OUTSCORELIB statement requests that all the functions be written to the same package. Upon completion, PROC SEVERITY sets the CMPLIB system option to the following value:

```
(sashelp.svrtdist work.scorefuncs)
```

The "All Fit Statistics" table in Output 28.8.1 shows that the lognormal distribution's scale model is the best and the inverse Gaussian's scale model is a close second according to the likelihood-based statistics.

Output 28.8.1 Comparison of Fitted Scale Models for Mean and VaR Illustration

The SEVERITY Procedure

All Fit Statistics

Note: The asterisk (*) marks the best model according to each column's criterion.

You can examine the scoring functions by viewing the Work.Scorefuncs library, which is essentially a SAS data set. For example, the preceding PROC SEVERITY step automatically generates and submits the following PROC FCMP statements to define the scoring functions SEV_MEAN_LOGN and SEV_QUANTILE_IGAUSS:

```
proc fcmp library=(sashelp.svrtdist) outlib=work.scorefuncs.sevfit;
   function SEV_MEAN_LOGN(y, x{*});
      _logscale_=0;
      _logscale_ = _logscale_ + ( 7.64722278930350E-01 * x{1});
      _logscale_ = _logscale_ + ( 2.99209540369860E+00 * x{2});
      _logscale_ = _logscale_ + (-1.00788916253430E+00 * x{3});
      _logscale_ = _logscale_ + ( 2.58883602184890E-01 * x{4});
      _logscale_ = _logscale_ + ( 5.00927479793970E+00 * x{5});
      _logscale_ = _logscale_ + ( 9.95078833050690E-01);
      return (LOGN_MEAN(y, _logscale_,  2.31592981635590E-01));
   endsub;

   function SEV_QUANTILE_IGAUSS(y, x{*});
      _logscale_=0;
      _logscale_ = _logscale_ + ( 7.64581738373520E-01 * x{1});
```

```
      _logscale_ = _logscale_ + ( 2.99159055015310E+00 * x{2});
      _logscale_ = _logscale_ + (-1.00793496641510E+00 * x{3});
      _logscale_ = _logscale_ + ( 2.58870460543840E-01 * x{4});
      _logscale_ = _logscale_ + ( 5.00996884646730E+00 * x{5});
      _scale_ =  2.77854870591020E+00 * exp(_logscale_);
      return (IGAUSS_QUANTILE(y, _scale_,  1.81511227238720E+01));
   endsub;
quit;
```

PROC SEVERITY detects all the distribution functions that are available in the current CMPLIB= search path (which always includes the Sashelp.Svrtdist library) for the distributions that you specify in the DIST statement, and it creates the corresponding scoring functions. You can define any distribution function that has the desired signature to compute an estimate of your choice, include its library in the CMPLIB= system option, and then specify the OUTSCORELIB statement to generate the corresponding scoring functions. Specifying the COMMONPACKAGE option in the OUTSCORELIB statement causes the name of the scoring function to take the form SEV_*function-suffix_dist*. If you do not specify the COMMONPACKAGE option, PROC SEVERITY creates a scoring function named SEV_*function-suffix* in a package named *dist*. You can invoke functions from a specific package only inside the FCMP procedure. If you want to invoke the scoring functions from a DATA step, then it is recommended that you specify the COMMONPACKAGE option when you specify multiple distributions in the DIST statement.

To illustrate the use of scoring functions, let Work.Reginput contain the scoring data, where the values of regressors in each observation define one scenario. Scoring functions make it very easy to compute the mean and VaR of each distribution's scale model for each of the scenarios, as the following steps illustrate for the lognormal and inverse Gaussian distributions by using a VaR level of 97.5%:

```
/*--- Set VaR level ---*/
%let varLevel=0.975;

/*--- Compute scores (mean and var) for the       ---
  --- scoring data by using the scoring functions ---*/
data scores;
   array x{*} x1-x5;
   set reginput;

   igauss_mean = sev_mean_igauss(., x);
   igauss_var  = sev_quantile_igauss(&varLevel, x);
   logn_mean   = sev_mean_logn(., x);
   logn_var    = sev_quantile_logn(&varLevel, x);
run;
```

The following DATA step accomplishes the same task by reading the parameter estimates that were written to the Work.Est data set by the previous PROC SEVERITY step:

```
/*--- Compute scores (mean and var) for the       ---
  --- scoring data by using the OUTEST= data set  ---*/
data scoresWithOutest(keep=x1-x5 igauss_mean igauss_var logn_mean logn_var);
   array _x_{*} x1-x5;
   array _xparmIgauss_{5} _temporary_;
   array _xparmLogn_{5} _temporary_;
   retain _Theta0_ Alpha0;
   retain _Mu0_ Sigma0;
   *--- read parameter estimates for igauss and logn models ---*;
```

```
   if (_n_ = 1) then do;
      set est(where=(upcase(_MODEL_)='IGAUSS' and _TYPE_='EST'));
      _Theta0_ = Theta; Alpha0 = Alpha;
      do _i_=1 to dim(_x_);
         if (_x_(_i_) = .R) then _xparmIgauss_(_i_) = 0;
         else _xparmIgauss_(_i_) = _x_(_i_);
      end;
      set est(where=(upcase(_MODEL_)='LOGN' and _TYPE_='EST'));
      _Mu0_ = Mu; Sigma0 = Sigma;
      do _i_=1 to dim(_x_);
         if (_x_(_i_) = .R) then _xparmLogn_(_i_) = 0;
         else _xparmLogn_(_i_) = _x_(_i_);
      end;
   end;
   set reginput;

   *---  predict mean and VaR for inverse Gaussian  ---*;
   * first compute X'*beta for inverse Gaussian *;
   _xbeta_ = 0.0;
   do _i_ = 1 to dim(_x_);
      _xbeta_ = _xbeta_ + _xparmIgauss_(_i_) * _x_(_i_);
   end;
   * now compute scale for inverse Gaussian *;
   _SCALE_ = _Theta0_ * exp(_xbeta_);
   igauss_mean = igauss_mean(., _SCALE_, Alpha0);
   igauss_var = igauss_quantile(&varLevel, _SCALE_, Alpha0);
   *---  predict mean and VaR for lognormal         ---*;
   * first compute X'*beta for lognormal*;
   _xbeta_ = 0.0;
   do _i_ = 1 to dim(_x_);
      _xbeta_ = _xbeta_ + _xparmLogn_(_i_) * _x_(_i_);
   end;
   * now compute Mu=log(scale) for lognormal *;
   _MU_ = _Mu0_ + _xbeta_;
   logn_mean = logn_mean(., _MU_, Sigma0);
   logn_var = logn_quantile(&varLevel, _MU_, Sigma0);
run;
```

The "Values Comparison Summary" table in Output 28.8.2 shows that the difference between the estimates that are produced by both methods is within the acceptable machine precision. However, the comparison of the DATA step complexity of each method clearly shows that the method that uses the scoring functions is much easier because it saves a lot of programming effort. Further, new distribution functions, such as the *dist*_MEAN functions that are illustrated here, are automatically discovered and converted to scoring functions by PROC SEVERITY. That enables you to focus your efforts on writing the distribution function that computes your desired score, which needs to be done only once. Then, you can create and use the corresponding scoring functions multiple times with much less effort.

Output 28.8.2 Comparison of Mean and VaR Estimates of Two Scoring Methods

```

Example 28.9: Scale Regression with Rich Regression Effects

This example illustrates the use of regression effects that include CLASS variables and interaction effects.

Consider that you, as an actuary at an automobile insurance company, want to evaluate the effect of certain external factors on the distribution of the severity of the losses that your policyholders incur. Such analysis can help you determine the relative differences in premiums that you should charge to policyholders who have different characteristics. Assume that when you collect and record the information about each claim, you also collect and record some key characteristics of the policyholder and the vehicle that is involved in the claim. This example focuses on the following five factors: type of car, safety rating of the car, gender of the policyholder, education level of the policyholder, and annual household income of the policyholder (which can be thought of as a proxy for the luxury level of the car). Let these regressors be recorded in the variables CarType (1: sedan, 2: sport utility vehicle), CarSafety (scaled to be between 0 and 1, the safest being 1), Gender (1: female, 2: male), Education (1: high school graduate, 2: college graduate, 3: advanced degree holder), and Income (scaled by a factor of 1/100,000), respectively. Let the historical data about the severity of each loss be recorded in the LossAmount variable of the Work.Losses data set. Let the data set also contain two additional variables, Deductible and Limit, that record the deductible and ground-up loss limit provisions, respectively, of the insurance policy that the policyholder has. The limit on ground-up loss is usually derived from the payment limit that a typical insurance policy states. Deductible serves as the left-truncation variable, and Limit serves as the right-censoring variable. The SAS statements that simulate an example of the Work.Losses data set are available in the PROC SEVERITY sample program *sevex09.sas*.

The variables CarType, Education, and Gender each contain a known, finite set of discrete values. By

specifying such variables as classification variables, you can separately identify the effect of each level of the variable on the severity distribution. For example, you might be interested in finding out how the magnitude of loss for a sport utility vehicle (SUV) differs from that for a sedan. This is an example of a main effect. You might also want to evaluate how the distribution of losses that are incurred by a policyholder with a college degree who drives a SUV differs from that of a policyholder with an advanced degree who drives a sedan. This is an example of an interaction effect. You can include various such types of effects in the scale regression model. For more information about the effect types, see the section "Specification and Parameterization of Model Effects" on page 2101. Analyzing such a rich set of regression effects can help you make more accurate predictions about the losses that a new applicant with certain characteristics might incur when he or she requests insurance for a specific vehicle, which can further help you with ratemaking decisions.

The following PROC SEVERITY step fits the scale regression model with a lognormal distribution to data in the Work.Losses data set, and stores the model and parameter estimate information in the Work.EstStore item store:

```
/* Fit scale regression model with different types of regression effects */
proc severity data=losses outstore=eststore
     print=all plots=none;
   loss lossAmount / lt=deductible rc=limit;
   class carType gender education;
   scalemodel carType gender carSafety income education*carType
              income*gender carSafety*income;
   dist logn;
run;
```

The SCALEMODEL statement in the preceding PROC SEVERITY step includes two main effects (carType and gender), two singleton continuous effects (carSafety and income), one interaction effect (education*carType), one continuous-by-class effect (income*gender), and one polynomial continuous effect (carSafety*income). For more information about effect types, see Table 28.10, "GLM Parameterization of Classification Variables and Effects," on page 2104.

When you specify a CLASS statement, it is recommended that you observe the "Class Level Information" table. For this example, the table is shown in Output 28.9.1. Note that if you specify BY-group processing, then the class level information might change from one BY group to the next, potentially resulting in a different parameterization for each BY group.

Output 28.9.1 Class Level Information Table

The SEVERITY Procedure

Class Level Information

Class	Levels	Values
carType	2	SUV Sedan
gender	2	Female Male
education	3	AdvancedDegree College High School

The regression modeling results for the lognormal distribution are shown in Output 28.9.2. The "Initial Parameter Values and Bounds" table is important especially because the preceding PROC SEVERITY step uses the default GLM parameterization, which is a singular parameterization—that is, it results in some redundant parameters. As shown in the table, the redundant parameters correspond to the last level of each

classification variable; this correspondence is a defining characteristic of a GLM parameterization. An alternative would be to use the reference parameterization by specifying the PARAM=REFERENCE option in the CLASS statement, which does not generate redundant parameters for effects that contain CLASS variables and enables you to specify a reference level for each CLASS variable.

Output 28.9.2 Initial Values for the Scale Regression Model with Class and Interaction Effects

Initial Parameter Values and Bounds

Parameter	Initial Value	Lower Bound	Upper Bound
Mu	4.88526	-709.78271	709.78271
Sigma	0.51283	1.05367E-8	Infty
carType SUV	0.56953	-709.78271	709.78271
carType Sedan	Redundant		
gender Female	0.41154	-709.78271	709.78271
gender Male	Redundant		
carSafety	-0.72742	-709.78271	709.78271
income	-0.33216	-709.78271	709.78271
carType*education SUV AdvancedDegree	0.31686	-709.78271	709.78271
carType*education SUV College	0.66361	-709.78271	709.78271
carType*education SUV High School	Redundant

income*gender Male	Redundant		
carSafety*income	0.13084	-709.78271	709.78271

The convergence and optimization summary information in Output 28.9.3 indicates that the scale regression model for the lognormal distribution has converged with the default optimization technique in five iterations.

Output 28.9.3 Optimization Summary for the Scale Regression Model with Class and Interaction Effects

Convergence Status
Convergence criterion (GCONV=1E-8) satisfied.

Optimization Summary	
Optimization Technique	Trust Region
Iterations	5
Function Calls	14
Log Likelihood	-8286.8

The "Parameter Estimates" table in Output 28.9.4 shows the distribution parameter estimates and estimates for various regression effects. You can use the estimates for effects that contain CLASS variables to infer the relative influence of various CLASS variable levels. For example, on average, the magnitude of losses that are incurred by the female drivers is $\exp(0.44145) \approx 1.56$ times greater than that of male drivers, and an SUV driver with an advanced degree incurs a loss that is on average $\exp(0.39393)/\exp(-0.35210) \approx 2.11$ times greater than the loss that a college-educated sedan driver incurs. Neither the continuous-by-class effect income*gender nor the polynomial continuous effect carSafety*income is significant in this example.

Output 28.9.4 Parameter Estimates for the Scale Regression with Class and Interaction Effects

Parameter Estimates

carType*education SUV High School	0	0	.	.	.
carType*education Sedan AdvancedDegree	1	-0.61064	0.05387	-11.34	<.0001
carType*education Sedan College	1	-0.35210	0.03942	-8.93	<.0001
carType*education Sedan High School	0	0	.	.	.
income*gender Female	1	-0.01486	0.06629	-0.22	0.8226
income*gender Male	0	0	.	.	.
carSafety*income	1	0.07045	0.11447	0.62	0.5383

If you want to update the model when new claims data arrive, then you can potentially speed up the estimation process by specifying the OUTSTORE= item store that is created by the preceding PROC SEVERITY step as an INSTORE= item store in a new PROC SEVERITY step as follows:

```
/* Refit scale regression model on new data different types of regression effects */
proc severity data=withNewLosses instore=eststore
     print=all plots=all;
   loss lossAmount / lt=deductible rc=limit;
   class carType gender education;
   scalemodel carType gender carSafety income education*carType
              income*gender carSafety*income;
   dist logn;
run;
```

PROC SEVERITY uses the parameter estimates in the INSTORE= item store to initialize the distribution and regression parameters.

Overview: SIMILARITY Procedure

The SIMILARITY procedure computes similarity measures associated with time-stamped data, time series, and other sequentially ordered numeric data. PROC SIMILARITY computes similarity measures for time-stamped transactional data (transactions) with respect to time by accumulating the data into a time series format, and it computes similarity measures for sequentially ordered numeric data (sequences) by respecting the ordering of the data.

Given two ordered numeric sequences (input and target), a similarity measure is a metric that measures the distance between the input and target sequences while taking into account the ordering of the data. The SIMILARITY procedure computes similarity measures between an input sequence and a target sequence, in addition to similarity measures that "slide" the target sequence with respect to the input sequence. The "slides" can be by observation index (sliding-sequence similarity measures) or by seasonal index (seasonal-sliding-sequence similarity measures).

In order to compare the raw input and the raw target time-stamped data, the raw data must be accumulated to a time series format. After the input and target time series are formed, the two accumulated time series can be compared as two ordered numeric sequences.

For raw time-stamped data, after the transactional data are accumulated to form time series and any missing values are interpreted, each accumulated time series can be functionally transformed, if desired. Transformations are useful when you want to stabilize the time series before computing the similarity measures. Transformations performed by the SIMILARITY procedure include the following:

- log (LOG)
- square-root (SQRT)
- logistic (LOGISTIC)
- Box-Cox (BOXCOX)
- user-defined transformations

Each time series can be transformed further by using simple differencing or seasonal differencing or both. Additional time series transformations can be performed by using various time series transformation and analysis techniques provided by this procedure or other SAS/ETS procedures.

After optionally transforming each time series, the accumulated and transformed time series can be stored in an output data set (OUT= data set).

After optional accumulation and transformation, each of these time series are the "working series," which can now be analyzed as sequences of numeric data. Each of these sequences can be a target sequence, an input sequence, or both a target and an input sequence. Throughout the remainder of this chapter, the term "original sequence" applies to both the original input and target sequence. The term "working sequence" applies to a version of both the original input and target sequence under investigation.

Each original sequence can be normalized prior to similarity analysis. Normalizations are useful when you want to compare the "shape" or "profile" of the time series. Normalizations performed by the SIMILARITY procedure include the following:

- standard (STANDARD)
- absolute (ABSOLUTE)
- user-defined normalizations

After each original sequence is optionally normalized, each working input sequence can be scaled to the target sequence prior to similarity analysis. Scaling is useful when you want to compare the input sequence to the target sequence while discounting the variation of the target sequence. Input sequence scaling performed by the SIMILARITY procedure include the following:

- standard (STANDARD)
- absolute (ABSOLUTE)
- user-defined scaling

After the working input sequence is optionally scaled to the target sequence, similarity measures can be computed. Similarity measures computed by the SIMILARITY procedure include the following:

- squared deviation (SQRDEV)
- absolute deviation (ABSDEV)
- mean square deviation (MSQRDEV)
- mean absolute deviation (MABSDEV)
- user-defined similarity measures

In computing the similarity measure between two time series, tasks are needed for transforming time series, normalizing sequences, scaling sequences, and computing metrics or measures. The SIMILARITY procedure provides built-in routines to perform these tasks. The SIMILARITY procedure also enables you to extend the procedure with user-defined routines.

All results of the similarity analysis can be stored in output data sets, printed, or graphed using the Output Delivery System (ODS).

The SIMILARITY procedure can process large amounts of time-stamped transactional data, time series, or sequential data. Therefore, the analysis results are useful for large-scale time series analysis, analogous time series forecasting, new product forecasting, or time series (temporal) data mining.

The SAS/ETS EXPAND procedure can be used for frequency conversion and transformations of time series. The TIMESERIES procedure can be used for large-scale time series analysis. The SAS/STAT DISTANCE procedure can be used to compute various measures of distance, dissimilarity, or similarity between observations (rows) of a SAS data set.

Getting Started: SIMILARITY Procedure

This section outlines the use of the SIMILARITY procedure and gives a cursory description of some of the analysis techniques that can be performed on time-stamped transactional data, time series, or sequentially ordered numeric data.

Given an input data set that contains numerous transaction variables recorded over time at no specific frequency, the SIMILARITY procedure can form equally spaced input and target time series as follows:

```
PROC SIMILARITY DATA=<input-data-set>
                OUT=<output-data-set>
                OUTSUM=<summary-data-set>;
   ID <time-ID-variable> INTERVAL=<frequency>
                         ACCUMULATE=<statistic>;
   INPUT <input-time-stamp-variables>;
   TARGET <target-time-stamp-variables>;
RUN;
```

The SIMILARITY procedure forms time series from the input time-stamped transactional data. It can provide results in output data sets or in other output formats using the Output Delivery System (ODS). The examples in this section are more fully illustrated in the section "Examples: SIMILARITY Procedure" on page 2249.

Time-stamped transactional data are often recorded at no fixed interval. Analysts often want to use time series analysis techniques that require fixed-time intervals. Therefore, the transactional data must be accumulated to form a fixed-interval time series.

Suppose that a bank wants to analyze the transactions that are associated with each of its customers over time. Further, suppose that the data set WORK.TRANSACTIONS contains three variables that are related to the customer transactions (CUSTOMER, DATE, and WITHDRAWAL) and one variable that contains an example fraudulent behavior (FRAUD).

The following statements illustrate how to use the SIMILARITY procedure to accumulate time-stamped transactional data to form a daily time series based on the accumulated daily totals of each type of transaction (WITHDRAWALS and FRAUD):

```
proc similarity data=transactions out=timedata;
   by customer;
   id date interval=day accumulate=total;
   input withdrawals;
   target fraud;
run;
```

The OUT=TIMEDATA option specifies that the resulting time series data for each customer are to be stored in the data set WORK.TIMEDATA. The INTERVAL=DAY option specifies that the transactions are to be accumulated on a daily basis. The ACCUMULATE=TOTAL option specifies that the sum of the transactions

are to be accumulated. After the transactional data are accumulated into a time series format, the time series data can be normalized so that the "shape" or "profile" is analyzed.

For example, the following statements build on the previous statements and demonstrate normalization of the accumulated time series:

```
proc similarity data=transactions out=timedata;
   by customer;
   id date interval=day accumulate=total;
   input withdrawals / NORMALIZE=STANDARD;
   target fraud      / NORMALIZE=STANDARD;
run;
```

The NORMALIZE=STANDARD option specifies that each accumulated time series observation is normalized by subtracting the mean and then dividing by the standard deviation of the accumulated time series. The WORK.TIMEDATA data set now contains the accumulated and normalized time series data for each customer.

After the transactional data are accumulated into a time series format and normalized to a mean of zero and standard deviation of one, similarity analysis can be performed on the accumulated and normalized time series.

For example, the following statements build on the previous statements and demonstrate similarity analysis of the accumulated and normalized time series:

```
proc similarity data=transactions
                out=timedata OUTSUM=SUMMARY;
   by customer;
   id date interval=day accumulate=total;
   input withdrawals / normalize=standard;
   target fraud      / normalize=standard MEASURE=MABSDEV;
run;
```

The MEASURE=MABSDEV option specifies the accumulated and normalized time series data that are associated with the variables WITHDRAWALS and FRAUD are to be compared by using mean absolute deviation. The OUTSUM=SUMMARY option specifies that the similarity analysis summary for each customer is to be stored in the data set WORK.SUMMARY.

Syntax: SIMILARITY Procedure

The following statements are used with the SIMILARITY procedure:

PROC SIMILARITY *options* **;**
BY *variables* **;**
ID *variable* **INTERVAL=** *interval options* **;**
FCMPOPT *options* **;**
INPUT *variable-list / options* **;**
TARGET *variable-list / options* **;**

Functional Summary

The statements and options that control the SIMILARITY procedure are summarized in Table 29.1.

Table 29.1 Functional Summary

Description	Statement	Option
Statements		
Specifies BY-group processing	BY	
Specifies the time ID variable	ID	
Specifies the FCMP options	FCMPOPT	
Specifies input variables to analyze	INPUT	
Specifies target variables to analyze	TARGET	
Data Set Options		
Specifies the input data set	PROC SIMILARITY	DATA=
Specifies the time series output data set	PROC SIMILARITY	OUT=
Specifies the measure summary output data set	PROC SIMILARITY	OUTMEASURE=
Specifies the path output data set	PROC SIMILARITY	OUTPATH=
Specifies the sequence output data set	PROC SIMILARITY	OUTSEQUENCE=
Specifies the summary output data set	PROC SIMILARITY	OUTSUM=
User-Defined Functions and Subroutine Options		
Specifies FCMP quiet mode	FCMPOPT	QUIET=
Specifies FCMP trace mode	FCMPOPT	TRACE=
Accumulation and Seasonality Options		
Specifies the accumulation frequency	ID	INTERVAL=
Specifies the length of seasonal cycle	PROC SIMILARITY	SEASONALITY=
Specifies the interval alignment	ID	ALIGN=
Specifies that the time ID variable values are not sorted	ID	NOTSORTED
Specifies the starting time ID value	ID	START=
Specifies the ending time ID value	ID	END=

Description	Statement	Option
Specifies the accumulation statistic	ID, INPUT, TARGET	ACCUMULATE=
Specifies the missing value interpretation	ID, INPUT, TARGET	SETMISS=
Specifies the zero value interpretation	ID, INPUT, TARGET	ZEROMISS=
Specifies the type of missing value trimming	INPUT, TARGET	TRIMMISS=
Time Series Transformation Options		
Specifies simple differencing	INPUT, TARGET	DIF=
Specifies seasonal differencing	INPUT, TARGET	SDIF=
Specifies the transformation	INPUT, TARGET	TRANSFORM=
Input Sequence Options		
Specifies normalization	INPUT	NORMALIZE=
Specifies scaling	INPUT	SCALE=
Target Sequence Options		
Specifies normalization	TARGET	NORMALIZE=
Similarity Measure Options		
Specifies the compression limits	TARGET	COMPRESS=
Specifies the expansion limits	TARGET	EXPAND=
Specifies the similarity measure	TARGET	MEASURE=
Specifies the similarity measure and path	TARGET	PATH=
Specifies the sequence slide	TARGET	SLIDE=
Printing and Graphical Control Options		
Specifies the time ID format	ID	FORMAT=
Specifies printed output	PROC SIMILARITY	PRINT=
Specifies detailed printed output	PROC SIMILARITY	PRINTDETAILS
Specifies graphical output	PROC SIMILARITY	PLOTS=
Miscellaneous Options		
Specifies that analysis variables are processed in ascending order	PROC SIMILARITY	SORTNAMES
Specifies the ordering of the processing of the input and target variables	PROC SIMILARITY	ORDER=

PROC SIMILARITY Statement

PROC SIMILARITY *options* **;**

The following options can be used in the PROC SIMILARITY statement.

DATA=*SAS-data-set*
names the SAS data set that contains the time series, transactional, or sequence input data for the procedure. If the DATA= option is not specified, the most recently created SAS data set is used.

ORDER=*order-option*
specifies the order in which the variables listed in the INPUT and TARGET statements are to be processed. This ordering affects the OUTSEQUENCE=, OUTPATH=, OUTMEASURE=, and OUTSUM= data sets, in addition to the printed and graphical output. The SORTNAMES option also affects the ordering of the analysis. You must specify one of the following *order-options*:

INPUT specifies that each INPUT variable be processed and then the TARGET variables be processed. The results are stored and printed based only on the INPUT variables.

INPUTTARGET specifies that each INPUT variable be processed and then the TARGET variables be processed. The results are stored and printed based on both the INPUT and TARGET variables. This is the default.

TARGET specifies that each TARGET variable be processed and then the INPUT variables be processed. The results are stored and printed based only on the TARGET variables.

TARGETINPUT specifies that each TARGET variable be processed and then the INPUT variables be processed. The results are stored and printed based on both the TARGET and INPUT variables.

OUT=*SAS-data-set*
names the output data set to contain the time series variables specified in the subsequent INPUT and TARGET statements. If an ID variable is specified in the ID statement, it is also included in the OUT= data set. The values are accumulated based on the ID statement INTERVAL= option or the ACCUMULATE= options or both. The values are transformed based on the INPUT or TARGET statement TRANSFORM=, DIF=, and SDIF= options in this order. The OUT= data set is particularly useful when you want to further analyze, model, or forecast the resulting time series with other SAS/ETS procedures.

OUTMEASURE=*SAS-data-set*
names the output data set to contain the detailed similarity measures by time ID value. The form of the OUTMEASURE= data set is determined by the PROC SIMILARITY statement SORTNAMES and ORDER= options.

OUTPATH=*SAS-data-set*
names the output data set to contain the path used to compute the similarity measures for each slide and warp. The form of the OUTPATH= data set is determined by the PROC SIMILARITY statement SORTNAMES and ORDER= options. If a user-defined similarity measure is specified, the path cannot be determined; therefore, the OUTPATH= data set does not contain information related to this measure.

OUTSEQUENCE=*SAS-data-set*
names the output data set to contain the sequences used to compute the similarity measures for each slide and warp. The form of the OUTSEQUENCE= data set is determined by the PROC SIMILARITY statement SORTNAMES and ORDER= options.

OUTSUM=*SAS-data-set*
names the output data set to contain the similarity measure summary. The OUTSUM= data set is particularly useful when analyzing large numbers of series and only the summary of the results are needed. The form of the OUTSUM= data set is determined by the PROC SIMILARITY statement SORTNAMES and ORDER= options.

PLOTS=*option*
PLOTS=(*options* **...)**
specifies the graphical output desired. To specify multiple *options*, separate them by spaces and enclose the group in parentheses. By default, the SIMILARITY procedure produces no graphical output. The following graphical *options* are available:

COSTS plots graphics for time warp costs.

DISTANCES plots graphics for similarity absolute and relative distances (OUTPATH= data set).

INPUTS plots graphics for input variable time series (OUT= data set).

MAPS plots graphics for time warp maps (OUTPATH= data set).

MEASURES plots graphics for similarity measures (OUTMEASURE= data set).

NORMALIZED plots graphics for both the input and target variable normalized sequence. These plots are displayed only when the INPUT or TARGET statement NORMALIZE= option is specified.

PATHS plots time warp paths graphics (OUTPATH= data set).

SCALED plots graphics for both the input variable scaled sequence. These plots are displayed only when the INPUT statement SCALE= option is specified.

SEQUENCES plots graphics for both the input and target variable sequence (OUTSEQUENCE= data set).

TARGETS plots graphics for the target variable time series (OUT= data set).

WARPS plots graphics for time warps (OUTPATH= data set).

ALL is the same as PLOTS=(INPUTS TARGETS SEQUENCES NORMALIZED SCALED DISTANCES PATHS MAPS WARPS COST MEASURES).

PRINT=*option*

PRINT=(*options* **. . .)**

specifies the printed output desired. To specify multiple *options*, separate them by spaces and enclose the group in parentheses. By default, the SIMILARITY procedure produces no printed output. The following printing *options* are available:

DESCSTATS	prints the descriptive statistics for the working time series.
PATHS	prints the path statistics table. If a user-defined similarity measure is specified, the path cannot be determined; therefore, the PRINT=PATHS table is not printed for this measure.
COSTS	prints the cost statistics table.
WARPS	prints the warp summary table.
SLIDES	prints the slides summary table.
SUMMARY	prints the similarity measure summary table.
ALL	is the same as PRINT=(DESCSTATS PATHS COSTS WARPS SLIDES SUMMARY).

PRINTDETAILS

specifies that the output requested with the PRINT= option be printed in greater detail.

SEASONALITY=*integer*

specifies the length of the seasonal cycle where *integer* ranges from one to 10,000. For example, SEASONALITY=3 means that every group of three time periods forms a seasonal cycle. By default, the length of the seasonal cycle is 1 (no seasonality) or the length implied by the INTERVAL= option specified in the ID statement. For example, INTERVAL=MONTH implies that the length of the seasonal cycle is 12.

SORTNAMES

specifies that the variables specified in the INPUT and TARGET statements be processed in alphabetical order of the variable names. By default, the SIMILARITY procedure processes the variables in the order in which they are listed. The ORDER= option also affects the ordering in which the analysis is performed.

BY Statement

A BY statement can be used with PROC SIMILARITY to obtain separate dummy variable definitions for groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.

- Specify the option NOTSORTED or DESCENDING in the BY statement for the SIMILARITY procedure. The NOTSORTED option does not mean that the data are unsorted, but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY-group processing, see *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide.*

FCMPOPT Statement

FCMPOPT *options* **;**

The FCMPOPT statement specifies the following options that are related to user-defined functions and subroutines:

QUIET=ON | OFF
specifies whether the nonfatal errors and warnings that are generated by the user-defined SAS language functions and subroutines are printed to the log. Nonfatal errors are usually associated with operations with missing values. The default is QUIET=ON.

TRACE=ON | OFF
specifies whether the user-defined SAS language functions and subroutines tracings are printed to the log. Tracings are the results of every operation executed. This option is generally used for debugging. The default is TRACE=OFF.

ID Statement

ID *variable* **INTERVAL=** *interval options* **;**

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date, time, or datetime values. In addition, the ID statement specifies the (desired) frequency associated with the time series. The ID statement options also specify how the observations are accumulated and how the time ID values are aligned to form the time series. The options specified affect all variables listed in subsequent INPUT and TARGET statements. If an ID statement is specified, the INTERVAL= option must also be specified. The other ID statement options are optional. If an ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID.

The following options can be used with the ID statement:

ACCUMULATE=*option*
specifies how the data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option. The ID variable contains the time ID values. Each time ID variable value corresponds to a specific time period. The accumulated values form the time series, which is used in subsequent analysis.

The ACCUMULATE= option is particularly useful when there are zero or more than one input observations that coincide with a particular time period (for example, time-stamped transactional data). The EXPAND procedure offers additional frequency conversions and transformations that can also be useful in creating a time series.

The following *options* determine how the observations are accumulated within each time period based on the ID variable and the frequency specified by the INTERVAL= option:

NONE	No accumulation occurs; the ID variable values must be equally spaced with respect to the frequency. This is the default option.
TOTAL	Observations are accumulated based on the total sum of their values.
AVERAGE | AVG	Observations are accumulated based on the average of their values.
MINIMUM | MIN	Observations are accumulated based on the minimum of their values.
MEDIAN | MED	Observations are accumulated based on the median of their values.
MAXIMUM | MAX	Observations are accumulated based on the maximum of their values.
N	Observations are accumulated based on the number of nonmissing observations.
NMISS	Observations are accumulated based on the number of missing observations.
NOBS	Observations are accumulated based on the number of observations.
FIRST	Observations are accumulated based on the first of their values.
LAST	Observations are accumulated based on the last of their values.
STDDEV | STD	Observations are accumulated based on the standard deviation of their values.
CSS	Observations are accumulated based on the corrected sum of squares of their values.
USS	Observations are accumulated based on the uncorrected sum of squares of their values.

If the ACCUMULATE= option is specified, the SETMISSING= option is useful for specifying how accumulated missing values are treated. If missing values should be interpreted as zero, then SETMISSING=0 should be used. The section "Details: SIMILARITY Procedure" on page 2227 describes accumulation in greater detail.

ALIGN=*option*

controls the alignment of SAS dates that are used to identify output observations. The ALIGN= option accepts the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. ALIGN=BEGINNING is the default.

END=*option*

specifies a SAS date, datetime, or time value that represents the end of the data. If the last time ID variable value is less than the END= value, the series is extended with missing values. If the last time ID variable value is greater than the END= value, the series is truncated. For example, END="&sysdate"D uses the automatic macro variable SYSDATE to extend or truncate the series to the current date. The START= and END= options can be used to ensure that data that are associated within each BY group contain the same number of observations.

FORMAT=*format*

specifies the SAS format for the time ID values. If the FORMAT= option is not specified, the default format is implied by the INTERVAL= option. For example, FORMAT=DATE9. specifies that the DATE9. SAS format be used. Notice that the terminating "." is required when specifying a SAS format.

INTERVAL=*interval*

specifies the frequency of the accumulated time series. For example, if the input data set consists of quarterly observations, then INTERVAL=QTR should be used. If the SEASONALITY= option is not specified, the length of the seasonal cycle is implied from the INTERVAL= option. For example, INTERVAL=QTR implies a seasonal cycle of length 4. If the ACCUMULATE= option is also specified, the INTERVAL= option determines the time periods for the accumulation of observations.

NOTSORTED

specifies that the time ID values are not in sorted order. The SIMILARITY procedure sorts the data with respect to the time ID prior to analysis if the NOTSORTED option is specified.

SETMISSING=*option* | *number*

specifies how missing values (either actual or accumulated) are interpreted in the accumulated time series. If a *number* is specified, missing values are set to that number. If a missing value indicates an unknown value, the SETMISSING= option should not be used. If a missing value indicates no value, then SETMISSING=0 should be used. You typically use SETMISSING=0 for transactional data, because no recorded data usually implies no activity. The following *options* can also be used to determine how missing values are assigned:

MISSING	Missing values are set to missing. This is the default option.
AVERAGE | AVG	Missing values are set to the accumulated average value.
MINIMUM | MIN	Missing values are set to the accumulated minimum value.
MEDIAN | MED	Missing values are set to the accumulated median value.
MAXIMUM | MAX	Missing values are set to the accumulated maximum value.
FIRST	Missing values are set to the accumulated first nonmissing value.
LAST	Missing values are set to the accumulated last nonmissing value.
PREVIOUS | PREV	Missing values are set to the previous period's accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.
NEXT	Missing values are set to the next period's accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.

START=*option*

specifies a SAS date, datetime, or time value that represents the beginning of the data. If the first time ID variable value is greater than the START= value, missing values are added to the beginning of the series. If the first time ID variable value is less than the START= value, the series is truncated. The START= and END= options can be used to ensure that data that are associated with each BY group contain the same number of observations.

ZEROMISS=*option*

specifies how beginning and ending zero values (either actual or accumulated) are interpreted in the accumulated time series. The following *options* can also be used to determine how beginning and ending zero values are assigned:

NONE	Beginning and ending zeros are unchanged. This is the default.
LEFT	Beginning zeros are set to missing.
RIGHT	Ending zeros are set to missing.
BOTH	Both beginning and ending zeros are set to missing.

If the accumulated series is all missing or zero, the series is not changed.

INPUT Statement

INPUT *variable-list* < / *options* > **;**

The INPUT statement lists the input numeric variables in the DATA= data set whose values are to be accumulated to form the time series or represent ordered numeric sequences (when no ID statement is specified).

An input data set variable can be specified in only one INPUT or TARGET statement. Any number of INPUT statements can be used. The following *options* can be used with an INPUT statement:

ACCUMULATE=*option*

specifies how the data set observations are accumulated within each time period for the variables listed in the INPUT statement. If the ACCUMULATE= option is not specified in the INPUT statement, accumulation is determined by the ACCUMULATE= option of the ID statement. If the ACCUMULATE= option is not specified in the ID statement or the INPUT statement, no accumulation is performed. For more information, see the ACCUMULATE= option in the ID statement.

DIF=(*numlist***)**

specifies the differencing to be applied to the accumulated time series. The list of differencing orders must be separated by spaces or commas. For example, DIF=(1,3) specifies first, then third order, differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the DIF= option. Simple differencing is useful when you want to detrend the time series before computing the similarity measures.

NORMALIZE=*option*

specifies the sequence normalization to be applied to the working input sequence. The following normalization *options* are provided:

NONE	No normalization is applied. This option is the default.
ABSOLUTE	Absolute normalization is applied.
STANDARD	Standard normalization is applied.
User-Defined	Normalization is computed by a user-defined subroutine that is created using the FCMP procedure, where *User-Defined* is the subroutine name.

Normalization is applied to the working input sequence, which can be a subset of the working input time series if the SLIDE=INDEX or SLIDE=SEASON option is specified.

SCALE=*option*

specifies the scaling of the working input sequence with respect to the working target sequence. Scaling is performed after normalization. The following scaling *options* are provided:

NONE	No scaling is applied. This option is the default.
ABSOLUTE	Absolute scaling is applied.
STANDARD	Standard scaling is applied.
User-Defined	Scaling is computed by a user-defined subroutine that is created using the FCMP procedure, where *User-Defined* is the subroutine name.

Scaling is applied to the working input sequence, which can be a subset of the working input time series if the SLIDE=INDEX or SLIDE=SEASON option is specified.

SDIF=(*numlist***)**

specifies the seasonal differencing to be applied to the accumulated time series. The list of seasonal differencing orders must be separated by spaces or commas. For example, SDIF=(1,3) specifies first, then third, order seasonal differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the SDIF= option. Seasonal differencing is useful when you want to deseasonalize the time series before computing the similarity measures.

SETMISSING=*option* | *number*

SETMISS=*option* | *number*

specifies how missing values (either actual or accumulated) are interpreted in the accumulated time series or ordered sequence for variables listed in the INPUT statement. If the SETMISSING= option is not specified in the INPUT statement, missing values are set based on the SETMISSING= option in the ID statement. If the SETMISSING= option is not specified in the ID statement or the INPUT statement, no missing value interpretation is performed. For more information, see the SETMISSING= option in the ID statement.

TRANSFORM=*option*

specifies the time series transformation to be applied to the accumulated time series. The following transformations are provided:

NONE	No transformation is applied. This option is the default.
LOG	Logarithmic transformation is applied.
SQRT	Square-root transformation is applied.
LOGISTIC	Logistic transformation is applied.
BOXCOX(*number*)	Box-Cox transformation with parameter is applied, where the real *number* is between –5 and 5.
User-Defined	Transformation is computed by a user-defined subroutine that is created using the FCMP procedure, where *User-Defined* is the subroutine name.

When the TRANSFORM= option is specified, the time series must be strictly positive unless a user-defined function is used.

TRIMMISSING=*option*

TRIMMISSING=*option*

specifies how missing values (either actual or accumulated) are trimmed from the accumulated time series or ordered sequence for variables that are listed in the INPUT statement. The following trimming options are provided:

NONE	No missing value trimming is applied.
LEFT	Beginning missing values are trimmed.
RIGHT	Ending missing values are trimmed.
BOTH	Both beginning and ending missing value are trimmed. This is the default.

ZEROMISS=*option*

specifies how beginning and ending zero values (either actual or accumulated) are interpreted in the accumulated time series or ordered sequence for variables listed in the INPUT statement. If the ZEROMISS= option is not specified in the INPUT statement, beginning and ending zero values are set based on the ZEROMISS= option of the ID statement. If the ZERO= option is not specified in the ID statement or the INPUT statement, no zero value interpretation is performed. For more information, see the ZEROMISS= option in the ID statement.

TARGET Statement

TARGET *variable-list* < / *options* > **;**

The TARGET statement lists the numeric target variables in the DATA= data set whose values are to be accumulated to form the time series or represent ordered numeric sequences (when no ID statement is specified).

An input data set variable can be specified in only one INPUT or TARGET statement. Any number of TARGET statements can be used. The following *options* can be used with a TARGET statement:

ACCUMULATE=*option*

specifies how the data set observations are accumulated within each time period for the variables listed in the TARGET statement. If the ACCUMULATE= option is not specified in the TARGET statement, accumulation is determined by the ACCUMULATE= option in the ID statement. If the ACCUMULATE= option is not specified in the ID statement or the TARGET statement, no accumulation is performed. For more information, see the ACCUMULATE= option in the ID statement.

COMPRESS=*option* | **(***options***)**

specifies the sliding sequence (global) and warping (local) compression range of the target sequence with respect to the input sequence. Compression of the target sequence is the same as expansion of the input sequence and vice versa. The compression limits are defined based on the length of the target sequence and are imposed on the target sequence. The following compression options are provided:

GLOBALABS=*integer*	specifies the absolute global compression, where *integer* ranges from zero to 10,000. GLOBALABS=0 implies no global compression, which is the default unless the GLOBALPCT= option is specified.

GLOBALPCT=*number* specifies global compression as a percentage of the length of the target sequence, where *number* ranges from zero to 100. GLOBALPCT=0 implies no global compression, which is the default. GLOBALPCT=100 implies maximum allowable compression.

LOCALABS=*integer* specifies the absolute local compression, where *integer* ranges from zero to 10,000. The default is maximum allowable absolute local compression unless the LOCALPCT= option is specified.

LOCALPCT=*number* specifies local compression as a percentage of the length of the target sequence, where *number* ranges from zero to 100. The percentage specified by the LOCALPCT= option must be less than the GLOBALPCT= option. LOCALPCT=0 implies no local compression. LOCALPCT=100 implies maximum allowable local compression. The default is LOCALPCT=100.

If the SLIDE=NONE or SLIDE=SEASON option is specified in the TARGET statement, the global compression options are ignored. To disallow local compression, use the option COMPRESS=(LOCALPCT=0 LOCALABS=0).

If the SLIDE=INDEX option is specified, the global compression options are not ignored. To completely disallow both global and local compression, use the option COMPRESS=(GLOBALPCT=0 LOCALPCT=0) or COMPRESS=(GLOBALABS=0 LOCALABS=0). To allow only local compression, use the option COMPRESS=(GLOBALPCT=0 GLOBALABS=0). These are the default compression options.

The preceding options can be used in combination to specify the desired amount of global and local compression as the following examples illustrate, where L_c denotes the global compression limit and l_c denotes the local compression limit:

- COMPRESS=(GLOBALPCT=20) allows the global and local compression to range from zero to $L_c = \min\left(\lfloor 0.2N_y \rfloor, \left(N_y - 1\right)\right)$.
- COMPRESS=(GLOBALPCT=20 GLOBALABS=10) allows the global and local compression to range from zero to $L_c = \min\left(\lfloor 0.2N_y \rfloor, \min\left(\left(N_y - 1\right), 10\right)\right)$.
- COMPRESS=(LOCALPCT=10) allows the local compression to range from zero to $l_c = \min\left(\lfloor 0.1N_y \rfloor, \left(N_y - 1\right)\right)$.
- COMPRESS=(LOCALPCT=20 LOCALABS=5) allows the local compression to range from zero to $l_c = \min\left(\lfloor 0.2N_y \rfloor, \min\left(\left(N_y - 1\right), 5\right)\right)$.
- COMPRESS=(GLOBALPCT=20 LOCALPCT=20) allows the global compression to range from zero to $L_c = \min\left(\lfloor 0.2N_y \rfloor, \left(N_y - 1\right)\right)$ and allows the local compression to range from zero to $l_c = \min\left(\lfloor 0.2N_y \rfloor, \left(N_y - 1\right)\right)$.
- COMPRESS=(GLOBALPCT=20 GLOBALABS=10 LOCALPCT=10 LOCALABS=5) allows the global compression to range from zero to $L_c = \min\left(\lfloor 0.2N_y \rfloor, \min\left(\left(N_y - 1\right), 10\right)\right)$ and allows the local compression to range from zero to $l_c = \min\left(\lfloor 0.1N_y \rfloor, \min\left(\left(N_y - 1\right), 5\right)\right)$.

Suppose T_z is the length of the input time series and N_y is the length of the target sequence. The *valid* global compression limit, L_c, is always limited by the length of the target sequence: $0 \leq L_c < N_y$.

Suppose N_x is the length of the input sequence and N_y is the length of the target sequence. The *valid* local compression limit, l_c, is always limited by the lengths of the input and target sequence: $\max\left(0, \left(N_y - N_x\right)\right) \leq l_c < N_y$.

DIF=(*numlist***)**
specifies the differencing to be applied to the accumulated time series. The list of differencing orders must be separated by spaces or commas. For example, DIF=(1,3) specifies first, then third, order differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the DIF= option. Simple differencing is useful when you want to detrend the time series before computing the similarity measures.

EXPAND=*option* **|** **(***options***)**
specifies the sliding sequence (global) and warping (local) expansion range of the target sequence with respect to the input sequence. Expansion of the target sequence is the same as compression of the input sequence and vice versa. The expansion limits are defined based on the length of the input sequence, but are imposed on the target sequence. The following expansion *options* are provided:

GLOBALABS=*integer* specifies the absolute global expansion, where *integer* ranges from zero to 10,000. GLOBALABS=0 implies no global expansion, which is the default unless the GLOBALPCT= option is specified.

GLOBALPCT=*number* specifies global expansion as a percentage of the length of the target sequence, where *number* ranges from zero to 100. GLOBALPCT=0 implies no global expansion, which is the default unless the GLOBALABS= option is specified. GLOBALPCT=100 implies maximum allowable global expansion.

LOCALABS=*integer* specifies the absolute local expansion, where *integer* ranges from zero to 10,000. The default is the maximum allowable absolute local expansion unless the LOCALPCT= option is specified.

LOCALPCT=*number* specifies local expansion as a percentage of the length of the target sequence, where *number* ranges from zero to 100. LOCALPCT=0 implies no local expansion. LOCALPCT=100 implies maximum allowable local expansion. The default is LOCALPCT=100.

If the SLIDE=NONE or SLIDE=SEASON option is specified in the TARGET statement, the global expansion options are ignored. To disallow local expansion, use the option EXPAND=(LOCALPCT=0 LOCALABS=0).

If the SLIDE=INDEX option is specified, the global expansion options are not ignored. To completely disallow both global and local expansion, use the option EXPAND=(GLOBALPCT=0 LOCALPCT=0) or EXPAND=(GLOBALABS=0 LOCALABS=0). To allow only local expansion, use the option EXPAND=(GLOBALPCT=0 GLOBALABS=0). These are the default expansion options.

The preceding options can be used in combination to specify the desired amount of global and local expansion as the following examples illustrate, where L_e denotes the global expansion limit and l_e denotes the local expansion limit:

- EXPAND=(GLOBALPCT=20) allows the global and local expansion to range from zero to $L_e = \min\left(\lfloor 0.2N_y \rfloor, (N_y - 1)\right)$.
- EXPAND=(GLOBALPCT=20 GLOBALABS=10) allows the global and local expansion to range from zero to $L_e = \min\left(\lfloor 0.2N_y \rfloor, \min\left((N_y - 1), 10\right)\right)$.
- EXPAND=(LOCALPCT=10) allows the local expansion to range from zero to $l_e = \min\left(\lfloor 0.1N_y \rfloor, (N_y - 1)\right)$.

- EXPAND=(LOCALPCT=10 LOCALABS=5) allows the local expansion to range from zero to $l_e = \min\left(\lfloor 0.1N_y \rfloor, \min\left(\left(N_y - 1\right), 5\right)\right)$.
- EXPAND=(GLOBALPCT=20 LOCALPCT=10) allows the global expansion to range from zero to $L_e = \min\left(\lfloor 0.2N_y \rfloor, \left(N_y - 1\right)\right)$ and allows the local expansion to range from zero to $l_e = \min\left(\lfloor 0.1N_y \rfloor, \left(N_y - 1\right)\right)$.
- EXPAND=(GLOBALPCT=20 GLOBALABS=10 LOCALPCT=10 LOCALABS=5) allows the global expansion to range from zero to $L_e = \min\left(\lfloor 0.2N_y \rfloor, \min\left(\left(N_y - 1\right), 10\right)\right)$ and allows the local expansion to range from zero to $l_e = \min\left(\lfloor 0.1N_y \rfloor, \min\left(\left(N_y - 1\right), 5\right)\right)$.

Suppose T_z is the length of the input time series and N_y is the length of the target sequence. The *valid* global expansion limit, L_e, is always limited by the length of the input time series: $0 \leq L_e < T_z$.

Suppose N_x is the length of the input sequence and N_y is the length of the target sequence. The *valid* local expansion limit, l_e, is always limited by the lengths of the input and target sequence: $\max\left(0, \left(N_x - N_y\right)\right) \leq l_e < N_x$.

MEASURE=*option*

specifies the similarity measure to be computed by using the working input and target sequences. The following similarity measures are provided:

SQRDEV	squared deviation. This option is the default.
ABSDEV	absolute deviation
MSQRDEV	mean squared deviation
MSQRDEVINP	mean squared deviation relative to the length of the input sequence
MSQRDEVTAR	mean squared deviation relative to the length of the target sequence
MSQRDEVMIN	mean squared deviation relative to the minimum valid path length
MSQRDEVMAX	mean squared deviation relative to the maximum valid path length
MABSDEV	mean absolute deviation
MABSDEVINP	mean absolute deviation relative to the length of the input sequence
MABSDEVTAR	mean absolute deviation relative to the length of the target sequence
MABSDEVMIN	mean absolute deviation relative to the minimum valid path length
MABSDEVMAX	mean absolute deviation relative to the maximum valid path length
User-Defined	The measure is computed by a user-defined function created by using the FCMP procedure, where *User-Defined* is the function name.

NORMALIZE=*option*

specifies the sequence normalization to be applied to the working target sequence. The following normalization *options* are provided:

NONE	No normalization is applied. This option is the default.
ABSOLUTE	Absolute normalization is applied.
STANDARD	Standard normalization is applied.
User-Defined	Normalization is computed by a user-defined subroutine that is created by using the FCMP procedure, where *User-Defined* is the subroutine name.

PATH=*option*

specifies the similarity measure and warping path information to be computed using the working input and target sequences. The following similarity measures and warping path are provided:

User-Defined The measure and path are computed by a user-defined subroutine that is created by using the FCMP procedure, where *User-Defined* is the subroutine name.

For computational efficiency, the PATH= option should be only used when you want to compute both the similarity measure and the warping path information. If only the similarity measure is needed, use the MEASURE= option. If you specify both the MEASURE= and PATH= option in the TARGET statement, the PATH= option takes precedence.

SDIF=(*numlist***)**

specifies the seasonal differencing to be applied to the accumulated time series. The list of seasonal differencing orders must be separated by spaces or commas. For example, SDIF=(1,3) specifies first, then third, order seasonal differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the SDIF= option. Seasonal differencing is useful when you want to deseasonalize the time series before computing the similarity measures.

SETMISSING=*option* | *number*

SETMISS=*option* | *number*

option specifies how missing values (either actual or accumulated) are interpreted in the accumulated time series for variables that are listed in the TARGET statement. If the SETMISSING= option is not specified in the TARGET statement, missing values are set based on the SETMISSING= option in the ID statement. If the SETMISSING= option is not specified in the ID statement or the TARGET statement, no missing value interpretation is performed. For more information, see the SETMISSING= option in the ID statement.

SLIDE=*option*

specifies the sliding of the target sequence with respect to the input sequence. The following slides are provided:

NONE No sequence sliding. The input time series is compared with the target sequence directly with no sliding. This option is the default.

INDEX Slide by time index. The input time series is compared with the target sequence by observation index.

SEASON Slide by seasonal index. The input time series is compared with the target sequence by seasonal index.

The SLIDE= option takes precedence over the COMPRESS= and EXPAND= options.

TRANSFORM=*option*

specifies the time series transformation to be applied to the accumulated time series. The following transformations are provided:

NONE No transformation is applied. This option is the default.

LOG Logarithmic transformation is applied.

SQRT Square-root transformation is applied.

LOGISTIC	Logistic transformation is applied.
BOXCOX(*number*)	Box-Cox transformation with parameter is applied, where the real *number* is between –5 and 5
User-Defined	Transformation is computed by a user-defined subroutine that is created by using the FCMP procedure, where *User-Defined* is the subroutine name.

When the TRANSFORM= option is specified, the time series must be strictly positive unless a user-defined function is used.

TRIMMISSING=*option*

TRIMMISS= *option*

specifies how missing values (either actual or accumulated) are trimmed from the accumulated time series or ordered sequence for variables that are listed in the TARGET statement. The following trimming options are provided:

NONE	No missing value trimming is applied.
LEFT	Beginning missing values are trimmed.
RIGHT	Ending missing values are trimmed.
BOTH	Both beginning and ending missing values are trimmed. This is the default.

ZEROMISS=*option*

specifies how beginning and ending zero values (either actual or accumulated) are interpreted in the accumulated time series or ordered sequence for variables listed in the TARGET statement. If the ZEROMISS= option is not specified in the TARGET statement, beginning and ending values are set based on the ZEROMISS= option in the ID statement. For more information, see the ZEROMISS= option in the ID statement.

Details: SIMILARITY Procedure

You can use the SIMILARITY procedure to do the following functions, which are done in the order shown. First, you can form time series data from transactional data with the options shown:

1. accumulation — ACCUMULATE= option
2. missing value interpretation — SETMISSING= option
3. zero value interpretation — ZEROMISS= option

Next, you can transform the accumulated time series to form the working time series with the following options. Transformations are useful when you want to stabilize the time series before computing the similarity measures. Simple and seasonal differencing are useful when you want to detrend or deseasonalize the time series before computing the similarity measures. Often, but not always, the TRANSFORM=, DIF=, and SDIF= options should be specified in the same way for both the target and input variables.

4. time series transformation — TRANSFORM= option
5. time series differencing — DIF= and SDIF= options
6. time series missing value trimming — TRIMMISSING= option
7. time series descriptive statistics — PRINT=DESCSTATS option

After the working series is formed, you can treat it as an ordered sequence that can be normalized or scaled. Normalizations are useful when you want to compare the "shape" or "profile" of the time series. Scaling is useful when you want to compare the input sequence to the target sequence while discounting the variation of the target sequence.

8. normalization — NORMALIZE= option
9. scaling — SCALE= option

After the working sequences are formed, you can compute similarity measures between input and target sequences:

10. sliding — SLIDE= option
11. warping — COMPRESS= and EXPAND= options
12. similarity measure — MEASURE= and PATH= options

The SLIDE= option specifies observation-index sliding, seasonal-index sliding, or no sliding. The COMPRESS= and EXPAND= options specify the warping limits. The MEASURE= and PATH= options specify how the similarity measures are computed.

Accumulation

If the ACCUMULATE= option is specified in the ID, INPUT, or TARGET statement, data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option in the ID statement. The ID variable contains the time ID values. Each time ID value corresponds to a specific time period. Accumulation is particularly useful when the input data set contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series, which is used in subsequent analyses.

For example, suppose a data set contains the following observations:

```
19MAR1999    10
19MAR1999    30
11MAY1999    50
12MAY1999    20
23MAY1999    20
```

If the INTERVAL=MONTH option is specified, all of the preceding observations fall within three time periods of March 1999, April 1999, and May 1999. The observations are accumulated within each time period as follows:

If the ACCUMULATE=NONE option is specified, an error is generated because the ID variable values are not equally spaced with respect to the specified frequency (MONTH).

If the ACCUMULATE=TOTAL option is specified, the data are accumulated as follows:

```
O1MAR1999    40
O1APR1999    .
O1MAY1999    90
```

If the ACCUMULATE=AVERAGE option is specified, the data are accumulated as follows:

```
O1MAR1999    20
O1APR1999    .
O1MAY1999    30
```

If the ACCUMULATE=MINIMUM option is specified, the data are accumulated as follows:

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=MEDIAN option is specified, the data are accumulated as follows:

```
O1MAR1999    20
01APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=MAXIMUM option is specified, the data are accumulated as follows:

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=FIRST option is specified, the data are accumulated as follows:

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=LAST option is specified, the data are accumulated as follows:

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=STDDEV option is specified, the data are accumulated as follows:

```
O1MAR1999    14.14
O1APR1999    .
O1MAY1999    17.32
```

As can be seen from the preceding examples, even though the data set observations contain no missing values, the accumulated time series can have missing values.

Missing Value Interpretation

Sometimes missing values should be interpreted as unknown values. But sometimes missing values are known, such as when missing values are created from accumulation and no observations should be interpreted as no (zero) value. In the former case, the SETMISSING= option in the ID, INPUT, or TARGET statement can be used to interpret how missing values are treated. The SETMISSING=0 option should be used when missing observations are to be treated as no (zero) values. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is used in subsequent analyses.

The SETMISSING=0 option should be used with missing observations are to be treated as a zero value. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is then used in subsequent analyses.

Zero Value Interpretation

When querying certain databases for time-stamped data based on a particular time range, time periods that contain no data are sometimes assigned zero values. For certain analyses, it is more desirable to assign these values to missing. Often, these beginning or ending zero values need to be interpreted as missing values. The ZEROMISS= option in the ID, INPUT, or TARGET statement specifies that the beginning, ending, or both the beginning and ending values are to be interpreted as zero values.

Time Series Transformation

Transformations are useful when you want to stabilize the time series before computing the similarity measures. There are four transformations available, for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log — is the logarithmic transformation,

$$w_t = \ln(y_t)$$

Logistic — is the logistic transformation,

$$w_t = \ln(c\,y_t/(1 - c\,y_t))$$

where the scaling factor c is

$$c = (1 - e^{-6})10^{-\mathrm{ceil}(\log_{10}(\max(y_t)))}$$

and $\mathrm{ceil}(x)$ is the smallest integer greater than or equal to x.

Square root — is the square root transformation,

$$w_t = \sqrt{y_t}$$

Box-Cox is the Box-Cox transformation,

$$w_t = \begin{cases} \frac{y_t^{\lambda}-1}{\lambda} & \lambda \neq 0 \\ \ln(y_t) & \lambda = 0 \end{cases}$$

User-Defined is the transformation computed by a user-defined subroutine that is created by using the FCMP procedure, where *User-Defined* is the subroutine name.

Other time series transformations can be performed prior to invoking the SIMILARITY procedure by using the SAS/ETS EXPAND procedure or the DATA step.

Time Series Differencing

After optionally transforming the series, the accumulated series can be simply or seasonally differenced using the INPUT or TARGET statement DIF= and SDIF= options. Simple and seasonal differencing are useful when you want to detrend or deseasonalize the time series before computing the similarity measures.

For example, suppose y_t is a monthly time series. The following examples of the DIF= and SDIF= options demonstrate how to simply and seasonally difference the time series: DIF=(1,3) specifies first, then third, order differencing; SDIF=(1,3) specifies first, then third, order seasonal differencing.

Additionally, assuming that y_t is strictly positive, the INPUT or TARGET statement TRANSFORM= option and the DIF= and SDIF= options can be combined.

Time Series Missing Value Trimming

In some instances, missing values should be interpreted as an unknown observation, but other times, missing values are known and should be interpreted as a zero value. This is the case when missing values are created from accumulation, and a missing observation should be interpreted as having no value (meaning a value of zero). In the former case, the SETMISSING=option in the ID, INPUT, or TARGET, statement can be used to interpret how missing observations should be treated. By default, missing values, at the beginning and ending of the data set, are trimmed from the data set prior to analysis. This can be performed using TRIMMISS=both.

Time Series Descriptive Statistics

After a series has been optionally accumulated and transformed with missing values interpreted, descriptive statistics can be computed for the resulting working series by specifying the PRINT=DESCSTATS option. This option produces an ODS table that contains the sum, mean, minimum, maximum, and standard deviation of the working series.

Input and Target Sequences

After the input and target working series are formed, they can be treated as two ordered sequences. Given an input time sequence, x_i, for $i = 1$ to N_x, where i is the input sequence index, and a target time sequence, y_j, for $j = 1$ to N_y, where j is the target sequence index, these sequences are analyzed for similarity.

Sliding Sequences

Similarity measures can be computed between the target sequence and any contiguous subsequences of the input time series.

There are three types of sequence sliding:

- no sliding
- slide by time index
- slide by season index

For more information, see Leonard et al. (2008).

Time Warping

Time warping allows for the comparison between target and input sequences of differing lengths by compressing or expanding the input sequence with respect the target sequence while respecting the order of the sequence elements.

For more information, see Leonard et al. (2008).

Sequence Normalization

The working (input or target) sequence can be normalized prior to further analysis. Let q_i be the original sequence with mean μ_q and standard deviation σ_q, and let r_t be the normalized sequence. The normalizations are defined as follows:

- Standard is the standard normalization

$$r_i = (q_i - \mu_q)/\sigma_q$$

- Absolute is the absolute normalization

$$r_i = (q_i - \min(q_i))/(\max(q_i) - \min(q_i))$$

- User-defined is a user-defined normalization created by the FCMP procedure.

Sequence Scaling

The working input sequence can be scaled to the working target sequence. Sequence scaling is applied after normalization. Let y_j be the working target sequence with mean μ_y and standard deviation σ_y. Let x_i be the working input sequence and let q_i be the scaled sequence. The scaling is defined as follows:

- Standard is the standard normalization

$$q_i = (x_i - \mu_y)/\sigma_y$$

- Absolute is the absolute scaling

$$q_i = (x_i - \min(y_j))/(\max(y_j) - \min(y_j))$$

- User-defined is a user-defined scaling created by the FCMP procedure.

Similarity Measures

The working input sequence can be compared to the working target sequence to create a similarity. For more information, see Leonard et al. (2008).

User-Defined Functions and Subroutines

A user-defined routine can be written in the SAS language by using the FCMP procedure or in the C language by using both the FCMP procedure and the PROTO procedure, respectively. The SIMILARITY procedure cannot use C language routines directly. The procedure can use only SAS language routines that might or might not call C language routines. Creating user-defined routines is more completely described in the FCMP procedure and the PROTO procedure documentation. The FCMP and PROTO procedures are part of Base SAS software.

The SAS language provides integrated memory management and exception handling such as operations on missing values. The C language provides flexibility and allows the integration of existing C language libraries. However, proper memory management and exception handling are solely the responsibility of the user. Additionally, the support for standard C libraries is restricted. If you have a choice, it is highly recommended that you write user-defined functions and subroutines in the SAS language using the FCMP procedure.

For each of the tasks previously described, the following sections describe the required subroutine or function signature and provide examples of using a user-defined routine with the SIMILARITY procedure.

Time Series Transformations

A user-defined transformation subroutine has the subroutine signature

```
SUBROUTINE <SUBROUTINE-NAME> ( <ARRAY-NAME>[*] );
```

where the *array-name* is the time series to be transformed.

For example, to duplicate the functionality of the built-in TRANSFORM=LOG option in the INPUT and TARGET statement, the following SAS statements create a user-defined version of this transformation called MYTRANSFORM and store this subroutine in the catalog SASUSER.MYSIMILAR:

```
proc fcmp outlib=sasuser.mysimilar.package;

   subroutine mytransform( series[*] );

      outargs series;

      length = DIM(series);

      do i = 1 to length;
         value = series[i];
         if value > 0 then do;
            series[i] = log( value );
         end;
         else do;
            series[i] = .;
         end;
      end;

   endsub;

run;
```

This user-defined subroutine can be specified in the TRANSFORM= option in the INPUT or TARGET statement as follows:

```
options cmplib = sasuser.mysimilar;

proc similarity ...;
...
input  myinput  / transform=mytransform;
target mytarget / transform=mytransform;
...
run;
```

Sequence Normalizations

A user-defined normalization subroutine has the signature

```
SUBROUTINE <SUBROUTINE-NAME> ( <ARRAY-NAME>[*] );
```

where the *array-name* is the sequence to be normalized.

For example, to duplicate the functionality of the built-in NORMALIZE=ABSOLUTE option in the INPUT and TARGET statement, the following SAS statements create a user-defined version of this normalization

called MYNORMALIZE and store this subroutine in the catalog SASUSER.MYSIMILAR:

```
proc fcmp outlib=sasuser.mysimilar.package;

   subroutine mynormalize( sequence[*] );

      outargs sequence;

      length = DIM(sequence);
      minimum = .; maximum = .;

      do i = 1 to length;
         value = sequence[i];
         if nmiss(minimum) | nmiss(maximum) then do;
            minimum = value;
            maximum = value;
         end;
         if nmiss(value) = 0 then do;
            if value < minimum then minimum = value;
            if value > maximum then maximum = value;
         end;
      end;

      do i = 1 to length;
         value = sequence[i];
         if nmiss( value ) | minimum > maximum then do;
            sequence[i] = .;
         end;
         else do;
            sequence[i] = (value - minimum) / (maximum - minimum);
         end;
      end;

   endsub;

run;
```

This user-defined subroutine can be specified in the NORMALIZE= option in the INPUT or TARGET statement as follows:

```
options cmplib = sasuser.mysimilar;

proc similarity ...;
   ...
   input  myinput  / normalize=mynormalize;
   target mytarget / normalize=mynormalize;
   ...
run;
```

Sequence Scaling

A user-defined scaling subroutine has the signature

```
SUBROUTINE <SUBROUTINE-NAME> ( <ARRAY-NAME>[*], <ARRAY-NAME>[*] );
```

where the first *array-name* is the target sequence and the second *array-name* is the input sequence to be scaled.

For example, to duplicate the functionality of the built-in SCALE=ABSOLUTE option in the INPUT statement, the following SAS statements create a user-defined version of this scaling called MYSCALE and store this subroutine in the catalog SASUSER.MYSIMILAR:

```
proc fcmp outlib=sasuser.mysimilar.package;

   subroutine myscale( target[*], input[*] );

      outargs input;

      length = DIM(target);
      minimum = .; maximum = .;

      do i = 1 to length;
         value = target[i];
         if nmiss(minimum) | nmiss(maximum) then do;
            minimum = value;
            maximum = value;
         end;
         if nmiss(value) = 0 then do;
            if value < minimum then minimum = value;
            if value > maximum then maximum = value;
         end;
      end;

      do i = 1 to length;
         value = input[i];
         if nmiss( value ) | minimum > maximum then do;
            input[i] = .;
         end;
         else do;
            input[i] = (value - minimum) / (maximum - minimum);
         end;
      end;

   endsub;

run;
```

This user-defined subroutine can be specified in the SCALE= option in the INPUT statement as follows:

```
options cmplib=sasuser.mysimilar;

proc similarity ...;
   ...
   input  myinput  / scale=myscale;
```

```
   ...
run;
```

Similarity Measures

A user-defined similarity measure function has the signature

```
FUNCTION <FUNCTION-NAME> ( <ARRAY-NAME>[*], <ARRAY-NAME>[*] );
```

where the first *array-name* is the target sequence and the second *array-name* is the input sequence. The return value of the function is the similarity measure associated with the target sequence and the input sequence.

For example, to duplicate the functionality of the built-in MEASURE=ABSDEV option in the TARGET statement with no warping, the following SAS statements create a user-defined version of this measure called MYMEASURE and store this subroutine in the catalog SASUSER.MYSIMILAR:

```
proc fcmp outlib=sasuser.mysimilar.package;

   function mymeasure( target[*], input[*] );

      length = min(DIM(target), DIM(input));
      sum = 0; num = 0;

      do i = 1 to length;
         x = input[i];
         w = target[i];
         if nmiss(x) = 0 & nmiss(w) = 0 then do;
            d = x - w;
            sum = sum + abs(d);
            num = num + 1;
         end;
      end;

      if num <= 0 then return(.);

      return(sum);

   endsub;

run;
```

This user-defined function can be specified in the MEASURE= option in the TARGET statement as follows:

```
options cmplib=sasuser.mysimilar;

proc similarity ...;
   ...
   target  mytarget  / measure=mymeasure;
   ...
run;
```

For another example, to duplicate the functionality of the built-in MEASURE=SQRDEV and MEASURE=ABSDEV options by using the C language, the following SAS statements create a user-defined C language version of these measures called DTW_SQRDEV_C and DTW_ABSDEV_C and store these

functions in the catalog SASUSER.CSIMIL.CFUNCS. DTW refers to dynamic time warping. These C language functions can then be called by SAS language functions and subroutines.

```
proc proto package=sasuser.csimil.cfuncs;

mapmiss double = 999999999;

double dtw_sqrdev_c( double * target / iotype=input,
                     int      targetLength,
                     double * input / iotype=input,
                     int      inputLength );

externc dtw_sqrdev_c;
 double dtw_sqrdev_c( double * target,
                      int      targetLength,
                      double * input,
                      int      inputLength )
   {
      int      i,j;
      double   x,w,d;
      double * prev = (double *)malloc( sizeof(double)*targetLength);
      double * curr = (double *)malloc( sizeof(double)*inputLength);
      if ( prev == 0 || curr == 0 ) return 999999999;

      x = input[0];
      for ( j=0; j<targetLength; j++ ) {
         w = target[j];
         d = x - w;
         d = d*d;
         if ( j == 0 ) prev[j] = d;
         else          prev[j] = d + prev[j-1];
      }

      for (i=1; i<inputLength; i++ ) {
         x = input[i];

         j = 0;
         w = target[j];
         d = x - w;
         d = d*d;
         curr[j] = d + prev[j];

         for (j=1; j<targetLength; j++ ) {
            w = target[j];
            d = x - w;
            d = d*d;
            curr[j] = d + fmin( prev[j],
                                fmin( prev[j-1], curr[j]));
         }

         if ( i < targetLength ) {
           for( j=0; j<inputLength; j++ )
             prev[j] = curr[j];
         }
```

```
       }

       d = curr[inputLength-1];
       free( (char*) prev);
       free( (char*) curr);
       return( d );
  }
externcend;

double dtw_absdev_c( double * target / iotype=input,
                     int      targetLength,
                     double * input / iotype=input,
                     int      inputLength );
externc dtw_absdev_c;
 double dtw_absdev_c( double * target,
                      int      targetLength,
                      double * input,
                      int      inputLength )
   {
      int      i,j;
      double   x,w,d;
      double * prev = (double *)malloc( sizeof(double)*targetLength);
      double * curr = (double *)malloc( sizeof(double)*inputLength);
      if ( prev == 0 || curr == 0 ) return 999999999;

      x = input[0];
      for ( j=0; j<targetLength; j++ ) {
        w = target[j];
        d = x - w;
        d = fabs(d);
        if (j == 0) prev[j] = d;
        else prev[j] = d + prev[j-1];
      }

      for (i=1; i<inputLength; i++ ) {
        x = input[i];

        j = 0;
        w = target[j];
        d = x - w;
        d = fabs(d);
        curr[j] = d + prev[j];

        for (j=1; j<targetLength; j++) {
          w = target[j];
          d = x - w;
          d = fabs(d);
          curr[j] = d + fmin( prev[j],
                              fmin( prev[j-1], curr[j] ));
        }

        if ( i < inputLength) {
          for ( j=0; j<targetLength; j++ )
             prev[j] = curr[j];
```

```
            }

          }

          d = curr[inputLength-1];
          free( (char*) prev);
          free( (char*) curr);
          return( d );
        }
    externcend;

run;
```

The preceding SAS statements create two C language functions that can then be used in SAS language functions or subroutines or both. However, these functions cannot be directly used by the SIMILARITY procedure. In order to use these C language functions in the SIMILARITY procedure, two SAS language functions must be created that call these two C language functions. The following SAS statements create two user-defined SAS language versions of these measures called DTW_SQRDEV and DTW_ABSDEV and stores these functions in the catalog SASUSER.MYSIMILAR.FUNCS. These SAS language functions use the previously created C language function; the SAS language functions can then be used by the SIMILARITY procedure.

```
proc fcmp outlib=sasuser.mysimilar.funcs
          inlib=sasuser.cfuncs;

   function dtw_sqrdev( target[*], input[*] );
      dev = dtw_sqrdev_c(target,DIM(target),input,DIM(input));
      return( dev );
   endsub;

   function dtw_absdev( target[*], input[*] );
      dev = dtw_absdev_c(target,DIM(target),input,DIM(input));
      return( dev );
   endsub;

run;
```

This user-defined function can be specified in the MEASURE= option in the TARGET statement as follows:

```
options cmplib=sasuser.mysimilar;

proc similarity ...;
   ...
   target  mytarget    / measure=dtw_sqrdev;
   target  yourtarget  / measure=dtw_absdev;
   ...
run;
```

Similarity Measures and Warping Path

A user-defined similarity measure and warping path information function has the signature

```
FUNCTION <FUNCTION-NAME> ( <ARRAY-NAME>[*], <ARRAY-NAME>[*],
                           <ARRAY-NAME>[*], <ARRAY-NAME>[*],
                           <ARRAY-NAME>[*] );
```

where the first *array-name* is the target sequence, the second *array-name* is the input sequence, the third *array-name* is the returned target sequence indices, the fourth *array-name* is the returned input sequence indices, and the fifth *array-name* is the returned path distances. The returned value of the function is the similarity measure. The last three returned arrays are used to compute the path and cost statistics.

The returned sequence indices must represent a valid warping path; that is, integers greater than zero and less than or equal to the sequence length and recorded in ascending order. The returned path distances must be nonnegative numbers.

Output Data Sets

The SIMILARITY procedure can create the OUT=, OUTMEASURE=, OUTPATH= , OUTSEQUENCE=, and OUTSUM= data sets. In general, these data sets contain the variables listed in the BY statement. The ID statement time ID variable is also included in the data sets when the time dimension is important. If an analysis step related to an output data step fails, then the values of this step are not recorded or are set to missing in the related output data set, and appropriate error and warning messages are recorded in the SAS log.

OUT= Data Set

The OUT= data set contains the variables that are specified in the BY, ID, INPUT, and TARGET statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN=, INTERVAL=, START=, and END= options. The values of the variables specified in the INPUT and TARGET statements are accumulated based on the ACCUMULATE= option, missing values are interpreted based on the SETMISSING= option, and zero values are interpreted using the ZEROMISS= option. The accumulated time series is transformed based on the TRANSFORM=, DIF=, and SDIF= options.

OUTMEASURE= Data Set

The OUTMEASURE= data set records the similarity measures between each INPUT and TARGET statement variable with respect to each time ID value. The form of the OUTMEASURE= data set depends on the SORTNAMES and ORDER= options. The OUTMEASURE= data set contains the variables specified in the BY statement in addition to the variables listed below.

For ORDER=INPUTTARGET and ORDER=TARGETINPUT, the OUTMEASURE= data set has the following form:

INPUT	input variable name
TARGET	target variable name
TIMEID	time ID values
INPSEQ	input sequence values
TARSEQ	target sequence values
SIM	similarity measures

The OUTMEASURE= data set is ordered by the variables _INPUT_, then _TARGET_, then _TIMEID_ when ORDER=INPUTTARGET. The OUTMEASURE= data set is ordered by the variables _TARGET_, then _INPUT_, then _TIMEID_ when ORDER=TARGETINPUT.

For ORDER=INPUT, the OUTMEASURE= data set has the following form:

INPUT	input variable name
TIMEID	time ID values
INPSEQ	input sequence values
target-names	similarity measures that are associated with each TARGET statement variable name

The OUTMEASURE= data set is ordered by the variables _INPUT_, then _TIMEID_.

For ORDER=TARGET, the OUTMEASURE= data set has the following form:

TARGET	target variable name
TIMEID	time ID values
TARSEQ	target sequence values
input-names	similarity measures that are associated with each INPUT statement variable name

The OUTMEASURE= data set is ordered by the variables _TARGET_, then _TIMEID_.

OUTPATH= Data Set

The OUTPATH= data set records the path analysis between each INPUT and TARGET statement variable. This data set records the path sequences for each slide index and for each warp index associated with the slide index. The sequence values recorded are normalized and scaled based on the NORMALIZE= and SCALE= options.

The OUTPATH= data set contains the variables specified in the BY statement and the following variables:

INPUT	input variable name
TARGET	target variable name
TIMEID	time ID values
SLIDE	slide index
WARP	warp index

INPSEQ	input sequence values
TARSEQ	target sequence values
INPPTH	input path index
TARPTH	target path index
METRIC	distance metric values

The Warp Index indicates the total amount of warping for each slide. A negative number represents compression of the target sequence. A positive number represents expansion of the target sequence. The Warp Index is always zero for SLIDE=NONE and SLIDE=SEASON.

The sorting of the OUTPATH= data set depends on the SORTNAMES and ORDER= options.

The OUTPATH= data set is ordered by the variables _INPUT_, then _TARGET_, then _TIMEID_ when ORDER=INPUTTARGET or ORDER=INPUT. The OUTPATH= data set is ordered by the variables _TARGET_, then _INPUT_, then _TIMEID_ when ORDER=TARGETINPUT or ORDER=TARGET.

If there are a large number of slides or warps or both, this data set might be large.

OUTSEQUENCE= Data Set

The OUTSEQUENCE= data set records the input and target sequences that are associated with each INPUT and TARGET statement variable. This data set records the input and target sequence values for each slide index and for each warp index that is associated with the slide index. The sequence values that are recorded are normalized and scaled based on the NORMALIZE= and SCALE= options. This data set also contains the similarity measure associated with the two sequences.

The OUTSEQUENCE= data set contains the variables specified in the BY statement in addition to the following variables:

INPUT	input variable name
TARGET	target variable name
TIMEID	time ID values
SLIDE	slide index
WARP	warp index
INPSEQ	input sequence values
TARSEQ	target sequence values
SIM	similarity measure
STATUS	sequence status

The sorting of the OUTSEQUENCE= data set depends on the SORTNAMES and ORDER= options.

The OUTSEQUENCE= data set is ordered by the variables _INPUT_, then _TARGET_, then _TIMEID_ when ORDER=INPUTTARGET or ORDER=INPUT. The OUTSEQUENCE= data set is ordered by the variables _TARGET_, then _INPUT_, then _TIMEID_ when ORDER=TARGETINPUT or ORDER=TARGET.

If there are a large number of slides or warps or both, this data set might be large.

OUTSUM= Data Set

The OUTSUM= data set summarizes the similarity measures between each INPUT and TARGET statement variable. The form of the OUTSUM= data set depends on the SORTNAMES and ORDER= options. If the SORTNAMES option is specified, each variable (INPUT or TARGET) is analyzed in ascending order. The OUTSUM= data set contains the variables specified in the BY statement in addition to the variables listed below.

For ORDER=INPUTTARGET and ORDER=TARGETINPUT, the OUTSUM= data set has the following form:

INPUT	input variable name
TARGET	target variable name
STATUS	status flag that indicates whether the requested analyses were successful
TIMEID	time ID values
SIM	similarity measure summary

The OUTSUM= data set is ordered by the variables _INPUT_, then _TARGET_ when ORDER=INPUTTARGET. The OUTSUM= data set is ordered by the variables _TARGET_, then _INPUT_ when ORDER=TARGETINPUT.

For ORDER=INPUT, the OUTSUM= data set has the following form:

INPUT	input variable name
STATUS	status flag that indicates whether the requested analyses were successful
target-names	similarity measure summary that is associated with each TARGET statement variable name

The OUTSUM= data set is ordered by the variable _INPUT_.

For ORDER=TARGET, the OUTSUM= data set has the following form:

TARGET	target variable name
STATUS	status flag that indicates whether the requested analyses were successful
input-names	similarity measure summary that is associated with each INPUT statement variable name

The OUTSUM= data set is ordered by the variable _TARGET_.

STATUS Variable Values

The _STATUS_ variable contains a code that specifies whether the similarity analysis has been successful or not. The _STATUS_ variable can take the following values:

0	Success
3000	Accumulation failure
4000	Missing value interpretation failure
6000	Series is all missing
7000	Transformation failure
8000	Differencing failure
9000	Unable to compute descriptive statistics
10000	Normalization failure
11000	Input contains embedded missing values
12000	Target contains embedded missing values
13000	Scaling failure
14000	Measure failure
15000	Path failure
16000	Slide summarization failure

Printed Output

The SIMILARITY procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. All output is controlled by the PRINT= and PRINTDETAILS options in the PROC SIMILARITY statement.

The sort, order, and form of the printed output depend on both the SORTNAMES option and the ORDER= option. If the SORTNAMES option is specified, each variable (INPUT or TARGET) is analyzed in ascending order. For ORDER=INPUTTARGET, the printed output is ordered by the INPUT statement variables (row) and then by the TARGET statement variables (row). For ORDER=TARGETINPUT, the printed output is ordered by the TARGET statement variables (row) and then by the INPUT statement variables (row). For ORDER=INPUT, the printed output is ordered by the INPUT statement variables (row) and then by the TARGET statement variables (column). For ORDER=TARGET, the printed output is ordered by the TARGET statement variables (row) and then by the INPUT statement variables (column).

In general, if an analysis step related to printed output fails, the values of that step are not printed and appropriate error and warning messages are recorded in the SAS log. The printed output is similar to the output data set; these similarities are described as follows:

PRINT=COSTS
prints the costs statistics.

PRINT=DESCSTATS
prints the descriptive statistics.

PRINT=PATHS
prints the path statistics.

PRINT=SLIDES
prints the sliding sequence summary.

PRINT=SUMMARY
prints the summary of similarity measures similar to the OUTSUM= data set.

PRINT=WARPS
prints the warp summary.

PRINTDETAILS
prints each table with greater detail.

ODS Table Names

Table 29.2 relates the PRINT= options to ODS tables.

Table 29.2 ODS Tables Produced in PROC SIMILARITY

ODS Table Name	Description	Option
CostStatistics	Cost statistics	PRINT=COSTS
DescStats	Descriptive statistics	PRINT=DESCSTATS
PathLimits	Path limits	PRINT=PATHS
PathStatistics	Path statistics	PRINT=PATHS
SlideMeasuresSummary	Summary of measure per slide	PRINT=SLIDES
MeasuresSummary	Measures summary	PRINT=SUMMARY
InputMeasuresSummary	Measures summary	PRINT=SUMMARY
TargetMeasuresSummary	Measures summary	PRINT=SUMMARY
WarpMeasuresSummary	Summary of measure per warp	PRINT=WARPS

The tables are related to a single series within a BY group.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

This section describes the use of ODS for creating graphics with the SIMILARITY procedure.

ODS Graph Names

PROC SIMILARITY assigns a name to each graph it creates by using ODS. You can use these names to selectively reference the graphs. The names are listed in Table 29.3.

Table 29.3 ODS Graphics Produced by PROC SIMILARITY

ODS Graph Name	Plot Description	Statement	PLOTS= Option
CostsPlot	Costs plot	SIMILARITY	COSTS
NormalizedSequencePlot	Normalized sequence plot	SIMILARITY	NORMALIZED
PathDistancePlot	Path distances plot	SIMILARITY	DISTANCES
PathDistanceHistogram	Path distances histogram	SIMILARITY	DISTANCES
PathRelativeDistancePlot	Path relative distances plot	SIMILARITY	DISTANCES
PathRelativeDistanceHistogram	Path relative distances histogram	SIMILARITY	DISTANCES
PathPlot	Path plot	SIMILARITY	PATHS
PathSequencesPlot	Path sequences plot	SIMILARITY	MAPS
PathSequencesScaledPlot	Scaled path sequences map plot	SIMILARITY	MAPS
ScaledSequencePlot	Scaled sequence plot	SIMILARITY	SCALED
SequencePlot	Sequence plot	SIMILARITY	SEQUENCES
SeriesPlot	Input time series plot	SIMILARITY	INPUTS
SimilarityPlot	Similarity measures plot	SIMILARITY	MEASURES
TargetSequencePlot	Target sequence plot	SIMILARITY	TARGETS
WarpPlot	Warping plot	SIMILARITY	WARPS
WarpScaledPlot	Scaled warping plot	SIMILARITY	WARPS

Time Series Plots

The time series plots (SeriesPlot) illustrate the input time series to be compared. The horizontal axis represents the input series time ID values, and the vertical axis represents the input series values.

Sequence Plots

The sequence plots (SequencePlot) illustrate the target and input sequences to be compared. The horizontal axis represents the (target or input) sequence index, and the vertical axis represents the (target or input) sequence values.

Path Plots

The path plot (PathPlot) and path limits plot (PathLimitsPlot) illustrate the path through the distance matrix. The horizontal axis represents the input sequence index, and the vertical axis represents the target sequence index. The dots represent the path coordinates. The upper parallel line represents the compression limit, and the lower parallel line represents the expansion limit. These plots visualize the path through the distance matrix. Vertical movements indicate compression, and horizontal movements represent expansion of the target sequence with respect to the input sequence. These plots are useful for visualizing the amount of expansion and compression along the path.

Time Warp Plots

The time warp plot (WarpPlot) and scaled time warp plot (WarpScaledPlot) illustrate the time warping. The horizontal axis represents the (input and target) sequence index. The upper line plot represents the target sequence. The lower line plot represents the input sequence. The lines that connect the input and target sequence values represent the mapping between the input and target sequence indices along the optimal path. These plots visualize the warping of the time index with respect to the input and target sequence values. Expansion of a single target sequence value occurs when it is mapped to more than one input sequence value. Expansion of a single input sequence value occurs when it is mapped to more than one target sequence value. The plots are useful for visualizing the mapping between the input and target sequence values along the path. The plots are useful for comparing the path sequences or input and target sequence after time warping.

Path Sequence Plots

The path sequence plot (PathSequencesPlot) and scaled path sequence plot (PathSequencesScaledPlot) illustrate the sequence mapping along the optimal path. The horizontal axis represents the path index. The dashed line represents the time warped input sequence. The solid line represents the time warped target sequence. These plots visualize the mapping between the input and target sequence values with respect to the path index. The scaled plot with the input and target sequence values are scaled and evenly separated for visual convenience.

Path Distance Plots

The path distance plots (PathDistancePlot) and path relative distance plots (PathRelativeDistancePlot) illustrate the path (relative) distances. The horizontal axis represents the path index. The vertical needles represent the (relative) distances. The horizontal reference lines indicate one and two standard deviations.

The path distance histogram (PathDistanceHistogram) and path relative distance histogram (PathDistanceRelativeHistogram) illustrate the distribution of the path (relative) distances. The bars represent the histogram, and the solid line represents a normal distribution with the same mean and variance.

Cost Plots

The cost plot (CostPlot) and cost limits plot (CostPlot) illustrate the cost of traversing the distance matrix. The horizontal axis represents the input sequence index, and the vertical axis represents the target sequence index. The colors and shading within the plot illustrate the incremental cost of traversing the distance matrix. The upper parallel line represents the compression limit, and the lower parallel line represents the expansion limit.

Examples: SIMILARITY Procedure

Example 29.1: Accumulating Transactional Data into Time Series Data

This example uses the SIMILARITY procedure to illustrate the accumulation of time-stamped transactional data that has been recorded at no particular frequency into time series data at a specific frequency. After the time series is created, the various SAS/ETS procedures related to time series analysis, similarity analysis, seasonal adjustment and decomposition, modeling, and forecasting can be used to further analyze the time series data.

Suppose that the input data set WORK.RETAIL contains the variables STORE and TIMESTAMP and numerous other numeric transaction variables. The BY variable STORE contains values that break up the transactions into groups (BY groups). The time ID variable TIMESTAMP contains SAS date values recorded at no particular frequency. The other data set variables contain the numeric transaction values to be analyzed. It is further assumed that the input data set is sorted by the variables STORE and TIMESTAMP.

The following statements form monthly time series from the transactional data based on the median value (ACCUMULATE=MEDIAN) of the transactions recorded with each time period. The accumulated time series values for time periods with no transactions are set to zero instead of missing (SETMISS=0). Only transactions recorded between the first day of 1998 (START='01JAN1998'D) and last day of 2000 (END='31JAN2000'D) are considered and if needed are extended to include this range.

```
proc similarity data=work.retail out=mseries;
   by store;
   id timestamp interval=month
                accumulate=median
                setmiss=0
                start='01jan1998'd
                end  ='31dec2000'd;
   target _NUMERIC_;
run;
```

The monthly time series data are stored in the data set WORK.MSERIES. Each BY group associated with the BY variable STORE contains an observation for each of the 36 months associated with the years 1998, 1999, and 2000. Each observation contains the variables STORE and TIMESTAMP and each of the analysis variables in the input DATA= data set.

After each set of transactions has been accumulated to form the corresponding time series, the accumulated time series can be analyzed by using various time series analysis techniques. For example, exponentially weighted moving averages can be used to smooth each series. The following statements use the EXPAND procedure to smooth the analysis variable named STOREITEM:

```
proc expand data=mseries
            out=smoothed
            from=month;
   by store;
   id timestamp;
   convert storeitem=smooth / transform=(ewma 0.1);
run;
```

The smoothed series is stored in the data set WORK.SMOOTHED. The variable SMOOTH contains the smoothed series.

If the time ID variable TIMESTAMP contains SAS datetime values instead of SAS date values, the INTERVAL= , START=, and END= options in the SIMILARITY procedure must be changed accordingly, and the following statements could be used to accumulate the datetime transactions to a monthly interval:

```
proc similarity data=work.retail
                out=tseries;
   by store;
   id timestamp interval=dtmonth
                accumulate=median
                setmiss=0
                start='01jan1998:00:00:00'dt
                end  ='31dec2000:00:00:00'dt;
   target _NUMERIC_;
run;
```

The monthly time series data are stored in the data set WORK.TSERIES, and the time ID values use a SAS datetime representation.

Example 29.2: Similarity Analysis

This simple example illustrates how to use similarity analysis to compare two time sequences. The following statements create an example data set that contains two time sequences of differing lengths:

```
data test;
input i y x;
datalines;
1   2  3
2   4  5
3   6  3
4   7  3
5   3  3
6   8  6
7   9  3
8   3  8
9  10  .
10 11  .
```

```
;
run;
```

The following statements perform similarity analysis on the example data set:

```
proc similarity data=test out=_null_
   print=all plot=all;
   input x;
   target y / measure=absdev;
run;
```

The DATA=TEST option specifies that the input data set WORK.TEST is to be used in the analysis. The OUT=_NULL_ option specifies that no output time series data set is to be created. The PRINT=ALL and PLOTS=ALL options specify that all ODS tables and graphs are to be produced. The INPUT statement specifies that the input variable is X. The TARGET statement specifies that the target variable is Y and that the similarity measure is computed using absolute deviation (MEASURE=ABSDEV).

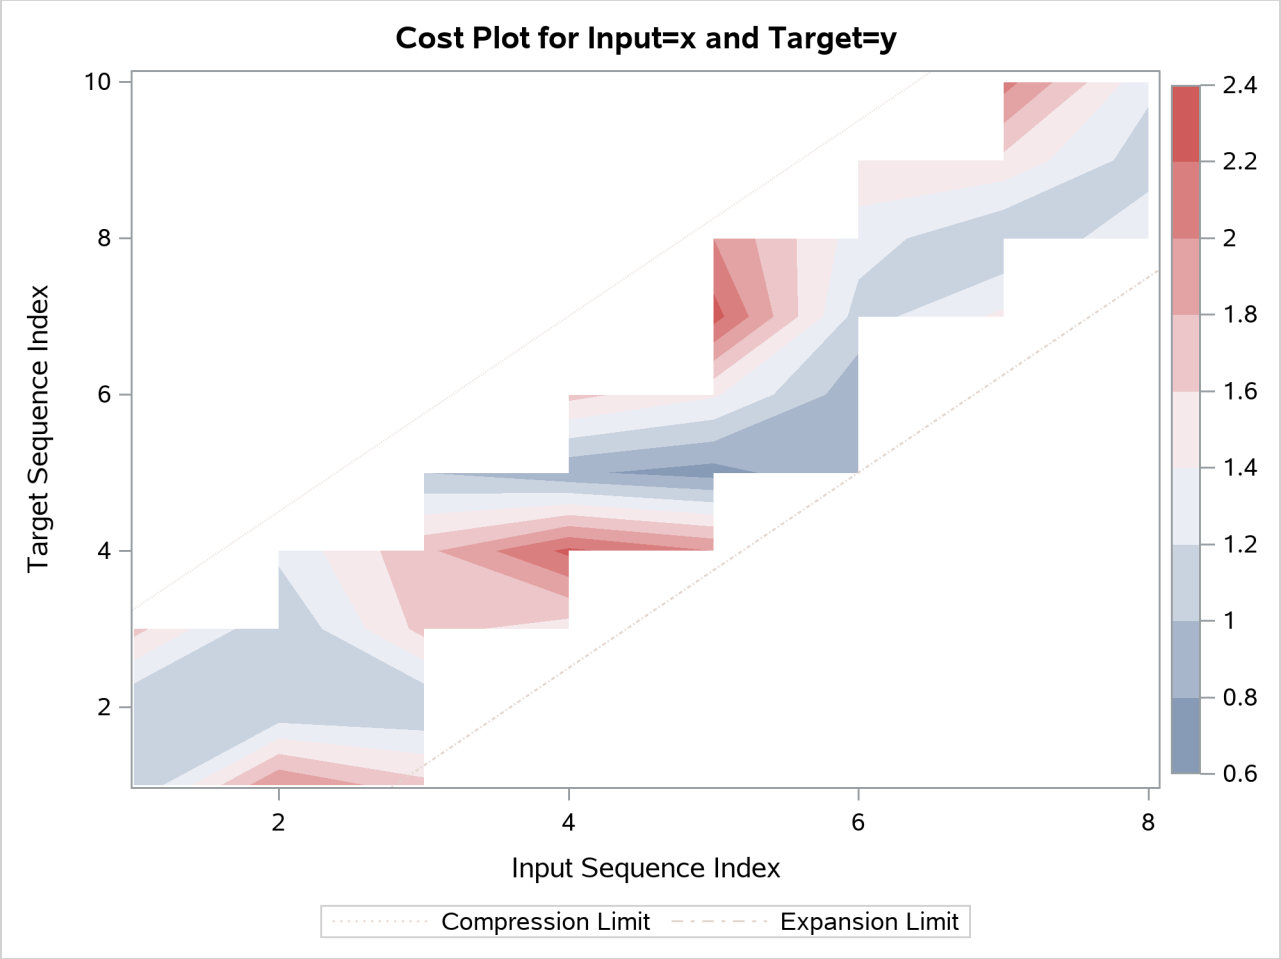
Expansion	2	None	0	7	2

Output 29.2.20 Cost Plot with Warping Limits



The following statements repeat the preceding similarity analysis on the example data set but store the results in output data sets:

```
proc similarity data=test out=series
   outsequence=sequences outpath=path outsum=summary;
   input x;
   target y / measure=absdev
              compress=(localabs=2)
              expand=(localabs=2);
run;
```

The OUT=SERIES, OUTSEQUENCE=SEQUENCES, OUTPATH=PATH, and OUTSUM=SUMMARY options specify that the output time series, time sequences, path analysis, and summary data sets be created, respectively.

Example 29.3: Sliding Similarity Analysis

This example illustrates how to use sliding similarity analysis to compare two time sequences. The SASHELP.WORKERS data set contains two similar time series variables (ELECTRIC and MASONRY), which represent employment over time. The following statements create an example data set that contains two time series of differing lengths, where the variable MASONRY has the first 12 and last 7 observations set to missing to simulate the lack of data associated with the target series:

```
data workers; set sashelp.workers;
   if '01JAN1978'D <= date < '01JAN1982'D then masonry = masonry;
   else masonry = .;
run;
```

The goal of sliding similarity measures analysis is find the slide index that corresponds to the most similar subsequence of the input series when compared to the target sequence. The following statements perform sliding similarity analysis on the example data set:

```
proc similarity data=workers out=_NULL_ print=(slides summary);
   id date interval=month;
   input  electric;
   target masonry / slide=index measure=msqrdev
                    expand=(localabs=3 globalabs=3)
                    compress=(localabs=3 globalabs=3);
run;
```

The DATA=WORKERS option specifies that the input data set WORK.WORKERS is to be used in the analysis. The OUT=_NULL_ option specifies that no output time series data set is to be created. The PRINT=(SLIDES SUMMARY) option specifies that the ODS tables related to the sliding similarity measures and their summary be produced. The INPUT statement specifies that the input variable is ELECTRIC. The TARGET statement specifies that the target variable is MASONRY and that the similarity measure be computed using mean squared deviation (MEASURE=MSQRDEV). The SLIDE=INDEX option specifies observation index sliding. The COMPRESS=(LOCALABS=3 GLOBALABS=3) option limits local and global absolute compression to 3. The EXPAND=(LOCALABS=3 GLOBALABS=3) option limits local and global absolute expansion to 3.

Output 29.3.1 Summary of the Slide Measures

The SIMILARITY Procedure

Slide Measures Summary for Input=ELECTRIC and Target=MASONRY

Slide Index	DATE	Slide Target Sequence Length	Slide Input Sequence Length	Slide Warping Amount	Slide Minimum Measure
0	JAN1977	48	51	3	497.6737
1	FEB1977	48	51	1	482.6777
2	MAR1977	48	51	0	474.1251
3	APR1977	48	51	0	490.7792
4	MAY1977	48	51	-2	533.0788
5	JUN1977	48	51	-3	605.8198
6	JUL1977	48	51	-3	701.7138
7	AUG1977	48	51	3	646.5918
8	SEP1977	48	51	3	616.3258
9	OCT1977	48	51	3	510.9836
10	NOV1977	48	51	3	382.1434
11	DEC1977	48	51	3	340.4702
12	JAN1978	48	51	2	327.0572
13	FEB1978	48	51	1	322.5460
14	MAR1978	48	51	0	325.2689
15	APR1978	48	51	-1	351.4161
16	MAY1978	48	51	-2	398.0490
17	JUN1978	48	50	-3	471.6931
18	JUL1978	48	49	-3	590.8089
19	AUG1978	48	48	0	595.2538
20	SEP1978	48	47	-1	689.2233
21	OCT1978	48	46	-2	745.8891
22	NOV1978	48	45	-3	679.1907

Output 29.3.2 Minimum Measure

Minimum Measure Summary

Input Variable	MASONRY
ELECTRIC	322.5460

This analysis results in 23 slides based on the observation index. The minimum measure (322.5460) occurs at slide index 13, which corresponds to the time value FEB1978. Note that the original data set SASHELP.WORKERS was modified beginning at the time value JAN1978. This similarity analysis justifies the belief that ELECTRIC lags MASONRY by one month based on the time series cross-correlation analysis despite the lack of target data (MASONRY).

The goal of seasonal sliding similarity measures is to find the seasonal slide index that corresponds to the most similar seasonal subsequence of the input series when compared to the target sequence. The following statements repeat the preceding similarity analysis on the example data set with seasonal sliding:

```
proc similarity data=workers out=_NULL_ print=(slides summary);
   id date interval=month;
   input  electric;
   target masonry / slide=season measure=msqrdev;
run;
```

Output 29.3.3 Summary of the Seasonal Slide Measures

The SIMILARITY Procedure

Slide Measures Summary for Input=ELECTRIC and Target=MASONRY

Slide Index	DATE	Slide Target Sequence Length	Slide Input Sequence Length	Slide Warping Amount	Slide Minimum Measure
0	JAN1977	48	48	0	1040.086
12	JAN1978	48	48	0	641.927

Output 29.3.4 Seasonal Minimum Measure

Minimum Measure Summary

Input Variable	MASONRY
ELECTRIC	641.9273

The analysis differs from the previous analysis in that the slides are performed based on the seasonal index (SLIDE=SEASON) with no warping. With a seasonality of 12, two seasonal slides are considered at slide indices 0 and 12 with the minimum measure (641.9273) occurring at slide index 12 which corresponds to the time value JAN1978. Note that the original data set SASHELP.WORKERS was modified beginning at the time value JAN1978. This similarity analysis justifies the belief that ELECTRIC and MASONRY have similar seasonal properties based on seasonal decomposition analysis despite the lack of target data (MASONRY).

Example 29.4: Searching for Historical Analogies

This example illustrates how to search for historical analogies by using seasonal sliding similarity analysis of transactional time-stamped data. The SASHELP.TIMEDATA data set contains the variable (VOLUME), which represents activity over time. The following statements create an example data set that contains two time series of differing lengths, where the variable HISTORY represents the historical activity and RECENT represents the more recent activity:

```
data timedata; set sashelp.timedata;
   drop volume;
   recent  = .;
   history = volume;
   if datetime >= '20AUG2000:00:00:00'DT then do;
      recent  = volume;
      history = .;
```

```
   end;
run;
```

The goal of seasonal sliding similarity measures is to find the seasonal slide index that corresponds to the most similar seasonal subsequence of the input series when compared to the target sequence. The following statements perform similarity analysis on the example data set with seasonal sliding:

```
proc similarity data=timedata out=_NULL_ outsequence=sequences
                outsum=summary;
   id datetime interval=dtday accumulate=total
               start='27JUL1997:00:00:00'dt
               end='21OCT2000:11:59:59'DT;
   input history / normalize=absolute;
   target recent / slide=season normalize=absolute measure=mabsdev;
run;
```

The DATA=TIMEDATA option specifies that the input data set WORK.TIMEDATA be used in the analysis. The OUT=_NULL_ option specifies that no output time series data set is to be created. The OUTSEQUENCE=SEQUENCES and OUTSUM=SUMMARY options specify the output sequences and summary data sets, respectively. The ID statement specifies that the time ID variable is DATETIME, which is to be accumulated on a daily basis (INTERVAL=DTDAY) by summing the transactions (ACCUMULATE=TOTAL). The ID statement also specifies that the data are accumulated on the weekly boundaries starting on the week of 27JUL1997 and ending on the week of 15OCT2000 (START='27JUL1997:00:00:00'DT END='21OCT2000:11:59:59'DT). The INPUT statement specifies that the input variable is HISTORY, which is to be normalized using absolute normalization (NORMALIZE=ABSOLUTE). The TARGET statement specifies that the target variable is RECENT, which is to be normalized by using absolute normalization (NORMALIZE=ABSOLUTE) and that the similarity measure be computed by using mean absolute deviation (MEASURE=MABSDEV). The SLIDE=SEASON options specifies season index sliding.

To illustrate the results of the similarity analysis, the output sequence data set must be subset by using the output summary data set.

```
data _NULL_; set summary;
   call symput('MEASURE', left(trim(putn(recent,'BEST20.'))));
run;

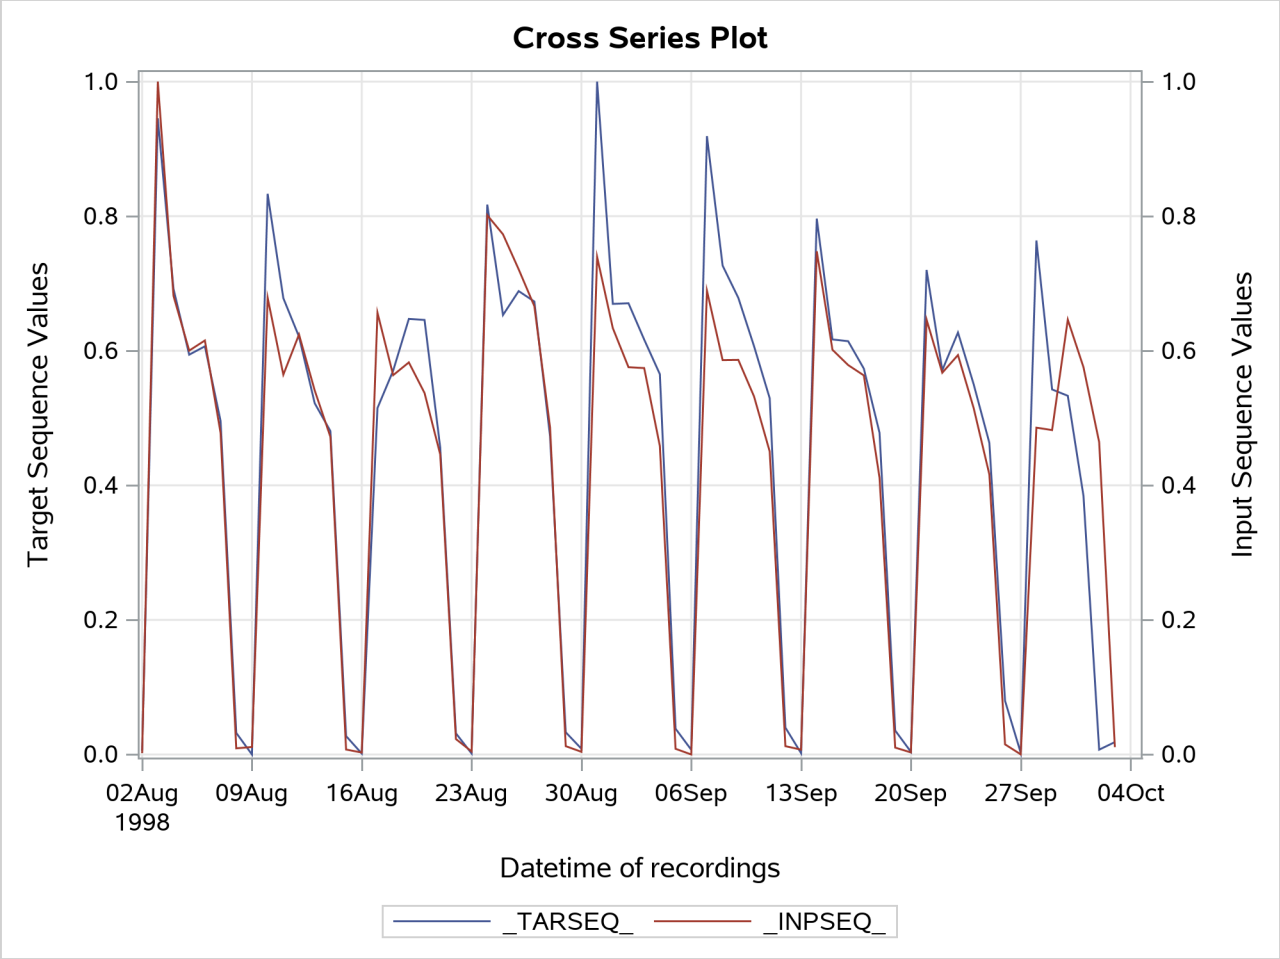
data result; set sequences;
   by _SLIDE_;
   retain flag 0;
   if first._SLIDE_  then do;
      if (&measure - 0.00001 < _SIM_ < &measure + 0.00001)
      then flag = 1;
   end;
   if flag then output;
   if last._SLIDE_ then flag = 0;
run;
```

The following statements generate a cross series plot of the results:

```
proc timeseries data=result out=_NULL_ crossplot=series;
   id datetime interval=dtday;
   var _TARSEQ_;
   crossvar _INPSEQ_;
run;
```

The cross series plot illustrates that the historical time series analogy most similar to the most recent time series data that started on 20AUG2000 occurred on 02AUG1998.

Output 29.4.1 Cross Series Plot of the Historical Time Series



Example 29.5: Clustering Time Series

This example illustrates how to cluster time series using a similarity matrix. The SASHELP.APPLIANC data set contains 24 variables that record sales histories. The following statements create a similarity matrix and store the matrix in the WORK.SIMMATRIX data set:

```
proc similarity data=sashelp.applianc out=_null_ outsum=simmatrix;
   target units_1--units_24 / measure=mabsdev normalize=absolute;
run;
```

The following statements cluster the rows of the similarity matrix and plot the dendrogram:

```
proc cluster data=simmatrix(drop=_status_) outtree=tree method=ward plots=dendrogram;
   id _input_;
run;
```

Overview: SIMLIN Procedure

The SIMLIN procedure reads the coefficients for a set of linear structural equations, which are usually produced by the SYSLIN procedure. PROC SIMLIN then computes the reduced form and, if input data are given, uses the reduced form equations to generate predicted values. PROC SIMLIN is especially useful when dealing with sets of structural difference equations. The SIMLIN procedure can perform simulation or forecasting of the endogenous variables.

The SIMLIN procedure can be applied only to models that are as follows:

- linear with respect to the parameters
- linear with respect to the variables
- square (as many equations as endogenous variables)
- nonsingular (the coefficients of the endogenous variables form an invertible matrix)

Getting Started: SIMLIN Procedure

The SIMLIN procedure processes the coefficients in a data set created by the SYSLIN procedure using the OUTEST= option or by another regression procedure such as PROC REG. To use PROC SIMLIN you must first produce the coefficient data set and then specify this data set in the EST= option of the PROC SIMLIN statement. You must also tell PROC SIMLIN which variables are endogenous and which variables are exogenous. List the endogenous variables in an ENDOGENOUS statement, and list the exogenous variables in an EXOGENOUS statement.

The following example illustrates the creation of an OUTEST= data set with PROC SYSLIN and the computation and printing of the reduced form coefficients for the model with PROC SIMLIN:

```
proc syslin data=in outest=e;
   model y1 = y2 x1;
   model y2 = y1 x2;
run;

proc simlin est=e;
   endogenous y1 y2;
   exogenous x1 x2;
run;
```

If the model contains lagged endogenous variables you must also use a LAGGED statement to tell PROC SIMLIN which variables contain lagged values, which endogenous variables they are lags of, and the number of periods of lagging. For dynamic models, the TOTAL and INTERIM= options can be used in the PROC SIMLIN statement to compute and print total and impact multipliers. (For an explanation of multipliers, see the section "Dynamic Multipliers" on page 2282.)

In the following example, the variables Y1LAG1, Y2LAG1, and Y2LAG2 contain lagged values of the endogenous variables Y1 and Y2. Y1LAG1 and Y2LAG1 contain values of Y1 and Y2 for the previous

observation, while Y2LAG2 contains 2 period lags of Y2. The LAGGED statement specifies the lagged relationships, and the TOTAL and INTERIM= options request multiplier analysis. The INTERIM=2 option prints matrices showing the impact that changes to the exogenous variables have on the endogenous variables after 1 and 2 periods.

```
data in; set in;
  y1lag1 = lag(y1);
  y2lag1 = lag(y2);
  y2lag2 = lag2(y2);
run;

proc syslin data=in outest=e;
   model y1 = y2 y1lag1 y2lag2 x1;
   model y2 = y1 y2lag1 x2;
run;

proc simlin est=e total interim=2;
   endogenous y1 y2;
   exogenous x1 x2;
   lagged y1lag1 y1 1 y2lag1 y2 1 y2lag2 y2 2;
run;
```

After the reduced form of the model is computed, the model can be simulated by specifying an input data set in the PROC SIMLIN statement and using an OUTPUT statement to write the simulation results to an output data set. The following example modifies the PROC SIMLIN step from the preceding example to simulate the model and stores the results in an output data set:

```
proc simlin est=e total interim=2 data=in;
   endogenous y1 y2;
   exogenous x1 x2;
   lagged y1lag1 y1 1 y2lag1 y2 1 y2lag2 y2 2;
   output out=sim predicted=y1hat y2hat
                  residual=y1resid y2resid;
run;
```

Prediction and Simulation

If an input data set is specified with the DATA= option in the PROC SIMLIN statement, the procedure reads the data and uses the reduced form equations to compute predicted and residual values for each of the endogenous variables. (If no data set is specified with the DATA= option, no simulation of the system is performed, and only the reduced form and multipliers are computed.)

The character of the prediction is based on the START= value. Until PROC SIMLIN encounters the START= observation, actual endogenous values are found and fed into the lagged endogenous terms. Once the START= observation is reached, dynamic simulation begins, where predicted values are fed into lagged endogenous terms until the end of the data set is reached.

The predicted and residual values generated here are different from those produced by the SYSLIN procedure since PROC SYSLIN uses the structural form with actual endogenous values. The predicted values computed by the SIMLIN procedure solve the simultaneous equation system. These reduced-form predicted values

are functions only of the exogenous and lagged endogenous variables and do not depend on actual values of current period endogenous variables.

Syntax: SIMLIN Procedure

The following statements can be used with PROC SIMLIN:

```
PROC SIMLIN options ;
    BY variables ;
    ENDOGENOUS variables ;
    EXOGENOUS variables ;
    ID variables ;
    LAGGED lag-var endogenous-var number . . . ;
    OUTPUT OUT=SAS-data-set options ;
```

Functional Summary

The statements and options controlling the SIMLIN procedure are summarized in Table 30.1.

Table 30.1 Functional Summary

Description	Statement	Option
Data Set Options

PROC SIMLIN Statement

PROC SIMLIN *options* **;**

The following options can be used in the PROC SIMLIN statement:

DATA=*SAS-data-set*
specifies the SAS data set containing input data for the simulation. If the DATA= option is used, the data set specified must supply values for all exogenous variables throughout the simulation. If the DATA= option is not specified, no simulation of the system is performed, and only the reduced form and multipliers are computed.

EST=*SAS-data-set*
specifies the input data set containing the structural coefficients of the system. If EST= is omitted the most recently created SAS data set is used. The EST= data set is normally a "TYPE=EST" data set produced by the OUTEST= option of PROC SYSLIN. However, you can also build the EST= data set with a SAS DATA step. For more information, see the section "EST= Data Set" on page 2283.

ESTPRINT
prints the structural coefficients read from the EST= data set.

INTERIM=*n*
requests that interim multipliers be computed for interim numbers 1 through *n*. If not specified, no interim multipliers are computed. This feature is available only if there are no lags greater than 1.

NOPRINT
suppresses all printed output.

NORED
suppresses the printing of the reduced form coefficients.

OUTEST=*SAS-data-set*
specifies an output SAS data set to contain the reduced form coefficients and multipliers, in addition to the structural coefficients read from the EST= data set. The OUTEST= data set has the same form as the EST= data set. If the OUTEST= option is not specified, the reduced form coefficients and multipliers are not written to a data set.

START=*n*
specifies the observation number in the DATA= data set where the dynamic simulation is to be started. By default, the dynamic simulation starts with the first observation in the DATA= data set for which all variables (including lags) are not missing.

TOTAL
requests that the total multipliers be computed. This feature is available only if there are no lags greater than 1.

TYPE=*value*
specifies the type of estimates to be read from the EST= data set. The TYPE= value must match the value of the _TYPE_ variable for the observations that you want to select from the EST= data set (TYPE=2SLS, for example).

BY Statement

BY *variables* **;**

A BY statement can be used with PROC SIMLIN to obtain separate analyses for groups of observations defined by the BY variables.

The BY statement can be applied to one or both of the EST= and DATA= input data sets. When a BY statement is used and both an EST= and a DATA= input data set are specified, PROC SIMLIN checks to see if one or both of the data sets contain the BY variables.

Thus, there are three ways of using the BY statement with PROC SIMLIN:

1. If the BY variables are found in the EST= data set only, PROC SIMLIN simulates over the entire DATA= data set once for each set of coefficients read from the BY groups in the EST= data set.
2. If the BY variables are found in the DATA= data set only, PROC SIMLIN performs separate simulations over each BY group in the DATA= data set, using the single set of coefficients in the EST= data set.
3. If the BY variables are found in both the EST= and DATA= data sets, PROC SIMLIN performs separate simulations over each BY group in the DATA= data set using the coefficients from the corresponding BY group in the EST= data set.

ENDOGENOUS Statement

ENDOGENOUS *variables* **;**

List the names of the endogenous (jointly dependent) variables in the ENDOGENOUS statement. The ENDOGENOUS statement can be abbreviated as ENDOG or ENDO.

EXOGENOUS Statement

EXOGENOUS *variables* **;**

List the names of the exogenous (independent) variables in the EXOGENOUS statement. The EXOGENOUS statement can be abbreviated as EXOG or EXO.

ID Statement

ID *variables* **;**

The ID statement can be used to restrict the variables copied from the DATA= data set to the OUT= data set. Use the ID statement to list the variables you want copied to the OUT= data set besides the exogenous, endogenous, lagged endogenous, and BY variables. If the ID statement is omitted, all the variables in the DATA= data set are copied to the OUT= data set.

LAGGED Statement

LAGGED *lag-var endogenous-var number . . .* **;**

For each lagged endogenous variable, specify the name of the lagged variable, the name of the endogenous variable that was lagged, and the degree of the lag. Only one LAGGED statement is allowed.

The following is an example of the use of the LAGGED statement:

```
proc simlin est=e;
   endog y1 y2;
   lagged y1lag1 y1 1  y2lag1 y2 1  y2lag3 y2 3;
run;
```

This statement specifies that the variable Y1LAG1 contains the values of the endogenous variable Y1 lagged one period; the variable Y2LAG1 refers to the values of Y2 lagged one period; and the variable Y2LAG3 refers to the values of Y2 lagged three periods.

OUTPUT Statement

OUTPUT OUT=*SAS-data-set options* **;**

The OUTPUT statement specifies that predicted and residual values be put in an output data set. A DATA= input data set must be supplied if the OUTPUT statement is used, and only one OUTPUT statement is allowed. The following options can be used in the OUTPUT statement:

OUT=*SAS-data-set*
names the output SAS data set to contain the predicted values and residuals. If OUT= is not specified, the output data set is named using the DATA*n* convention.

PREDICTED=*names*

P=*names*
names the variables in the output data set that contain the predicted values of the simulation. These variables correspond to the endogenous variables in the order in which they are specified in the ENDOGENOUS statement. Specify up to as many names as there are endogenous variables. If you specify names in the PREDICTED= option for only some of the endogenous variables, predicted values for the remaining variables are not output. The names must not match any variable name in the input data set.

RESIDUAL=*names*

R=*names*
names the variables in the output data set that contain the residual values from the simulation. The residuals are the differences between the actual values of the endogenous variables from the DATA= data set and the predicted values from the simulation. These variables correspond to the endogenous variables in the order in which they are specified in the ENDOGENOUS statement. Specify up to as many names as there are endogenous variables. The names must not match any variable name in the input data set.

The following is an example of the use of the OUTPUT statement. This example outputs predicted values for Y1 and Y2 and outputs residuals for Y1.

```
proc simlin est=e;
   endog y1 y2;
   output out=b predicted=y1hat y2hat
                residual=y1resid;
run;
```

Details: SIMLIN Procedure

The following sections explain the structural and reduced forms, dynamic multipliers, input data sets, and the model simulation process in more detail.

Defining the Structural Form

An EST= input data set supplies the coefficients of the equation system. The data set containing the coefficients is normally a "TYPE=EST" data set created by the OUTEST= option of PROC SYSLIN or another regression procedure. The data set contains the special variables _TYPE_, _DEPVAR_, and INTERCEPT. You can also supply the structural coefficients of the system to PROC SIMLIN in a data set produced by a SAS DATA step as long as the data set is of the form TYPE=EST. For a discussion of the special TYPE=EST type of SAS data set, see SAS/STAT software documentation.

Suppose that there is a $g \times 1$ vector of endogenous variables $\mathbf{y}_t$, an $l \times 1$ vector of lagged endogenous variables $\mathbf{y}_t^L$, and a $k \times 1$ vector of exogenous variables $\mathbf{x}_t$, including the intercept. Then, there are g structural equations in the simultaneous system that can be written

$$\mathbf{G}\mathbf{y}_t = \mathbf{C}\mathbf{y}_t^L + \mathbf{B}\mathbf{x}_t$$

where $\mathbf{G}$ is the matrix of coefficients of current period endogenous variables, $\mathbf{C}$ is the matrix of coefficients of lagged endogenous variables, and $\mathbf{B}$ is the matrix of coefficients of exogenous variables. $\mathbf{G}$ is assumed to be nonsingular.

Computing the Reduced Form

First, the SIMLIN procedure computes reduced form coefficients by premultiplying by $\mathbf{G}^{-1}$:

$$\mathbf{y}_t = \mathbf{G}^{-1}\mathbf{C}\mathbf{y}_t^L + \mathbf{G}^{-1}\mathbf{B}\mathbf{x}_t$$

This can be written as

$$\mathbf{y}_t = \Pi_1\mathbf{y}_t^L + \Pi_2\mathbf{x}_t$$

where $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$ and $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$ are the reduced form coefficient matrices.

The reduced form matrices $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$ and $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$ are printed unless the NORED option is specified in the PROC SIMLIN statement. The structural coefficient matrices $\mathbf{G}$, $\mathbf{C}$, and $\mathbf{B}$ are printed when the ESTPRINT option is specified.

Dynamic Multipliers

For models that have only first-order lags, the equation of the reduced form of the system can be rewritten

$$\mathbf{y}_t = \mathbf{D}\mathbf{y}_{t-1} + \Pi_2\mathbf{x}_t$$

$\mathbf{D}$ is a matrix formed from the columns of Π_1 plus some columns of zeros, arranged in the order in which the variables meet the lags. The elements of Π_2 are called *impact multipliers* because they show the immediate effect of changes in each exogenous variable on the values of the endogenous variables. This equation can be rewritten as

$$\mathbf{y}_t = \mathbf{D}^2\mathbf{y}_{t-2} + \mathbf{D}\Pi_2\mathbf{x}_{t-1} + \Pi_2\mathbf{x}_t$$

The matrix formed by the product $\mathbf{D}\Pi_2$ shows the effect of the exogenous variables one lag back; the elements in this matrix are called *interim multipliers* and are computed and printed when the INTERIM= option is specified in the PROC SIMLIN statement. The *i*th period interim multipliers are formed by $\mathbf{D}^i\Pi_2$.

The series can be expanded as

$$\mathbf{y}_t = \mathbf{D}^\infty\mathbf{y}_{t-\infty} + \sum_{i=0}^{\infty}\mathbf{D}^i\,\Pi_2\mathbf{x}_{t-i}$$

A permanent and constant setting of a value for x has the following cumulative effect:

$$\left(\sum_{i=0}^{\infty}\mathbf{D}^i\right)\Pi_2\mathbf{x} = (\mathbf{I}-\mathbf{D})^{-1}\Pi_2\mathbf{x}$$

The elements of $(\mathbf{I}-\mathbf{D})^{-1}\Pi_2$ are called the *total multipliers*. Assuming that the sum converges and that $(\mathbf{I}-\mathbf{D})$ is invertible, PROC SIMLIN computes the total multipliers when the TOTAL option is specified in the PROC SIMLIN statement.

Multipliers for Higher-Order Lags

The dynamic multiplier options require the system to have no lags of order greater than one. This limitation can be circumvented, since any system with lags greater than one can be rewritten as a system where no lag is greater than one by forming new endogenous variables that are single-period lags.

For example, suppose you have the third-order single equation

$$y_t = ay_{t-3} + b\mathbf{x}_t$$

This can be converted to a first-order three-equation system by introducing two additional endogenous variables, $y_{1,t}$ and $y_{2,t}$, and computing corresponding first-order lagged variables for each endogenous variable: y_{t-1}, $y_{1,t-1}$, and $y_{2,t-1}$. The higher-order lag relations are then produced by adding identities to link the endogenous and identical lagged endogenous variables:

$$y_{1,t} = y_{t-1}$$

$$y_{2,t} = y_{1,t-1}$$
$$y_t = a y_{2,t-1} + b\mathbf{X}_t$$

This conversion using the SYSLIN and SIMLIN procedures requires three steps:

1. Add the extra endogenous and lagged endogenous variables to the input data set using a DATA step. Note that two copies of each lagged endogenous variable are needed for each lag reduced, one to serve as an endogenous variable and one to serve as a lagged endogenous variable in the reduced system.
2. Add IDENTITY statements to the PROC SYSLIN step to equate each added endogenous variable to its lagged endogenous variable copy.
3. In the PROC SIMLIN step, declare the added endogenous variables in the ENDOGENOUS statement and define the lag relations in the LAGGED statement.

For an illustration of how to convert an equation system with higher-order lags into a larger system with only first-order lags, see Example 30.2.

EST= Data Set

Normally, PROC SIMLIN uses an EST= data set produced by PROC SYSLIN with the OUTEST= option. This data set is in the form expected by PROC SIMLIN. If there is more than one set of estimates produced by PROC SYSLIN, you must use the TYPE= option in the PROC SIMLIN statement to select the set to be simulated. Then PROC SIMLIN reads from the EST= data set only those observations with a _TYPE_ value corresponding to the TYPE= option (for example, TYPE=2SLS) or with a _TYPE_ value of IDENTITY.

The SIMLIN procedure can only solve square, nonsingular systems. If you have fewer equations than endogenous variables, you must specify IDENTITY statements in the PROC SYSLIN step to bring the system up to full rank. If there are g endogenous variables and $m < g$ stochastic equations with unknown parameters, then you use m MODEL statements to specify the equations with parameters to be estimated and you must use $g - m$ IDENTITY statements to complete the system.

You can build your own EST= data set with a DATA step rather than use PROC SYSLIN. The EST= data set must contain the endogenous variables, the lagged endogenous variables (if any), and the exogenous variables in the system (if any). If any of the equations have intercept terms, the variable INTERCEPT must supply these coefficients. The EST= data set should also contain the special character variable comp _DEPVAR_ to label the equations.

The EST= data set must contain one observation for each equation in the system. The values of the lagged endogenous variables must contain the $\mathbf{C}$ coefficients. The values of the exogenous variables and the INTERCEPT variable must contain the $\mathbf{B}$ coefficients. The values of the endogenous variables, however, must contain the negatives of the $\mathbf{G}$ coefficients. This is because the SYSLIN procedure writes the coefficients to the OUTEST= data set in the form

$$0 = \mathbf{H}\mathbf{y}_t + \mathbf{C}\mathbf{y}_t^L + \mathbf{B}\mathbf{x}_t$$

where $\mathbf{H} = -\mathbf{G}$.

For more information about building the EST= data set, see the section "Multipliers for Higher-Order Lags" on page 2282 and Example 30.2.

DATA= Data Set

The DATA= data set must contain all of the exogenous variables. Values for all of the exogenous variables are required for each observation for which predicted endogenous values are desired. To forecast past the end of the historical data, the DATA= data set should contain nonmissing values for all of the exogenous variables and missing values for the endogenous variables for the forecast periods, in addition to the historical data. (For an illustration, see Example 30.1.)

In order for PROC SIMLIN to output residuals and compute statistics of fit, the DATA= data set must also contain the endogenous variables with nonmissing actual values for each observation for which residuals and statistics are to be computed.

If the system contains lags, initial values must be supplied for the lagged variables. This can be done by including either the lagged variables or the endogenous variables, or both, in the DATA= data set. If the lagged variables are not in the DATA= data set or if they have missing values in the early observations, PROC SIMLIN prints a warning and uses the endogenous variable values from the early observations to initialize the lags.

OUTEST= Data Set

The OUTEST= data set contains all the variables read from the EST= data set. The variables in the OUTEST= data set are as follows:

- the BY statement variables, if any
- _TYPE_, a character variable that identifies the type of observation
- _DEPVAR_, a character variable containing the name of the dependent variable for the observation
- the endogenous variables
- the lagged endogenous variables
- the exogenous variables
- INTERCEPT, a numeric variable containing the intercept values
- _MODEL_, a character variable containing the name of the equation
- _SIGMA_, a numeric variable containing the estimated error variance of the equation (output only if present in the EST= data set)

The observations read from the EST= data set that supply the structural coefficients are copied to the OUTEST= data set, except that the signs of endogenous coefficients are reversed. For these observations, the _TYPE_ variable values are the same as in the EST= data set.

In addition, the OUTEST= data set contains observations with the following _TYPE_ values:

REDUCED — the reduced form coefficients. The endogenous variables for this group of observations contain the inverse of the endogenous coefficient matrix $\mathbf{G}$. The lagged endogenous variables contain the matrix $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$. The exogenous variables contain the matrix $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$.

IMULT*i* — the interim multipliers, if the INTERIM= option is specified. There are *gn* observations for the interim multipliers, where *g* is the number of endogenous variables and *n* is the value of the INTERIM=*n* option. For these observations the _TYPE_ variable has the value IMULT*i*, where the interim number *i* ranges from 1 to *n*.

The exogenous variables in groups of *g* observations that have a _TYPE_ value of IMULT*i* contain the matrix $\mathbf{D}^i\Pi_2$ of multipliers at interim *i*. The endogenous and lagged endogenous variables for this group of observations are set to missing.

TOTAL — the total multipliers, if the TOTAL option is specified. The exogenous variables in this group of observations contain the matrix $(\mathbf{I} - \mathbf{D})^{-1}\Pi_2$. The endogenous and lagged endogenous variables for this group of observations are set to missing.

OUT= Data Set

The OUT= data set normally contains all of the variables in the input DATA= data set, plus the variables named in the PREDICTED= and RESIDUAL= options in the OUTPUT statement.

You can use an ID statement to restrict the variables that are copied from the input data set. If an ID statement is used, the OUT= data set contains only the BY variables (if any), the ID variables, the endogenous and lagged endogenous variables (if any), the exogenous variables, plus the PREDICTED= and RESIDUAL= variables.

The OUT= data set contains an observation for each observation in the DATA= data set. When the actual value of an endogenous variable is missing in the DATA= data set, or when the DATA= data set does not contain the endogenous variable, the corresponding residual is missing.

Printed Output

Structural Form

The following items are printed as they are read from the EST= input data set. Structural zeros are printed as dots in the listing of these matrices.

1. Structural Coefficients for Endogenous Variables. This is the $\mathbf{G}$ matrix, with *g* rows and *g* columns.
2. Structural Coefficients for Lagged Endogenous Variables. These coefficients make up the $\mathbf{C}$ matrix, with *g* rows and *l* columns.
3. Structural Coefficients for Exogenous Variables. These coefficients make up the $\mathbf{B}$ matrix, with *g* rows and *k* columns.

Reduced Form

1. The reduced form coefficients are obtained by inverting $\mathbf{G}$ so that the endogenous variables can be directly expressed as functions of only lagged endogenous and exogenous variables.
2. Inverse Coefficient Matrix for Endogenous Variables. This is the inverse of the $\mathbf{G}$ matrix.
3. Reduced Form for Lagged Endogenous Variables. This is $\Pi_1 = \mathbf{G}^{-1}\mathbf{C}$, with g rows and l columns. Each value is a dynamic multiplier that shows how past values of lagged endogenous variables affect values of each of the endogenous variables.
4. Reduced Form for Exogenous Variables. This is $\Pi_2 = \mathbf{G}^{-1}\mathbf{B}$, with g rows and k columns. Its values are called *impact multipliers* because they show the immediate effect of each exogenous variable on the value of the endogenous variables.

Multipliers

Interim and total multipliers show the effect of a change in an exogenous variable over time.

1. Interim Multipliers. These are the interim multiplier matrices. They are formed by multiplying Π_2 by powers of $\mathbf{D}$. The dth interim multiplier is $\mathbf{D}^d\Pi_2$. The interim multiplier of order d shows the effects of a change in the exogenous variables after d periods. Interim multipliers are only available if the maximum lag of the endogenous variables is 1.
2. Total Multipliers. This is the matrix of total multipliers, $\mathrm{T} = (\mathbf{I} - \mathbf{D})^{-1}\Pi_2$. This matrix shows the cumulative effect of changes in the exogenous variables. Total multipliers are only available if the maximum lag is one.

Statistics of Fit

If the DATA= option is used and the DATA= data set contains endogenous variables, PROC SIMLIN prints a statistics-of-fit report for the simulation. The statistics printed include the following. (Summations are over the observations for which both y_t and $\hat{y}_t$ are nonmissing.)

1. the number of nonmissing errors. (Number of observations for which both y_t and $\hat{y}_t$ are nonmissing.)
2. the mean error: $\frac{1}{n}\sum(y_t - \hat{y}_t)$
3. the mean percent error: $\frac{100}{n}\sum\frac{(y_t - \hat{y}_t)}{y_t}$
4. the mean absolute error: $\frac{1}{n}\sum|y_t - \hat{y}_t|$
5. the mean absolute percent error $\frac{100}{n}\sum\frac{|y_t - \hat{y}_t|}{y_t}$
6. the root mean square error: $\sqrt{\frac{1}{n}\sum(y_t - \hat{y}_t)^2}$
7. the root mean square percent error: $\sqrt{\frac{100}{n}\sum(\frac{(y_t - \hat{y}_t)}{y_t})^2}$

ODS Table Names

PROC SIMLIN assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 30.2.

Table 30.2 ODS Tables Produced in PROC SIMLIN

ODS Table Name	Description	Option
Endogenous	Structural coefficients for endogenous variables	Default

TotalMult	Total multipliers	TOTAL=
FitStatistics	Fit statistics	Default

Examples: SIMLIN Procedure

Example 30.1: Simulating Klein's Model I

In this example, the SIMLIN procedure simulates a model of the U.S. economy called Klein's Model I. The SAS data set KLEIN is used as input to the SYSLIN and SIMLIN procedures.

```
data klein;
   input year c p w i x wp g t k wsum;
   date=mdy(1,1,year);
   format date year.;
   y   = c + i + g - t;
   yr  = year - 1931;
   klag = lag( k );
   plag = lag( p );
   xlag = lag( x );
   if year >= 1921;
   label c   ='consumption'
         p   ='profits'
         w   ='private wage bill'
         i   ='investment'
```

```
          k   ='capital stock'
          y   ='national income'
          x   ='private production'
          wsum='total wage bill'
          wp  ='govt wage bill'
          g   ='govt demand'
          t   ='taxes'
          klag='capital stock lagged'
          plag='profits lagged'
          xlag='private product lagged'
          yr  ='year-1931';
datalines;
1920     .  12.7     .    .  44.9    .     .     .  182.8     .
1921  41.9  12.4  25.5 -0.2  45.6  2.7   3.9   7.7  182.6  28.2

   ... more lines ...
```

First, the model is specified and estimated using the SYSLIN procedure, and the parameter estimates are written to an OUTEST= data set. The printed output produced by the SYSLIN procedure is not shown here; see Example 35.1 in Chapter 35 for the printed output of the PROC SYSLIN step.

```
title1 'Simulation of Klein''s Model I using SIMLIN';
proc syslin 3sls data=klein outest=a;

   instruments klag plag xlag wp g t yr;
   endogenous c p w i x wsum k y;

   consume: model    c = p plag wsum;
   invest:  model    i = p plag klag;
   labor:   model    w = x xlag yr;

   product: identity x = c + i + g;
   income:  identity y = c + i + g - t;
   profit:  identity p = x - w - t;
   stock:   identity k = klag + i;
   wage:    identity wsum = w + wp;
run;
```

The OUTEST= data set A created by the SYSLIN procedure contains parameter estimates to be used by the SIMLIN procedure. The OUTEST= data set is shown in Output 30.1.1.

Output 30.1.1 The OUTEST= Data Set Created by PROC SYSLIN

Using the OUTEST= data set A produced by the SYSLIN procedure, the SIMLIN procedure can now compute the reduced form and simulate the model. The following statements perform the simulation:

```
title1 'Simulation of Klein''s Model I using SIMLIN';
proc simlin data=klein
            est=a type=3sls
            estprint
            total interim=2
            outest=b;
   endogenous c p w i x wsum k y;
   exogenous  wp g t yr;
```

```
   lagged  klag k 1   plag p 1   xlag x 1;
   id year;
   output out=c p=chat phat what ihat xhat wsumhat khat yhat
                r=cres pres wres ires xres wsumres kres yres;
run;
```

The reduced form coefficients and multipliers are added to the information read from EST= data set A and written to the OUTEST= data set B. The predicted and residual values from the simulation are written to the OUT= data set C specified in the OUTPUT statement.

The SIMLIN procedure first prints the structural coefficient matrices read from the EST= data set, as shown in Output 30.1.2 through Output 30.1.4.

Output 30.1.2 SIMLIN Procedure Output — Endogenous Structural Coefficients

Simulation of Klein's Model I using SIMLIN

The SIMLIN Procedure

Structural Coefficients for Endogenous Variables								
Variable	c	p	w	i	x	wsum	k	y
c	1.0000	-0.1249	.	.	.	-0.7901	.	.
i	.	0.0131	.	1.0000	.	.	.	.
w	.	.	1.0000	.	-0.4005	.	.	.
x	-1.0000	.	.	-1.0000	1.0000	.	.	.
y	-1.0000	.	.	-1.0000	.	.	.	1.0000
p	.	1.0000	1.0000	.	-1.0000	.	.	.
k	.	.	.	-1.0000	.	.	1.0000	.
wsum	.	.	-1.0000	.	.	1.0000	.	.

Output 30.1.3 SIMLIN Procedure Output — Lagged Endogenous Structural Coefficients

Structural Coefficients for Lagged Endogenous Variables			
Variable	klag	plag	xlag
c	.	0.1631	.
i	-0.1948	0.7557	.
w	.	.	0.1813
x	.	.	.
y	.	.	.
p	.	.	.
k	1.0000	.	.
wsum	.	.	.

Output 30.1.4 SIMLIN Procedure Output — Exogenous Structural Coefficients

Structural Coefficients for Exogenous Variables					
Variable	**wp**	**g**	**t**	**yr**	**Intercept**
c	.	.	.	.	16.4408
i	.	.	.	.	28.1778
w	.	.	.	0.1497	1.7972
x	.	1.0000	.	.	0
y	.	1.0000	-1.0000	.	0
p	.	.	-1.0000	.	0
k	.	.	.	.	0
wsum	1.0000	.	.	.	0

The SIMLIN procedure then prints the inverse of the endogenous variables coefficient matrix, as shown in Output 30.1.5.

Output 30.1.5 SIMLIN Procedure Output — Inverse Coefficient Matrix

Inverse Coefficient Matrix for Endogenous Variables								
Variable	**c**	**i**	**w**	**x**	**y**	**p**	**k**	**wsum**
c	1.6347	0.6347	1.0957	0.6347	0	0.1959	0	1.2915
p	0.9724	0.9724	-0.3405	0.9724	0	1.1087	0	0.7682
w	0.6496	0.6496	1.4406	0.6496	0	0.0726	0	0.5132
i	-0.0127	0.9873	0.004453	-0.0127	0	-0.0145	0	-0.0100
x	1.6219	1.6219	1.1001	1.6219	0	0.1814	0	1.2815
wsum	0.6496	0.6496	1.4406	0.6496	0	0.0726	0	1.5132

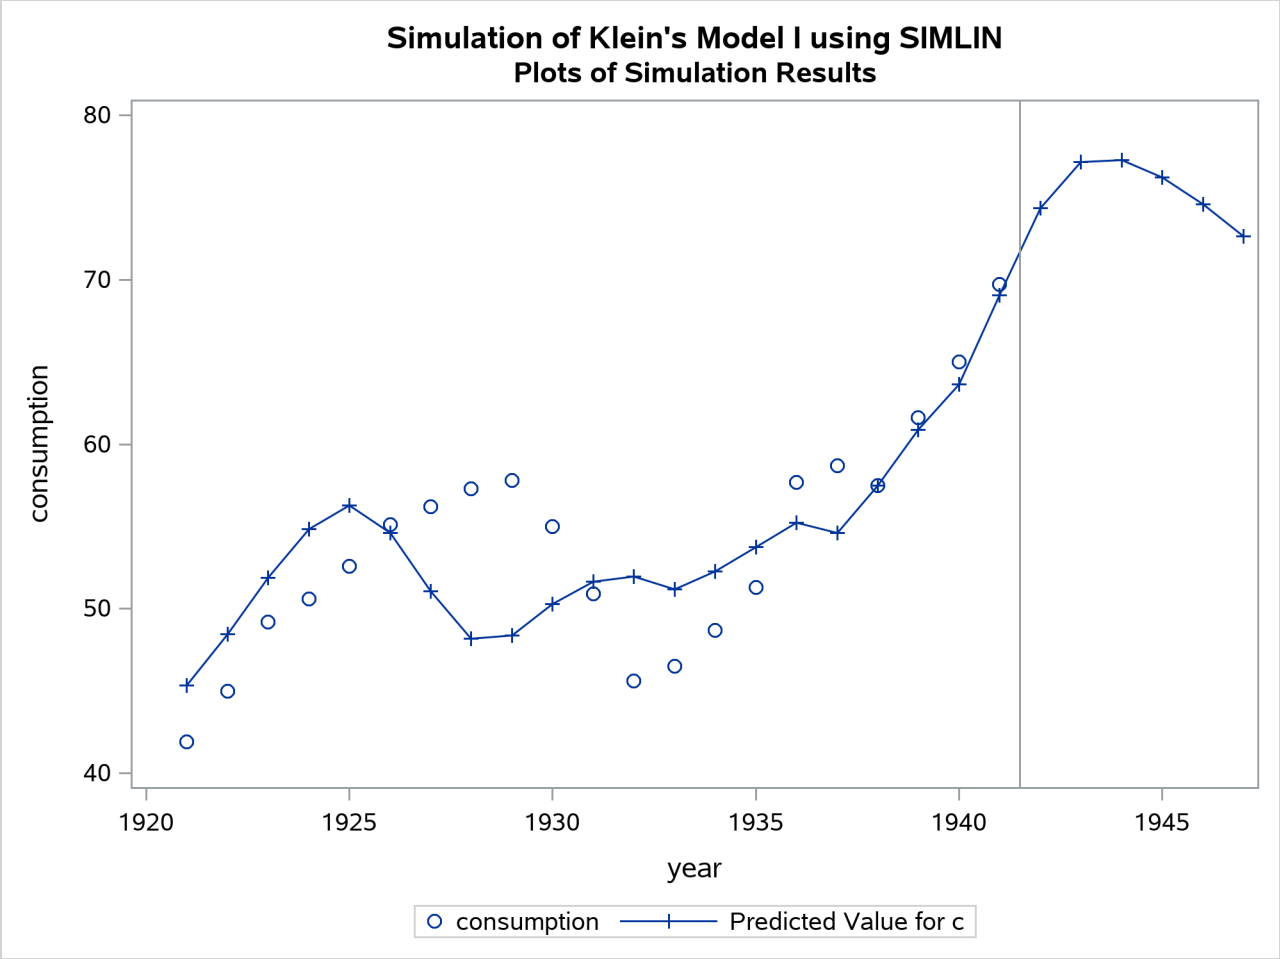
The actual and predicted values for the variable C are plotted in Output 30.1.11.

```
title2 'Plots of Simulation Results';
proc sgplot data=c;
   scatter x=year y=c;
   series x=year y=chat / markers markerattrs=(symbol=plus);
   refline 1941.5 / axis=x;
run;
```

Output 30.1.11 Plot of Actual and Predicted Consumption



Example 30.2: Multipliers for a Third-Order System

This example shows how to fit and simulate a single-equation dynamic model with third-order lags. It then shows how to convert the third-order equation into a three-equation system with only first-order lags, so that the SIMLIN procedure can compute multipliers. (For more information, see the section "Multipliers for Higher-Order Lags" on page 2282.)

The input data set TEST is created from simulated data. A partial listing of the data set TEST produced by PROC PRINT is shown in Output 30.2.1.

Output 30.2.1 Partial Listing of Input Data Set

Simulate Equation with Third-Order Lags

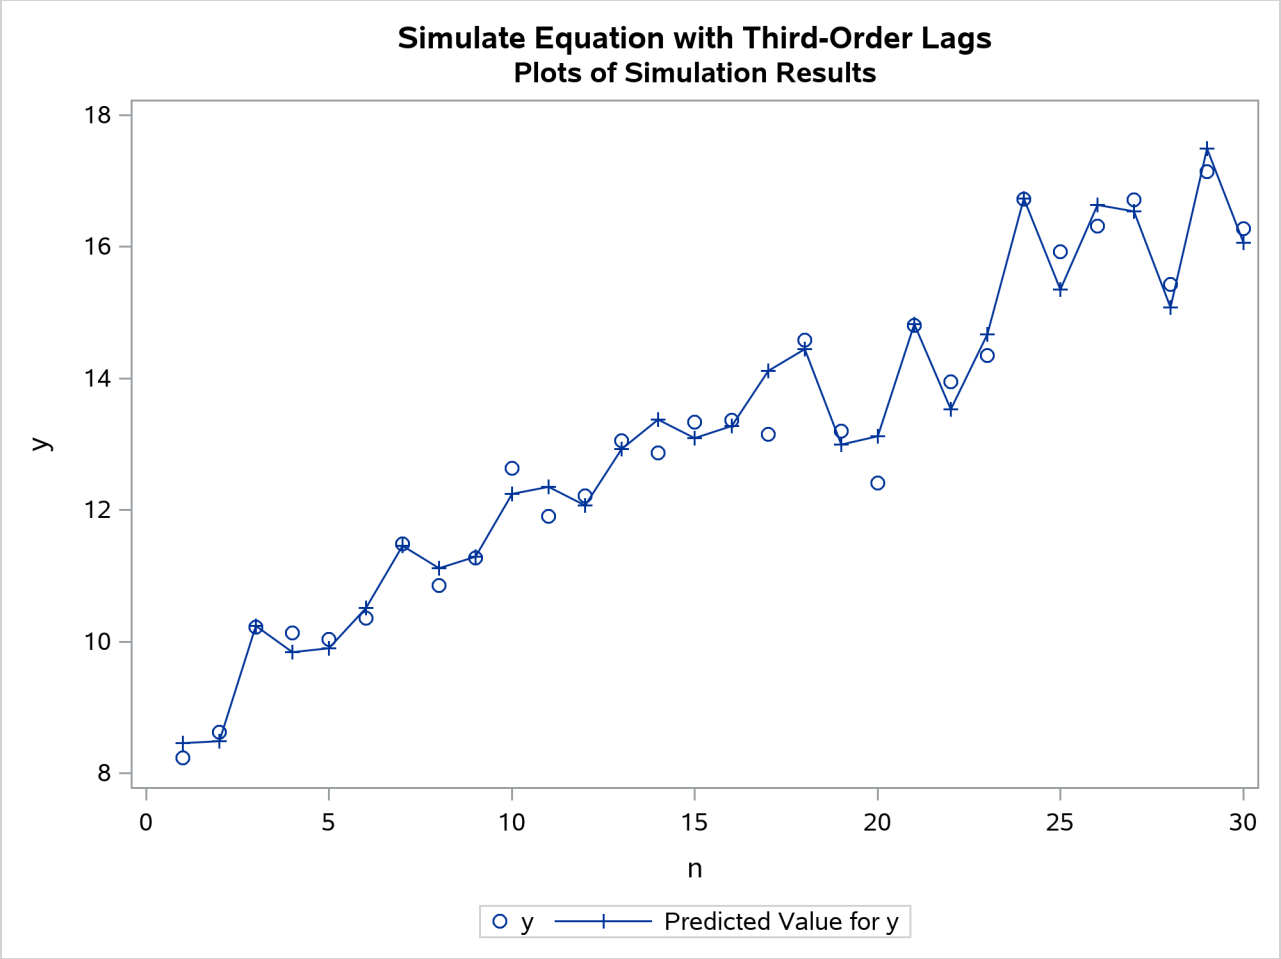
The following statements plot the actual and predicted values, as shown in Output 30.2.5:

```
title2 'Plots of Simulation Results';
proc sgplot data=out1;
   scatter x=n y=y;
   series x=n y=yhat / markers markerattrs=(symbol=plus);
run;
```

Output 30.2.5 Plot of Predicted and Actual Values



Next, the input data set TEST is modified by creating two new variables, YLAG1X and YLAG2X, that are equal to YLAG1 and YLAG2. These variables are used in the SYSLIN procedure. (The estimates produced by PROC SYSLIN are the same as before and are not shown.) A listing of the OUTEST= data set B created by PROC SYSLIN is shown in Output 30.2.6.

```
data test2;
   set test;
   ylag1x=ylag1;
   ylag2x=ylag2;
run;

title2 'Estimation of parameters and definition of identities';
proc syslin data=test2 outest=b;
   endogenous y ylag1x ylag2x;
   model y=ylag3 x;
   identity ylag1x=ylag1;
   identity ylag2x=ylag2;
run;

title2 'Listing of OUTEST= data set from PROC SYSLIN';
```

```
proc print data=b;
run;
```

Output 30.2.6 Listing of OUTEST= Data Set Created from PROC SYSLIN

Simulate Equation with Third-Order Lags
Listing of OUTEST= data set from PROC SYSLIN

Obs	_TYPE_	_STATUS_	_MODEL_	_DEPVAR_	_SIGMA_	Intercept	ylag3	x	ylag1	ylag2	y	ylag1x	ylag2x
1	OLS	0 Converged	y	y	0.22675	0.14239	0.77121	-1.77668	.	.	-1	.	.
2	IDENTITY	0 Converged		ylag1x	.	0.00000	.	.	1	.	.	-1	.
3	IDENTITY	0 Converged		ylag2x	.	0.00000	.	.	.	1	.	.	-1

The SIMLIN procedure is used to compute the reduced form and multipliers. The OUTEST= data set B from PROC SYSLIN is used as the EST= data set for the SIMLIN procedure. The following statements perform the multiplier analysis:

```
title2 'Simulation of transformed first-order equation system';

proc simlin est=b data=test2 total interim=2;
   endogenous y ylag1x ylag2x;
   exogenous  x;
   lagged  ylag1 y 1  ylag2 ylag1x 1  ylag3 ylag2x 1;
   id n;
   output out=out2 predicted=yhat residual=yresid;
run;
```

Output 30.2.7 shows the interim 2 and total multipliers printed by the SIMLIN procedure.

Overview: SPATIALREG Procedure

The SPATIALREG (spatial regression) procedure analyzes spatial econometric models for cross-sectional data whose observations are spatially referenced or georeferenced. For example, housing price data that are collected from 48 continental states in the United States fall into the category of spatially referenced data. Compared to nonspatial regression models, spatial econometric models are capable of handling spatial interaction and spatial heterogeneity in a regression setting (Anselin 2001).

The SPATIALREG procedure supports the following models:

- linear model
- linear model with spatial lag of X (SLX) effects
- spatial autoregressive (SAR) model
- spatial Durbin model (SDM)
- spatial error model (SEM)
- spatial Durbin error model (SDEM)
- spatial moving average (SMA) model
- spatial Durbin moving average (SDMA) model
- spatial autoregressive moving average (SARMA) model
- spatial Durbin autoregressive moving average (SDARMA) model

- spatial autoregressive confused (SAC) model
- spatial Durbin autoregressive confused (SDAC) model

In general, SARMA, SDARMA, SAC, and SDAC models can require two spatial weights matrices. If you fit these four types of models by using the SPATIALREG procedure in SAS/ETS 14.2, the two spatial weights matrices are assumed to be identical.

Spatial econometric models have been widely used in economics, political science, sociology, and other fields. For example, LeSage and Pace (2009) provide a detailed introduction to commonly used spatial econometric models from both frequentist and Bayesian perspectives. A brief introduction to spatial econometric models is also provided by Elhorst (2013).

The SPATIALREG procedure in SAS/ETS 14.2 primarily uses the maximum likelihood estimation to achieve parameter estimation. Initial values for the nonlinear optimizations are usually calculated by ordinary least squares (OLS).

Getting Started: SPATIALREG Procedure

The SPATIALREG procedure is similar to other SAS regression model procedures, except that you usually need to provide a secondary data set (in the WMAT= option). The spatial weights matrix defines all pairwise spatial relationships and is the most vital component of a spatial regression model. For more information about how to create spatial weights matrix, see the section "Specifying the Spatial Weights Matrix" on page 2333.

The following statements fit a SAR model:

```
proc spatialreg data=one Wmat=W;
   model y = x1 x2 / type=SAR;
run;
```

The response variable y is continuous, and the data set W, which you specify in the WMAT= option, contains the spatial relationships among all spatial units in the data. In this case, W is either contiguity or weights. You specify the TYPE=SAR option to request a SAR model.

The following example illustrates PROC SPATIALREG by using a real-world data set. The data set CRIMEOH is taken from Anselin (1988) and can be found in the SAS/ETS Sample Library. This data set contains variables such as INCOME (household income, measured in $1000), HVALUE (housing value by $1000), and CRIME (number of crimes, including residential burglaries and vehicle thefts, measured per 1,000 households) in 49 neighborhoods in Columbus, Ohio. You want to examine how household income and housing value affect the number of crimes in the 49 neighborhoods of interest.

The first 10 observations in the CRIMEOH data set are shown in Figure 31.1.

Figure 31.1 Columbus Crime Data

Obs	crime	income	hvalue	lat	lon
1	18.802	21.232	44.567	35.62	42.38
2	32.388	4.477	33.200	36.50	40.52
3	38.426	11.337	37.125	36.71	38.71
4	0.178	8.438	75.000	33.36	38.41
5	15.726	19.531	80.467	38.80	44.07
6	30.627	15.956	26.350	39.82	41.18
7	50.732	11.252	23.225	40.01	38.00
8	26.067	16.029	28.750	43.75	39.28
9	48.585	9.873	18.000	39.61	34.91
10	34.001	13.598	96.400	47.61	36.42

The following SAS statements fit a linear regression model to the CRIMEOH data set:

```
proc spatialreg data=crimeoh;
   model crime = income hvalue / type=LINEAR;
run;
```

The "Model Fit Summary" table, shown in Figure 31.2, lists several fit summary statistics about the model. By default, the SPATIALREG procedure uses the Newton-Raphson optimization technique. The maximum log-likelihood value is shown, in addition to two information measures, Akaike's information criterion (AIC) and Schwarz's Bayesian information criterion (SBC). AIC or SBC can be used for model selection. For a set of candidate models, the model with the smallest AIC or SBC is often preferred.

Figure 31.2 Fit Summary Statistics for a Linear Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Model Fit Summary	
Dependent Variable	crime
Number of Observations	49
Data Set	WORK.CRIMEOH
Model	Linear
Log Likelihood	-187.37709
Maximum Absolute Gradient	7.59852E-7
Number of Iterations	16
Optimization Method	Newton-Raphson
AIC	382.75418
SBC	390.32146

The parameter estimates of the model and their standard errors are shown in Figure 31.3. Based on the p-values, both INCOME and HVALUE are significant at the 0.05 level.

Figure 31.3 Parameter Estimates of the Linear Model

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	68.618863	4.588210	14.96	<.0001
income	1	-1.597304	0.323739	-4.93	<.0001
hvalue	1	-0.273931	0.099989	-2.74	0.0062
_sigma2	1	122.751696	24.799493	4.95	<.0001

The following statements fit a SAR model to the CRIMEOH data set:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime = income hvalue / type=SAR;
run;
```

The NONORMALIZE option requests that the spatial weights matrix that is specified in the CRIMEWMAT data set be used "as is" rather than be row-standardized. The "Model Fit Summary" table, shown in Figure 31.4, lists several fit summary statistics about the SAR model. For this model, the value of AIC is about 374.78—smaller than 382.75, which is the AIC value for the preceding linear model. Based on AIC, the SAR model is preferred.

Figure 31.4 Fit Summary Statistics for a SAR Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Model Fit Summary	
Dependent Variable	crime
Number of Observations	49
Data Set	WORK.CRIMEOH
Spatial Weights	WORK.CRIMEWMAT
Model	SAR
Log Likelihood	-182.38860
Maximum Absolute Gradient	2.7871E-7
Number of Iterations	16
Optimization Method	Newton-Raphson
AIC	374.77720
SBC	384.23630

The parameter estimates of the SAR model and their standard errors are shown in Figure 31.5. According to the p-values, both INCOME and HVALUE are significant at the 0.05 level. In addition, the spatial autoregressive coefficient ρ is estimated to be about 0.431, with a p-value of 0.0005.

Figure 31.5 Parameter Estimates of the SAR Model

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	45.077070	7.870590	5.73	<.0001
income	1	-1.031531	0.328403	-3.14	0.0017
hvalue	1	-0.265924	0.088218	-3.01	0.0026
_rho	1	0.431020	0.123594	3.49	0.0005
_sigma2	1	95.487066	19.506312	4.90	<.0001

The following statements fit an SDM model. Unlike the previous SAR model, SDM accounts for exogenous interaction effects by introducing spatial lags of two explanatory variables—INCOME and HVALUE.

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime = income hvalue / type=SAR;
   spatialeffects income hvalue;
run;
```

The fit summary statistics for the SDM model are shown in Figure 31.6. Parameter estimates are provided in Figure 31.7.

Figure 31.6 Fit Summary Statistics for the SDM Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Model Fit Summary	
Dependent Variable	crime
Number of Observations	49
Data Set	WORK.CRIMEOH
Spatial Weights	WORK.CRIMEWMAT
Model	SDM
Log Likelihood	-181.39141
Maximum Absolute Gradient	5.44802E-8
Number of Iterations	16
Optimization Method	Newton-Raphson
AIC	376.78282
SBC	390.02556

Figure 31.7 Parameter Estimates for the SDM Model

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	42.803457	13.924487	3.07	0.0021
income	1	-0.914206	0.336439	-2.72	0.0066
hvalue	1	-0.293745	0.088857	-3.31	0.0009
W_income	1	-0.519640	0.594772	-0.87	0.3823
W_hvalue	1	0.245716	0.176854	1.39	0.1647
_rho	1	0.426492	0.167492	2.55	0.0109
_sigma2	1	91.779519	18.909222	4.85	<.0001

The spatial autoregressive coefficient ρ is estimated to be 0.426 with a p-value of 0.0109 based on an asymptotic t test. This result seems to suggest that there is a significantly positive spatial dependence in the number of crimes.

In the SPATIALREG procedure, the null hypothesis $H_0 : \rho = 0$ can also be tested against the alternative $H_a : \rho \neq 0$ by using the likelihood ratio (LR) test, Lagrange multiplier (LM) test, and Wald test. For the LR test, the test statistic is equal to $-2(\mathcal{L}_{\text{linear}} - \mathcal{L}_{\text{SAR}}) = -2(-187.38 + 182.39) = 9.98$, where $\mathcal{L}_{\text{linear}}$ and $\mathcal{L}_{\text{SAR}}$ are the log likelihoods for the linear regression model and SAR model, respectively. The likelihood ratio test is significant at the 0.05 level, providing strong evidence of spatial dependence in the data.

Syntax: SPATIALREG Procedure

The following statements are available in the SPATIALREG procedure:

PROC SPATIALREG < *options* > ;
BOUNDS *bound1* < , *bound2* . . . > ;
BY *variables* ;
CLASS *variables* ;
INIT *initvalue1* < , *initvalue2* . . . > ;
MODEL *dependent* = < *regressors* >< / *options* > ;
NLOPTIONS < *options* > ;
OUTPUT < **OUT=***SAS-data-set* >< *output-options* > ;
PERFORMANCE *options* ;
RESTRICT *restriction1* < , *restriction2* . . . > ;
TEST *equation1* < , *equation2* . . . >< */test-options* > ;
SPATIALEFFECTS < *model-spatial-effect-regressors* > ;
SPATIALID *variable* ;

You can specify more than one MODEL statement, as shown in the section "Example 31.3: Fitting Multiple Models" on page 2358. The CLASS statement must precede the MODEL statement. If you include the SPATIALEFFECTS statement, it must be paired with and appear after the MODEL statement.

Functional Summary

Table 31.1 summarizes the statements and options that you can use with the SPATIALREG procedure.

Table 31.1 PROC SPATIALREG Functional Summary

PROC SPATIALREG Statement

PROC SPATIALREG < *options* > **;**

You can specify the following options in the PROC SPATIALREG statement.

Data Set Options

DATA=*SAS-data-set*

specifies the primary SAS data set that contains dependent variables, and explanatory variables, and so on.

WMAT=*SAS-data-set*

specifies the secondary spatial weights data set, which can be used to construct the spatial weights matrix $\mathbf{W}$. Loosely speaking, the entries of $\mathbf{W}$, $w(\mathrm{s}_i, \mathrm{s}_j)$, define the amount of influence that a unit s_j has over a unit s_i. The entries $w(\mathrm{s}_i, \mathrm{s}_j)$ must be nonnegative and have zeros on the diagonal; that is, $w(\mathrm{s}_i, \mathrm{s}_j) \geq 0$ and $w(\mathrm{s}_i, \mathrm{s}_i) = 0$, where $i, j = 1, 2, \ldots, n$, with n being the total number of spatial units in the data. Any nonzero diagonal elements $w(\mathrm{s}_i, \mathrm{s}_i)$ are replaced with 0. The spatial weights matrix can be asymmetric; that is, it is not necessary that $w(\mathrm{s}_i, \mathrm{s}_j) = w(\mathrm{s}_j, \mathrm{s}_i)$. For information about missing spatial weights in $\mathbf{W}$, see the section "NONORMALIZE" on page 2310.

The $\mathbf{W}$ matrix can take two different forms. First, you can provide a full spatial weights matrix. In this case, the data set that you specify in the WMAT= option has n rows. However, the number of columns can be either $n + 1$ or n, depending on whether you need a spatial ID variable to match observations in two data sets that are specified by the DATA= option and WMAT= option. If you need a SPATIALID statement to specify a spatial ID variable for the purpose of matching observations, the data set that you specify in the WMAT= option needs to have $n+1$ columns. In this case, the spatial ID variable can appear in any column in the data set. Otherwise, the number of columns in the data set that you specify in the WMAT= option should be n.

Second, you can also specify the spatial weights matrix by using a compact form when appropriate. In this form, the number of observations in the data set that you specify in the WMAT= option should match the number of nonzero elements in the spatial weights matrix. Moreover, the number of columns in this data set should be three. The first two columns give the row and column indices for nonzero entries in the spatial weights matrix. The third column in the data set contains the nonzero entries in the spatial weights matrix. If you use the compact form for the spatial weights matrix, you must include a SPATIALID statement to match observations in the two data sets that are specified in the DATA=

option and WMAT= option. For more information about the SPATIALID statement, see the section "SPATIALID Statement" on page 2319. For more information about the compact representation of the spatial weights matrix, see the section "Compact Representation of Spatial Weights Matrix" on page 2334.

NONORMALIZE
suppresses the row standardization of the spatial weights matrix that is specified in the WMAT= option. By default, the spatial weights matrix is row-standardized; that is, the spatial weights matrix has unit row sum. If the NONORMALIZE option is specified, spatial weights are used "as is" except for $w(s_i, s_i)$, which is always treated as 0. This implies that an entry $w(s_i, s_j)$ in the $\mathbf{W}$ matrix cannot be missing for $i \neq j$ if the NONORMALIZE option is specified. If this option is not specified, missing spatial weights are replaced with zeros.

Approximation Control Options

For the SAR, SDM, SEM, and SDEM models, you can specify the following *options*:

APPROXIMATION=(< *approx-options* >)
specifies options that are related to approximating the Jacobian, as described in the section "Approximations to the Jacobian" on page 2338. You must specify one or more of the following *approx-options*:

CHEBYSHEV | TAYLOR
specifies the approximation method. By default, Chebyshev approximation is used. The Taylor approximation is used only if you specify the TAYLOR option.

NMC=*number*
specifies a positive integer as the number of standard random normal draws for the Monte Carlo simulation that approximates the traces of powers of the spatial weights matrix $\mathbf{W}$. If the SEED= option is specified, NMC=100 by default. If neither the NMC= option nor the SEED= option is specified, Monte Carlo simulation is not used and the traces of powers of the spatial weights matrix $\mathbf{W}$ are computed exactly. For more information, see the section "Approximations to the Jacobian" on page 2338.

ORDER=*number*
specifies a positive integer as the order of series in Taylor approximation or Chebyshev approximation. If Taylor approximation is used, ORDER=50 by default. If Chebyshev approximation is used, ORDER=5 by default.

SEED=*number*
specifies an integer seed in the range 1 to $2^{31} - 1$ for the random number generator that is used for the Monte Carlo simulation that approximates the traces of powers of the spatial weights matrix $\mathbf{W}$. If the NMC= option is specified, SEED=1 by default. If neither the NMC= option nor the SEED= option is specified, Monte Carlo simulation is not used and the traces of powers of the spatial weights matrix $\mathbf{W}$ are computed exactly. For more information, see the section "Approximations to the Jacobian" on page 2338. Specifying a seed enables you to reproduce your analysis.

Output Data Set Options

COVOUT
writes the covariance matrix for the parameter estimates to the OUTEST= data set. This option is valid when you specify the OUTEST= option.

OUTEST=*SAS-data-set*
writes the parameter estimates to the specified output data set.

Printing Options

CORRB
prints the correlation matrix of the parameter estimates. You can also specify this option in the MODEL statement.

COVB
prints the covariance matrix of the parameter estimates. You can also specify this option in the MODEL statement.

NOPRINT
suppresses all printed output.

Estimation Control Options

COVEST=HESSIAN | OP | QML
specifies the type of covariance matrix for the parameter estimates. You can specify the following types:

HESSIAN	specifies the covariance from the Hessian matrix.
OP	specifies the covariance from the outer product matrix.
QML	specifies the covariance from the outer product and Hessian matrices.

By default, COVEST=HESSIAN. The quasi-maximum-likelihood estimates are computed using COVEST=QML. For all models except the linear and SLX models, only COVEST=HESSIAN is supported.

Optimization Process Control Options

PROC SPATIALREG uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. All the NLO options are available in the NLOPTIONS statement. For more information, see the section "NLOPTIONS Statement" on page 2316. In addition, you can specify the following option in the PROC SPATIALREG statement:

METHOD=CONGRA | DBLDOG | NEWRAP | NMSIMP | NONE | NRRIDG | QUANEW | TRUREG
specifies the iterative minimization method to use. You can specify the following *values*:

CONGRA	specifies the conjugate-gradient method.
DBLDOG	specifies the double-dogleg method.
NEWRAP	specifies the Newton-Raphson method.

NMSIMP specifies the Nelder-Mead simplex method.

NONE specifies that optimization not be performed.

NRRIDG specifies the Newton-Raphson ridge method.

QUANEW specifies the quasi-Newton method.

TRUREG specifies the trust region method.

By default, METHOD=NEWRAP.

BOUNDS Statement

BOUNDS *bound1* < *, bound2 . . .* > **;**

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. You can specify any number of BOUNDS statements.

Each *bound* is composed of parameter names, constants, and inequality operators as follows:

item operator item < *operator item operator item . . .* >

Each *item* can be a constant, a parameter name, or a list of parameter names. Each *operator* can be <, >, <=, or >=.

You can use both the BOUNDS statement and the RESTRICT statement to impose boundary constraints; however, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints. For more information about the RESTRICT statement, see the section "RESTRICT Statement" on page 2317.

The following BOUNDS statement constrains the estimates of the parameter for `z` to be negative, the parameters for `x1` through `x10` to be between 0 and 1, and the parameter for spatial lag of the `x1` to be less than 1:

```
bounds z < 0,
       0 < x1-x10 < 1,
       W_x1 < 1;
```

BY Statement

BY *variables* **;**

A BY statement can be used in PROC SPATIALREG to obtain separate analyses of observations in groups that are defined by the BY variables. When you use a BY statement, the primary input data set (specified in the DATA= option) should be sorted by the BY variables.

CLASS Statement

CLASS *variable* < *(options)* > . . . < *variable* < *(options)* > > < */global-options* > **;**

The CLASS statement names the classification variables that are used to group (classify) data in the analysis. Classification variables can be either character or numeric.

Class levels are determined from the formatted values of the CLASS *variables*. Thus, you can use formats to group values into levels. For more information, see the discussion of the FORMAT procedure in *SAS Language Reference: Dictionary*. The CLASS statement must precede the MODEL statement.

Most options can be specified as either individual variable *options* or *global-options*. You can specify *options* for each variable by enclosing the options in parentheses after the *variable* name. You can also specify *global-options* for the CLASS statement by placing them after a slash (/). *Global-options* are applied to all the variables that are specified in the CLASS statement. If you specify more than one CLASS statement, the *global-options* that are specified in any one CLASS statement apply to all CLASS statements. However, individual CLASS variable *options* override the *global-options*.

You can specify the following values for either an *option* or a *global-option*:

MISSING
treats missing values (., ._, .A, . . . , .Z for numeric variables and blanks for character variables) as valid levels for the CLASS variable.

ORDER=DATA | FORMATTED | FREQ | INTERNAL
specifies the sort order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option can be useful when you use the CONTRAST statement. By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. When ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

The following table shows how PROC SPATIALREG interprets values of the ORDER= option:

Value of ORDER=	Levels Sorted By
DATA	Order of appearance in the input data set
FORMATTED	External formatted values, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) values
INTERNAL	Unformatted value

For more information about sort order, see the chapter on the SORT procedure in *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Programmers Guide: Essentials*.

PARAM=*keyword*
specifies the parameterization method for the classification variable or variables. You can specify any of the *keywords* shown in the following table; by default, PARAM=GLM.

Design matrix columns are created from CLASS variables according to the corresponding coding schemes:

Value of PARAM=	Coding
EFFECT	Effect coding
GLM	Less-than-full-rank reference cell coding (this *keyword* can be used only as a *global-option*)
REFERENCE **REF**	Reference cell coding

All parameterizations are full rank, except for the GLM parameterization. The REF= option in the CLASS statement determines the reference level for effect and reference coding and for their orthogonal parameterizations. It also indirectly determines the reference level for a singular GLM parameterization through the order of levels.

REF=*'level' | keyword*
specifies the reference level for PARAM=EFFECT, PARAM=REFERENCE, and their orthogonalizations. When PARAM=GLM, the REF= option specifies a level of the classification variable to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the linear estimates with a singular parameterization.

For an individual variable REF= option (but not for a global REF= option), you can specify the *level* of the variable to use as the reference level. Specify the formatted value of the variable if a format is assigned. For a global or individual variable REF= option, you can specify one of the following *keywords*:

FIRST designates the first ordered level as reference.

LAST designates the last ordered level as reference.

By default, REF=LAST.

INIT Statement

INIT *initvalue1 < , initvalue2 . . . >* **;**

The INIT statement sets initial values for parameters in the optimization.

Each *initvalue* is written as a parameter or parameter list, followed by an optional equal sign (=), followed by a number:

parameter < = > number

For continuous regressors, the names of the parameters are the same as the corresponding variables. For a regressor that is a CLASS variable, the parameter name combines the corresponding CLASS variable name with the variable level. For interaction and nested regressors, the parameter names combine the names of all the regressors. The names of the parameters can be seen in the OUTEST= data set. By default, initial values are determined by OLS regression. Initial values can be displayed by using the ITPRINT option in the PROC SPATIALREG statement.

MODEL Statement

MODEL *dependent-variable = <regressors> </ options>* **;**

The MODEL statement specifies the *dependent-variable* and independent covariates (*regressors*) for the regression model. If you specify no *regressors*, PROC SPATIALREG fits a model that contains only an intercept. The *dependent-variable* is treated as a continuous variable in the primary input data set (specified in the DATA= option). Models in PROC SPATIALREG do not allow missing values. If there are missing values, you get an error message.

You can specify more than one MODEL statement. You can specify the following *options* in the MODEL statement after a slash (/):

NOINT
suppresses the intercept parameter.

TYPE=LINEAR | SAC | SAR | SARMA | SEM | SMA
specifies the type of model to be fitted. If you specify this option in both the MODEL statement and the PROC SPATIALREG statement, the MODEL statement overrides the PROC SPATIALREG statement. You can specify the following model types:

LINEAR	specifies the linear model.
SAC	specifies the spatial autoregressive confused model.
SAR	specifies the spatial autoregressive model.
SARMA	specifies the spatial autoregressive moving average model.
SEM	specifies the spatial error model.
SMA	specifies the spatial moving average model.

By default, TYPE=SAR.

Printing Options

CORRB
prints the correlation matrix of the parameter estimates. You can also specify this option in the PROC SPATIALREG statement.

COVB
prints the covariance matrix of the parameter estimates. You can also specify this option in the PROC SPATIALREG statement.

ITPRINT
prints the objective function and parameter estimates at each iteration. The objective function is the negative log-likelihood function. You can also specify this option in the PROC SPATIALREG statement.

PRINTALL
requests all available output. You can also specify this option in the PROC SPATIALREG statement.

NLOPTIONS Statement

NLOPTIONS < *options* > **;**

The NLOPTIONS statement provides the options to control the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. For a list of all the options available in the NLOPTIONS statement, see Chapter 6, "Nonlinear Optimization Methods."

OUTPUT Statement

OUTPUT < **OUT=***SAS-data-set* > < *output-options* > **;**

The OUTPUT statement creates a new SAS data set that contains all the variables in the input data set and, optionally, the estimates of $\mathbf{x}_i'\boldsymbol{\beta}$, the expected value of the response variable, and the residual.

You can specify only one OUTPUT statement for each MODEL statement. You can specify the following *output-options*:

OUT=*SAS-data-set*
names the output data set.

XBETA=*name*
names the variable that contains estimates of $\mathbf{x}_i'\boldsymbol{\beta}$.

PRED=*name*

MEAN=*name*
assigns a name to the variable that contains the predicted value of the response variable.

RESID=*name*

RESIDUAL=*name*
assigns a name to the variable that contains the residuals (that is, the difference between the observed and predicted values of the response variable).

PERFORMANCE Statement

PERFORMANCE < *performance-options* > **;**

The PERFORMANCE statement controls the number of threads that are used in the optimization phase. You can also specify that multithreading not be used in the optimization phase by using the NOTHREADS option.

You can specify only one PERFORMANCE statement. You can specify the following *performance-options*:

DETAILS
specifies that a timing table be included in the output.

NOTHREADS
specifies that no threads be used during optimization.

NTHREADS=*number*
specifies the number of threads to be used during optimization.

If you use both the NTHREADS= and NOTHREADS options, then the NTHREADS= option is ignored. If you use a PERFORMANCE statement, then it overrides any global threading settings that might have been set using the CPUCOUNT=, THREADS, or NOTHREADS system option.

RESTRICT Statement

RESTRICT *restriction1* < *, restriction2 . . .* > **;**

The RESTRICT statement imposes linear restrictions on the parameter estimates. You can specify any number of RESTRICT statements.

Each *restriction* is written as an expression, followed by an equality operator (=) or an inequality operator (<, >, <=, >=), followed by a second expression:

parameter < number

Restriction expressions can be composed of parameter names; constants; and the operators times ($*$), plus ($+$), and minus ($-$). The restriction expressions must be a linear function of the parameters. For continuous regressors, the names of the parameters are the same as the names of the corresponding variables. For a regressor that is a CLASS variable, the parameter name combines the corresponding CLASS variable name with the variable level. For interaction and nested regressors, the parameter names combine the names of all the regressors. The names of the parameters can be seen in the OUTEST= data set.

Lagrange multipliers are reported in the "Parameter Estimates" table for all the active linear constraints. They are identified by the names Restrict1, Restrict2, and so on. The p-values of these Lagrange multipliers are computed using a beta distribution (LaMotte 1994). Nonactive (nonbinding) restrictions have no effect on the estimation results and are not noted in the output.

For example, the following RESTRICT statement constrains the spatial autoregressive coefficient ρ to 0, which removes endogenous interaction effects:

```
restrict _rho = 0;
```

TEST Statement

<'label':> **TEST** *equation [,equation. . .] </ options>* **;**

The TEST statement performs Wald, Lagrange multiplier, and likelihood ratio tests of linear hypotheses about the parameters in your model. Each equation specifies a linear hypothesis to be tested. All hypotheses in one TEST statement are tested jointly. Variable names in the equations must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT refers to the coefficient of the intercept. The keywords _rho and _lambda refer to the autoregressive coefficients ρ and λ, respectively. In addition, the keyword _sigma2 refers to the variance parameter σ^2.

You can specify the following options after the slash (/):

ALL
requests Wald, Lagrange multiplier, and likelihood ratio tests.

LM
requests the Lagrange multiplier test.

LR
requests the likelihood ratio test.

WALD
requests the Wald test.

The following statements illustrate the use of the TEST statement:

```
proc spatialreg data=dat;
   model y = x1 x2 x3/type=LINEAR;
   test x1 = 0, x2 * .5 + 2 * x3 = 0/ALL;
   test_int: test intercept = 0, x3 = 0/LR;
run;
```

The first test investigates the joint hypothesis that $\beta_1 = 0$ and $0.5\beta_2 + 2\beta_3 = 0$.

Only linear equality tests are permitted in PROC SPATIALREG. Tests expressions can be composed only of algebraic operations that use the addition symbol (+), subtraction symbol (–), and multiplication symbol (*).

The TEST statement accepts labels that are reproduced in the printed output. TEST statements can be labeled in two ways: a TEST statement can be preceded by a label followed by a colon, or the keyword TEST can be followed by a quoted string. If both are present, PROC SPATIALREG uses the label preceding the colon. If no label is specified, PROC SPATIALREG automatically labels the tests.

SPATIALID Statement

SPATIALID *variable* **;**

For models that require a spatial weights matrix, the SPATIALID statement specifies a variable that identifies a spatial unit for each observation in the two data sets that are specified in the DATA= option and WMAT= option in the PROC SPATIALREG statement. The variable that is specified in the SPATIALID statement is also used to match the rows and columns within the WMAT= data set. You do not need a SPATIALID statement if no matching is needed for the two data sets specified in the DATA= option and WMAT= option. If you do need a SPATIALID statement, only one SPATIALID statement and one spatial ID variable are allowed. The values of the spatial ID variable in either the DATA= data set or the WMAT= data set cannot be missing.

The variable in the SPATIALID statement can be either numeric or character. However, the type of spatial ID variable in the two data sets specified in the DATA= option and WMAT= option must be the same. When the spatial ID variable is numeric, it needs to be integer-valued. If you specify a number that is not an integer, PROC SPATIALREG uses the integer part of that number for matching.

SPATIALEFFECTS Statement

SPATIALEFFECTS < *model-spatial-effect-regressors* > < */options* > **;**

The SPATIALEFFECTS statement enables you to specify covariates (such as X) whose spatial lag, WX, is to be added to the MODEL statement.

PROC SPATIALREG adds the spatially weighted *model-spatial-effect-regressors* to regressors that are specified in the MODEL statement. For example, if you specify q variables $z_1, \ldots, z_q$ in the SPATIALEFFECTS statement, then each of q spatially weighted variables, as represented by each column of $\mathbf{WZ}$, has a parameter to be included in the regression. Here, $\mathbf{WZ}$ denotes the matrix product of $\mathbf{W}$ and $\mathbf{Z}$. In addition, $\mathbf{Z}$ is the design matrix formed by the q variables $z_1, \ldots, z_q$. The spatial weights matrix $\mathbf{W}$ comes from the data set that is specified in the WMAT= option. The "Parameter Estimates" table in the displayed output shows the estimates for spatially weighted *model-spatial-effect-regressors*; they are labeled with the prefix "W_". For example, if you specify z (a variable in your primary data set) as a spatial effect explanatory variable, then the "Parameter Estimates" table labels the corresponding parameter estimate "W_z".

Details: SPATIALREG Procedure

Specification of Regressors

Each term in a model, called a *regressor*, is a variable or combination of variables. Regressors are specified in a special notation that uses variable names and operators. There are two kinds of variables: classification (CLASS) variables and continuous variables. There are two primary operators: crossing and nesting. A third operator, the bar operator, is used to simplify effect specification.

In the SAS System, classification variables are declared in the CLASS statement. (They can also be called categorical, qualitative, discrete, or nominal variables.) Classification variables can be either numeric or character. The values of a classification variable are called *levels*. For example, the classification variable Sex has the levels "male" and "female."

In a model, an independent variable that is not declared in the CLASS statement is assumed to be continuous. Continuous variables, which must be numeric, are used for covariates. For example, the heights and weights of subjects are continuous variables. A response variable is a continuous variable and must also be numeric.

Types of Regressors

Seven different types of regressors are used in the SPATIALREG procedure. In the following list, assume that A, B, C, D, and E are CLASS variables and that X1 and X2 are continuous variables:

- Regressors are specified by writing continuous variables by themselves: X1 X2.
- Polynomial regressors are specified by joining (crossing) two or more continuous variables with asterisks: X1*X1 X1*X2.
- Dummy regressors are specified by writing CLASS variables by themselves: A B C.
- Dummy interactions are specified by joining classification variables with asterisks: A*B B*C A*B*C.
- Nested regressors are specified by following a dummy variable or dummy interaction with a classification variable or list of classification variables enclosed in parentheses. The dummy variable or dummy interaction is nested within the regressor that is listed in parentheses: B(A) C(B*A) D*E(C*B*A). In this example, B(A) is read as "B nested within A."
- Continuous-by-class regressors are written by joining continuous variables and classification variables with asterisks: X1*A.
- Continuous-nesting-class regressors consist of continuous variables followed by a classification variable interaction enclosed in parentheses: X1(A) X1*X2(A*B).

An example of the general form of an effect that involves several variables is

X1*X2*A*B*C(D*E)

This example contains an interaction between continuous terms and classification terms that are nested within more than one classification variable. The continuous list comes first, followed by the dummy list, followed by the nesting list in parentheses. Note that asterisks can appear within the nested list but not immediately before the left parenthesis.

The MODEL statement uses these effects. Some examples of MODEL statements that use various kinds of effects are shown in Table 31.2, where a, b, and c represent classification variables. The variables x and z are continuous.

Table 31.2 Examples of MODEL Statement and Effects

Specification	Type of Model
`model y=x;`	Simple regression
`model y=x z;`	Multiple regression
`model y=x x*x;`	Polynomial (quadratic) regression
`model y=a;`	Regression with one classification variable
`model y=a b c;`	Regression with multiple classification variables
`model y=a b a*b;`	Regression with classification variables and their interactions
`model y=a b(a) c(b a);`	Regression with classification variables and their interactions
`model y=a x;`	Regression with both continuous and classification variables
`model y=a x(a);`	Separate-slopes regression
`model y=a x x*a;`	Homogeneity-of-slopes regression

Bar Operator

You can shorten the specification of a large factorial model by using the bar operator. For example, two ways of writing the model for a full three-way factorial model follow:

```
model Y = A B C   A*B A*C B*C   A*B*C;

model Y = A|B|C;
```

When the bar (|) is used, the right and left sides become effects, and the cross between them becomes an effect. Multiple bars are permitted. The expressions are expanded from left to right, using rules 2–4 from Searle (1971, p. 390).

- Multiple bars are evaluated from left to right. For example, A | B | C is evaluated as follows:

$$\begin{aligned} \text{A | B | C} &\rightarrow \{\,\text{A | B}\,\}\,\text{| C} \\ &\rightarrow \{\,\text{A B A*B}\,\}\,\text{| C} \\ &\rightarrow \text{A B A*B C A*C B*C A*B*C} \end{aligned}$$

- Crossed and nested groups of variables are combined. For example, A(B) | C(D) generates A*C(B D), among other terms.

- Duplicate variables are removed. For example, A(C) | B(C) generates A*B(C C), among other terms, and the extra C is removed.
- Effects are discarded if a variable occurs in both the crossed and nested parts of an effect. For example, A(B) | B(D E) generates A*B(B D E), but this effect is discarded immediately.

You can also specify the maximum number of variables involved in any effect that results from bar evaluation by specifying that maximum number, preceded by an @ sign, at the end of the bar effect. For example, the specification A | B | C@2 would result in only those effects that contain no more than two variables: in this case, A B A*B C A*C and B*C.

More examples of using the | and @ operators follow:

A | C(B)	is equivalent to	A C(B) A*C(B)
A(B) | C(B)	is equivalent to	A(B) C(B) A*C(B)
A(B) | B(D E)	is equivalent to	A(B) B(D E)
A | B(A) | C	is equivalent to	A B(A) C A*C B*C(A)
A | B(A) | C@2	is equivalent to	A B(A) C A*C
A | B | C | D@2	is equivalent to	A B A*B C A*C B*C D A*D B*D C*D
A*B(C*D)	is equivalent to	A*B(C D)

Missing Values

Missing values can occur in both the primary data set (specified in the DATA= option) and the secondary spatial weights data set (specified in the WMAT= option). PROC SPATIALREG does not allow missing values in the primary input data set. If any observation in the primary input data set has a missing value for one or more of the regressors or the dependent variable, PROC SPATIALREG will not fit the model. If any observation in the primary data set has a missing value for the spatial ID variable when you specify the SPATIALID statement, PROC SPATIALREG will not fit the model. In such cases, an error message is issued.

For the secondary spatial weights data set, a missing value for the spatial ID variable is not allowed when you specify the SPATIALID statement. Moreover, missing spatial weights are not allowed if you specify the NONORMALIZE option. In these cases, PROC SPATIALREG issues an error message and skips the model fitting.

Spatial Autoregressive Models

The spatial autoregressive (SAR) model is useful for incorporating the spatial dependence in the dependent variable—that is, the endogenous interaction effect. Let y_i denote the observation associated with a spatial unit s_i for $i = 1, 2, \ldots, n$. For these spatial units, let an $n \times n$ matrix $\mathbf{W}$ with nonnegative elements be a spatial weights matrix. Further, let $\mathbf{x}_i$ be a $p \times 1$ vector that denotes values of p regressors recorded for the spatial unit s_i. The SAR model can be formulated as

$$y_i = \rho \sum_{j=1}^{n} W_{ij} y_j + \mathbf{x}_i' \boldsymbol{\beta} + \epsilon_i$$

where $i = 1, 2, \ldots, n$. Here ρ is the spatial autoregressive coefficient and $\boldsymbol{\beta}$ is a $p \times 1$ parameter vector. Moreover, W_{ij} is the (i, j)th element of the matrix $\mathbf{W}$ subject to $W_{ii} = 0$. For the error term ϵ_i related to the spatial unit s_i, it is assumed that $\epsilon_i \overset{\text{iid}}{\sim} \mathrm{N}(0, \sigma^2)$.

The SAR model is often described in vector form as

$$\mathbf{y} = \rho \mathbf{W}\mathbf{y} + \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, y_2, \ldots, y_n)'$, $\mathbf{X}$ is an $n \times p$ matrix where each row consists of $\mathbf{x}_i'$, and $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_n)'$.

The standard estimator for the SAR model is the maximum likelihood estimator (MLE). For the SAR model, the log-likelihood function is (Anselin 2001)

$$\mathcal{L} = -\frac{n}{2} \ln(2\pi\sigma^2) - \frac{(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})'(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})}{2\sigma^2} + \ln |\mathbf{A}|$$

where $\mathbf{A} = \mathbf{I}_n - \rho\mathbf{W}$, with $\mathbf{I}_n$ being an $n \times n$ identity matrix. $|\mathbf{A}|$ denotes the determinant of $\mathbf{A}$.

The gradients can be derived as follows:

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} = \frac{\mathbf{X}'(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})}{\sigma^2}$$

$$\frac{\partial \mathcal{L}}{\partial \rho} = \frac{1}{\sigma^2} \mathbf{y}'\mathbf{W}'(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta}) - \mathrm{tr}(\mathbf{A}^{-1}\mathbf{W})$$

$$\frac{\partial \mathcal{L}}{\partial \sigma^2} = -\frac{n}{2\sigma^2} + \frac{(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})'(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})}{2\sigma^4}$$

For the $n \times n$ matrix $\mathbf{A}$, $\mathrm{tr}(\mathbf{A}) = \sum_{i=1}^{n} a_{ii}$, where a_{ii} is the ith diagonal element of $\mathbf{A}$.

A SAR model does not account for exogenous interaction effects. However, in practice, the value of the dependent variable y for a spatial unit might be affected by some independent exploratory variables of other spatial units as well. In such a case, you can use the SDM model instead.

Spatial Durbin Models

Unlike a SAR model, a spatial Durbin model (SDM) can account for exogenous interaction effects in addition to the endogenous interaction effects. Let y_i denote the observation associated with a spatial unit s_i for $i = 1, 2, \ldots, n$. For these spatial units, let $\mathbf{W}$ be an $n \times n$ spatial weights matrix of your choice. Further, assume that $\mathbf{x}_i$ is a $p \times 1$ vector that denotes values of p regressors recorded for the spatial unit s_i. Similarly, assume that $\mathbf{z}_i$ is a $q \times 1$ vector that denotes values of q regressors measured at unit s_i.

The SDM model can be described in vector form as (LeSage and Pace 2009)

$$\mathbf{y} = \rho\mathbf{W}\mathbf{y} + \mathbf{X}\boldsymbol{\beta} + \mathbf{W}\mathbf{Z}\boldsymbol{\theta} + \boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, y_2, \ldots, y_n)'$ and $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_n)'$ with $\epsilon_i \overset{\text{iid}}{\sim} \mathrm{N}(0, \sigma^2)$. Moreover, $\mathbf{X}$ is an $n \times p$ matrix where each row consists of $\mathbf{x}_i'$, and $\mathbf{Z}$ is an $n \times q$ matrix where each row consists of $\mathbf{z}_i'$. In addition, $\boldsymbol{\beta}$ and $\boldsymbol{\theta}$ are $p \times 1$ and $q \times 1$ parameter vectors, respectively.

By letting $\widetilde{\mathbf{X}} = [\mathbf{X} \;\; \mathbf{W}\mathbf{Z}]$ and $\widetilde{\boldsymbol{\beta}} = (\boldsymbol{\beta}' \; \boldsymbol{\theta}')'$, you can rewrite the SDM model as

$$\mathbf{y} = \rho\mathbf{W}\mathbf{y} + \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}} + \boldsymbol{\epsilon}$$

The log-likelihood function for the SDM model is

$$\mathcal{L} = -\frac{n}{2}\ln(2\pi\sigma^2) - \frac{(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})'(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})}{2\sigma^2} + \ln|\mathbf{A}|$$

where $\mathbf{A} = \mathbf{I}_n - \rho\mathbf{W}$.

For the SDM model, the gradients are

$$\frac{\partial\mathcal{L}}{\partial\widetilde{\boldsymbol{\beta}}} = \frac{\widetilde{\mathbf{X}}'(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})}{\sigma^2}$$

$$\frac{\partial\mathcal{L}}{\partial\rho} = \frac{1}{\sigma^2}\mathbf{y}'\mathbf{W}'(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}}) - \mathrm{tr}(\mathbf{A}^{-1}\mathbf{W})$$

$$\frac{\partial\mathcal{L}}{\partial\sigma^2} = -\frac{n}{2\sigma^2} + \frac{(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})'(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})}{2\sigma^4}$$

Both the SAR model and the SDM model account for endogenous interaction effects. However, in some cases there might be an interaction among error terms. In such cases, you might consider a spatial error model, which addresses spatial interaction among error terms.

Spatial Error Models

The spatial error model (SEM) accounts for spatial dependence in the error terms rather than in the dependent variable. Let y_i denote the observation associated with the spatial unit $\mathbf{s}_i$ for $i = 1, 2, \ldots, n$. For these spatial units, let $\mathbf{W}$ be an $n \times n$ spatial weights matrix. Further, let $\mathbf{x}_i$ be a $p \times 1$ vector that denotes values of p regressors recorded at unit $\mathbf{s}_i$.

The SEM model can be described in vector form by using the following two-stage formulation (LeSage and Pace 2009),

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$$

$$\mathbf{u} = \lambda \mathbf{W}\mathbf{u} + \boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, y_2, \ldots, y_n)'$ and $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_n)'$, with $\epsilon_i \overset{\text{iid}}{\sim} \mathrm{N}(0, \sigma^2)$. Moreover, $\mathbf{X}$ is an $n \times p$ matrix where each row consists of $\mathbf{x}_i'$. In addition, $\boldsymbol{\beta}$ is a $p \times 1$ parameter vector.

The log-likelihood function for the SEM model is

$$\mathcal{L} = -\frac{n}{2}\ln(2\pi\sigma^2) - \frac{[\mathbf{B}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})]'[\mathbf{B}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})]}{2\sigma^2} + \ln|\mathbf{B}|$$

where $\mathbf{B} = \mathbf{I}_n - \lambda\mathbf{W}$.

For the SEM model, the gradients are

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} = \frac{(\mathbf{B}\mathbf{X})'[\mathbf{B}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})]}{\sigma^2}$$

$$\frac{\partial \mathcal{L}}{\partial \lambda} = \frac{1}{\sigma^2}[\mathbf{W}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})]'[\mathbf{B}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})] - \mathrm{tr}(\mathbf{B}^{-1}\mathbf{W})$$

$$\frac{\partial \mathcal{L}}{\partial \sigma^2} = -\frac{n}{2\sigma^2} + \frac{[\mathbf{B}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})]'[\mathbf{B}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})]}{2\sigma^4}$$

In addition to the interaction effects among error terms, you might also want to include exogenous interaction effects in the model. In such cases, you need to consider a spatial Durbin error model (SDEM).

Spatial Durbin Error Models

The spatial Durbin error model (SDEM) accounts for spatial dependence among the error terms and the exogenous interaction effect. Let y_i denote the observation associated with the spatial unit $\mathbf{s}_i$ for $i = 1, 2, \ldots, n$. For these spatial units, let $\mathbf{W}$ be an $n \times n$ spatial weights matrix. Further, let $\mathbf{x}_i$ be a $p \times 1$ vector that denotes values of p regressors recorded at unit $\mathbf{s}_i$. Similarly, let $\mathbf{z}_i$ be a $q \times 1$ vector that denotes values of q regressors measured at unit $\mathbf{s}_i$.

The SDEM can be described in vector form by using the following two-stage formulation (LeSage and Pace 2009),

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{W}\mathbf{Z}\boldsymbol{\theta} + \mathbf{u}$$

$$\mathbf{u} = \lambda \mathbf{W}\mathbf{u} + \boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, y_2, \ldots, y_n)'$ and $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_n)'$, with $\epsilon_i \overset{\text{iid}}{\sim} \mathrm{N}(0, \sigma^2)$. Moreover, $\mathbf{X}$ and $\mathbf{Z}$ are $n \times p$ and $n \times q$ matrices, where each row consists of $\mathbf{x}_i'$ and $\mathbf{z}_i'$, respectively. In addition, $\boldsymbol{\beta}$ and $\boldsymbol{\theta}$ are $p \times 1$ and $q \times 1$ parameter vectors, respectively.

By letting $\widetilde{\mathbf{X}} = [\mathbf{X} \;\; \mathbf{WZ}]$ and $\widetilde{\boldsymbol{\beta}} = (\boldsymbol{\beta}' \; \boldsymbol{\theta}')'$, the SDEM model can be rewritten as

$$\mathbf{y} = \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}} + \mathbf{B}^{-1}\boldsymbol{\epsilon}$$

where $\mathbf{B} = \mathbf{I}_n - \lambda\mathbf{W}$.

The log-likelihood function for the SDEM model is

$$\mathcal{L} = -\frac{n}{2}\ln(2\pi\sigma^2) - \frac{\left[\mathbf{B}(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]'\left[\mathbf{B}(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]}{2\sigma^2} + \ln|\mathbf{B}|$$

For the SDEM model, the gradients are

$$\frac{\partial\mathcal{L}}{\partial\widetilde{\boldsymbol{\beta}}} = \frac{(\mathbf{B}\widetilde{\mathbf{X}})'\left[\mathbf{B}(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]}{\sigma^2}$$

$$\frac{\partial\mathcal{L}}{\partial\lambda} = \frac{1}{\sigma^2}\left[\mathbf{W}(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]'\left[\mathbf{B}(\mathbf{y} - \widetilde{\mathbf{X}}\boldsymbol{\beta})\right] - \mathrm{tr}(\mathbf{B}^{-1}\mathbf{W})$$

$$\frac{\partial\mathcal{L}}{\partial\sigma^2} = -\frac{n}{2\sigma^2} + \frac{\left[\mathbf{B}(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]'\left[\mathbf{B}(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]}{2\sigma^4}$$

Spatial Moving Average Models

The spatial moving average (SMA) model accounts for spatial dependence among the error terms; thus it is similar to the SEM model but with a different autocorrelation structure. The SMA model is used for modeling local autocorrelation. Let y_i denote the observation associated with the spatial unit s_i for $i = 1, 2, \ldots, n$. For these spatial units, let $\mathbf{W}$ be an $n \times n$ spatial weights matrix. Further, let $\mathbf{x}_i$ be a $p \times 1$ vector that denotes values of p regressors recorded at unit s_i.

The SMA model can be described in vector form by using the following two-stage formulation,

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$$

$$\mathbf{u} = (\mathbf{I}_n - \lambda\mathbf{W})\boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, y_2, \ldots, y_n)'$ and $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_n)'$, with $\epsilon_i \overset{\text{iid}}{\sim} \mathrm{N}(0, \sigma^2)$. Moreover, $\mathbf{X}$ is an $n \times p$ matrix that has $\mathbf{x}_i'$ in each row, and $\mathbf{Z}$ is an $n \times q$ matrix that has of $\mathbf{z}_i'$ in each row. In addition, $\boldsymbol{\beta}$ is a $p \times 1$ parameter vector.

The log-likelihood function for the SMA model is

$$\mathcal{L} = -\frac{n}{2}\ln(2\pi\sigma^2) - \frac{\left[\mathbf{B}^{-1}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})\right]'\left[\mathbf{B}^{-1}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})\right]}{2\sigma^2} - \ln|\mathbf{B}|$$

where $\mathbf{B} = \mathbf{I}_n - \lambda\mathbf{W}$.

For the SMA model, the gradients are

$$\frac{\partial \mathcal{L}}{\partial \boldsymbol{\beta}} = \frac{(\mathbf{B}^{-1}\mathbf{X})'\left[\mathbf{B}^{-1}(\mathbf{y}-\mathbf{X}\boldsymbol{\beta})\right]}{\sigma^2}$$

$$\frac{\partial \mathcal{L}}{\partial \lambda} = -\frac{1}{\sigma^2}\left[\mathbf{B}^{-1}(\mathbf{y}-\mathbf{X}\boldsymbol{\beta})\right]'\left[\mathbf{B}^{-1}\mathbf{W}\right]\left[\mathbf{B}^{-1}(\mathbf{y}-\mathbf{X}\boldsymbol{\beta})\right] + \operatorname{tr}(\mathbf{B}^{-1}\mathbf{W})$$

$$\frac{\partial \mathcal{L}}{\partial \sigma^2} = -\frac{n}{2\sigma^2} + \frac{\left[\mathbf{B}^{-1}(\mathbf{y}-\mathbf{X}\boldsymbol{\beta})\right]'\left[\mathbf{B}^{-1}(\mathbf{y}-\mathbf{X}\boldsymbol{\beta})\right]}{2\sigma^4}$$

Spatial Durbin Moving Average Models

The term spatial Durbin moving average (SDMA) model is used to refer to the SMA model with exogenous interaction effects. Let y_i denote the observation associated with the spatial unit s_i for $i = 1, 2, \ldots, n$. For these spatial units, let $\mathbf{W}$ be an $n \times n$ spatial weights matrix. Further, let $\mathbf{x}_i$ be a $p \times 1$ vector that denotes values of p regressors recorded at unit s_i. Similarly, let $\mathbf{z}_i$ be a $q \times 1$ vector that denotes values of q covariates measured at unit s_i.

The SDMA model can be described in vector form as

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{W}\mathbf{X}\boldsymbol{\theta} + (\mathbf{I}_n - \lambda\mathbf{W})\boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, y_2, \ldots, y_n)'$ and $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_n)'$, with $\epsilon_i \overset{\text{iid}}{\sim} \mathrm{N}(0, \sigma^2)$. Moreover, $\mathbf{X}$ and $\mathbf{Z}$ are $n \times p$ and $n \times q$ matrices, where each row consists of $\mathbf{x}_i'$ and $\mathbf{z}_i'$, respectively. In addition, $\boldsymbol{\beta}$ is a $p \times 1$ parameter vector and $\boldsymbol{\theta}$ is a $q \times 1$ parameter vector, respectively.

By letting $\widetilde{X} = [\mathbf{X}\ \mathbf{W}\mathbf{Z}]$ and $\widetilde{\boldsymbol{\beta}} = (\boldsymbol{\beta}'\ \boldsymbol{\theta}')'$, the SDMA model can be written as

$$\mathbf{y} = \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}} + \mathbf{B}\boldsymbol{\epsilon}$$

The log-likelihood function for the SDMA model is

$$\mathcal{L} = -\frac{n}{2}\ln(2\pi\sigma^2) - \frac{\left[\mathbf{B}^{-1}(\mathbf{y}-\widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]'\left[\mathbf{B}^{-1}(\mathbf{y}-\widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]}{2\sigma^2} - \ln|\mathbf{B}|$$

where $\mathbf{B} = \mathbf{I}_n - \lambda\mathbf{W}$ and $|\mathbf{B}|$ denotes the determinant of matrix $\mathbf{B}$.

For the SDMA model, the gradients are

$$\frac{\partial \mathcal{L}}{\partial \widetilde{\boldsymbol{\beta}}} = \frac{(\mathbf{B}^{-1}\widetilde{\mathbf{X}})'\left[\mathbf{B}^{-1}(\mathbf{y}-\widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]}{\sigma^2}$$

$$\frac{\partial \mathcal{L}}{\partial \lambda} = -\frac{1}{\sigma^2}\left[\mathbf{B}^{-1}(\mathbf{y}-\widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]'\left[\mathbf{B}^{-1}\mathbf{W}\right]\left[\mathbf{B}^{-1}(\mathbf{y}-\widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right] + \operatorname{tr}(\mathbf{B}^{-1}\mathbf{W})$$

$$\frac{\partial \mathcal{L}}{\partial \sigma^2} = -\frac{n}{2\sigma^2} + \frac{\left[\mathbf{B}^{-1}(\mathbf{y}-\widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]'\left[\mathbf{B}^{-1}(\mathbf{y}-\widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]}{2\sigma^4}$$

Spatial Autoregressive Moving Average Models

The spatial autoregressive moving average (SARMA) model, like the SMA model, can account for spatial dependence among the error terms. In addition, the SARMA model enables you to account for spatial dependence in the dependent variable, as the SAR model does. Let y_i denote the observation associated with the spatial unit $\mathbf{s}_i$ for $i = 1, 2, \ldots, n$. For these spatial units, let the $n \times n$ matrices $\mathbf{W}_1$ and $\mathbf{W}_2$ with nonnegative elements be two spatial weights matrices. In practice, $\mathbf{W}_1$ and $\mathbf{W}_2$ can be identical. Further, it is assumed that $\mathbf{x}_i$ is a $p \times 1$ vector that denotes values of p covariates recorded at unit $\mathbf{s}_i$.

The SARMA model can be described in the vector form by using the following two-stage formulation (LeSage and Pace 2009),

$$\mathbf{y} = \rho\mathbf{W}_1\mathbf{y} + \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$$

$$\mathbf{u} = (\mathbf{I}_n - \lambda\mathbf{W}_2)\boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, y_2, \ldots, y_n)'$ and $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_n)'$, with $\epsilon_i \overset{\text{iid}}{\sim} \mathrm{N}(0, \sigma^2)$. Moreover, $\mathbf{X}$ is an $n \times p$ matrix that consists of $\mathbf{x}_i'$ in each row. In addition, $\boldsymbol{\beta}$ is a $p \times 1$ parameter vector, and $\mathbf{I}_n$ is an $n \times n$ identity matrix.

The log-likelihood function for the SARMA model is

$$\mathcal{L} = -\frac{n}{2}\ln(2\pi\sigma^2) - \frac{\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})\right]'\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})\right]}{2\sigma^2} + \ln|\mathbf{A}| - \ln|\mathbf{B}|$$

where $\mathbf{A} = \mathbf{I}_n - \rho\mathbf{W}_1$, $\mathbf{B} = \mathbf{I}_n - \lambda\mathbf{W}_2$ and $|\cdot|$ denotes the matrix determinant operator.

For the SARMA model, the gradients are

$$\frac{\partial\mathcal{L}}{\partial\boldsymbol{\beta}} = \frac{(\mathbf{B}^{-1}\mathbf{X})'\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})\right]}{\sigma^2}$$

$$\frac{\partial\mathcal{L}}{\partial\rho} = \frac{\left(\mathbf{B}^{-1}\mathbf{W}_1\mathbf{y}\right)'\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})}{\sigma^2} - \mathrm{tr}(\mathbf{A}^{-1}\mathbf{W}_1)$$

$$\frac{\partial\mathcal{L}}{\partial\lambda} = -\frac{1}{\sigma^2}\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})\right]'\left[\mathbf{B}^{-1}\mathbf{W}_2\right]\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})\right] + \mathrm{tr}(\mathbf{B}^{-1}\mathbf{W}_2)$$

$$\frac{\partial\mathcal{L}}{\partial\sigma^2} = -\frac{n}{2\sigma^2} + \frac{\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})\right]'\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})\right]}{2\sigma^4}$$

Spatial Durbin Autoregressive Moving Average Models

You can also accommodate exogenous interaction effects in the SARMA model. The term spatial Durbin autoregressive moving average (SDARMA) model is used to refer to such an extension of the SARMA model. Let y_i denote the observation associated with the spatial unit $\mathbf{s}_i$ for $i = 1, 2, \ldots, n$. For these spatial units, let $\mathbf{W}_1$ and $\mathbf{W}_2$ be two spatial weights matrices. Further, let $\mathbf{x}_i$ be a $p \times 1$ vector that denotes values of p regressors recorded at unit $\mathbf{s}_i$. Similarly, let $\mathbf{z}_i$ be a $q \times 1$ vector that denotes values of q regressors measured at unit $\mathbf{s}_i$.

The SDARMA model can be described in vector form by using the following two-stage formulation,

$$\mathbf{y} = \rho\mathbf{W}_1\mathbf{y} + \mathbf{X}\boldsymbol{\beta} + \mathbf{W}_1\mathbf{Z}\boldsymbol{\theta} + \mathbf{u}$$

$$\mathbf{u} = (\mathbf{I}_n - \lambda\mathbf{W}_2)\boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, y_2, \ldots, y_n)'$ and $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_n)'$, with $\epsilon_i \overset{\text{iid}}{\sim} \mathrm{N}(0, \sigma^2)'$. Moreover, $\mathbf{X}$ is an $n \times p$ matrix that has $\mathbf{x}_i'$ in each row, $\mathbf{Z}$ is an $n \times q$ matrix that has $\mathbf{z}_i'$ in each row. In addition, $\boldsymbol{\beta}$ is a $p \times 1$ parameter vector.

By letting $\widetilde{X} = [\mathbf{X} \;\; \mathbf{W}_1\mathbf{Z}]$ and $\widetilde{\boldsymbol{\beta}} = (\boldsymbol{\beta}' \; \boldsymbol{\theta}')'$, the SDARMA model can be written as

$$\mathbf{y} = \rho\mathbf{W}_1\mathbf{y} + \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}} + (\mathbf{I}_n - \lambda\mathbf{W}_2)\boldsymbol{\epsilon}$$

The log-likelihood function for the SDARMA model is

$$\mathcal{L} = -\frac{n}{2}\ln(2\pi\sigma^2) - \frac{\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]'\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]}{2\sigma^2} + \ln|\mathbf{A}| - \ln|\mathbf{B}|$$

where $\mathbf{A} = \mathbf{I}_n - \rho\mathbf{W}_1$ and $\mathbf{B} = \mathbf{I}_n - \lambda\mathbf{W}_2$.

For the SDARMA model, the gradients are

$$\frac{\partial\mathcal{L}}{\partial\widetilde{\boldsymbol{\beta}}} = \frac{(\mathbf{B}^{-1}\widetilde{\mathbf{X}})'\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]}{\sigma^2}$$

$$\frac{\partial\mathcal{L}}{\partial\rho} = \frac{\left(\mathbf{B}^{-1}\mathbf{W}_1\mathbf{y}\right)'\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})}{\sigma^2} - \mathrm{tr}(\mathbf{A}^{-1}\mathbf{W}_1)$$

$$\frac{\partial\mathcal{L}}{\partial\lambda} = -\frac{1}{\sigma^2}\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]'\left[\mathbf{B}^{-1}\mathbf{W}_2\right]\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right] + \mathrm{tr}(\mathbf{B}^{-1}\mathbf{W}_2)$$

$$\frac{\partial\mathcal{L}}{\partial\sigma^2} = -\frac{n}{2\sigma^2} + \frac{\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]'\left[\mathbf{B}^{-1}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]}{2\sigma^4}$$

Spatial Autoregressive Confused Models

The spatial autoregressive confused (SAC) model, like the SARMA model, can accommodate spatial dependence in both the dependent variable and error terms. However, the covariance structure for the error terms in a SAC model is different from that of the SARMA model. Let y_i denote the observation associated with the spatial unit s_i for $i = 1, 2, \ldots, n$. For these spatial units, let $\mathbf{W}_1$ and $\mathbf{W}_2$ be two spatial weights matrices. Further, let $\mathbf{x}_i$ be a $p \times 1$ vector that denotes values of p regressors recorded at unit s_i.

The SAC model can be described in vector form by using the following two-stage formulation (LeSage and Pace 2009),

$$\mathbf{y} = \rho\mathbf{W}_1\mathbf{y} + \mathbf{X}\boldsymbol{\beta} + \mathbf{u}$$

$$\mathbf{u} = \lambda\mathbf{W}_2\boldsymbol{u} + \boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, y_2, \ldots, y_n)'$ and $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_n)'$, with $\epsilon_i \overset{\text{iid}}{\sim} \mathrm{N}(0, \sigma^2)'$. Moreover, $\mathbf{X}$ is an $n \times p$ matrix that has $\mathbf{x}_i'$ in each row. In addition, $\boldsymbol{\beta}$ is a $p \times 1$ parameter vector.

The log-likelihood function for the SAC model is

$$\mathcal{L} = -\frac{n}{2}\ln(2\pi\sigma^2) - \frac{[\mathbf{B}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})]'[\mathbf{B}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})]}{2\sigma^2} + \ln|\mathbf{A}| + \ln|\mathbf{B}|$$

where $\mathbf{A} = \mathbf{I}_n - \rho\mathbf{W}_1$ and $\mathbf{B} = \mathbf{I}_n - \lambda\mathbf{W}_2$.

For the SAC model, the gradients are

$$\frac{\partial\mathcal{L}}{\partial\boldsymbol{\beta}} = \frac{(\mathbf{B}\mathbf{X})'[\mathbf{B}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})]}{\sigma^2}$$

$$\frac{\partial\mathcal{L}}{\partial\rho} = \frac{(\mathbf{B}\mathbf{W}_1\mathbf{y})'\mathbf{B}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})}{\sigma^2} - \mathrm{tr}(\mathbf{A}^{-1}\mathbf{W}_1)$$

$$\frac{\partial\mathcal{L}}{\partial\lambda} = \frac{1}{\sigma^2}[\mathbf{W}_2(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})]'[\mathbf{B}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})] - \mathrm{tr}(\mathbf{B}^{-1}\mathbf{W}_2)$$

$$\frac{\partial\mathcal{L}}{\partial\sigma^2} = -\frac{n}{2\sigma^2} + \frac{[\mathbf{B}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})]'[\mathbf{B}(\mathbf{A}\mathbf{y} - \mathbf{X}\boldsymbol{\beta})]}{2\sigma^4}$$

Spatial Durbin Autoregressive Confused Models

The SAC model can be extended to account for exogenous interaction effects. The term spatial Durbin autoregressive confused (SDAC) model is used to refer to such an extension of the SAC model. Let y_i denote the observation associated with the spatial unit s_i for $i = 1, 2, \ldots, n$. For these spatial units, let $\mathbf{W}_1$ and $\mathbf{W}_2$ be two spatial weights matrices. Further, let $\mathbf{x}_i$ be a $p \times 1$ vector that denotes values of p regressors recorded at unit s_i. Similarly, assume that $\mathbf{z}_i$ is a $q \times 1$ vector that denotes values of q regressors measured at unit s_i.

The SDAC model can be described in vector form by using the following two-stage formulation,

$$\mathbf{y} = \rho\mathbf{W}_1\mathbf{y} + \mathbf{X}\boldsymbol{\beta} + \mathbf{W}_1\mathbf{Z}\boldsymbol{\theta} + \mathbf{u}$$

$$\mathbf{u} = (\mathbf{I}_n - \lambda\mathbf{W}_2)^{-1}\boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, y_2, \ldots, y_n)'$ and $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_n)'$, with $\epsilon_i \overset{\text{iid}}{\sim} \mathrm{N}(0, \sigma^2)$. Moreover, $\mathbf{X}$ is an $n \times p$ matrix that has $\mathbf{x}_i'$ in each row, $\mathbf{Z}$ is an $n \times q$ matrix that has $\mathbf{z}_i'$ in each row. In addition, $\boldsymbol{\beta}$ is a $p \times 1$ parameter vector.

By letting $\widetilde{X} = [\mathbf{X} \;\; \mathbf{W}_1\mathbf{Z}]$ and $\widetilde{\boldsymbol{\beta}} = (\boldsymbol{\beta}' \; \boldsymbol{\theta}')'$, the SDAC model can be rewritten as

$$\mathbf{y} = \rho\mathbf{W}_1\mathbf{y} + \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}} + (\mathbf{I}_n - \lambda\mathbf{W}_2)^{-1}\boldsymbol{\epsilon}$$

The log-likelihood function for the SDAC model is

$$\mathcal{L} = -\frac{n}{2}\ln(2\pi\sigma^2) - \frac{\left[\mathbf{B}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]'\left[\mathbf{B}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]}{2\sigma^2} + \ln|\mathbf{A}| + \ln|\mathbf{B}|$$

For the SDAC model, the gradients are

$$\frac{\partial\mathcal{L}}{\partial\widetilde{\boldsymbol{\beta}}} = \frac{(\mathbf{B}\widetilde{\mathbf{X}})'\left[\mathbf{B}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]}{\sigma^2}$$

$$\frac{\partial\mathcal{L}}{\partial\rho} = \frac{(\mathbf{B}\mathbf{W}_1\mathbf{y})'\,\mathbf{B}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})}{\sigma^2} - \mathrm{tr}(\mathbf{A}^{-1}\mathbf{W}_1)$$

$$\frac{\partial\mathcal{L}}{\partial\lambda} = \frac{1}{\sigma^2}\left[\mathbf{W}_2(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]'\left[\mathbf{B}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right] - \mathrm{tr}(\mathbf{B}^{-1}\mathbf{W}_2)$$

$$\frac{\partial\mathcal{L}}{\partial\sigma^2} = -\frac{n}{2\sigma^2} + \frac{\left[\mathbf{B}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]'\left[\mathbf{B}(\mathbf{A}\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})\right]}{2\sigma^4}$$

Linear Regression Models

You can also fit a linear regression model in PROC SPATIALREG. In this case, let y_i denote the observation associated with the spatial unit $\mathbf{s}_i$ for $i = 1, 2, \ldots, n$. Further, let $\mathbf{x}_i$ be a $p \times 1$ vector that denotes values of p regressors recorded at unit $\mathbf{s}_i$.

The linear regression model can be described in vector form as

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, y_2, \ldots, y_n)'$ and $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_n)'$, with $\epsilon_i \overset{\text{iid}}{\sim} \mathrm{N}(0, \sigma^2)$. Moreover, $\mathbf{X}$ is an $n \times p$ matrix that has $\mathbf{x}_i'$ in each row.

The log-likelihood function for the linear regression model is

$$\mathcal{L} = -\frac{n}{2}\ln(2\pi\sigma^2) - \frac{(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})'(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})}{2\sigma^2}$$

For the linear regression model, the gradients are

$$\frac{\partial\mathcal{L}}{\partial\boldsymbol{\beta}} = \frac{\mathbf{X}'(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})}{\sigma^2}$$

$$\frac{\partial\mathcal{L}}{\partial\sigma^2} = -\frac{n}{2\sigma^2} + \frac{(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})'(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})}{2\sigma^4}$$

The Hessians take the following forms:

$$\frac{\partial^2 \mathcal{L}}{\partial \boldsymbol{\beta} \partial \boldsymbol{\beta}'} = -\frac{\mathbf{X}'\mathbf{X}}{\sigma^2}$$

$$\frac{\partial^2 \mathcal{L}}{\partial \boldsymbol{\beta} \partial \sigma^2} = -\frac{\mathbf{X}'(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})}{\sigma^4}$$

$$\frac{\partial^2 \mathcal{L}}{\partial \sigma^4} = \frac{n}{2\sigma^4} - \frac{(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})'(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})}{\sigma^6}$$

Spatial Lag of X Models

The spatial lag of X (SLX) model assumes no endogenous interaction effects or spatial dependence in the error terms. Instead, it incorporates only exogenous interaction effects into the linear regression model. Let y_i denote the observation associated with the spatial unit s_i for $i = 1, 2, \ldots, n$. For these spatial units, let $\mathbf{W}$ be a spatial weights matrix. Further, let $\mathbf{x}_i$ be a $p \times 1$ vector that denotes values of p regressors recorded at unit s_i. Similarly, let $\mathbf{z}_i$ be a $q \times 1$ vector that denotes values of q regressors measured at unit s_i.

The SLX model can be described in vector form as

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{WZ}\boldsymbol{\theta} + \boldsymbol{\epsilon}$$

where $\mathbf{y} = (y_1, y_2, \ldots, y_n)'$ and $\boldsymbol{\epsilon} = (\epsilon_1, \epsilon_2, \ldots, \epsilon_n)'$, with $\epsilon_i \overset{\text{iid}}{\sim} \mathrm{N}(0, \sigma^2)$. Moreover, $\mathbf{X}$ is an $n \times p$ matrix that has $\mathbf{x}_i'$ in each row, $\mathbf{Z}$ is an $n \times q$ matrix that has $\mathbf{z}_i'$ in each row. In addition, $\boldsymbol{\beta}$ is a $p \times 1$ parameter vector.

By letting $\widetilde{X} = [\mathbf{X} \;\; \mathbf{WZ}]$ and $\widetilde{\boldsymbol{\beta}} = (\boldsymbol{\beta}' \; \boldsymbol{\theta}')'$, the SLX model can be rewritten as

$$\mathbf{y} = \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}} + \boldsymbol{\epsilon}$$

The log-likelihood function for the SLX model is

$$\mathcal{L} = -\frac{n}{2}\ln(2\pi\sigma^2) - \frac{(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})'(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})}{2\sigma^2}$$

For the SLX model, the gradients are

$$\frac{\partial \mathcal{L}}{\partial \widetilde{\boldsymbol{\beta}}} = \frac{(\widetilde{\mathbf{X}})'(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})}{\sigma^2}$$

$$\frac{\partial \mathcal{L}}{\partial \sigma^2} = -\frac{n}{2\sigma^2} + \frac{(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})'(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})}{2\sigma^4}$$

The Hessians take the following forms:

$$\frac{\partial^2 \mathcal{L}}{\partial \widetilde{\boldsymbol{\beta}} \partial \widetilde{\boldsymbol{\beta}}'} = -\frac{\widetilde{\mathbf{X}}'\widetilde{\mathbf{X}}}{\sigma^2}$$

$$\frac{\partial^2 \mathcal{L}}{\partial \widetilde{\boldsymbol{\beta}} \partial \sigma^2} = -\frac{\widetilde{\mathbf{X}}'(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})}{\sigma^4}$$

$$\frac{\partial^2 \mathcal{L}}{\partial \sigma^4} = \frac{n}{2\sigma^4} - \frac{(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})'(\mathbf{y} - \widetilde{\mathbf{X}}\widetilde{\boldsymbol{\beta}})}{\sigma^6}$$

Specifying the Spatial Weights Matrix

The spatial weights matrix **W** plays a vital role in spatial econometric modeling. If you fit a purely linear model without SLX effects, you do not need a **W** matrix. For other types of models in PROC SPATIALREG, you need to provide a spatial weights matrix to fit the model. Although the creation of the **W** matrix is often problem-specific, there are some general guidelines to consider. Two common ways to create the **W** matrix are k-order binary contiguity matrices and k-nearest neighbor matrices (Elhorst 2013).

k-Order Binary Contiguity Matrices

You start with the spatial contiguity matrix **C**. In the case of the first-order neighbors ($k = 1$), a value of 1 for the (i, j)th entry in **C** indicates that the two units i and j are neighbors to each other, and 0 indicates otherwise. The neighbor relationship is often defined based on sharing of a common boundary. To generalize this, a k-order neighbor ($k \geq 2$) of a unit i can be any units whose neighbors are $(k-1)$-order neighbors of unit i. In this sense, the two units i and j that are not first-order neighbors can still be second-order neighbors if unit j is the neighbor to a first-order neighbor of unit i.

As an example, a first-order binary contiguity matrix might look like the following:

$$\mathbf{C} = \begin{pmatrix} \text{SID} & \text{L1} & \text{L2} & \text{L3} & \text{L4} \\ \text{L1} & 0 & 1 & 0 & 1 \\ \text{L2} & 1 & 0 & 0 & 0 \\ \text{L3} & 0 & 0 & 0 & 1 \\ \text{L4} & 1 & 0 & 1 & 0 \end{pmatrix}$$

The diagonal elements of **C** are zeros because, in general, a unit is not considered to be a neighbor of itself. Moreover, the two units L2 and L4 are neighbors of L1; L2 has L1 as its only neighbor; L3 has L4 as its only neighbor; and L4 has L1 and L3 as its neighbors. You can create the spatial weights matrix **W** by row-standardizing the contiguity matrix **C**. To do so, you divide entries in each row of **C** by the sum of that row. The spatial weights matrix **W**, which is the row-standardized version of **C**, is as follows:

$$\mathbf{W} = \begin{pmatrix} \text{SID} & \text{L1} & \text{L2} & \text{L3} & \text{L4} \\ \text{L1} & 0 & \frac{1}{2} & 0 & \frac{1}{2} \\ \text{L2} & 1 & 0 & 0 & 0 \\ \text{L3} & 0 & 0 & 0 & 1 \\ \text{L4} & \frac{1}{2} & 0 & \frac{1}{2} & 0 \end{pmatrix}$$

k-Nearest Neighbor Matrices

You can create a spatial contiguity matrix based on a distance metric. Let d_{ij} denote the distance between the two units i and j, which might be the Euclidean distance between centroids of the two spatial units. Let $(\text{lon}_i, \text{lat}_i)$ and $(\text{lon}_j, \text{lat}_j)$ be the centroids of units i and j, where $1 \leq i, j \leq n$, and lon and lat denote the longitude and latitude, respectively. Under the Euclidean distance metric, the distance d_{ij} between units i and j is

$$d_{ij} = \sqrt{(\text{lat}_i - \text{lat}_j)^2 + (\text{lon}_i - \text{lon}_j)^2}$$

After computing the distance between the unit i and other units under a certain metric, you sort d_{ij} in ascending order; for example, $d_{ij_1} \leq d_{ij_2} \leq \cdots \leq d_{ij_k} \leq \cdots \leq d_{ij_{n-1}}$. For a given k, let $N_k(i) = \{j_1, j_2, \ldots, j_k\}$ be

the set that contains the indices of k-nearest neighbors of unit i; then the (i, j)th entries of the contiguity matrix $\mathbf{C}$ are defined as

$$C_{ij} = \begin{cases} 1 & \text{if } j \in N_k(i) \\ 0 & \text{otherwise} \end{cases}$$

The (i, j)th entry of the corresponding row-standardized matrix $\mathbf{W}$ is $W_{ij} = C_{ij} \left\{ \sum_{j \in N_k(i)} C_{ij} \right\}^{-1}$.

Unlike the k-order binary contiguity matrix, which is often symmetric by construction, k-nearest neighbor matrices can be asymmetric. To obtain a symmetric k-nearest neighbor matrices, you can define the (i, j)th entries of the contiguity matrix $\mathbf{C}$ as follows:

$$C_{ij} = \begin{cases} 1 & \text{if } j \in N_k(i) \text{ or } i \in N_k(j) \\ 0 & \text{otherwise} \end{cases}$$

In addition to the Euclidean distance measure, you can use other distance metrics as appropriate. A variant of k-nearest neighbor matrices $\mathbf{C}^*$ that is used in some empirical studies defines its (i, j)th entries as

$$C^*_{ij} = \begin{cases} 1 & \text{if } d_{ij} \le d_{\text{cutoff}} \\ 0 & \text{otherwise} \end{cases}$$

where d_{cutoff} is a prespecified threshold distance.

In addition to the two constructions of spatial weights matrices that are presented earlier, see Elhorst (2013) and the references therein for more information about other ways to create a spatial weights matrix. In practice, you can define the neighbor relation that is problem-specific. For example, you can define two spatial units that are far apart to be neighbors because they share some attributes (such as population sizes larger than 500,000).

The data set that you specify in the WMAT= option is row-standardized by default to create a spatial weights matrix. This means that if you specify WMAT=C, PROC SPATIALREG row-standardizes the spatial contiguity matrix to create a spatial weights matrix. If you want to suppress row standardization, you must specify the NONORMALIZE option.

Compact Representation of Spatial Weights Matrix

When the number of spatial units n increases, the amount of memory that it takes to store n^2 entries of the spatial contiguity matrix $\mathbf{C}$ or the spatial weights matrix $\mathbf{W}$ increases dramatically. To circumvent the storage issue, PROC SPATIALREG enables you to provide a compact representation of $\mathbf{W}$ (or $\mathbf{C}$) when appropriate. With the compact matrix representation, you provide a data set that contains three variables by using the WMAT= option. The first two variables identify the row r and column c of $\mathbf{W}$ (or $\mathbf{C}$), and (r, c) can be expressed either as numerical indices or as values of the variable specified in the SPATIALID statement. The third variable contains the nonzero value of $\mathbf{W}$ (or $\mathbf{C}$) for row r and column c. With this compact representation, the number of observations in the data set specified in the WMAT= option equals the total number of nonzero entries in $\mathbf{W}$ (or $\mathbf{C}$).

You must use a SPATIALID statement if you want to use the compact representation of the spatial contiguity or spatial weights matrix. With the compact representation, the first two variables of the data set that you

specify in the WMAT= option must be of the same type. First, the first two columns in that data set can be row and column index for each nonzero entry in **W** (or **C**). In this case, the SPATIALID variable is numeric type. Alternatively, the first two columns in the WMAT= data set can be characters that are the names of two neighboring spatial units in **W** (or **C**). In this second case, the SPATIALID variable is character type.

For example, the compact representation of the spatial weights matrix **W**,

$$\mathbf{W} = \begin{pmatrix} 0 & 0.5 & 0 & 0.5 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0.5 & 0 & 0.5 & 0 \end{pmatrix}$$

would look like the following:

```
data Ws;
  input SID cSID Weight;
  datalines;
  1 2 0.5
  1 4 0.5
  2 1 1.0
  3 4 1.0
  4 1 0.5
  4 3 0.5
  ;
run;
```

For the spatial contiguity matrix **C**,

$$\mathbf{C} = \begin{pmatrix} 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \end{pmatrix}$$

the compact representation would look like the following:

```
data Cs;
  input SID cSID Weight;
  datalines;
  1 2 1.0
  1 4 1.0
  2 1 1.0
  3 4 1.0
  4 1 1.0
  4 3 1.0
  ;
run;
```

If the spatial weights matrix is the same as matrix **W** in the section "***k*-Order Binary Contiguity Matrices**" on page 2333, its compact representation would be as follows:

```
data Ws2;
  input SID $ cSID $ Weight;
  datalines;
  L1 L2 0.5
```

```
  L1 L4 0.5
  L2 L1 1.0
  L3 L4 1.0
  L4 L1 0.5
  L4 L3 0.5
  ;
run;
```

If the spatial contiguity matrix is the same as matrix **C** in the section "*k*-Order Binary Contiguity Matrices" on page 2333, its compact representation can be given in the data set Cs2 as follows:

```
data Cs2;
  input SID $ cSID $ Weight;
  datalines;
  L1 L2 1.0
  L1 L4 1.0
  L2 L1 1.0
  L3 L4 1.0
  L4 L1 1.0
  L4 L3 1.0
  ;
run;
```

Spatial ID Matching

Depending on the type of model that you use in PROC SPATIALREG, you might need to specify two data sets: one in the DATA= option and the other in the WMAT= option. However, in some cases, these two data sets might not come in the same order in terms of spatial units. In such cases, you must use a SPATIALID statement to specify a spatial ID variable in order to match observations in these two data sets.

As an example, assume that the data set you specify in the DATA= option looks like the following:

```
data example;
  input SID $ x1 x2 y;
  datalines;
  L1  0.3  0.5  0.9
  L3 -0.7  0.8 -0.4
  L2  0.4 -1.2  0.6
  L8 -1.7  1.2 -0.5
  L4  1.4  0.9  0.3
  L5  2.3  1.5  1.9
  L7 -0.9 -0.8 -1.3
  L6  1.4 -1.6 -2.0
  ;
run;
```

Suppose the spatial contiguity matrix that you specify in the WMAT= option looks like the following:

```
data cmat;
  input SID $ L1 L8 L3 L4 L7 L6 L5 L2;
  datalines;
  L1  0 1 0 1 0 1 0 1
  L2  1 0 0 0 1 0 0 0
```

```
  L6  1 0 1 0 0 0 0 0
  L4  1 0 0 0 1 0 0 0
  L3  0 0 0 0 1 1 0 0
  L7  0 0 1 1 0 0 0 1
  L5  0 1 0 0 0 0 0 0
  L8  1 0 0 0 0 0 1 0
  ;
run;
```

As you can see, rows in the two data sets Example and Cmat do not share identically sorted SID values. The second row in the Example data set contains the observation for a spatial unit L3, and its neighbor information is given in the fifth row of the Cmat data set. Moreover, the rows and columns of the spatial weights data set Cmat are not in the same order. The following SAS statements fit a SAR model to these data:

```
proc spatialreg data=example Wmat=cmat;
  model y=x1 x2/type=SAR;
  spatialid SID;
run;
```

The SPATIALID statement enables you to match rows and columns of Cmat in addition to rows of Example and Cmat. Without the SPATIALID statement, you need to sort Cmat so that the order of its rows and columns matches that of Example. The sorted data set, Cmat2, would look like the following:

```
data cmat2;
  input SID $ L1 L3 L2 L8 L4 L5 L7 L6;
  datalines;
  L1  0 0 1 1 1 0 0 1
  L3  0 0 0 0 0 0 1 1
  L2  1 0 0 0 0 0 1 0
  L8  1 0 0 0 0 1 0 0
  L4  1 0 0 0 0 0 1 0
  L5  0 0 0 1 0 0 0 0
  L7  0 1 1 0 1 0 0 0
  L6  1 1 0 0 0 0 0 0
  ;
run;
```

Parameter Space of Spatial Coefficients

For all models except linear regression models in PROC SPATIALREG, the autoregressive parameters ρ and λ are often assumed to satisfy some assumptions to ensure consistency of the maximum likelihood estimator (Elhorst 2013). For SAR and SDM models, the Jacobian term involves the log-determinant of $\mathbf{I} - \rho\mathbf{W}_1$, and the parameter space of ρ is often specified such that $\mathbf{I} - \rho\mathbf{W}_1$ is nonsingular. For SEM, SMA, SDM, and SDMA models, the Jacobian term involves the log-determinant of $\mathbf{I} - \lambda\mathbf{W}_1$, and the parameter space of λ is often specified such that $\mathbf{I} - \lambda\mathbf{W}_1$ is nonsingular. For SAC, SDAC, SARMA, and SDARMA models, the Jacobian term involves the log-determinants of both $\mathbf{I} - \rho\mathbf{W}_1$ and $\mathbf{I} - \lambda\mathbf{W}_1$. As a result, the parameter space of ρ and λ is often specified such that both $\mathbf{I} - \rho\mathbf{W}_1$ and $\mathbf{I} - \lambda\mathbf{W}_1$ are nonsingular.

In the SPATIALREG procedure, the parameter space of spatial coefficients ρ and λ depends on the spatial weights matrix $\mathbf{W}$ that you choose. For $\mathbf{W}$, the parameter space of the autoregressive parameters ρ and λ in PROC SPATIALREG is determined as follows:

1. For a symmetric $\mathbf{W}$, the nonsingularity condition requires $\rho \in \left(\omega_{\min}^{-1}, \omega_{\max}^{-1}\right)$ and $\lambda \in \left(\omega_{\min}^{-1}, \omega_{\max}^{-1}\right)$. Here $\omega_{\min}$ and $\omega_{\max}$ denote the smallest (that is, most negative) and largest real eigenvalues of $\mathbf{W}$, respectively.

2. If $\mathbf{W}$ is symmetric and subsequently row-standardized, the nonsingularity condition requires $\rho \in \left({\omega^*_{\min}}^{-1}, 1\right)$ and $\lambda \in \left({\omega^*_{\min}}^{-1}, 1\right)$. Here $\omega^*_{\min}$ denotes the smallest purely real eigenvalue of the row-standardized $\mathbf{W}$.

3. If $\mathbf{W}$ is asymmetric and subsequently row-standardized, the nonsingularity condition requires $\rho \in \left({r^*_{\min}}^{-1}, 1\right)$ and $\lambda \in \left({r^*_{\min}}^{-1}, 1\right)$. Here $r^*_{\min}$ denotes the smallest purely real eigenvalue of the row-standardized $\mathbf{W}$.

4. When Taylor approximation or Chebyshev approximation is used for SAR and SDM models, $\mathbf{W}$ is required to be row-standardized. In these cases, the restriction on the autoregressive coefficient ρ is $\rho \in (-1, 1)$.

   For the interpretation of the spatial coefficient ρ, a significant and positive (or negative) value of ρ in the SAR, SDM, SAC, SDAC, SARMA, and SDARMA models would suggest positive (or negative) spatial lag dependence. Similarly, a significant and positive (or negative) value of λ in the SEM, SDEM, SAC, and SDAC models would suggest positive (or negative) spatial error dependence, which is contrary to the SMA, SDMA, SARMA, and SDARMA models. For the SMA, SDMA, SARMA, and SDARMA models, a significant and positive (or negative) value of λ would suggest negative (or positive) spatial error dependence.

Approximations to the Jacobian

In order for PROC SPATIALREG to obtain maximum likelihood estimates for all models except linear regression models, it needs to compute the Jacobian term because that term appears in the log-likelihood function. The Jacobian term is $\ln|\mathbf{I}_n - \rho\mathbf{W}|$ for SDMs and SAR models and $\ln|\mathbf{I}_n - \lambda\mathbf{W}|$ for SEMs and SDEMs, where n is the number of observations and $\mathbf{W}$ is the spatial weights matrix. When n is not large, the Jacobian is computed as

$$\ln|\mathbf{I}_n - \rho\mathbf{W}| = \sum_{i=1}^{n} \ln|1 - \rho\omega_i|$$

where ω_i are the eigenvalues of $\mathbf{W}$. This computation requires that all eigenvalues of $\mathbf{W}$ be precomputed, which works fine for small data sets. However, when n is large, computing the Jacobian term by using the eigenvalue method can be computationally infeasible. Instead, you can use approximations to the Jacobian.

The SPATIALREG procedure supports two different approximations to the Jacobian for SDMs, SEMs, SDEMs, and SAR models: Taylor approximation or Chebyshev approximation. Using SDMs and SAR models as an example, the two approximations for the Jacobian term can be described as follows (for more information, see LeSage and Pace 2009, and the references therein):

- Taylor approximation uses finite, lower-order series to approximate the log-determinant as

$$\ln|\mathbf{I}_n - \rho\mathbf{W}| \approx -\sum_{k=1}^{q} \frac{\rho^k \operatorname{tr}\left(\mathbf{W}^k\right)}{k}$$

- Chebyshev approximation uses finite, lower-order Chebyshev polynomials of the first kind to approximate the log-determinant as

$$\ln|\mathbf{I}_n - \rho\mathbf{W}| \approx \sum_{k=0}^{q} c_k(\rho)\operatorname{tr}\left(T_k(\mathbf{W})\right)$$

  where $T_0(\mathbf{W}) = \mathbf{I}_n$, $T_1(\mathbf{W}) = \mathbf{W}$, and $T_{k+1}(\mathbf{W}) = 2\mathbf{W}T_k(\mathbf{W}) - T_{k-1}(\mathbf{W})$ for $k = 1, 2, \ldots, q$. The coefficients $c_k(\rho)$ are defined as

$$c_k(\rho) = \begin{cases} \frac{1}{q+1}\sum_{j=0}^{q} \ln(1-\rho\cos\theta_j)\cos(k\theta_j) & \text{if } k = 0 \\ \frac{2}{q+1}\sum_{j=0}^{q} \ln(1-\rho\cos\theta_j)\cos(k\theta_j) & \text{if } k > 0 \end{cases}$$

  with $\theta_j = (j+1)\pi/(q+1)$ for $j = 0, 1, \ldots, q$.

The traces of powers of $\mathbf{W}$ can be computed exactly or approximated using Monte Carlo simulation. The Monte Carlo simulation is done as follows,

$$\operatorname{tr}\left(\mathbf{W}^k\right) \approx \frac{1}{M}\sum_{l=1}^{M} \frac{n}{\mathbf{u}_l'\mathbf{u}_l}\mathbf{u}_l'\mathbf{W}^k\mathbf{u}_l$$

where $\mathbf{u}_l \overset{\text{iid}}{\sim} \mathrm{N}(\mathbf{0}, \mathbf{I}_n)$ and M is the total number of Monte Carlo samples.

When you apply these two approximations, it is often assumed that the maximum eigenvalue of $\mathbf{W}$ equals 1 and the minimum eigenvalue of $\mathbf{W}$ is greater than or equal to –1 (see LeSage and Pace 2009, and the references therein). One way to satisfy this assumption is to use a row-standardized spatial weights matrix that is similar to a symmetric matrix. If the spatial weights matrix is not symmetric or similar to a symmetric matrix, it becomes more difficult to apply Chebyshev approximation and thus requires extra care (LeSage and Pace 2009).

When you request an approximation to the Jacobian, the choices that you need to make might include the approximation method to use (that is, Taylor approximation or Chebyshev approximation); the order of series q; and the number of Monte Carlo samples (that is, M). Your choice can be accommodated through the APPROXIMATION= option in the PROC SPATIALREG statement. For the approximation method, you can use the keyword TAYLOR in the APPROXIMATION= option to request Taylor approximation. Otherwise, the approximation method defaults to Chebyshev approximation. You specify ORDER=q in the APPROXIMATION= option to request a series of order q when approximating the log-determinant. In addition, you specify NMC=M in the APPROXIMATION= option to request M Monte Carlo samples to be drawn when approximating the traces of powers of $\mathbf{W}$. In addition, you can use the SEED= suboption of the APPROXIMATION= option to specify an integer seed for a random number generator to replicate your analysis.

Parameter Naming Conventions for RESTRICT, TEST, BOUNDS, and INIT Statements

This section describes how you refer to the parameters when using either the RESTRICT, TEST, BOUNDS, or INIT statement. The examples are presented using the RESTRICT statement. However, the same remarks apply to referencing parameters when you use the TEST, BOUNDS, or INIT statement.

To impose a restriction on a parameter related to a regressor in the MODEL statement, you simply use the name of the regressor itself. Suppose your model is

```
model y = x1-x3 / type=SAR;
```

where x1-x3 are continuous variables. Suppose you want to restrict the parameter associated with the regressor x3 to be greater than 1.7. You should provide the following statement:

```
RESTRICT x3 > 1.7;
```

To impose a restriction on a parameter associated with a regressor in the SPATIALEFFECTS statement, you can form the name of the parameter by prefixing W_ to the name of the regressor. Suppose your MODEL and SPATIALEFFECTS statements are as follows:

```
model y = x1-x3 / type=SAR;
spatialeffects x1 x2 x3;
```

Suppose you want to restrict the parameter related to the x3 regressor in the SPATIALEFFECTS statement to be less than 1.0. You should refer to the parameter as W_x3 and provide the following statement:

```
RESTRICT W_x3 < 1.0;
```

Even though the regressor x3 appears in both the MODEL and SPATIALEFFECTS statements, the parameter associated with x3 in the MODEL statement is, of course, different from the parameter associated with x3 in the SPATIALEFFECTS statement. Thus, when the name of a regressor is used in a RESTRICT statement without any prefix, it refers to the parameter associated with that regressor in the MODEL statement. Meanwhile, when the name of a regressor is used in a RESTRICT statement with the prefix W_, it refers to the parameter associated with that regressor in the SPATIALEFFECTS statement. Note that the intercept is not included in the SPATIALEFFECTS statement.

Referring to Class Level Parameters

When your MODEL includes a CLASS variable, you can impose restrictions on the parameters associated with each of the levels related to that variable as described in this section.

Suppose your CLASS variable is named C and has three levels: 0, 1, 2. Suppose your model is the following:

```
class C;
model y = x1 x2 C;
```

Adding a CLASS variable as a regressor to your model introduces additional parameters to your model, each of which is associated with one of the levels of that variable. You can form the name of the parameter associated with a particular level of your CLASS variable by inserting the underscore character between the name of the variable and the value of the level. Thus, to restrict the parameter associated with level 0 of the CLASS variable C to always be greater than 0.7, you should refer to the parameter as C_0 and provide the following statement:

```
RESTRICT C_0 > 0.7;
```

When the value of a level is a negative number, you must replace the minus sign with an underscore when you form the name of the parameter associated with that particular level of the CLASS variable. For example, suppose your CLASS variable is named D and has four levels: –1, 0, 1, 2. Suppose your model is the following:

```
class D;
model y = x1 x2 D;
```

To restrict the parameter associated with level –1 of the CLASS variable D to always be less than 0.4, you should refer to the parameter as D__1 (note that there are two underscores in this parameter name: one to connect the name of the variable to its value and the other to replace the minus sign in the value itself). The following statement imposes the restriction on the parameter in question:

```
RESTRICT D__1 < 0.4;
```

Depending on the parameterization that you impose on your CLASS variable, one of the parameters associated with its levels can be dropped from your model before optimization in order to avoid collinearity. For example, when the default parameterization GLM is imposed, the parameter associated with the last level of your CLASS variable is dropped before optimization. If you attempt to impose a restriction on a dropped parameter by using the RESTRICT statement, you receive an error message in the log.

For example, suppose once again that your CLASS variable is named C and that it has three levels: 0, 1, 2. Suppose your model is the following:

```
class C;
model y = x1 x2 C;
```

Because no additional options were specified in the CLASS statement, the GLM parameterization is assumed. This entails that the parameter named C_2 (which is the parameter associated with the last level of your CLASS variable) will be dropped from your model before the optimizer is invoked. Therefore, you generate an error if you attempt to restrict the C_2 parameter in any way by referring to it in a RESTRICT statement. For example, the following RESTRICT statement generates an error:

```
RESTRICT C_2 < 0.3;
```

Referring to Parameters Associated with Interactions between Regressors

When a regressor in your model involves an interaction between other regressors, you can impose restrictions on the parameters associated with the interaction as described in this section.

Suppose you have the following model:

```
model y = x1 x2 x3*x4;
```

You can form the name of the parameter associated with the interaction regressor x3*x4 by replacing the multiplication sign with an underscore. Thus, x3_x4 refers to the parameter associated with the interaction regressor x3*x4.

Referring to interactions between regressors and CLASS variables is handled in exactly the same way. Suppose you have a CLASS variable named C that has three levels (0, 1, 2), and that your model is the following:

```
class C;
model y = x1 x2 C*x3;
```

The interaction between the continuous variable x3 and the CLASS variable C introduces three additional parameters, which are named x3_C_0, x3_C_1, and x3_C_2. Note that, although the order of the terms in the interaction is C followed by x3, the name of the parameter associated with the interaction is formed by placing the name of the continuous variable x3 first, followed by an underscore, followed by the name of the CLASS variable C, followed by another underscore, and then followed by the level value. Once again, depending on the parameterization that you specify in your CLASS statement, for each interaction in your model that involves a CLASS variable, one of the parameters associated with that interaction can be dropped from your model before optimization.

The name of a parameter associated with a nested interaction is formed in a slightly different way. Suppose you have a CLASS variable named C that has three levels (0, 1, 2) and your model is the following:

```
class C;
model y = x1 x2 x3(C);
```

The nested interaction between the continuous variable x3 and the CLASS variable C introduces three additional parameters, which are named x3_C__0, x3_C__1, and x3_C__2. Note how the name in each case was formed from the name of the regressor by replacing the left and right parentheses with underscores and then appending another underscore followed by the level value.

Referring to Implicit Parameters

For all models in PROC SPATIALREG, one or more implicit parameters are added to your model before optimization. You can impose restrictions on these implicit parameters as follows.

If you have a linear model or SLX model, the _sigma2 parameter is added to your model. For the SAR or SDM model, the _rho and _sigma2 parameters are added to your model.

If you specify TYPE=SEM or TYPE=SMA, the _lambda and _sigma2 parameters are added to your model. If you specify the TYPE=SAC or TYPE=SARMA option, then three implicit parameters are added to your model: _rho, _lambda, and _sigma2.

Whenever your model type dictates the addition of one or more of these implicit parameters, you can impose restrictions on the implicit parameters by referring to them by name. For example, assuming that your model type implies the existence of the _rho parameter, you can restrict _rho to be greater than 0 as follows:

```
RESTRICT _rho > 0.0;
```

Computational Resources

The time and memory that PROC SPATIALREG requires are proportional to the number of parameters in the model and the number of observations in the data set being analyzed. Also affecting resources are the method that is chosen to calculate the variance-covariance matrix and the optimization method. All optimization methods available through the METHOD= option have similar memory use requirements.

The processing time might differ for each method, depending on the number of iterations and functional calls needed. The data set is read into memory to save processing time. If not enough memory is available to hold the data, the SPATIALREG procedure stores the data in a utility file on disk and rereads the data as needed from this file. When this occurs, the execution time of the procedure increases substantially. The gradient and the variance-covariance matrix must be held in memory. If the model has p parameters, including the intercept, then at least $8(p + p(p+1)/2)$ bytes are needed. If the quasi–maximum likelihood method is used to estimate the variance-covariance matrix (COVEST=QML), an additional $8p(p+1)/2$ bytes of memory are needed.

Processing time is also a function of the number of iterations needed to converge to a solution for the model parameters. The number of iterations cannot be known in advance. The MAXITER= option can be used to limit the number of iterations that PROC SPATIALREG performs. The convergence criteria can be altered by nonlinear optimization options available in the PROC SPATIALREG statement. For a list of all the nonlinear optimization options, see Chapter 6, "Nonlinear Optimization Methods."

Nonlinear Optimization Options

PROC SPATIALREG uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. In the PROC SPATIALREG statement, you can specify nonlinear optimization options that are then passed to the NLO subsystem. For a list of all the nonlinear optimization options, see Chapter 6, "Nonlinear Optimization Methods."

Covariance Matrix Types

The SPATIALREG procedure enables you to specify the estimation method for the covariance matrix. The COVEST=HESSIAN option estimates the covariance matrix based on the inverse of the Hessian matrix, COVEST=OP uses the outer product of gradients, and COVEST=QML produces the covariance matrix based on both the Hessian and outer product matrices. By default, COVEST=HESSIAN.

Although all three methods produce asymptotically equivalent results, they differ in computational intensity and produce results that might differ in finite samples. The COVEST=OP option provides the covariance matrix that is usually the easiest to compute. In some cases, the OP approximation is considered more efficient than the Hessian or QML approximation because it contains fewer random elements. The QML approximation is computationally the most complex, because both the outer product of gradients and the Hessian matrix are required. In most cases, the OP or Hessian approximation is preferred to QML. The need to use QML approximation arises in some cases when the model is misspecified and the information matrix equality does not hold.

When Taylor approximation or Chebyshev approximation is used for the SAR and SDM models, only COVEST=HESSIAN is supported.

Displayed Output

PROC SPATIALREG produces the following displayed output.

Class Level Information

If you specify the CLASS statement, the SPATIALREG procedure displays a table that contains the following information:

- CLASS variable name
- number of levels of the CLASS variable
- list of values of the CLASS variable

Iteration History for Parameter Estimates

If you specify the ITPRINT or PRINTALL option in the PROC SPATIALREG statement, PROC SPATIALREG displays a table that contains the following information for each iteration. Some information is specific to the model-fitting procedure that you choose (for example, Newton-Raphson, trust region, quasi-Newton).

- iteration number
- number of restarts since the fitting began
- number of function calls
- number of active constraints at the current solution
- value of the objective function (the negative log-likelihood value) at the current solution
- change in the objective function from previous iteration
- value of the maximum absolute gradient element
- step size (for Newton-Raphson and quasi-Newton methods)
- slope of the current search direction (for Newton-Raphson and quasi-Newton methods)
- lambda (for trust region method)
- radius value at current iteration (for trust region method)

Model Fit Summary

The "Model Fit Summary" table contains the following information:

- dependent variable name
- number of observations used
- data set name
- name of the spatial weights data set (specified by the WMAT= option)
- type of model that was fit
- log-likelihood value at solution
- maximum absolute gradient at solution
- number of iterations
- AIC value at the solution (a smaller value indicates a better fit)
- SBC value at the solution (a smaller value indicates a better fit)

Below the "Model Fit Summary" table is a statement about whether the algorithm successfully converged.

Parameter Estimates

The "Parameter Estimates" table displays the estimates of the model parameters. In the SAR model, estimates are also displayed for the autoregressive coefficient ρ and the variance of the error terms σ^2. For the SEM, SDEM, SMA, and SDMA models, estimates are given for the autoregressive coefficient λ and the variance of the error terms σ^2. In addition, for SAC, SDAC, SARMA, and SDARMA models, estimates are given for the autoregressive coefficients ρ and λ, and the variance of the error terms σ^2. In the linear and SLX models, estimates are given for the variance of the error terms σ^2.

"_rho" is the internal name of the autoregressive coefficient ρ in the SAR, SDM, SARMA, SDARMA, SAC, and SDAC models. The t statistic given for "_rho" is a test of autoregressive coefficient. In addition, "_lambda" is the internal name of the autoregressive coefficient λ in the SEM, SDEM, SMA, SARMA, SAC, and SDAC models. Moreover, "_sigma2" is the internal name of the variance parameter σ^2.

Last Evaluation of the Gradient

If you specify the ITPRINT option in the MODEL statement, the SPATIALREG procedure displays the last evaluation of the gradient vector.

Covariance of Parameter Estimates

If you specify the COVB option in the MODEL statement or in the PROC SPATIALREG statement, the SPATIALREG procedure displays the estimated covariance matrix, defined as the inverse of the information matrix, evaluated at the final iteration.

Correlation of Parameter Estimates

If you specify the CORRB option in the MODEL statement or in the PROC SPATIALREG statement, PROC SPATIALREG displays the estimated correlation matrix. It is based on the Hessian matrix that is used in the final iteration.

OUTPUT OUT= Data Set

The OUTPUT statement creates a new SAS data set that contains all the variables in the input data set and, optionally, the estimates of $\mathbf{x}_i'\boldsymbol{\beta}$, the expected value of the response variable, and the residual.

OUTEST= Data Set

The OUTEST= data set has two rows: the first row (with _TYPE_='PARM') contains each of the parameter estimates in the model, and the second row (with _TYPE_='STD') contains the standard errors for the parameter estimates in the model.

If you specify the COVOUT option in the PROC SPATIALREG statement, the OUTEST= data set also contains the covariance matrix for the parameter estimates. The covariance matrix appears in the observations for which _TYPE_='COV', and the _NAME_ variable labels the rows with the parameter names.

The names of the parameters are used as variable names. These are the same names that are used in the INIT, BOUNDS, and RESTRICT statements.

ODS Table Names

PROC SPATIALREG assigns a name to each table that it creates. You can use these names to denote the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 31.3.

Table 31.3 ODS Tables Produced in PROC SPATIALREG

ODS Table Name	Description	Option
ODS Tables Created by the MODEL Statement		
ClassLevels	Class levels	Default
FitSummary	Summary of nonlinear estimation	Default
ConvergenceStatus	Convergence status	Default
ParameterEstimates	Parameter estimates	Default
CovB	Covariance of parameter estimates	COVB

Table 31.3 *continued*

ODS Table Name	Description	Option
CorrB	Correlation of parameter estimates	CORRB

Examples: SPATIALREG Procedure

Example 31.1: Columbus Crime Data

Data Description and Objective

The data set CRIMEOH contains data from Columbus, Ohio, about the number of crimes (including residential burglaries and vehicle thefts) and possible determinants of crime. This data set is taken from Anselin (1988) and can be found in the SAS/ETS Sample Library.

The variable CRIME represents the number of crimes in 49 neighborhoods of Columbus, Ohio. Additional variables in the data set that you want to evaluate as determinants of crimes include INCOME (household income by $1000) and HVALUE (housing value by $1000). Summary statistics for these variables are computed by the following statements and presented in Output 31.1.1:

```
proc means data=crimeoh;
   var crime income hvalue;
run;
```

Output 31.1.1 Summary Statistics

The MEANS Procedure

Variable	N	Mean	Std Dev	Minimum	Maximum
crime	49	35.1288367	16.7320385	0.1780000	68.8920000
income	49	14.3749388	5.7033781	4.4770000	31.0700000
hvalue	49	38.4362245	18.4660693	17.9000000	96.4000000

The spatial relationships among the 49 neighborhoods are summarized using the first-order neighbor contiguity matrix, contained in the CRIMEWMAT data set. This data set is also taken from Anselin (1988) and can be found in the SAS/ETS Sample Library.

Spatial Autoregressive (SAR) Model

The following statements fit a SAR model to the data by using the regressors INCOME and HVALUE:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime=income hvalue / type=SAR;
run;
```

In this example, the TYPE=SAR option in the MODEL statement specifies a SAR model. The NONORMALIZE option indicates that the spatial weights data set CRIMEWMAT should be used "as is" rather than be row-standardized. The parameter estimates for this model are shown in Output 31.1.2. According to the results, the spatial autoregressive coefficient ρ is positive and significant at the 0.05 level. This indicates that there is a positive spatial dependence in the data.

Output 31.1.2 Parameter Estimates of SAR Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	45.077070	7.870590	5.73	<.0001
income	1	-1.031531	0.328403	-3.14	0.0017
hvalue	1	-0.265924	0.088218	-3.01	0.0026
_rho	1	0.431020	0.123594	3.49	0.0005
_sigma2	1	95.487066	19.506312	4.90	<.0001

Spatial Durbin Model (SDM)

To fit an SDM model, you specify the SPATIALEFFECTS statement together with the TYPE=SAR option. In this example, the spatial lags of the regressors INCOME and HVALUE are considered in the SDM model.

The following statements fit an SDM model to the CRIMEOH data:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime=income hvalue / type=SAR;
   spatialeffects income hvalue;
run;
```

The parameter estimates are given in Output 31.1.3. As in the SAR model, the spatial autoregressive coefficient ρ in the SDM model is positive and significant at the 0.05 level, indicating a positive spatial dependence in the data.

Output 31.1.3 Parameter Estimates of SDM Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	42.803457	13.924487	3.07	0.0021
income	1	-0.914206	0.336439	-2.72	0.0066
hvalue	1	-0.293745	0.088857	-3.31	0.0009
W_income	1	-0.519640	0.594772	-0.87	0.3823
W_hvalue	1	0.245716	0.176854	1.39	0.1647
_rho	1	0.426492	0.167492	2.55	0.0109
_sigma2	1	91.779519	18.909222	4.85	<.0001

In order to avoid potential collinearity with the intercept term in the MODEL statement, the SPATIALEFFECTS statement always excludes the intercept term. This means that only the explicitly specified variables in the SPATIALEFFECTS statement are used to construct spatial lag of covariate effects.

Spatial Error Model (SEM)

To fit an SEM model, use the TYPE=SEM option.

The following statements fit an SEM model to the CRIMEOH data:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime=income hvalue / type=SEM;
run;
```

The parameter estimates are shown in Output 31.1.4. According to this output, the p-value for the spatial autoregressive parameter λ is 0.0002. The results indicate that there is a significant positive dependence in the errors.

Output 31.1.4 Parameter Estimates of SEM Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	59.891926	5.884117	10.18	<.0001
income	1	-0.941303	0.370268	-2.54	0.0110
hvalue	1	-0.302253	0.090552	-3.34	0.0008
_lambda	1	0.561779	0.152413	3.69	0.0002
_sigma2	1	95.572632	20.037633	4.77	<.0001

Spatial Durbin Error Model (SDEM)

To fit an SDEM model, use the SPATIALEFFECTS statement together with the TYPE=SEM option. In this example, the spatial lags of the regressors INCOME and HVALUE are considered in the SDEM model.

The following statements fit an SDEM model to the CRIMEOH data:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime=income hvalue / type=SEM;
   spatialeffects income hvalue;
run;
```

The parameter estimates are shown in Output 31.1.5.

Output 31.1.5 Parameter Estimates of SDEM Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	73.540584	8.860968	8.30	<.0001
income	1	-1.051699	0.322436	-3.26	0.0011
hvalue	1	-0.275607	0.091154	-3.02	0.0025
W_income	1	-1.156553	0.592915	-1.95	0.0511
W_hvalue	1	0.111754	0.202366	0.55	0.5808
_lambda	1	0.425397	0.173831	2.45	0.0144
_sigma2	1	92.533614	19.090022	4.85	<.0001

Spatial Moving Average (SMA) Model

To fit an SMA model, use the TYPE=SMA option.

The following statements fit an SMA model to the CRIMEOH data:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime=income hvalue / type=SMA;
run;
```

The parameter estimates are shown in Output 31.1.6. According to the results, the spatial coefficient λ is negative and significant at the 0.05 level on the basis of the t statistic. This indicates a positive spatial dependence in the errors.

Output 31.1.6 Parameter Estimates of SMA Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	59.252971	5.934861	9.98	<.0001
income	1	-0.921806	0.363482	-2.54	0.0112
hvalue	1	-0.287393	0.086880	-3.31	0.0009
_lambda	1	-0.799089	0.277861	-2.88	0.0040
_sigma2	1	117.731990	26.373322	4.46	<.0001

Spatial Durbin Moving Average (SDMA) Model

To fit an SDMA model, use the SPATIALEFFECTS statement together with the TYPE=SMA option. In this example, the spatial lags of the regressors INCOME and HVALUE are considered in the SDMA model.

The following statements fit an SDMA model to the CRIMEOH data:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime=income hvalue / type=SMA;
   spatialeffects income hvalue;
run;
```

Partial output is shown in Output 31.1.7. According to the results, the spatial coefficient λ is negative and significant at the 0.05 level on the basis of the t statistic. This indicates a positive spatial dependence in the errors.

Output 31.1.7 Parameter Estimates of SDMA Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	73.944211	9.083977	8.14	<.0001
income	1	-1.065635	0.312045	-3.42	0.0006
hvalue	1	-0.266840	0.092400	-2.89	0.0039
W_income	1	-1.074757	0.584955	-1.84	0.0662
W_hvalue	1	0.067568	0.209867	0.32	0.7475
_lambda	1	-0.642124	0.296638	-2.16	0.0304
_sigma2	1	103.502516	22.487027	4.60	<.0001

Spatial Autoregressive Confused (SAC) Model

To fit an SAC model, use the TYPE=SAC option.

The following statements fit the SAC model to the CRIMEOH data:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime=income hvalue / type=SAC;
run;
```

The parameter estimates are shown in Output 31.1.8.

Output 31.1.8 Parameter Estimates of SAC Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	47.778897	9.278436	5.15	<.0001
income	1	-1.025839	0.334006	-3.07	0.0021
hvalue	1	-0.281636	0.093366	-3.02	0.0026
_rho	1	0.368144	0.181118	2.03	0.0421
_lambda	1	0.166525	0.298114	0.56	0.5764
_sigma2	1	95.597124	19.474273	4.91	<.0001

Spatial Durbin Autoregressive Confused (SDAC) Model

To fit an SDAC model, use the SPATIALEFFECTS statement together with the TYPE=SAC option. In this example, the spatial lags of the regressors INCOME and HVALUE are considered in the SDAC model.

The following statements fit an SDAC model to the CRIMEOH data:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime=income hvalue / type=SAC;
   spatialeffects income hvalue;
run;
```

The parameter estimates are shown in Output 31.1.9.

Output 31.1.9 Parameter Estimates of SDAC Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

_sigma2	1	93.133958	19.187743	4.85	<.0001

Spatial Autoregressive Moving Average (SARMA) Model

To fit a SARMA model, use the TYPE=SARMA option.

The following statements fit a SARMA model to the CRIMEOH data:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime=income hvalue / type=SARMA;
run;
```

The parameter estimates are shown in Output 31.1.10.

Output 31.1.10 Parameter Estimates of SARMA Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	48.973247	9.602039	5.10	<.0001
income	1	-1.016359	0.337215	-3.01	0.0026

_sigma2	1	97.992936	21.253768	4.61	<.0001

Spatial Durbin Autoregressive Moving Average (SDARMA) Model

To fit an SDARMA model, use the SPATIALEFFECTS statement together with the TYPE=SARMA option. In this example, the spatial lags of the regressors INCOME and HVALUE are considered in the SDARMA model.

The following statements fit an SDARMA model without an intercept term to the CRIMEOH data:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime=income hvalue / type=SARMA noint;
   spatialeffects income hvalue;
run;
```

The parameter estimates are shown in Output 31.1.11.

Output 31.1.11 Parameter Estimates of SDARMA Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Parameter Estimates

_sigma2	1	86.990404	19.034142	4.57	<.0001

Linear Regression Model

To fit a linear model, use the TYPE=LINEAR option.

The following statements fit a linear model to the CRIMEOH data:

```
proc spatialreg data=crimeoh;
   model crime=income hvalue / type=LINEAR;
run;
```

Partial output is shown in Output 31.1.12.

Output 31.1.12 Parameter Estimates of Linear Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Parameter Estimates

income	1	-1.597304	0.323739	-4.93	<.0001
hvalue	1	-0.273931	0.099989	-2.74	0.0062
_sigma2	1	122.751696	24.799493	4.95	<.0001

Spatial Lag of X Model

To fit an SLX model, use the SPATIALEFFECTS statement together with the TYPE=LINEAR option. In this example, the spatial lags of the regressors INCOME and HVALUE are considered in the linear model.

The following statements fit an SLX model to the CRIMEOH data:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
   model crime=income hvalue / type=LINEAR;
   spatialeffects income hvalue;
run;
```

The parameter estimates are shown in Output 31.1.13.

Output 31.1.13 Parameter Estimates of SLX Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: crime

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	75.028184	6.279950	11.95	<.0001
income	1	-1.109020	0.354232	-3.13	0.0017
hvalue	1	-0.289734	0.096058	-3.02	0.0026
W_income	1	-1.370866	0.531889	-2.58	0.0100
W_hvalue	1	0.191785	0.189841	1.01	0.3124
_sigma2	1	107.292373	21.676329	4.95	<.0001

Example 31.2: Models with Spatial ID Matching

Data Description and Objective

Two simulated data sets, SIMDATA and SIMW, are used to illustrate models with spatial ID matching in PROC SPATIALREG.

The SIMDATA data set contains 50 observations and five variables. The variable SID identifies each spatial unit in the data. Three explanatory variables are x1, x2, and x3. The dependent variable is y. The SIMW data set defines the spatial contiguity for all 50 spatial units. The first column, SID, in the SIMW data set identifies each spatial unit. The remaining entries in the SIMW data set are binary and define whether two spatial units are neighbors. A value of 1 indicates that two spatial units are neighbors, and 0 indicates otherwise.

Summary statistics for all variables except SID in the SIMDATA data set are computed by the following statements and presented in Output 31.2.1:

```
proc means data=simdata;
   var x1 x2 x3 y;
run;
```

Output 31.2.1 Summary Statistics

The MEANS Procedure

Variable	N	Mean	Std Dev	Minimum	Maximum
x1	50	-0.0076329	1.0989504	-2.4523193	1.6539456
x2	50	-0.0829941	0.9671181	-2.5725767	2.4034547
x3	50	-0.0894387	0.9975304	-2.4470049	2.6720533
y	50	1.1569199	1.5687060	-1.9399423	4.7136835

Because the SIMDATA and SIMW data sets are ordered differently in terms of the values of SID, the SPATIALID statement is needed to match observations in SIMDATA and SIMW. The following statements fit a SAR model to the data by using three regressors, x1, x2, and x3:

```
proc spatialreg data=simdata Wmat=simw;
  model y=x1-x3 / type=SAR;
  spatialid SID;
run;
```

The parameter estimates for this model are shown in Output 31.2.2.

Output 31.2.2 Parameter Estimates of SAR Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: y

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	1.780650	0.098703	18.04	<.0001

_rho	1	-0.473713	0.063008	-7.52	<.0001
_sigma2	1	0.131509	0.026350	4.99	<.0001

To fit an SDM model that includes exogenous interaction effects of x1, x2, and x3, submit the following statements:

```
proc spatialreg data=simdata Wmat=simw;
  model y=x1-x3/ type=SAR;
  spatialeffects x1-x3;
  spatialid SID;
run;
```

The parameter estimates for this model are shown in Output 31.2.3.

Output 31.2.3 Parameter Estimates of SDM Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: y

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	1.932575	0.198882	9.72	<.0001
x1	1	0.548505	0.049806	11.01	<.0001
x2	1	0.686012	0.056266	12.19	<.0001
x3	1	-0.890162	0.053516	-16.63	<.0001
W_x1	1	0.172300	0.154018	1.12	0.2633
W_x2	1	0.023744	0.198557	0.12	0.9048
W_x3	1	-0.324806	0.228032	-1.42	0.1543
_rho	1	-0.639755	0.164652	-3.89	0.0001
_sigma2	1	0.120527	0.024729	4.87	<.0001

If you want to fit another type of model, you need to change the TYPE= option. As an example, if you want to fit an SEM model instead of a SAR model to the data, you can use the following statements:

```
proc spatialreg data=simdata Wmat=simw;
  model y=x1-x3 / type=SEM;
  spatialid SID;
run;
```

The parameter estimates for this model are shown in Output 31.2.4.

Output 31.2.4 Parameter Estimates of SEM Model

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: y

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	1.166289	0.029514	39.52	<.0001
x1	1	0.487975	0.049086	9.94	<.0001
x2	1	0.634442	0.061776	10.27	<.0001
x3	1	-0.831250	0.054780	-15.17	<.0001
_lambda	1	-0.964826	0.132514	-7.28	<.0001
_sigma2	1	0.147434	0.031318	4.71	<.0001

Example 31.3: Fitting Multiple Models

You can fit more than one model by making only one call to PROC SPATIALREG. For example, if you want to fit both SAR and SEM models to the CRIMEOH data set, you can use the following statements:

```
proc spatialreg data=crimeoh Wmat=crimeWmat NONORMALIZE;
  model crime=income hvalue / type=SAR;
  model crime=income hvalue / type=SEM;
run;
```

The parameter estimates for the SAR and SEM models are shown in Output 31.3.1 and Output 31.3.2, respectively.

Output 31.3.1 Parameter Estimates of SAR Model

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	45.077070	7.870590	5.73	<.0001
income	1	-1.031531	0.328403	-3.14	0.0017
hvalue	1	-0.265924	0.088218	-3.01	0.0026
_rho	1	0.431020	0.123594	3.49	0.0005
_sigma2	1	95.487066	19.506312	4.90	<.0001

Output 31.3.2 Parameter Estimates of SEM Model

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	59.891926	5.884117	10.18	<.0001
income	1	-0.941303	0.370268	-2.54	0.0110
hvalue	1	-0.302253	0.090552	-3.34	0.0008
_lambda	1	0.561779	0.152413	3.69	0.0002
_sigma2	1	95.572632	20.037633	4.77	<.0001

Example 31.4: Compact Representation of a Spatial Weights Matrix

When a spatial weights matrix is sparse, you might want to provide its compact representation rather than the full matrix to PROC SPATIALREG. In this case, you must use a SPATIALID statement. This example shows you how to use the compact representation of a spatial weights matrix in PROC SPATIALREG. For illustration, the simulated data sets SIMDATA and SIMW in "Example 31.2: Models with Spatial ID Matching" on page 2356 are used here. The compact representation of the spatial weights matrix in the SIMW data set is created and saved in the SIMW_COMPACT data set.

The first 10 observations in the SIMW_COMPACT data set are shown in Figure 31.4.1.

Output 31.4.1 SIMW_COMPACT Data Set

Obs	SID	cSID	Value
1	L50	L45	1
2	L30	L22	1
3	L42	L46	1
4	L32	L35	1
5	L7	L25	1
6	L33	L25	1
7	L50	L25	1
8	L23	L50	1
9	L9	L7	1
10	L45	L36	1

The following statements fit a SAR model:

```
proc spatialreg data=simdata Wmat=simw_compact;
  model y=x1-x3 / type=SAR;
  spatialid SID;
run;
```

The parameter estimates for this model are shown in Output 31.4.2.

Output 31.4.2 Parameter Estimates of SAR Model with Compact Representation

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: y

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	1.780650	0.098703	18.04	<.0001
x1	1	0.573329	0.047395	12.10	<.0001
x2	1	0.707048	0.057181	12.37	<.0001
x3	1	-0.902843	0.053314	-16.93	<.0001
_rho	1	-0.473713	0.063008	-7.52	<.0001
_sigma2	1	0.131509	0.026350	4.99	<.0001

To fit an SEM model instead of a SAR model to the data, you can use the following statements:

```
proc spatialreg data=simdata Wmat=simw_compact;
  model y=x1-x3 / type=SEM;
  spatialid SID;
run;
```

The parameter estimates for this model are shown in Output 31.4.3.

Output 31.4.3 Parameter Estimates of SEM Model with Compact Representation

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: y

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	1.166289	0.029514	39.52	<.0001
x1	1	0.487975	0.049086	9.94	<.0001
x2	1	0.634442	0.061776	10.27	<.0001
x3	1	-0.831250	0.054780	-15.17	<.0001
_lambda	1	-0.964826	0.132514	-7.28	<.0001
_sigma2	1	0.147434	0.031318	4.71	<.0001

Example 31.5: Taylor and Chebyshev Approximations

When you have a large data set (that is, the number of spatial units in your data is large), it becomes burdensome to fit some models. This is partially because all models except linear regression models involve the calculation of the determinant of the matrix of a large size (such as $|\mathbf{I} - \rho\mathbf{W}|$ in a SAR model). In these cases, Taylor and Chebyshev approximations in PROC SPATIALREG can be helpful. The SPATIALREG procedure enables you to estimate both SAR and SDM models with a relatively large spatial weights matrix by using these two approximations. Using the two small data sets SIMDATA and SIMW in "Example 31.2: Models with Spatial ID Matching" on page 2356, you will see how you can invoke the two approximations in PROC SPATIALREG.

The following statements fit a SAR model by using Chebyshev approximation:

```
proc spatialreg data=simdata Wmat=simw approximation=(ORDER=10);
  model y=x1-x3 / type=SAR;
  spatialid SID;
run;
```

The parameter estimates for this model are shown in Output 31.5.1. Note that the spatial weights matrix in the SIMW data set is a full matrix. Compared with Output 31.2.2, Chebyshev approximation yields very similar parameter estimates.

Output 31.5.1 Parameter Estimates of SAR Model with Chebyshev Approximation

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: y

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	1.780638	0.098699	18.04	<.0001
x1	1	0.573329	0.047395	12.10	<.0001
x2	1	0.707050	0.057181	12.37	<.0001
x3	1	-0.902843	0.053314	-16.93	<.0001
_rho	1	-0.473704	0.063004	-7.52	<.0001
_sigma2	1	0.131509	0.026350	4.99	<.0001

Using the compact representation of the spatial weights matrix, you can submit the following statements to fit a SAR model by using Chebyshev approximation:

```
proc spatialreg data=simdata Wmat=simw_compact approximation=(ORDER=10);
  model y=x1-x3 / type=SAR;
  spatialid SID;
run;
```

The parameter estimates for this model are shown in Output 31.5.2, which is identical to Output 31.5.1.

Output 31.5.2 Parameter Estimates of SAR Model with Chebyshev Approximation and Compact Representation

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: y

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	1.780638	0.098699	18.04	<.0001
x1	1	0.573329	0.047395	12.10	<.0001
x2	1	0.707050	0.057181	12.37	<.0001
x3	1	-0.902843	0.053314	-16.93	<.0001
_rho	1	-0.473704	0.063004	-7.52	<.0001
_sigma2	1	0.131509	0.026350	4.99	<.0001

The following statements fit an SDM model by using Taylor approximation:

```
proc spatialreg data=simdata Wmat=simw approximation=(Taylor ORDER=50);
  model y=x1-x3/ type=SAR;
  spatialeffects x1-x3;
  spatialid SID;
run;
```

The parameter estimates for this model are shown in Output 31.5.3. Compared with Output 31.2.3, the SDM model that is fit using Taylor approximation yields almost identical parameter estimates.

Output 31.5.3 Parameter Estimates of SDM Model with Taylor Approximation

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: y

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	1.932575	0.198882	9.72	<.0001
x1	1	0.548505	0.049806	11.01	<.0001
x2	1	0.686012	0.056266	12.19	<.0001
x3	1	-0.890162	0.053516	-16.63	<.0001
W_x1	1	0.172300	0.154018	1.12	0.2633
W_x2	1	0.023744	0.198557	0.12	0.9048
W_x3	1	-0.324806	0.228032	-1.42	0.1543
_rho	1	-0.639755	0.164652	-3.89	0.0001
_sigma2	1	0.120527	0.024729	4.87	<.0001

With the compact representation, the following statements fit the SDM model by using Taylor approximation:

```
proc spatialreg data=simdata Wmat=simw_compact
     approximation=(Taylor ORDER=50);
  model y=x1-x3/ type=SAR;
  spatialeffects x1-x3;
  spatialid SID;
run;
```

The parameter estimates for this model are shown in Output 31.5.4, which is identical to Output 31.5.3.

Output 31.5.4 Parameter Estimates of SDM Model with Taylor Approximation and Compact Representation

The SPATIALREG Procedure

Model: MODEL 1
Dependent Variable: y

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > |t|
Intercept	1	1.932575	0.198882	9.72	<.0001
x1	1	0.548505	0.049806	11.01	<.0001
x2	1	0.686012	0.056266	12.19	<.0001

Overview: SPECTRA Procedure

The SPECTRA procedure performs spectral and cross-spectral analysis of time series. You can use spectral analysis techniques to look for periodicities or cyclical patterns in data.

The SPECTRA procedure produces estimates of the spectral and cross-spectral densities of a multivariate time series. Estimates of the spectral and cross-spectral densities of a multivariate time series are produced using a finite Fourier transform to obtain periodograms and cross-periodograms. The periodogram ordinates are smoothed by a moving average to produce estimated spectral and cross-spectral densities. PROC SPECTRA can also test whether or not the data are white noise.

PROC SPECTRA uses the finite Fourier transform to decompose data series into a sum of sine and cosine waves of different amplitudes and wavelengths. The finite Fourier transform decomposition of the series x_t is

$$x_t = \frac{a_0}{2} + \sum_{k=1}^{m-1} f_k (a_k \cos \omega_k t + b_k \sin \omega_k t)$$

$$f_k = \begin{cases} 1/2 & \text{if } n \text{ is even and } k = m-1 \\ 1 & \text{otherwise} \end{cases}$$

where

t	is the time subscript, $t = 0, 1, 2, \ldots, n-1$
x_t	are the equally spaced time series data
n	is the number of observations in the time series
m	is the number of frequencies in the Fourier decomposition: $m = \frac{n+2}{2}$ if n is even, $m = \frac{n+1}{2}$ if n is odd
k	is the frequency subscript, $k = 0, 1, 2, \ldots, m-1$
a_0	is the mean term: $a_0 = 2\overline{x}$
a_k	are the cosine coefficients
b_k	are the sine coefficients
ω_k	are the Fourier frequencies: $\omega_k = \frac{2\pi k}{n}$

Functions of the Fourier coefficients a_k and b_k can be plotted against frequency or against wave length to form *periodograms*. The amplitude periodogram J_k is defined as follows:

$$J_k = \frac{n}{2}(a_k^2 + b_k^2)$$

Several definitions of the term periodogram are used in the spectral analysis literature. The following discussion refers to the J_k sequence as the periodogram.

The periodogram can be interpreted as the contribution of the kth harmonic ω_k to the total sum of squares (in an analysis of variance sense) in the decomposition of the process into two-degree-of-freedom components for each of the m frequencies. When n is even, $sin(\omega_{\frac{n}{2}})$ is zero, and thus the last periodogram value is a one-degree-of-freedom component.

The periodogram is a volatile and inconsistent estimator of the spectrum. The spectral density estimate is produced by smoothing the periodogram. Smoothing reduces the variance of the estimator but introduces a bias. The weight function used for the smoothing process, W(), often called the kernel or spectral window, is specified with the WEIGHTS statement. It is related to another weight function, $w()$, the lag window, that is used in other methods to taper the correlogram rather than to smooth the periodogram. Many specific weighting functions have been suggested in the literature (Fuller 1976; Jenkins and Watts 1968; Priestley 1981). Table 32.3 later in this chapter gives the relevant formulas when the WEIGHTS statement is used.

Letting i represent the imaginary unit $\sqrt{-1}$, the cross-periodogram is defined as follows:

$$J_k^{xy} = \frac{n}{2}(a_k^x a_k^y + b_k^x b_k^y) + i\frac{n}{2}(a_k^x b_k^y - b_k^x a_k^y)$$

The cross-spectral density estimate is produced by smoothing the cross-periodogram in the same way as the periodograms are smoothed using the spectral window specified by the WEIGHTS statement.

The SPECTRA procedure creates an output SAS data set whose variables contain values of the periodograms, cross-periodograms, estimates of spectral densities, and estimates of cross-spectral densities. The form of the output data set is described in the section "OUT= Data Set" on page 2380.

Getting Started: SPECTRA Procedure

To use the SPECTRA procedure, specify the input and output data sets and options for the analysis you want in the PROC SPECTRA statement, and list the variables to analyze in the VAR statement. The procedure produces no printed output unless the WHITETEST option is specified in the PROC SPECTRA statement. The periodogram, spectral density, and other results are written to the OUT= data set, depending on the options used.

For example, to compute the Fourier transform of a variable X in a data set A, use the following statements:

```
proc spectra data=a out=b coef;
   var x;
run;
```

This PROC SPECTRA step writes the Fourier coefficients a_k and b_k to the variables COS_01 and SIN_01 in the output data set B.

When a WEIGHTS statement is specified, the periodogram is smoothed by a weighted moving average to produce an estimate of the spectral density of the series. The following statements write a spectral density estimate for X to the variable S_01 in the output data set B:

```
proc spectra data=a out=b s;
   var x;
   weights 1 2 3 4 3 2 1;
run;
```

When the VAR statement specifies more than one variable, you can perform cross-spectral analysis by specifying the CROSS option in the PROC SPECTRA statement. The CROSS option by itself produces the cross-periodograms for all two-way combinations of the variables listed in the VAR statement. For example, the following statements write the real and imaginary parts of the cross-periodogram of X and Y to the variables RP_01_02 and IP_01_02 in the output data set B:

```
proc spectra data=a out=b cross;
   var x y;
run;
```

To produce cross-spectral density estimates, specify both the CROSS option and the S option. The cross-periodogram is smoothed using the weights specified by the WEIGHTS statement in the same way as the spectral density. The squared coherency and phase estimates of the cross-spectrum are computed when the K and PH options are used.

The following example computes cross-spectral density estimates for the variables X and Y:

```
proc spectra data=a out=b cross s;
   var x y;
   weights 1 2 3 4 3 2 1;
run;
```

The real part and imaginary part of the cross-spectral density estimates are written to the variables CS_01_02 and QS_01_02, respectively.

Syntax: SPECTRA Procedure

The following statements are used with the SPECTRA procedure:

PROC SPECTRA *options* **;**
BY *variables* **;**
VAR *variables* **;**
WEIGHTS < *weights* > < *kernel* > **;**

Functional Summary

Table 32.1 summarizes the statements and options that control the SPECTRA procedure.

Table 32.1 Functional Summary

Description	Statement	Option
Statements		
Specify BY-group processing	BY	
Specify the variables to be analyzed	VAR	
Specify weights for spectral density estimates	WEIGHTS	
Data Set Options		
Specify the input data set	PROC SPECTRA	DATA=
Specify the output data set	PROC SPECTRA	OUT=
Output Control Options		
Output the amplitudes of the cross-spectrum	PROC SPECTRA	A
Output the Fourier coefficients	PROC SPECTRA	COEF

Table 32.1 *continued*

Description	Statement	Option
Output the periodogram	PROC SPECTRA	P
Output the spectral density estimates	PROC SPECTRA	S
Output cross-spectral analysis results	PROC SPECTRA	CROSS
Output squared coherency of the cross-spectrum	PROC SPECTRA	K
Output the phase of the cross-spectrum	PROC SPECTRA	PH
Smoothing Options		
Specify the Bartlett kernel	WEIGHTS	BART
Specify the Parzen kernel	WEIGHTS	PARZEN
Specify the quadratic spectral kernel	WEIGHTS	QS
Specify the Tukey-Hanning kernel	WEIGHTS	TUKEY
Specify the truncated kernel	WEIGHTS	TRUNCAT
Other Options		
Subtract the series mean	PROC SPECTRA	ADJMEAN
Specify an alternate quadrature spectrum estimate	PROC SPECTRA	ALTW
Request tests for white noise	PROC SPECTRA	WHITETEST

PROC SPECTRA Statement

PROC SPECTRA *options* **;**

The following options can be used in the PROC SPECTRA statement:

A

outputs the amplitude variables (A_*nn* _*mm*) of the cross-spectrum.

ADJMEAN

CENTER

subtracts the series mean before performing the Fourier decomposition. This sets the first periodogram ordinate to 0 rather than $2n$ times the squared mean. This option is commonly used when the periodograms are to be plotted to prevent a large first periodogram ordinate from distorting the scale of the plot.

ALTW

specifies that the quadrature spectrum estimate is computed at the boundaries in the same way as the spectral density estimate and the cospectrum estimate are computed.

COEF
outputs the Fourier cosine and sine coefficients of each series.

CROSS
is used with the P and S options to output cross-periodograms and cross-spectral densities when more than one variable is listed in the VAR statement.

DATA=*SAS-data-set*
names the SAS data set that contains the input data. If the DATA= option is omitted, the most recently created SAS data set is used.

K
outputs the squared coherency variables (K_*nn _mm*) of the cross-spectrum. The K_*nn _mm* variables are identically 1 unless weights are given in the WEIGHTS statement and the S option is specified.

OUT=*SAS-data-set*
names the output data set created by PROC SPECTRA to store the results. If the OUT= option is omitted, the output data set is named by using the DATA*n* convention.

P
outputs the periodogram variables. The variables are named P_*nn*, where *nn* is an index of the original variable with which the periodogram variable is associated. When both the P and CROSS options are specified, the cross-periodogram variables RP_*nn_mm* and IP_*nn_mm* are also output.

PH
outputs the phase variables (PH_*nn _mm*) of the cross-spectrum.

S
outputs the spectral density estimates. The variables are named S_*nn*, where *nn* is an index of the original variable with which the estimate variable is associated. When both the S and CROSS options are specified, the cross-spectral variables CS_*nn _mm* and QS_*nn _mm* are also output.

WHITETEST
prints two tests of the hypothesis that the data are white noise. For more information, see the section "White Noise Test" on page 2379.

Note that the CROSS, A, K, and PH options are meaningful only if more than one variable is listed in the VAR statement.

BY Statement

BY *variables* **;**

A BY statement can be used with PROC SPECTRA to obtain separate analyses for groups of observations defined by the BY variables.

VAR Statement

VAR *variables* **;**

The VAR statement specifies one or more numeric variables that contain the time series to analyze. The order of the variables in the VAR statement list determines the index, *nn*, used to name the output variables. The VAR statement is required.

WEIGHTS Statement

WEIGHTS *weight-constants | kernel-specification* **;**

The WEIGHTS statement specifies the relative weights used in the moving average applied to the periodogram ordinates to form the spectral density estimates. A WEIGHTS statement must be used to produce smoothed spectral density estimates. You can specify the relative weights in two ways: you can specify them explicitly as explained in the section "Using Weight Constants Specification" on page 2375, or you can specify them implicitly by using the kernel specification as explained in the section "Using Kernel Specifications" on page 2376. If the WEIGHTS statement is not used, only the periodogram is produced.

Using Weight Constants Specification

Any number of weighting constants can be specified. The constants should be positive and symmetric about the middle weight. The middle constant (or the constant to the right of the middle if an even number of weight constants are specified) is the relative weight of the current periodogram ordinate. The constant immediately following the middle one is the relative weight of the next periodogram ordinate, and so on. The actual weights used in the smoothing process are the weights specified in the WEIGHTS statement scaled so that they sum to $\frac{1}{4\pi}$.

The moving average reflects at each end of the periodogram. The first periodogram ordinate is not used; the second periodogram ordinate is used in its place.

For example, a simple triangular weighting can be specified using the following WEIGHTS statement:

```
weights 1 2 3 2 1;
```

Using Kernel Specifications

You can specify five different kernels in the WEIGHTS statement. The syntax for the statement is

WEIGHTS [PARZEN][BART][TUKEY][TRUNCAT][QS] [c e] ;

where $c >= 0$ and $e >= 0$ are used to compute the bandwidth parameter as

$$\mathrm{l}(q) = cq^e$$

and q is the number of periodogram ordinates +1:

$$q = \mathrm{floor}(n/2) + 1$$

To specify the bandwidth explicitly, set $c =$ to the desired bandwidth and $e = 0$.

For example, a Parzen kernel can be specified using the following WEIGHTS statement:

```
weights parzen 0.5 0;
```

For more information, see the section "Kernels" on page 2377.

Details: SPECTRA Procedure

Input Data

Observations in the data set analyzed by the SPECTRA procedure should form ordered, equally spaced time series. No more than 99 variables can be included in the analysis.

Data are often detrended before analysis by the SPECTRA procedure. This can be done by using the residuals output by a SAS regression procedure. Optionally, the data can be centered using the ADJMEAN option in the PROC SPECTRA statement, since the zero periodogram ordinate corresponding to the mean is of little interest from the point of view of spectral analysis.

Missing Values

Missing values are excluded from the analysis by the SPECTRA procedure. If the SPECTRA procedure encounters missing values for any variable listed in the VAR statement, the procedure determines the longest contiguous span of data that has no missing values for the variables listed in the VAR statement and uses that span for the analysis.

Computational Method

If the number of observations n factors into prime integers that are less than or equal to 23, and the product of the square-free factors of n is less than 210, then PROC SPECTRA uses the fast Fourier transform developed by Cooley and Tukey and implemented by Singleton (1969). If n cannot be factored in this way, then PROC SPECTRA uses a Chirp-Z algorithm similar to that proposed by Monro and Branch (1977). To reduce memory requirements, when n is small, the Fourier coefficients are computed directly using the defining formulas.

Kernels

Kernels are used to smooth the periodogram by using a weighted moving average of nearby points. A smoothed periodogram is defined by the following equation:

$$\hat{J}_i(\mathrm{l}(q)) = \sum_{\tau=-\mathrm{l}(q)}^{\mathrm{l}(q)} \mathrm{w}\left(\frac{\tau}{\mathrm{l}(q)}\right) \tilde{J}_{i+\tau}$$

where $\mathrm{w}(x)$ is the kernel or weight function. At the endpoints, the moving average is computed cyclically; that is,

$$\tilde{J}_{i+\tau} = \begin{cases} J_{i+\tau} & 0 <= i+\tau <= q \\ J_{-(i+\tau)} & i+\tau < 0 \\ J_{q-(i+\tau)} & i+\tau > q \end{cases}$$

The SPECTRA procedure supports the following kernels. They are listed with their default bandwidth functions.

Bartlett: KERNEL BART

$$\begin{aligned} \mathrm{w}(x) &= \begin{cases} 1-|x| & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases} \\ \mathrm{l}(q) &= \frac{1}{2} q^{1/3} \end{aligned}$$

Parzen: KERNEL PARZEN

$$\begin{aligned} \mathrm{w}(x) &= \begin{cases} 1-6|x|^2+6|x|^3 & 0 \leq |x| \leq \frac{1}{2} \\ 2(1-|x|)^3 & \frac{1}{2} \leq |x| \leq 1 \\ 0 & \text{otherwise} \end{cases} \\ \mathrm{l}(q) &= q^{1/5} \end{aligned}$$

Quadratic spectral: KERNEL QS

$$\begin{aligned} \mathrm{w}(x) &= \frac{25}{12\pi^2 x^2}\left(\frac{\sin(6\pi x/5)}{6\pi x/5} - \cos(6\pi x/5)\right) \\ \mathrm{l}(q) &= \frac{1}{2}q^{1/5} \end{aligned}$$

Tukey-Hanning: KERNEL TUKEY

$$\begin{aligned} \mathrm{w}(x) &= \begin{cases} (1+\cos(\pi x))/2 & |x|\leq 1 \\ 0 & \text{otherwise} \end{cases} \\ \mathrm{l}(q) &= \frac{2}{3}q^{1/5} \end{aligned}$$

Truncated: KERNEL TRUNCAT

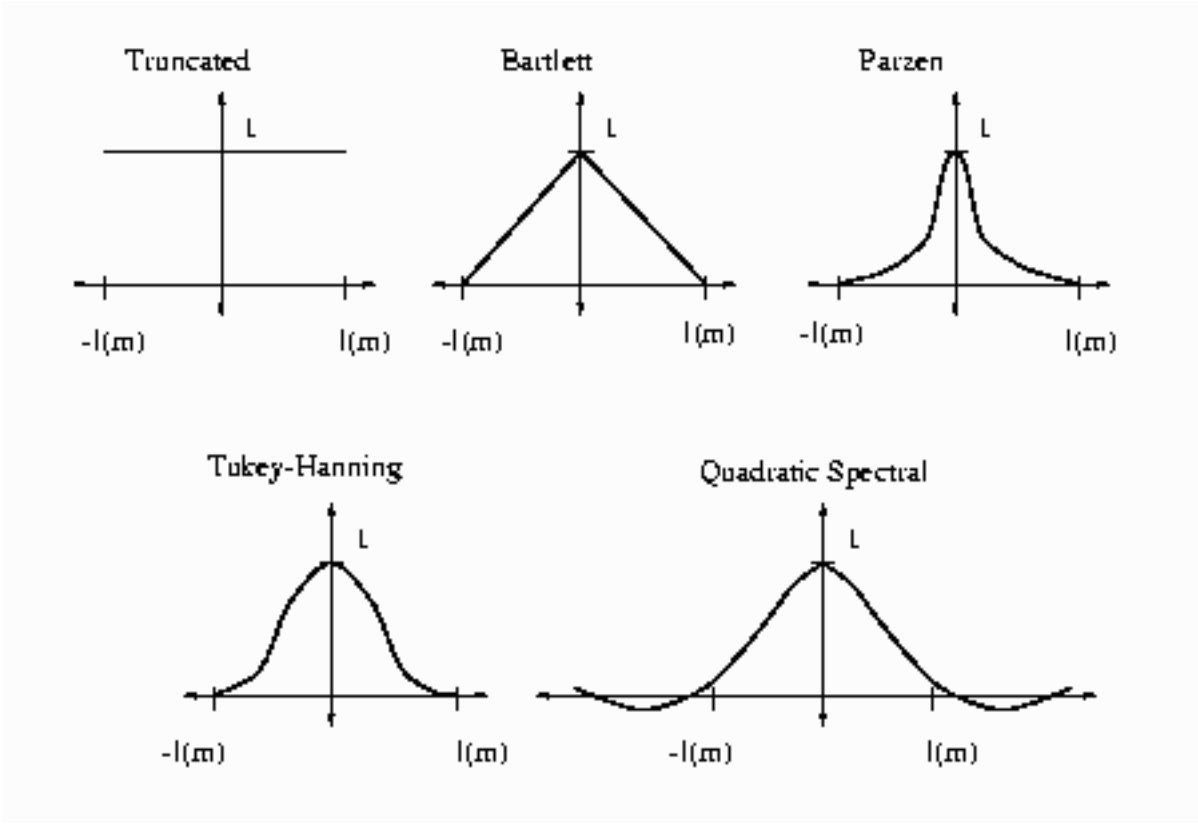
$$\begin{aligned} \mathrm{w}(x) &= \begin{cases} 1 & |x|\leq 1 \\ 0 & \text{otherwise} \end{cases} \\ \mathrm{l}(q) &= \frac{1}{4}q^{1/5} \end{aligned}$$

A summary of the default values of the bandwidth parameters, c and e, associated with the kernel smoothers in PROC SPECTRA are listed in Table 32.2.

Table 32.2 Bandwidth Parameters

Kernel	c	e
Bartlett	1/2	1/3
Parzen	1	1/5
Quadratic	1/2	1/5
Tukey-Hanning	2/3	1/5
Truncated	1/4	1/5

Figure 32.1 Kernels for Smoothing



For more information about the properties of these kernels, see Andrews (1991).

White Noise Test

PROC SPECTRA prints two test statistics for white noise when the WHITETEST option is specified: Fisher's Kappa (Davis 1941; Fuller 1976) and Bartlett's Kolmogorov-Smirnov statistic (Bartlett 1966; Fuller 1976; Durbin 1967).

If the time series is a sequence of independent random variables with mean 0 and variance σ^2, then the periodogram, J_k, will have the same expected value for all k. For a time series with nonzero autocorrelation, each ordinate of the periodogram, J_k, will have different expected values. The Fisher's Kappa statistic tests whether the largest J_k can be considered different from the mean of the J_k. Critical values for the Fisher's Kappa test can be found in Fuller 1976.

The Kolmogorov-Smirnov statistic reported by PROC SPECTRA has the same asymptotic distribution as Bartlett's test (Durbin 1967). The Kolmogorov-Smirnov statistic compares the normalized cumulative periodogram with the cumulative distribution function of a uniform(0,1) random variable. The normalized cumulative periodogram, F_j, of the series is

$$F_j = \frac{\sum_{k=1}^{j} J_k}{\sum_{k=1}^{m} J_k}, j = 1, 2 \ldots, m-1$$

where $m = \frac{n}{2}$ if n is even or $m = \frac{n-1}{2}$ if n is odd. The test statistic is the maximum absolute difference of the normalized cumulative periodogram and the uniform cumulative distribution function. Approximate p-values for Bartlett's Kolmogorov-Smirnov test statistics are provided with the test statistics. Small p-values cause you to reject the null-hypothesis that the series is white noise.

Transforming Frequencies

The variable FREQ in the data set created by the SPECTRA procedure ranges from 0 to π. Sometimes it is preferable to express frequencies in cycles per observation period, which is equal to $\frac{1}{2\pi}$FREQ.

To express frequencies in cycles per unit time (for example, in cycles per year), multiply FREQ by $\frac{d}{2\pi}$, where d is the number of observations per unit of time. For example, for monthly data, if the desired time unit is years then d is 12. The period of the cycle is $\frac{2\pi}{d \times \mathrm{FREQ}}$, which ranges from $\frac{2}{d}$ to infinity.

OUT= Data Set

The OUT= data set contains $\frac{n}{2} + 1$ observations, if n is even, or $\frac{n+1}{2}$ observations, if n is odd, where n is the number of observations in the time series or the span of data being analyzed if missing values are present in the data. For more information, see the section "Missing Values" on page 2376.

The variables in the new data set are named according to the following conventions. Each variable to be analyzed is associated with an index. The first variable listed in the VAR statement is indexed as 01, the second variable as 02, and so on. Output variables are named by combining indexes with prefixes. The prefix always identifies the nature of the new variable, and the indices identify the original variables from which the statistics were obtained.

Variables that contain spectral analysis results have names that consist of a prefix, an underscore, and the index of the variable analyzed. For example, the variable S_01 contains spectral density estimates for the first variable in the VAR statement. Variables that contain cross-spectral analysis results have names that consist of a prefix, an underscore, the index of the first variable, another underscore, and the index of the second variable. For example, the variable A_01_02 contains the amplitude of the cross-spectral density estimate for the first and second variables in the VAR statement.

Table 32.3 shows the formulas and naming conventions used for the variables in the OUT= data set. Let X be variable number *nn* in the VAR statement list and let Y be variable number *mm* in the VAR statement list. Table 32.3 shows the output variables that contain the results of the spectral and cross-spectral analysis of X and Y.

In Table 32.3 the following notation is used. Let W_j be the vector of $2p + 1$ smoothing weights given by the WEIGHTS statement, normalized to sum to $\frac{1}{4\pi}$. Note that the weights are either explicitly provided using the constant specification or are implicitly determined by the kernel specification in the WEIGHTS statement.

The subscript of W_j runs from W_{-p} to W_p, so that W_0 is the middle weight in the list. Let $\omega_k = \frac{2\pi k}{n}$, where $k = 0, 1, \ldots, \mathrm{floor}(\frac{n}{2})$.

Table 32.3 Variables Created by PROC SPECTRA

Variable	Description
FREQ	Frequency in radians from 0 to π (Note: Cycles per observation is $\frac{\text{FREQ}}{2\pi}$.)
PERIOD	Period or wavelength: $\frac{2\pi}{\text{FREQ}}$ (Note: PERIOD is missing for FREQ=0.)
COS_*nn*	Cosine transform of X: $a_k^x = \frac{2}{n}\sum_{t=1}^{n} X_t \cos(\omega_k(t-1))$
SIN_*nn*	Sine transform of X: $b_k^x = \frac{2}{n}\sum_{t=1}^{n} X_t \sin(\omega_k(t-1))$
P_*nn*	Periodogram of X: $J_k^x = \frac{n}{2}[(a_k^x)^2 + (b_k^x)^2]$
S_*nn*	Spectral density estimate of X: $F_k^x = \sum_{j=-p}^{p} W_j J_{k+j}^x$ (except across endpoints)
RP_*nn* _*mm*	Real part of cross-periodogram X and Y: $\text{real}(J_k^{xy}) = \frac{n}{2}(a_k^x a_k^y + b_k^x b_k^y)$
IP_*nn* _*mm*	Imaginary part of cross-periodogram of X and Y: $\text{imag}(J_k^{xy}) = \frac{n}{2}(a_k^x b_k^y - b_k^x a_k^y)$
CS_*nn* _*mm*	Cospectrum estimate (real part of cross-spectrum) of X and Y: $C_k^{xy} = \sum_{j=-p}^{p} W_j \text{real}(J_{k+j}^{xy})$ (except across endpoints)
QS_*nn* _*mm*	Quadrature spectrum estimate (imaginary part of cross-spectrum) of X and Y: $Q_k^{xy} = \sum_{j=-p}^{p} W_j \text{imag}(J_{k+j}^{xy})$ (except across endpoints)
A_*nn* _*mm*	Amplitude (modulus) of cross-spectrum of X and Y: $A_k^{xy} = \sqrt{(C_k^{xy})^2 + (Q_k^{xy})^2}$
K_*nn* _*mm*	Coherency squared of X and Y: $K_k^{xy} = (A_k^{xy})^2/(F_k^x F_k^y)$
PH_*nn* _*mm*	Phase spectrum in radians of X and Y: $\Phi_k^{xy} = \arctan(Q_k^{xy}/C_k^{xy})$

Printed Output

By default PROC SPECTRA produces no printed output.

When the WHITETEST option is specified, the SPECTRA procedure prints the following statistics for each variable in the VAR statement:

1. the name of the variable
2. M–1, the number of two-degrees-of-freedom periodogram ordinates used in the test
3. MAX(P(*)), the maximum periodogram ordinate
4. SUM(P(*)), the sum of the periodogram ordinates
5. Fisher's Kappa statistic
6. Bartlett's Kolmogorov-Smirnov test statistic
7. approximate *p*-value for Bartlett's Kolmogorov-Smirnov test statistic

For more information, see the section "White Noise Test" on page 2379.

ODS Table Names: SPECTRA Procedure

PROC SPECTRA assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table:

Table 32.4 ODS Tables Produced in PROC SPECTRA

ODS Table Name	Description	Option
WhiteNoiseTest	White noise test	WHITETEST
Kappa	Fisher's Kappa statistic	WHITETEST
Bartlett	Bartlett's Kolmogorov-Smirnov statistic	WHITETEST

Examples: SPECTRA Procedure

Example 32.1: Spectral Analysis of Sunspot Activity

This example analyzes Wolfer's sunspot data (Anderson 1971). The following statements read and plot the data:

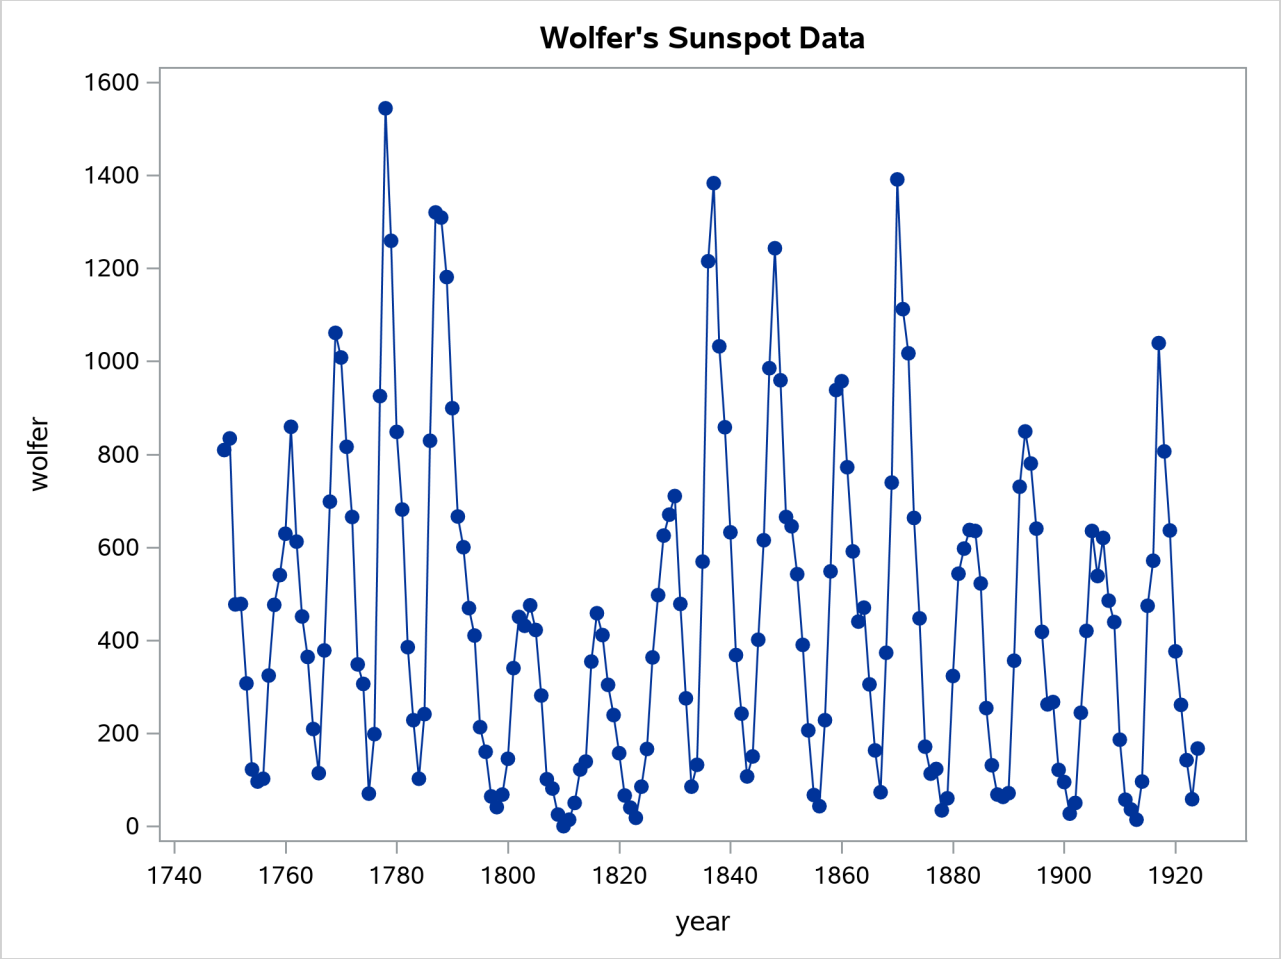
```
title "Wolfer's Sunspot Data";
data sunspot;
   input year wolfer @@;
datalines;
1749  809 1750  834 1751  477 1752  478 1753  307 1754  122 1755   96

   ... more lines ...

proc sgplot data=sunspot;
   series x=year y=wolfer / markers markerattrs=(symbol=circlefilled);
   xaxis values=(1740 to 1930 by 10);
   yaxis values=(0 to 1600 by 200);
run;
```

The plot of the sunspot series is shown in Output 32.1.1.

Output 32.1.1 Plot of Original Sunspot Data



The spectral analysis of the sunspot series is performed by the following statements:

```
proc spectra data=sunspot out=b p s adjmean whitetest;
   var wolfer;
   weights 1 2 3 4 3 2 1;
run;

proc print data=b(obs=12);
run;
```

The PROC SPECTRA statement specifies the P and S options to write the periodogram and spectral density estimates to the OUT= data set B. The WEIGHTS statement specifies a triangular spectral window for smoothing the periodogram to produce the spectral density estimate. The ADJMEAN option zeros the frequency 0 value and avoids the need to exclude that observation from the plots. The WHITETEST option prints tests for white noise.

The Fisher's Kappa test statistic of 16.070 is larger than the 5% critical value of 7.2, so the null hypothesis that the sunspot series is white noise is rejected (see the table of critical values in Fuller (1976)).

The Bartlett's Kolmogorov-Smirnov statistic is 0.6501, and its approximate p-value is < 0.0001. The small p-value associated with this test leads to the rejection of the null hypothesis that the spectrum represents

white noise.

The printed output produced by PROC SPECTRA is shown in Output 32.1.2. The output data set B created by PROC SPECTRA is shown in part in Output 32.1.3.

Output 32.1.2 White Noise Test Results

Kappa	16.70489

Bartlett's Kolmogorov-Smirnov Statistic: Maximum absolute difference of the standardized partial sums of the periodogram and the CDF of a uniform(0,1) random variable.	
Test Statistic	0.650055
Approximate P-Value	<.0001

Output 32.1.3 First 12 Observations of the OUT= Data Set

Wolfer's Sunspot Data

Obs	FREQ	PERIOD	P_01	S_01
1	0.00000	.	0.00	59327.52
2	0.03570	176.000	3178.15	61757.98
3	0.07140	88.000	2435433.22	69528.68
4	0.10710	58.667	1077495.76	66087.57
5	0.14280	44.000	491850.36	53352.02
6	0.17850	35.200	2581.12	36678.14
7	0.21420	29.333	181163.15	20604.52
8	0.24990	25.143	283057.60	15132.81
9	0.28560	22.000	188672.97	13265.89
10	0.32130	19.556	122673.94	14953.32
11	0.35700	17.600	58532.93	16402.84
12	0.39270	16.000	213405.16	18562.13

The following statements plot the periodogram and spectral density estimate by the frequency and period:

```
proc sgplot data=b;
   series x=freq y=p_01 / markers markerattrs=(symbol=circlefilled);
run;

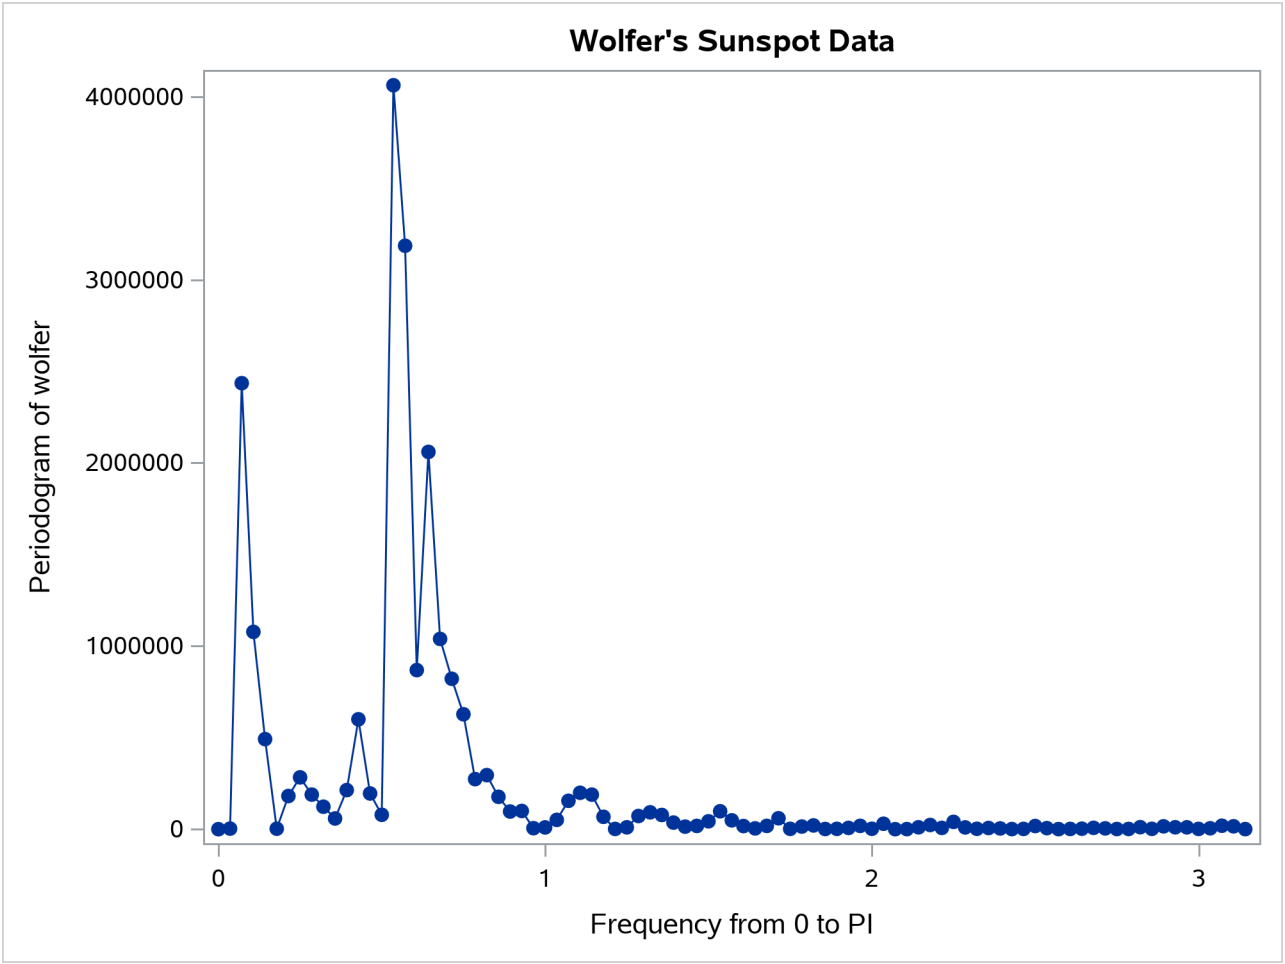
proc sgplot data=b;
   series x=period y=p_01 / markers markerattrs=(symbol=circlefilled);
run;

proc sgplot data=b;
   series x=freq y=s_01 / markers markerattrs=(symbol=circlefilled);
run;

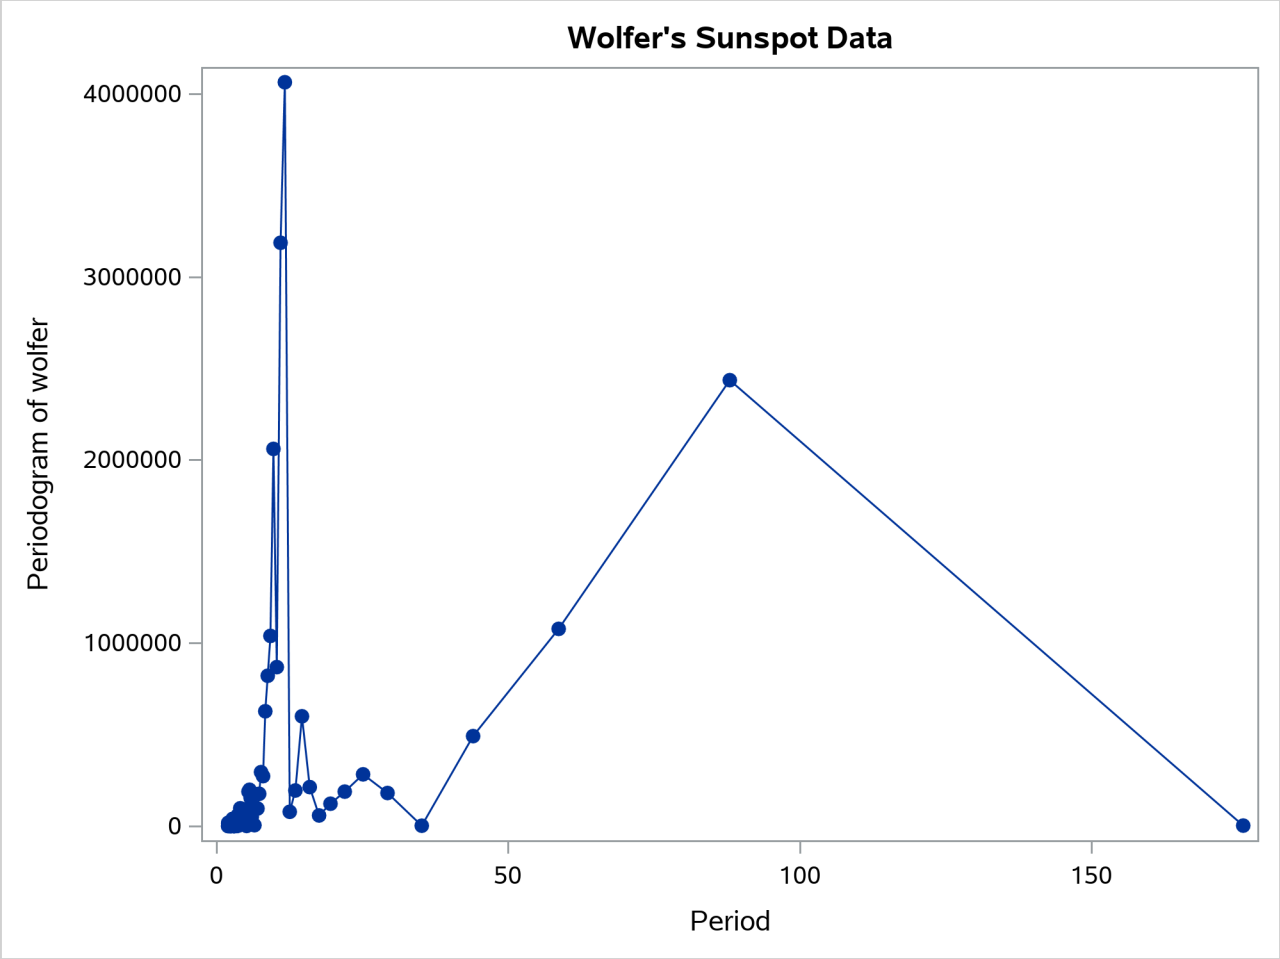
proc sgplot data=b;
   series x=period y=s_01 / markers markerattrs=(symbol=circlefilled);
run;
```

The periodogram is plotted against the frequency in Output 32.1.4 and plotted against the period in Output 32.1.5. The spectral density estimate is plotted against the frequency in Output 32.1.6 and plotted against the period in Output 32.1.7.

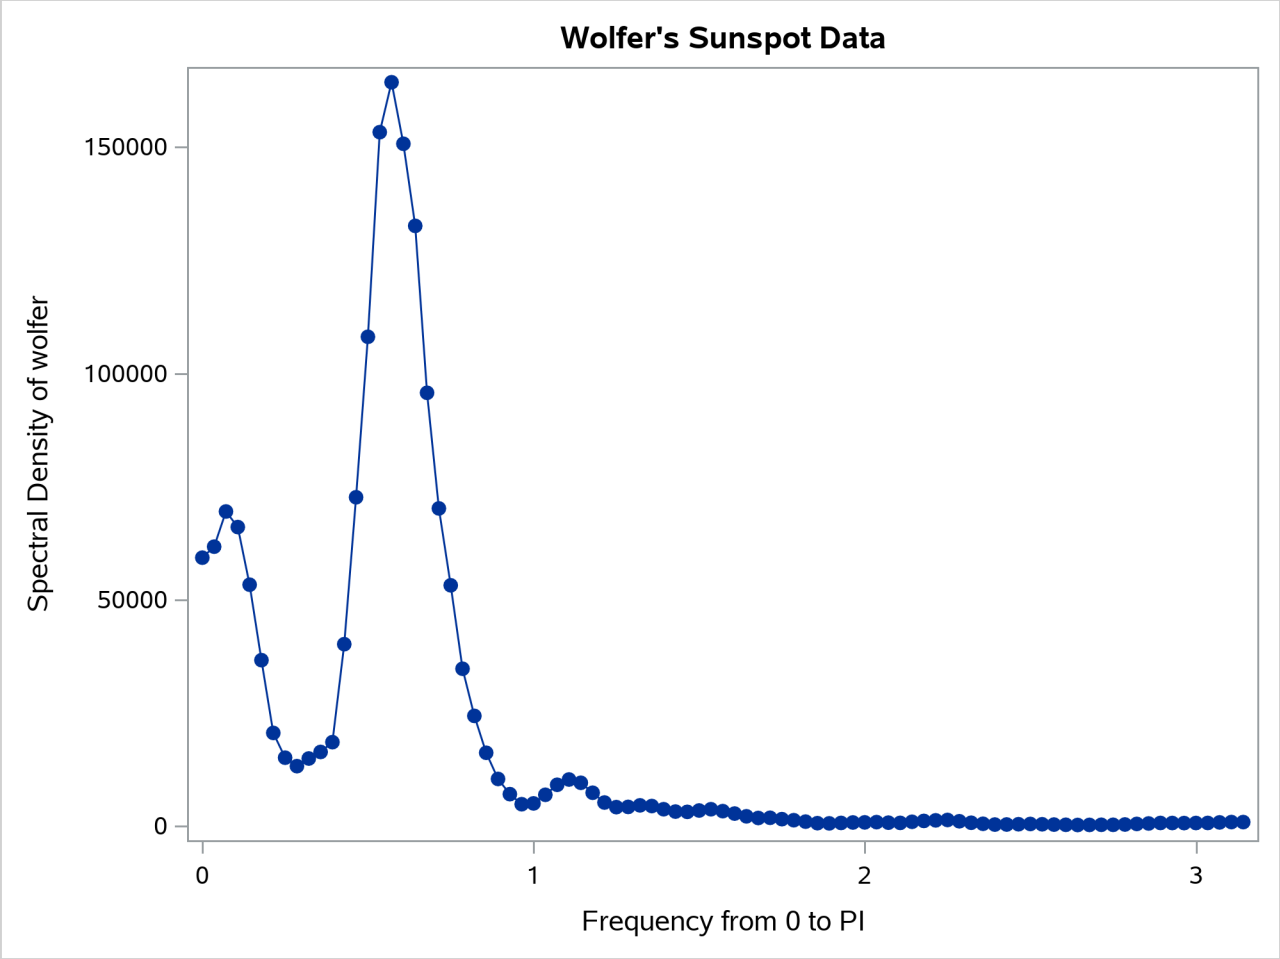
Output 32.1.4 Plot of Periodogram by Frequency



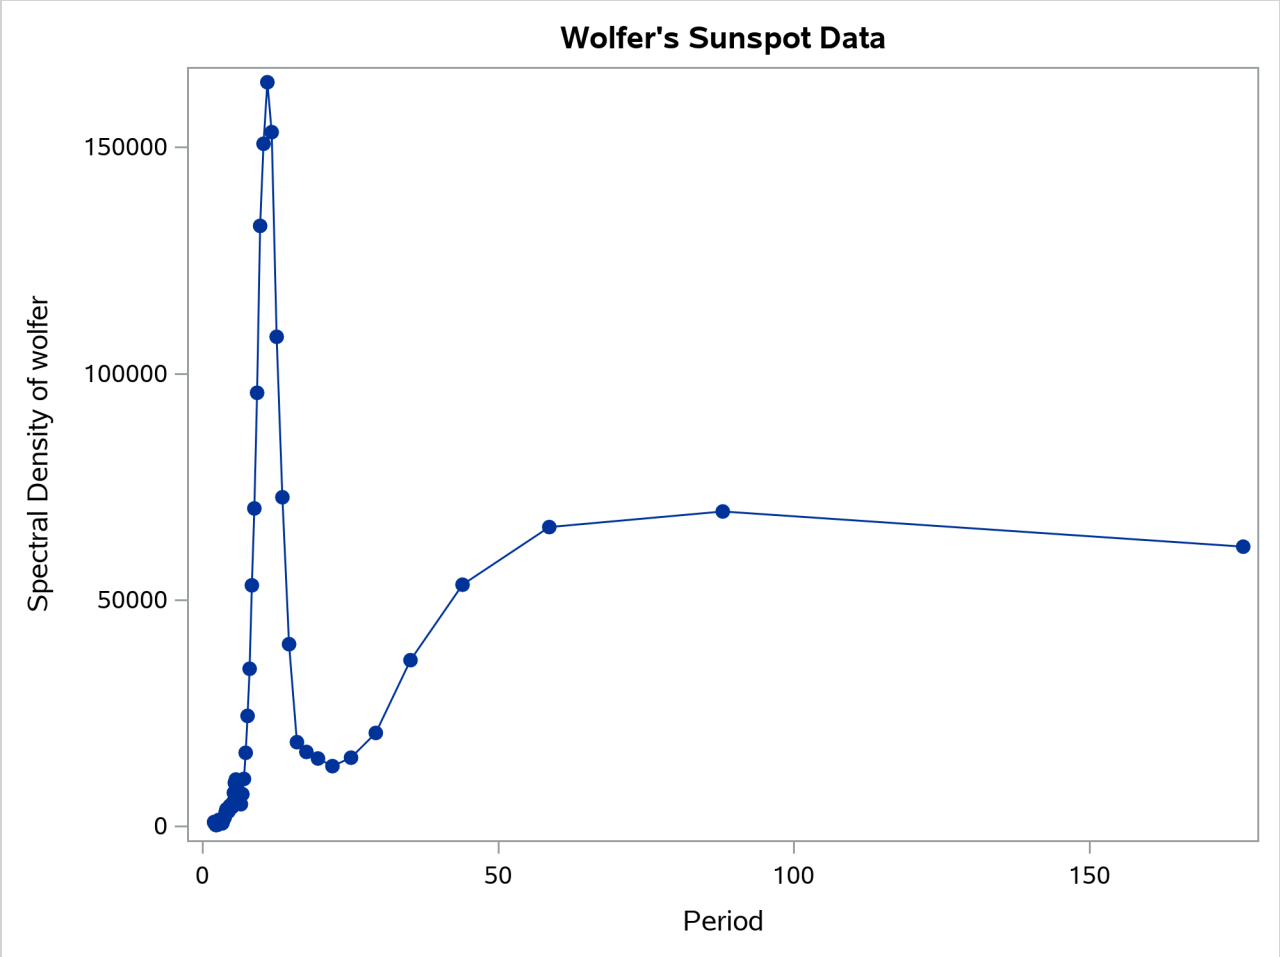
Output 32.1.5 Plot of Periodogram by Period



Output 32.1.6 Plot of Spectral Density Estimate by Frequency



Output 32.1.7 Plot of Spectral Density Estimate by Period



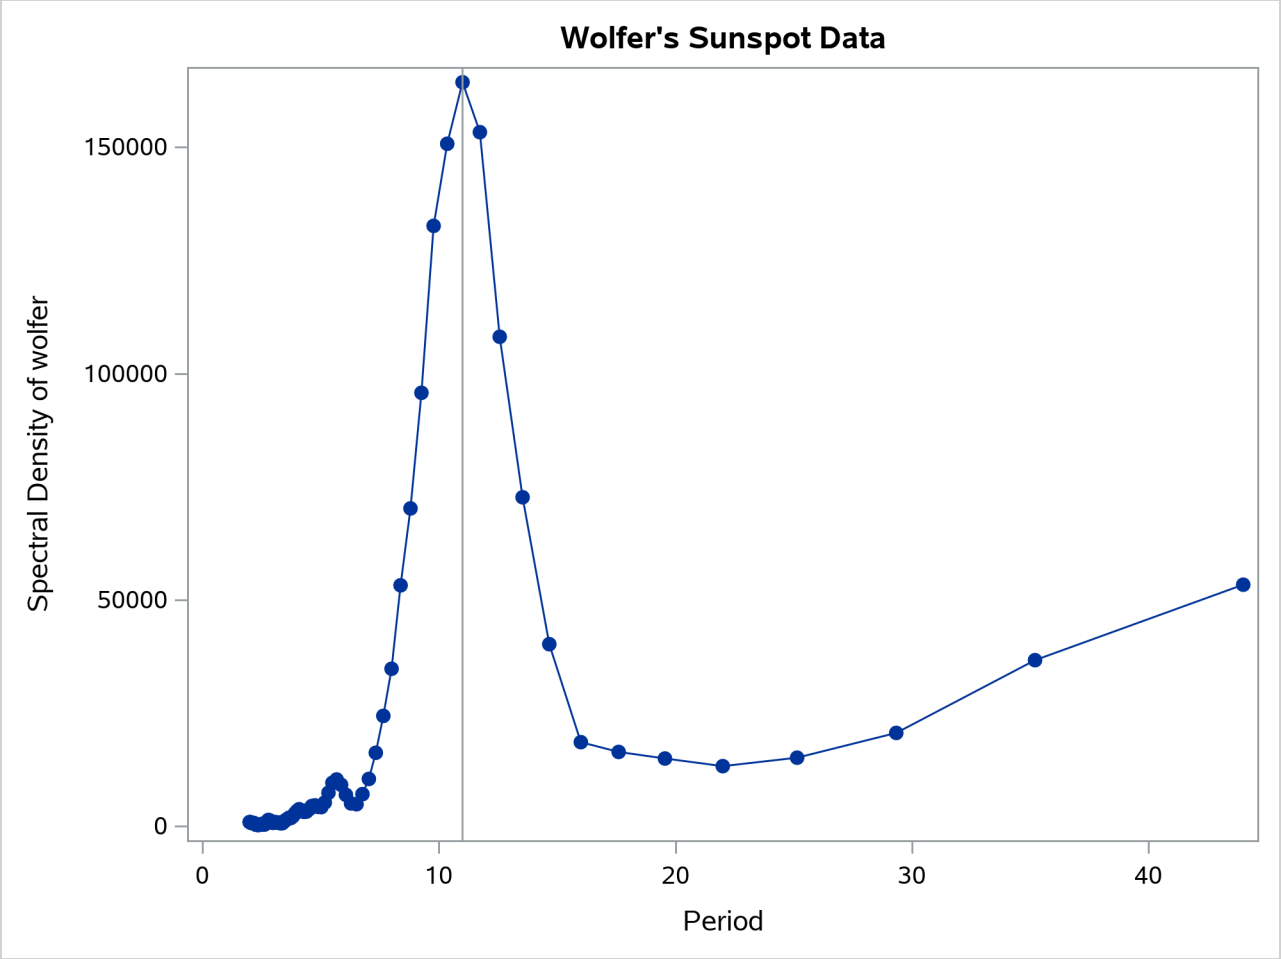
Since PERIOD is the reciprocal of frequency, the plot axis for PERIOD is stretched for low frequencies and compressed at high frequencies. One way to correct for this is to use a WHERE statement to restrict the plots and exclude the low frequency components. The following statements plot the spectral density for periods less than 50:

```
proc sgplot data=b;
   where period < 50;
   series x=period y=s_01 / markers markerattrs=(symbol=circlefilled);
   refline 11 / axis=x;
run;
title;
```

The spectral analysis of the sunspot series confirms a strong 11-year cycle of sunspot activity. The plot makes this clear by drawing a reference line at the 11 year period, which highlights the position of the main peak in the spectral density.

Output 32.1.8 shows the plot. Contrast Output 32.1.8 with Output 32.1.7.

Output 32.1.8 Plot of Spectral Density Estimate by Period to 50 Years



Example 32.2: Cross-Spectral Analysis

This example uses simulated data to show cross-spectral analysis for two variables X and Y. X is generated by an AR(1) process; Y is generated as white noise plus an input from X lagged 2 periods. All output options are specified in the PROC SPECTRA statement. PROC CONTENTS shows the contents of the OUT= data set.

```
data a;
   xl = 0; xll = 0;
   do i = - 10 to 100;
      x = .4 * xl  + rannor(123);
      y = .5 * xll + rannor(123);
      if i > 0 then output;
      xll = xl; xl = x;
   end;
run;
```

```
proc spectra data=a out=b cross coef a k p ph s;
   var x y;
   weights 1 1.5 2 4 8 9 8 4 2 1.5 1;
run;

proc contents data=b position;
run;
```

The PROC CONTENTS report for the output data set B is shown in Output 32.2.1.

Output 32.2.1 Contents of PROC SPECTRA OUT= Data Set

Overview: SSM Procedure

State space models (SSMs) are used for analyzing continuous response variables that are recorded sequentially according to a numeric indexing variable. In many cases, the indexing variable is time and the observations are collected at regular time intervals—for example, hourly, weekly, or monthly. In such cases, the resulting data are called time series data. In other cases, the indexing variable might not be time or the observations might not be equally spaced according to the indexing variable. These more general types of sequential data are called longitudinal data. Because of their sequential nature, these types of data exhibit some characteristic features. For example, chronologically closer measurements tend to be highly correlated while measurements farther apart are essentially uncorrelated. Data can be trending in a particular direction and can have seasonal or other periodic patterns. SSMs are specially designed to model such sequential data. They apply to both univariate and multivariate response situations and can easily incorporate predictor (independent variable) information when it is available.

The SSM procedure performs state space modeling of univariate and multivariate time series and longitudinal data. You can do the following with the SSM procedure:

- analyze quite general linear state space models
- use an expressive language to specify an SSM. An SSM specification consists of specifying a variety of matrices—for example, the state transition matrix and the covariance matrices of the state and observation disturbances. The SSM procedure provides language similar to a DATA step for specifying the elements of these matrices. The matrix elements can be user-defined functions of data variables and unknown parameters.
- easily specify several commonly needed univariate and multivariate SSMs by using only a few keywords. These SSMs include the principal univariate and multivariate structural models for regularly spaced data and a variety of trend and cycle models for the longitudinal data.
- estimate unknown model parameters by (restricted) maximum likelihood. The likelihood function is computed by using the (diffuse) Kalman filter algorithm.
- print, or output to a data set, the series forecasts, residuals, and the full-sample estimates of any linear combination of the underlying state variables. These estimates are obtained by using the (diffuse) Kalman filter and smoother algorithm.
- generate residual diagnostic plots and plots useful for detecting structural breaks

Background

State space models are widely used in a variety of fields such as engineering, statistics, econometrics, and agriculture. There are numerous references that deal with state space modeling, particularly with the state space modeling of time series data. State space modeling of longitudinal data has received a little less attention. The primary reference for the modeling techniques implemented in the SSM procedure is Harvey (1989). It contains treatment of both the time series and longitudinal data. Other useful books about this subject are Pelagatti (2015); Durbin and Koopman (2012); Jones (1993); Anderson and Moore (1979). In addition, informative articles about state space modeling of longitudinal data include Wecker and Ansley (1983); Kohn and Ansley (1991); De Jong and Mazzi (2001); Eubank, Huang, and Wang (2003); Selukar (2015). For the implementation details of the diffuse Kalman filter and smoother (the main computational tool used by the SSM procedure), the main references are a series of articles (De Jong 1989, 1991; De Jong and Chu-Chun-Lin 2003) and the references therein.

Getting Started: SSM Procedure

This example illustrates how you can use the SSM procedure to analyze a panel of time series. The following data set, Cigar, contains information about yearly per capita cigarette sales for 46 geographic regions in the United States over the period 1963–1992. The variables lsales, lprice, lndi, and lpimin denote the per capita cigarette sales, price per pack of cigarettes, per capita disposable income, and minimum price in adjoining regions per pack of cigarettes, respectively (all in the natural log scale). The variable year contains the observation year, and the variable region contains an integer between 1 to 46 that serves as the unique identifier for the region. For additional data description see Baltagi and Levin (1992); Baltagi (1995). The data are sorted by year.

```
data cigar;
    input year region lsales lprice lndi lpimin;
    label lsales = 'Log cigarette sales in packs per capita';
    label lprice = 'Log price per pack of cigarettes';
    label lndi = 'Log per capita disposable income';
    label lpimin = 'Log minimum price in adjoining regions
                    per pack of cigarettes';
    year = intnx( 'year', '1jan63'd, year-63 );
    format year year.;
datalines;
63 1 4.54223 3.35341 7.3514 3.26194
63 2 4.82831 3.17388 7.5729 3.21487
63 3 4.63860 3.29584 7.3000 3.25037
63 4 4.95583 3.23080 7.9288 3.17388
63 5 5.05114 3.28840 7.9772 3.26576

   ... more lines ...
```

The goal of the analysis is to study the impact of the regressors on the smoking behavior and to understand the changes in the smoking patterns in different regions over the years. Consider the following model for

lsales:

$$\text{lsales}_{i,t} = \boldsymbol{\mu}_{i,t} + \text{lprice}\,\boldsymbol{\beta}_1 + \text{lndi}\,\boldsymbol{\beta}_2 + \text{lpimin}\,\boldsymbol{\beta}_3 + \boldsymbol{\epsilon}_{i,t}$$

This model represents lsales in a region i and in a year t as a sum of region-specific trend components $\boldsymbol{\mu}_{i,t}$, the regression effects due to lprice, lndi, and lpimin, and the observation noise $\boldsymbol{\epsilon}_{i,t}$. Different variations of this model are obtained by considering different models for the trend component $\boldsymbol{\mu}_{i,t}$. Proper modeling of the trend component is important because it captures differences between the regions because of unrecorded factors such as demographic changes over time, results of anti-smoking campaigns, and so on. The following statements specify and fit one such model:

```
proc ssm data=Cigar plots=residual;
   id year interval=year;
   array RegionArray{46} region1-region46;
   do i=1 to 46;
      RegionArray[i] = (region=i);
   end;
   trend IrwTrend(ll) cross(matchparm)=(RegionArray) levelvar=0;
   irregular wn;
   model lsales = lprice lndi lpimin IrwTrend wn;
   eval TrendPlusReg = IrwTrend + lprice + lndi + lpimin;
   output out=forCigar pdv press;
run;
```

The PROC SSM statement specifies the input data set, Cigar, which contains analysis variables such as the response variable, lsales, and the predictor variables, lprice, lndi, and lpimin. The PLOTS=RESIDUAL option in the PROC SSM statement produces residual diagnostic plots. The optional ID statement specifies a numeric index variable (often a SAS date or datetime variable), which is year in this case. The INTERVAL=YEAR option in the ID statement indicates that the measurements are collected on a yearly basis. The next few statements define a 46-dimensional array of dummy variables, RegionArray, such that RegionArray[i] is 1 if region is i and is 0 otherwise. The next three statements, TREND, IRREGULAR, and MODEL, constitute the model specification part of the program:

- **`trend IrwTrend(ll) cross(matchparm)=(RegionArray) levelvar=0;`** defines a trend, named IrwTrend, of local linear type (which is signified by the keyword *ll* used within the parenthesis after the name). A local linear trend—a trend with time-varying level and time-varying slope—depends on two parameters: the disturbance variance of the level equation and the disturbance variance of the slope equation (see the section "Local Linear Trend" on page 2447 for more information). The LEVELVAR=0 specification fixes the disturbance variance of the level equation to 0, which results in a trend model called an *integrated random walk* (IRW). An IRW model tends to produce a smoother trend than a general local linear trend. In the limiting case, if the disturbance variance of the slope equation is also 0, the IRW trend reduces to a straight line (with a fixed intercept and slope). In addition, because of the use of the 46-dimensional array, RegionArray, in the CROSS= option (**`cross(matchparm)=(RegionArray)`**), this trend specification amounts to fitting a separate IRW trend for each region. This is because, as a result of the CROSS= option, IrwTrend is treated as a linear combination of 46 (the number of variables in RegionArray) stochastically independent, integrated random walks,

$$\text{IrwTrend}_t = \sum_{i=1}^{46} \text{RegionArray}[i]\,\boldsymbol{\mu}_{i,t}$$

where each $\mu_{i,t}$ is an integrated random walk. Note that since RegionArray[i] is a binary variable, lrwTrend equals $\mu_{i,t}$ when region is i. Lastly, the use of MATCHPARM option specifies that the different IRW trends $\mu_{i,t}$ use the same disturbance variance parameter for their slope equation. This is done mainly for parsimony. Based on the model diagnostics shown later, this appears to be a reasonable model simplification.

- **`irregular wn;`** defines the observation noise $\epsilon_{i,t}$, named wn, as a sequence of independent, identically distributed, zero-mean, Gaussian variables—a white noise sequence.
- **`model lsales = lprice lndi lpimin lrwTrend wn;`** defines the model for lsales as a sum of regression effects that involve lprice, lndi, and lpimin, a trend term, lrwTrend, and the observation noise wn.

The last two statements, EVAL and OUTPUT, control certain aspects of the procedure output. The following EVAL statement defines a linear combination, named TrendPlusReg, of selected terms in the MODEL statement:

```
eval TrendPlusReg = lrwTrend + lprice + lndi + lpimin;
```

This EVAL statement causes the SSM procedure to produce an estimate of TrendPlusReg (and its standard error), which can then be printed or output to a data set. TrendPlusReg contains all the terms in the model except for the observation noise and thus can be regarded as the *explanatory* part of the model. In the OUTPUT statement, you can specify an output data set that stores all the component estimates that are produced by the procedure. The following OUTPUT statement specifies forCigar as the output data set:

```
output out=forCigar pdv press;
```

The PDV option causes variables such as region1–region46, which are defined by the DATA step statements within the SSM procedure, also to be included in the output data set. The PRESS option causes the printing of fit measures that are based on the delete-one cross validation errors (see the section "Delete-One Cross Validation and Structural Breaks" on page 2443 for more information).

All the models that are specified in the SSM procedure possess a state space representation. For more information, see the section "State Space Model and Notation" on page 2430. The SSM procedure output begins with a table (not shown here) of the input data set that provides the name and other information. Next, the "Model Summary" table, shown in Figure 33.1, provides basic model information, such as the following:

- the dimension of the underlying state equation, 92 (because each of the 46 IRW trends $\mu_{i,t}$ contributes two elements to the state)
- the diffuse dimension of the model, 95 (which is equal to the three regressors plus the 92 diffuse initial states of $\mu_{i,t}$)
- the number of model parameters, 2 (which is the common disturbance variance of the slope equation in lrwTrend and the variance of the noise term wn)

This information is very useful in determining the computational complexity of the model (the larger state size, 92, explains the relatively long computing time—as much as two minutes on some desktops—for this example).

Figure 33.1 Summary of the Underlying State Space Model

The SSM Procedure

Model Summary	
Model Property	**Value**
Number of Model Equations	1
State Dimension	92
Dimension of the Diffuse Initial Condition	95
Number of Parameters	2

The index variable information is shown in Figure 33.2. Among other things, it categorizes the data to be of the type *Regular with Replication*, which implies that the data are regularly spaced with respect to the ID variable and at least some observations have the same ID value. This is clearly true in this example: the data are yearly without any gaps, and there are 46 observations in each year—one per region.

Figure 33.2 Index Variable Information

ID Variable Information					
Name	**Start**	**End**	**Max Delta**	**NDistinct**	**Type**
year	1963	1992	1	30	Regular with Replication

Figure 33.3 provides simple summary information about the response variable. It shows that lsales has no missing values and no induced missing values because the predictors in the model, lprice, lndi, and lpimin, do not have any missing values either.

Figure 33.3 Response Variable Summary

Response Variable Information							
	Number of Observations						
Name	**Total**	**Missing**	**Induced Missing**	**Minimum**	**Maximum**	**Mean**	**Std Deviation**
lsales	1380	0	0	3.98	5.7	4.79	0.225

The regression coefficients of lprice, lndi, and lpimin are shown in Figure 33.4. As expected, the coefficient of lprice is negative and the coefficients of lndi and lpimin are positive, all being statistically significant. This is consistent with the expectation that the cigarette sales are adversely affected by the price and are positively correlated with the disposable income. The estimated effect of lpimin, called the bootlegging effect by Baltagi and Levin (1992), is statistically significant but smaller than the effects of lprice and lndi.

Figure 33.4 Estimated Regression Coefficients

Regression Parameter Estimates					
Response Variable	**Regression Variable**	**Estimate**	**Standard Error**	**t Value**	**Pr > |t|**
lsales	**lprice**	-0.3480	0.0232	-15.01	<.0001
lsales	**lndi**	0.1425	0.0344	4.15	<.0001
lsales	**lpimin**	0.0619	0.0269	2.30	0.0214

Figure 33.5 Estimated Model Parameters

Model Parameter Estimates

Component	Type	Parameter	Estimate	Standard Error	t Value
lrwTrend	LL Trend	Slope Variance	0.000169	0.0000219	7.72
wn	Irregular	Variance	0.000592	0.0000342	17.29

Figure 33.5 shows the estimates of the disturbance variance of the slope equation in lrwTrend and the variance of the noise term wn.

Figure 33.6 shows a panel of residual normality diagnostic plots. These plots show that the residuals are symmetrically distributed but contain slightly larger than expected number of extreme residuals. Figure 33.7 shows the plot of residuals versus time. There the residuals do not exhibit any obvious pattern; however, the plot does show that more extreme residuals appear before 1970 and after 1989. On the whole, however, these plots do not exhibit serious violations of model assumptions.

Figure 33.6 Residual Normality Check

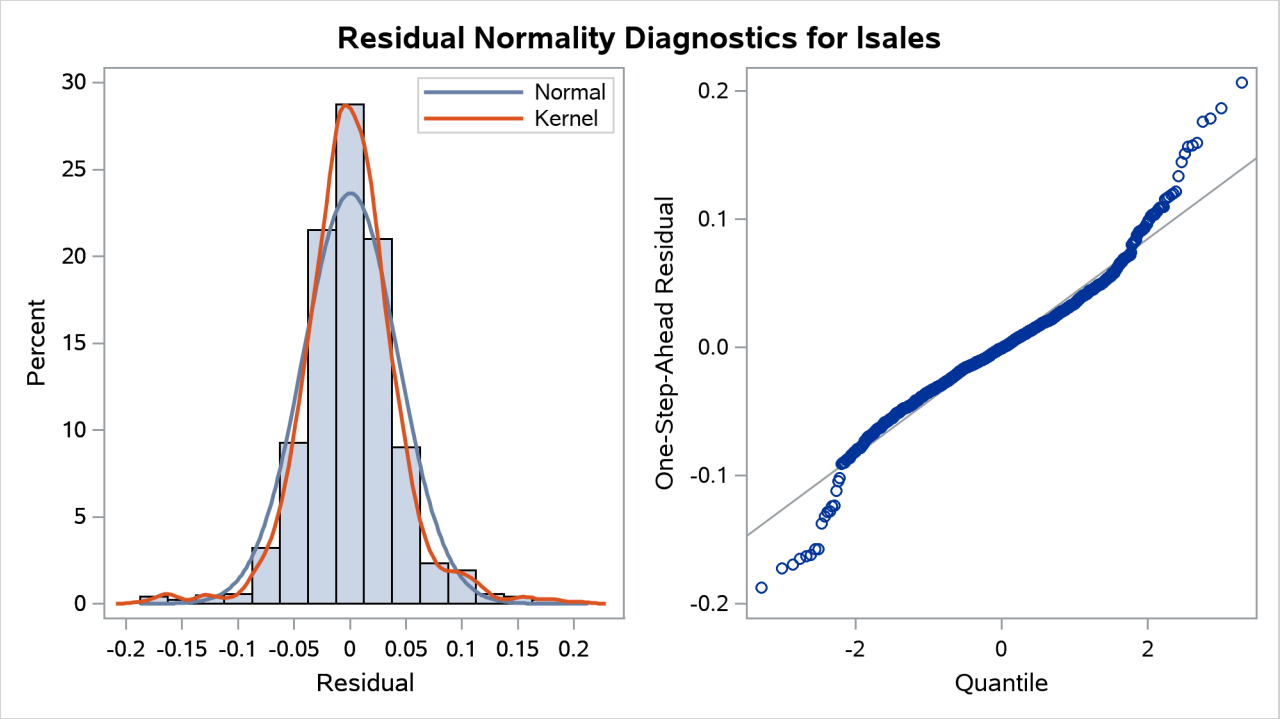

Figure 33.7 Standardized Residuals Plotted against Time

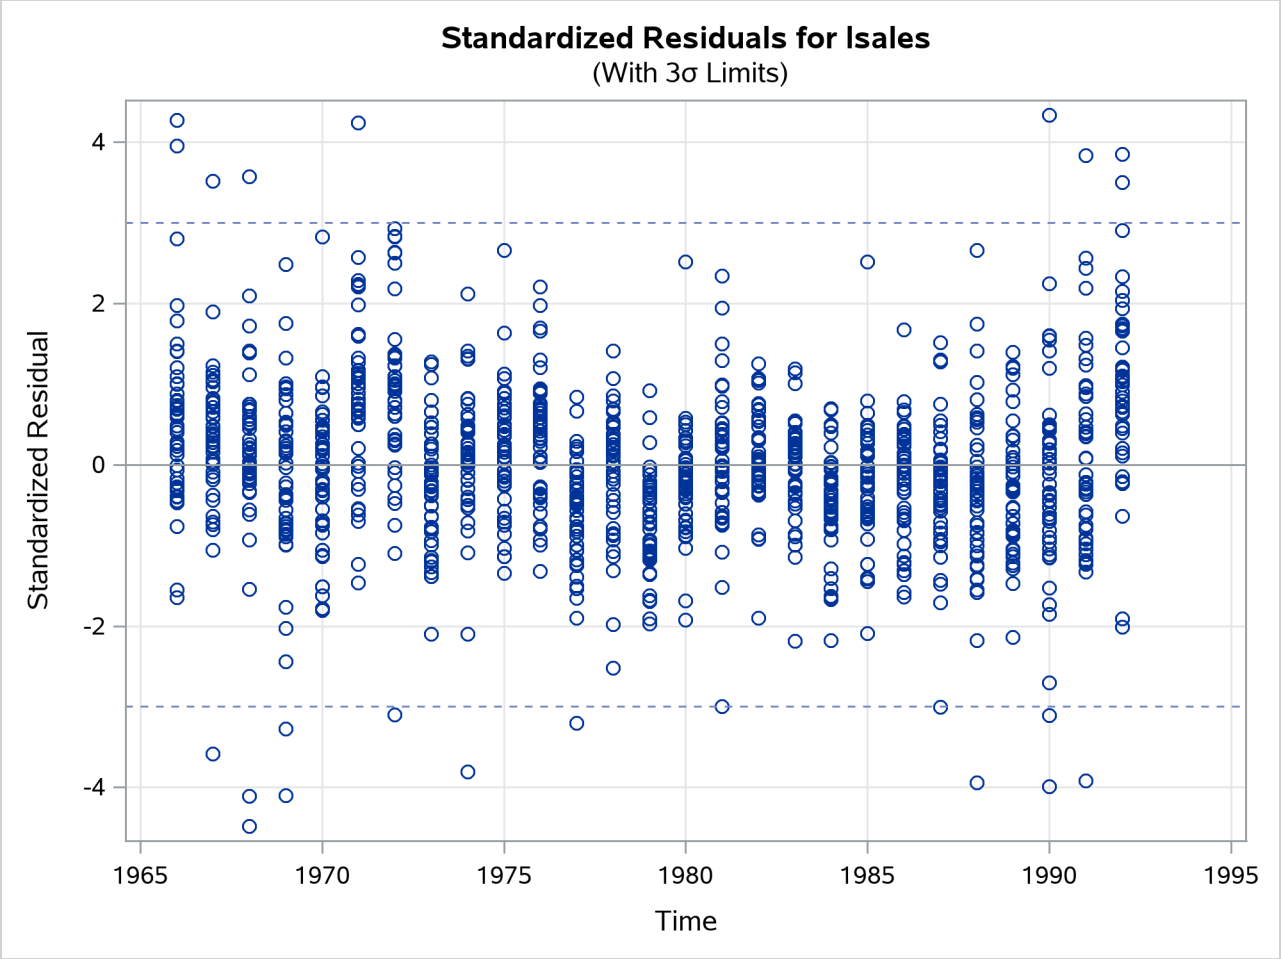

Figure 33.8 shows the details of the likelihood computations such as the number of nonmissing response values used and the likelihood of the fitted model. For more information, see the section "Likelihood Computation and Model-Fitting Phase" on page 2439. Figure 33.8 shows the likelihood-based information criteria in lower-is-better format, which are useful for model comparison.

Figure 33.8 Likelihood Computation Details

Profile Log Likelihood	2169.6232

Figure 33.9 Information Criteria

Information Criteria		
Statistic	Diffuse Likelihood Based	Profile Likelihood Based
AIC (lower is better)	-4488.093	-4145.246
BIC (lower is better)	-4477.776	-3637.952
AICC (lower is better)	-4488.084	-4130.417
HQIC (lower is better)	-4484.220	-3955.472
CAIC (lower is better)	-4475.776	-3540.952

In addition to the regression estimates, it is useful to analyze the estimates of different model components such as the trend component lrwTrend and the linear combination TrendPlusReg. These estimates can be printed by using the PRINT= option provided in the TREND and EVAL statements, or they can be output to a data set (as it is done in this illustration). This latter option is particularly useful for graphical exploration of these components by standard graphical procedures such as SGPLOT and SGPANEL procedures. The following statements produce a panel of plots that shows how well the proposed model fits the observed cigarette sales in the first three regions, which correspond to Alabama, Arizona, and Arkansas. The output data set, forCigar, contains all the needed information: Smoothed_TrendPlusReg contains the smoothed (full-sample) estimate of TrendPlusReg, and Smoothed_Lower_TrendPlusReg and Smoothed_Upper_TrendPlusReg contain its 95% lower and upper confidence limits. In addition, for easy readability, a user-defined format (RegionFormat), which is created by using the FORMAT procedure (not shown), is used to associate the region names to region values.

```
proc sgpanel data=forCigar noautolegend;
   where region <= 3;
   format region RegionFormat.;
   title 'Region-Specific Sales Patterns with 95% Confidence Band';
   panelby region / columns=3;
   band x=year lower=Smoothed_Lower_TrendPlusReg
   upper=Smoothed_Upper_TrendPlusReg;
   scatter x=year y=lsales;
   series x=year y= Smoothed_TrendPlusReg;
run;
```

Figure 33.10 Cigarette Sales Patterns for the First Three Regions

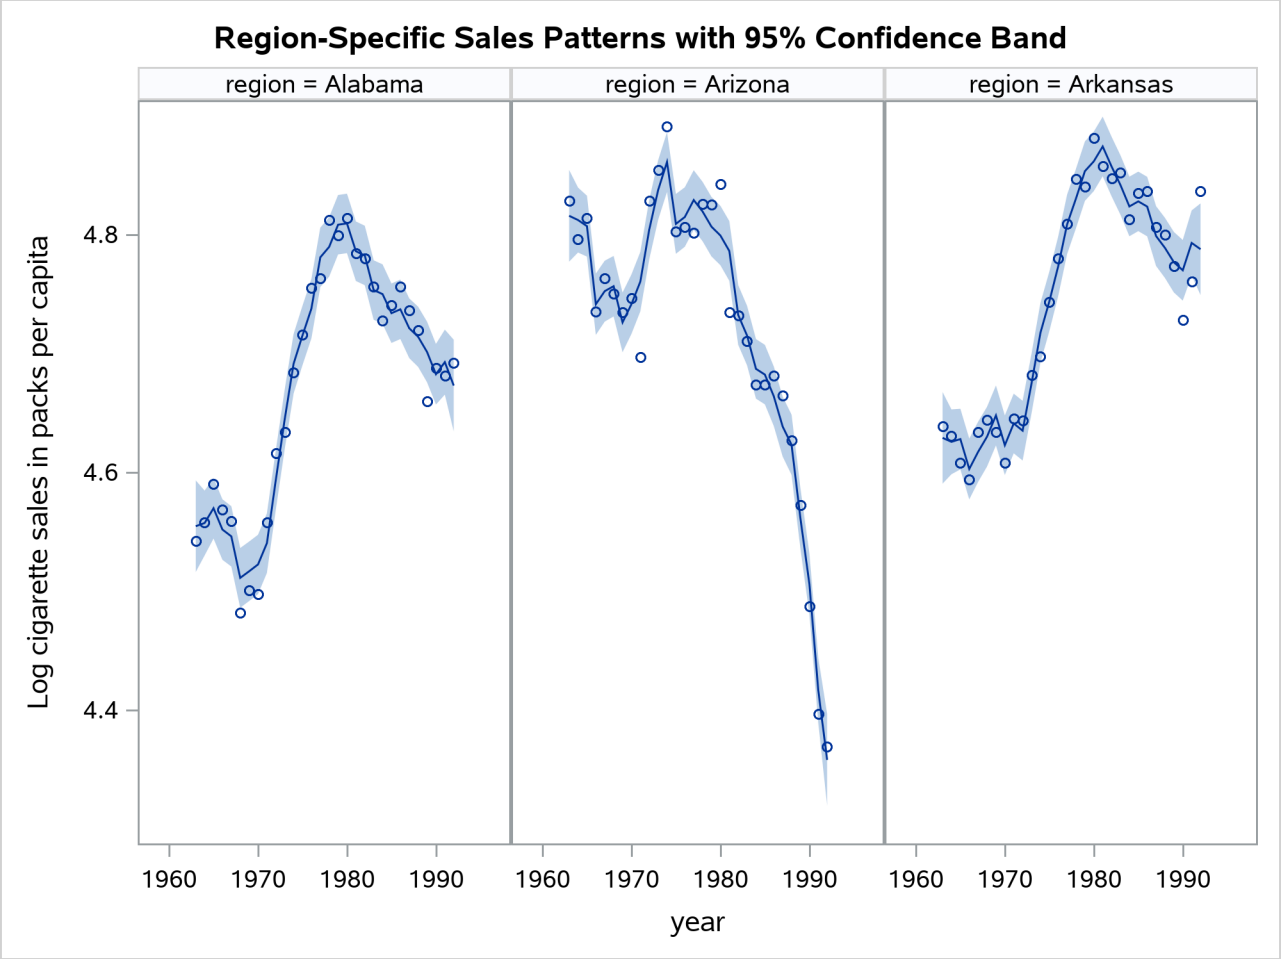

Figure 33.10 seems to indicate that the model fits the data reasonably well. It also shows that Arizona differs markedly from Alabama and Arkansas in its cigarette sales pattern over the years. The following statements produce a similar panel of plots that show the estimate of trend without the regression effects:

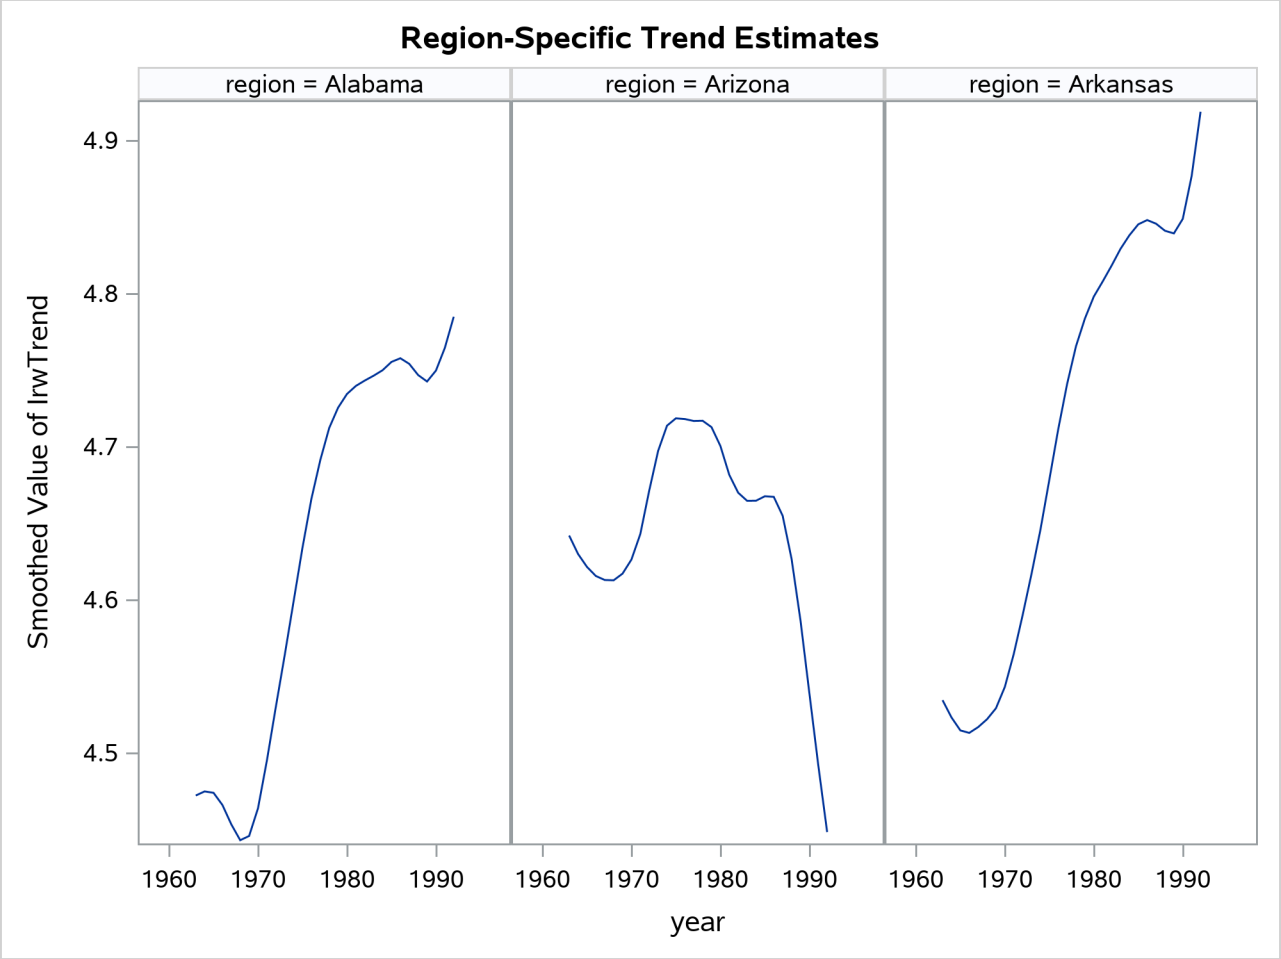
```
proc sgpanel data=forCigar noautolegend;
   where region <= 3;
   format region RegionFormat.;
   title 'Region-Specific Trend Estimates';
   panelby region / columns=3;
   series x=year y= smoothed_IrwTrend;
run;
```

Figure 33.11 Estimate of IrwTrend for the First Three Regions



The trend patterns, shown in Figure 33.11, seem to suggest that after accounting for the regression effects, per capita cigarette sales were on the rise in Alabama and Arkansas while they were declining in Arizona.

Syntax: SSM Procedure

The following statements are available in the SSM procedure:

PROC SSM < *options* > **;**
BY *variables* **;**
COMPONENT *name* **=** (*variables*)* *state* < / *options* > **;**
DEPLAG *name*(*response-variable*) *lag-term1* < *lag-term2 . . .* > **;**
EVAL *name* **=** *expression* < / *options* > **;**
ID *variable* < *option* > **;**
IRREGULAR *name* < *options* > **;**
MODEL *response* **=** *variables* < / *options* > **;**
OUTPUT < *options* > **;**
PARMS *variables* < / *options* > **;**
Programming statements **;**
STATE *name*(*dim*)< *options* > **;**
TREND *name*(*type*)< *options* > **;**

You can specify all statements except the BY, ID, and the OUTPUT statements multiple times. The PROC SSM statement and at least one MODEL statement are required. In addition to these statements, you can use most DATA step programming statements to define new variables that are needed for specifying different parts of the state space model.

NOTE: In the statement options described throughout this section, whenever you use a list to specify the elements of the system matrices, the list elements must all be of the same type: either all of them must be variables or all of them must be numbers. In addition, if the list contains more than one variable, then they cannot be of the array type. These are not serious restrictions. When the list contains mix of variables and numbers, you can redefine the numbers as constant variables. Similarly, you can reformulate a list that contains a mix of variables of array and non-array types as just one array by combining all its elements in a new array.

Functional Summary

Table 33.1 summarizes the statements and options that control the SSM procedure. Most commonly needed scenarios are listed; for more information, see the individual statements.

Table 33.1 PROC SSM Functional Summary

Description	Statement	Option
Data Set Options		
Specifies the input data set	PROC SSM	DATA=
Writes series and component forecasts to an output data set	OUTPUT	OUT=
Model Specification Options		
Specifies the index variable	ID	

Table 33.1 *continued*

Description	Statement	Option
Defines variables as model parameters	PARMS	
Specifies a response variable and the associated observation equation	MODEL	
Specifies a state subsection	STATE	
Specifies the transition matrix of a state subsection	STATE	T
Specifies the disturbance covariance matrix of a state subsection	STATE	COV
Specifies the size of the diffuse initial condition of a state subsection	STATE	A1
Specifies the initial covariance matrix of a state subsection	STATE	COV1
Specifies a state subsection for a predefined structural model	STATE	TYPE=
Specifies the regressors in a state equation	STATE	W
Specifies the input vector in a state equation	STATE	SINPUT=
Specifies a component	COMPONENT	
Specifies a predefined trend component	TREND	
Likelihood Optimization Process Control Options		
Specifies the optimization technique	PROC SSM	OPTIMIZER(TECH=)
Limits the number of iterations	PROC SSM	OPTIMIZER(MAXITER=)
Outlier and Structural Break Detection Options		
Turns on the search for additive outliers (AO)		Default
Turns on the search for structural breaks in a state subsection	STATE	CHECKBREAK
Turns on the search for structural breaks in a state subsection associated with a trend	TREND	CHECKBREAK
Specifies the significance level for additive outlier tests	OUTPUT	AO(ALPHA=)
Limits the reported number of additive outliers	OUTPUT	AO(MAXNUM=)
Limits the reported number of additive outliers to a percentage of the series length	OUTPUT	AO(MAXPCT=)
Specifies the significance level for structural break tests	OUTPUT	BREAK(ALPHA=)
Limits the reported number of structural breaks	OUTPUT	BREAK(MAXNUM=)
Limits the reported number of structural breaks to a percentage of the series length	OUTPUT	BREAK(MAXPCT=)
Turns on the search for maximal state shock	OUTPUT	MAXSHOCK
Graphical Residual and Outlier Analysis Options		
Creates a panel of plots that consists of residual normality plots	PROC SSM	PLOTS=RESIDUAL(NORMAL)

Table 33.1 *continued*

Description	Statement	Option
Creates the standardized residual plot against time	PROC SSM	PLOTS=RESIDUAL(STD)
Creates a panel of plots that consists of prediction error normality plots	PROC SSM	PLOTS=AO(NORMAL)
Creates the standardized prediction error plot against time	PROC SSM	PLOTS=AO(STD)
Creates the plot of maximal state shock chi-square statistics against time	PROC SSM	PLOTS=MAXSHOCK
Output Control Options		
Specifies the significance level of the forecast confidence limits	OUTPUT	ALPHA=
Prints the prediction error sum of squares table	OUTPUT	PRESS
Specifies a linear combination of components to be output	EVAL	
Global Printing and Plotting Options		
Turns off all printing for the procedure	PROC SSM	NOPRINT
Turns on all printing options for the procedure	PROC SSM	PRINTALL
Turns off all plotting for the procedure	PROC SSM	PLOTS=NONE
Turns on all plotting options for the procedure	PROC SSM	PLOTS=ALL
Printing State Equation System Matrix Options		
Prints the transition matrix that is associated with a state subsection	STATE	PRINT=T
Prints the disturbance covariance matrix that is associated with a state subsection	STATE	PRINT=COV
Prints the initial covariance matrix that is associated with a state subsection	STATE	PRINT=COV1
Prints the autoregressive coefficient matrix that is associated with a state subsection	STATE	PRINT=AR
Prints the moving average coefficient matrix that is associated with a state subsection	STATE	PRINT=MA
Printing Component, Series Forecast, and Smoothed Estimate Options		
Prints the series forecasts	MODEL	PRINT=FILTER
Prints the full-sample estimates of missing series values	MODEL	PRINT=SMOOTH
Prints the smoothed trend estimate	TREND	PRINT=SMOOTH
Prints the filtered trend estimate	TREND	PRINT=FILTER
Prints the smoothed component estimate	COMPONENT	PRINT=SMOOTH
Prints the filtered component estimate	COMPONENT	PRINT=FILTER
Prints the smoothed component estimate	EVAL	PRINT=SMOOTH
Prints the filtered component estimate	EVAL	PRINT=FILTER

Table 33.1 *continued*

Description	Statement	Option
BY Groups		
Specifies BY-group processing	BY	

PROC SSM Statement

PROC SSM < *options* > **;**

The PROC SSM statement is required. You can specify the following *options* in the PROC SSM statement:

BREAKPEAKS
prints an alternate form of the break summary tables when the CHECKBREAK option is used in the STATE or TREND statement or when the MAXSHOCK option is used in the OUTPUT statement. In this alternate form, the summary tables report the significant peaks of the shock statistics curves; see Example 33.8 for examples of these curves.

DATA=*SAS-data-set*
specifies the name of the SAS data set that contains the variables needed for the analysis. If you do not specify this option, PROC SSM uses the most recently created SAS data set.

LIKE=DIFFUSE | MARGINAL
specifies the type of likelihood to use for parameter estimation. You can specify the following values:

DIFFUSE specifies diffuse likelihood.

MARGINAL specifies marginal likelihood.

By default, LIKE=DIFFUSE. For more information about different likelihood types, see the section "Likelihood Computation and Model-Fitting Phase" on page 2439.

NOPRINT
turns off all the printing and plotting for the procedure. Any subsequent print options are ignored.

PLOTS < **(***global-plot-options***) > = ***plot-request* < *(options)* >

PLOTS< **(***global-plot-options***) > = (** *plot-request* < *(options)* > **< . . .** *plot-request* < *(options)* > **>)**
controls the plots produced with ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses around it. Here are some examples:

```
plots=none
plots=all
plots=residual
plots=residual(normal)
plots=(maxshock residual(normal))
plots(unpack)=residual
```

If you do not specify any specific *plot-request*, then by default PROC SSM produces the plot of standardized residuals against time. For general information about ODS Graphics, see Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Global Plot Options

The *global-plot-options* apply to all relevant plots generated by the SSM procedure. The following *global-plot-option* is supported:

UNPACK
displays each graph separately. (By default, some graphs can appear together in a single panel.)

Specific Plot Options

The following list describes the specific *plot-requests* and their *options*:

ALL
produces all plots appropriate for the particular analysis.

AO< (*prediction-error-plot-options***) >**
produces the prediction error plots—one for each response variable. You can specify the following *prediction-error-plot-options*:

NORMAL
produces a summary panel of the prediction error diagnostics, which consist of the following:

- histogram of prediction errors
- normal quantile plot of prediction errors

STD
produces a scatter plot of standardized prediction errors against time.

MAXSHOCK
produces a scatter plot of maximal state shock statistics against time.

NONE
suppresses all plots.

RESIDUAL < (*residual-plot-options***) >**
produces the residuals plots—one for each response variable. You can specify the following *residual-plot-options*:

NORMAL
produces a summary panel of the residual diagnostics, which consist of the following:

- histogram of residuals
- normal quantile plot of residuals

STD
produces a scatter plot of standardized residuals against time.

For more information about the precise meaning of the terms *maximal state shock statistics* and *prediction errors*, see the section "Delete-One Cross Validation and Structural Breaks" on page 2443.

PRINTALL
turns on all the printing options for the procedure. All subsequent NOPRINT options in the procedure are ignored.

STATEINFO
prints two tables that provide information about the composition of the state vector in terms of the components specified in the model. One table describes the composition of state $\boldsymbol{\alpha}_t$, and the other table describes the diffuse vector $\boldsymbol{\delta}$ and the regressors, which are part of the initial condition specification $\boldsymbol{\alpha}_1$. For more information about the state space model notation, see the section "State Space Model and Notation" on page 2430.

OPTIMIZER(<TECHNIQUE=*technique***> <MAXITER=***integer***>)**
specifies options that are associated with the optimizer used in the maximum likelihood parameter estimation. The default settings of the optimization process are adequate in most problems. However, in some cases it might be useful to change the optimization technique or to change the maximum number of iterations. You can specify one of the following *techniques*:

ACTIVESET	corresponds to the active-set method.
DBLDOG	corresponds to the double-dogleg method.
INTERIORPOINT	corresponds to the primal-dual interior point method.
NEWRAP	corresponds to the Newton-Raphson method.
QUANEW	corresponds to the (dual) quasi-Newton method.
TRUREG	corresponds to the trust region method.

The default technique is TRUREG. The INTERIORPOINT and ACTIVESET techniques are documented in Chapter 10, "The Nonlinear Programming Solver" (*SAS/OR User's Guide: Mathematical Programming*), and the remaining techniques are documented in Chapter 6, "Nonlinear Optimization Methods." You can alter the maximum number of iterations setting in the nonlinear optimization search by specifying a nonnegative *integer* as the MAXITER= value.

ZSPARSE
enables the exploitation of the sparsity of the $\mathbf{Z}_t$ matrices in the observation equation during the modeling calculations (see the section "State Space Model and Notation" on page 2430 for further information). The use of this option can improve the computational efficiency of models that have a large state dimension and sparse $\mathbf{Z}_t$ matrices—that is, many of their elements are zero. You should use the ZSPARSE option only when the state dimension is sufficiently large (at least 30) and a good percentage (at least 50%) of $\mathbf{Z}_t$ entries are zero; otherwise, the computational efficiency can in fact degrade. For example, the illustration that is discussed in the section "Getting Started: SSM Procedure" on page 2398 is a good candidate for the use of the ZSPARSE option:

```
proc ssm data=Cigar plots=residual zsparse;
```

BY Statement

BY *variables* **;**

A BY statement can be used in the SSM procedure to process a data set in groups of observations that are defined by the BY variables. The model specified by using the MODEL and other statements is applied to all the groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. The BY variables are one or more variables in the input data set. The BY variables cannot be used in the model specification; in particular, they cannot be used as response variables or regressors in a MODEL statement.

COMPONENT Statement

COMPONENT *name* **=** **(***var1 var2 . . . | number1 number2 . . .***)** ***** *state* **<** **/** *options* **>** **;**

COMPONENT *name* **=** *state*[*integer*] **<** **/** *options* **>** **;**

COMPONENT *name* **=** **(***Variable* | *Number***)*** *state*[*integer*] **<** **/** *options* **>** **;**

The COMPONENT statement specifies a component (a linear combination of state elements), named *name*. You can use *name* later as a term in the right-hand side of the MODEL statement, which defines the observation equation. The estimate of *name* is output to the OUT= data set that is specified in the OUTPUT statement. In addition, you can print the component estimate by using the PRINT= option.

The first form of the COMPONENT statement defines a component as a dot product of a state subsection *state* and a row vector *(var1 var2 . . .)*. The value of *state* can be the name of a state subsection that is defined by using a STATE statement elsewhere in the program, or it can be the name of the state that is associated with a trend component defined by using a TREND statement elsewhere in the program (see the section "TREND Statement" on page 2426 for more information about the naming of the state that is associated with a trend component). The row vector *(var1 var2 . . .)*, which can be either a list of numbers or a list of variables, must be of the same dimension as the actual dimension of the state subsection. The dot product form—also called the explicit dot product form—of the component specification is unambiguous; however, it requires detailed knowledge of the state vector underlying the *state* specification. Suppose that mystate is a two-dimensional state defined by a STATE statement elsewhere in the program and that X1 and X2 are (numeric) predictor variables. The following are valid examples of the dot product form of the COMPONENT statement:

```
component c1 = (x1 x2) * mystate;
component c2 = (1 1) * mystate;
```

The second and the third forms of the COMPONENT statement are a shortened version of the first form. The second form defines the component as a particular element of state—for example, state[3] defines the component as the third element of *state*. The specified *integer* must lie between 1 and *dim*, the nominal dimension of state. The second form of component specification has another important use when the STATE statement that defines *state* uses the TYPE= option to set its type or when *state* is associated with a trend component. In these cases, the second form of the component specification assumes additional meaning

when the nominal state dimension and the actual state dimensions differ (specifically the state types LL, SEASON, CYCLE, and VARMA and the states associated with all the trend types). For example, if *state* is a three-dimensional seasonal component, state[2] signifies an appropriate linear combination of *state* that results in the second of the three seasonals that constitute the three-dimensional seasonal. Similar interpretation holds for the CYCLE type. For more information, see the sections "Multivariate Season" on page 2453 and "Predefined Structural Models" on page 2450. The third form extends the second form by permitting multiplication by a variable or a number.

NOTE: A component that is based on a state associated with a trend component cannot be used as a right-hand side term in any MODEL statement. That is, it is defined purely for output purposes (either printed or output to a data set). However, it can be used as a term in the expression that is specified in an EVAL statement to build more complex linear combinations for output.

You can specify the following *options* to print the filtered or smoothed estimate of the component:

PRINT=FILTER | SMOOTH

PRINT=(< FILTER > < SMOOTH >)
requests printing of the filtered or smoothed estimate of the specified component.

DEPLAG Statement

DEPLAG *name*(*response-variable*) *lag-term1 < lag-term2 . . . >* **;**

The DEPLAG statement defines a term, named *name*, that consists of a linear combination of lagged response variables. You can use *name* later as a right-hand-side term in the MODEL statement for the response variable, as specified in *name(response-variable)*. For a multivariate model, a separate DEPLAG statement is needed for each MODEL statement that has a right-hand-side term that involves lagged response variables. The linear combination of lagged response variables is specified by using one or more *lag-terms*. Each *lag-term* specifies the lags that are associated with one of the response variables.

A *lag-term* is specified in one of the following forms:

lag-response-variable(**LAGS=***maximum-lag*)

lag-response-variable(**LAGS=(***integer1 integer2 . . .*)**)**

lag-response-variable(**LAGS=***maximum-lag* **COEFF=(***number1 number2 . . .*) | (*variable1 variable2 . . .*)**)**

lag-response-variable(**LAGS=(***integer1 integer2 . . .*) **COEFF=(***number1 number2 . . .*) | (*variable1 variable2 . . .*)**)**

The *lag-response-variable* in the lag term specification can be the same as the response variable that corresponds to the model equation (which is specified in *name(response-variable)*), or it can be a different response variable.

The first form of specification is useful when all lags up to the *maximum-lag*, which must be a positive integer, are present in the lag term. The second form is useful when only certain lags, which are specified as a list of positive integers in parentheses, are present. In these two cases, the lag coefficients are not specified and they are treated as unknown parameters to be estimated from the data.

The COEFF= option in the last two forms enable you to specify lag coefficients. The COEFF= option must follow the LAGS= option. You can use the COEFF=(*number1 number2 . . .*) option to specify the lag

coefficients as known values. Similarly, you can use the COEFF=(*variable1 variable2* ...) option to specify user-defined variables as lag coefficients; the user-defined variables can be functions of parameters (which are defined by using the PARMS statement) and input variables. However, the lag coefficients cannot depend on any of the response variables. The number of coefficients specified in the COEFF= option must exactly equal the number of lags specified in the LAGS= option.

There can be at most one DEPLAG statement associated with a particular MODEL statement (you can specify all the needed lag terms in a single DEPLAG statement).

As an illustration, let lagsFORy1 and lagsFORy2 represent the following linear combinations of lagged response variables Y1, Y2, and Y3:

$$\text{lagsFORy1} = \theta_{11} Y1_{t-1} + \theta_{12} Y1_{t-2} + \theta_{22} Y2_{t-2} + \theta_{23} Y2_{t-3} + 1.2 Y3_{t-1} - 2.1 Y3_{t-2}$$

$$\text{lagsFORy2} = \text{Phi1} Y1_{t-1} + \text{Phi2} Y1_{t-2} + \theta_{21} Y2_{t-1}$$

where Phi1 and Phi2 denote user-defined variables and θ_{ij} denote generic parameters. You can specify lagsFORy1 (which is used in the model equation for Y1) and lagsFORy2 (which is used in the model equation for Y2) as follows:

```
deplag lagsFORy1(y1) y1(lags=2) y2(lags=(2 3)) y3(lags=2 coeff=(1.2 -2.1));
deplag lagsFORy2(y2) y1(lags=2 coeff=(phi1 phi2)) y2(lags=1);
... more statements ...;
model y1 = lagsFORy1 ...;
model y2 = lagsFORy2 ...;
model y3 = ...;
... more statements ...;
```

assuming that the right-hand side of the MODEL equation for Y3 does not have a term that involves lags of response variables.

The DEPLAG statement in PROC SSM has the same purpose as the DEPLAG statement in PROC UCM (see Chapter 41, "The UCM Procedure"). However, there are many differences in the syntax of the two statements, mainly because PROC SSM supports much more complex models. The syntax difference between the two DEPLAG statements can be illustrated by considering the differencing specification—$(1 - B)(1 - B^{12}) = (1 - B - B^{12} + B^{13})$—in the well-known airline model (ARIMA(0, 1, 1)(0, 1, 1)12 model). You can specify the lag-term that is implied by the differencing in the airline model in PROC UCM as follows:

```
deplag lags=(1)(12) phi=1 1 noest;
```

In PROC SSM the same specification has the following form:

```
deplag airLags(y) y(lags=(1 12 13) coeff=(1 1 -1));
```

Both these specifications define the same lag-term: $(y_{t-1} + y_{t-12} - y_{t-13})$.

For an example of the use of lagged response variables in a model specification, see Example 33.13. For more information about models that have dependent lags, see the section "Models with Dependent Lags" on page 2456.

NOTE: Models that have lagged response variables are permitted only if the data form a time series (either univariate or multivariate). The SSM procedure adds one more restriction on the models that use lagged response variables: the variables in the list that define a component in any of the COMPONENT statements must be free of unknown parameters. This restriction is artificial and is made primarily to reduce the overall complexity of the model. In future versions of the SSM procedure, this restriction might go away.

EVAL Statement

EVAL *name* **=** *number1*variable1 + number2*variable2 + . . .* < */ options* > **;**

The EVAL statement defines a linear combination, named *name*, of the terms used in the right-hand side of a MODEL statement. You can specify any variables (for example, predictor variables and names of components) in the expression of the EVAL statement; however, you cannot specify in this expression any observation disturbances that are specified by the IRREGULAR statement and any model terms that are specified by the DEPLAG statement. Suppose C1 and C2 are two components (defined by COMPONENT statements elsewhere in the program), T1 is a trend component, and X1 is a regression variable used in a model. The following are valid examples of the EVAL statement:

```
eval e1 = c1 - c2;
eval e2 = t1 + c1 + x1;
eval e2 = t1 + 2*c1 - 1.5*x1;
```

The estimates of linear combinations defined by the EVAL statement (for example, E1, E2, and E3) are output to the OUT= data set that is specified in the OUTPUT statement.

The components used in a given EVAL expression must correspond to distinct state subsections. This requirement is imposed only to simplify the overall readability of the program and does not limit the type of linear combinations that can be specified; if two components in the right hand side of an EVAL expression share the same state subsection, a new component that combines the effect of these two components can always be defined.

In addition, you can print these estimates by using the following PRINT= options:

PRINT=FILTER | SMOOTH

PRINT=(< **FILTER** > < **SMOOTH** >**)**

requests printing of the filtered or smoothed estimate of the specified linear combination.

NOTE: The expression builder in the EVAL statement is primitive. For example, you cannot use parentheses to group terms.

ID Statement

ID *variable* < *option* > **;**

The ID statement names a numeric variable to associate a sequence value—usually related to a time stamp—to the observations in the input data set. The observations within a BY group must be ordered in ascending order by the ID variable. Often the ID variable's values are SAS date, time, or datetime values, and each observation within a BY group has a unique ID value. Generally, however, the ID variable can be any numeric variable, and there can be multiple observations with the same ID value. If the ID values are SAS date, time, or datetime values, you can specify the associated unit of time—for example, day, week or month—by using the INTERVAL= option. If an ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID. Whenever an ID variable is specified, a variable, _ID_DELTA_, is automatically created that can be used as any input data set variable in the programming statements. _ID_DELTA_ contains the distance between two successive ID values. The first _ID_DELTA_ value is arbitrarily taken as one. If the INTERVAL= option is specified, the distance between the ID values is measured in terms of the number of

intervals; therefore, for regularly spaced data, _ID_DELTA_ is identically equal to one. You can specify the following *option* in the ID statement:

INTERVAL=*value*
specifies the unit of time interval that is used for measuring the ID values. INTERVAL=*value* is used in conjunction with the ID variable to check that the input data are in the proper order. For a complete discussion of the supported intervals, see Chapter 4, "Date Intervals, Formats, and Functions."

IRREGULAR Statement

IRREGULAR *name* < *options* > **;**

The IRREGULAR statement specifies a one-dimensional white noise component, which can be used to specify the observation error in a MODEL statement. You can specify the following *options* in the IRREGULAR statement:

PRINT=SMOOTH
requests printing of the smoothed estimate of the specified irregular component.

VARIANCE=*variable* | *number*
specifies the variance of the white noise. Any nonnegative value, including 0, is permissible. If the *variable* contains unknown parameters, they are estimated from the data. Similarly, if the VARIANCE= option is not specified, the variance is estimated from the data.

MODEL Statement

MODEL *response* **=** *variables* < / *options* > **;**

A MODEL statement specifies an observation equation that describes a response variable as a sum of regression effects and components that are defined in the program. The response variable must be a numeric variable from the input data set. The variables used in the right-hand side of the model expression can be numeric variables from the input data set, numeric variables defined by using programming statements, or names of components that are specified in the COMPONENT, DEPLAG, TREND, or IRREGULAR statements.

For a multivariate model, a separate MODEL statement is needed for each of the response variables. In this case, the observation errors, which are specified in an IRREGULAR statement, must be different in each MODEL statement.

The components that are specified in a given MODEL statement must correspond to distinct state subsections. This requirement is imposed only to simplify the overall readability of the program and does not limit the type of models that can be specified; if two components on the right-hand side of a MODEL statement share the same state subsection, a new component that combines the effect of these two components can always be defined.

You can specify the following *options* in the MODEL statement; they must be separated from the list of terms in the right-hand side of the model equation by a slash (/):

AGGREGATE(START=*startFlag*)

SUM(START=*startFlag*)

produces a table of full-sample predictions of the temporally aggregated values of the response variable that is specified in the MODEL statement. The variable that you specify in the START= option, *startFlag*, must be a zero-one variable that flags the start of an aggregation interval—equal to 1 at the start of an interval and 0 otherwise. For example, you can use this option to obtain the forecasts of weekly (or monthly) totals from a daily series. In this case, the value of *startFlag* is 1 at the start of the week (or month) and 0 otherwise. For more information, see the section "Temporal Aggregation and Temporal Distribution" on page 2457. This option is valid only if the data form a time series (either univariate or multivariate). If you use the AGGREGATE option in a MODEL statement, you cannot use the DISTRIBUTE option in the same statement or in another MODEL statement.

DISTRIBUTE(START=*startFlag*)

indicates that the response variable that is specified in the MODEL statement is a temporally aggregated version of an unobserved variable. The variable that you specify in the START= option, *startFlag*, must be a zero-one variable that flags the start of an aggregation interval—equal to 1 at the start of an interval and 0 otherwise. This option can be used only when the data form a time series (either univariate or multivariate) and when the overall model specification does not contain terms that involve lagged response variables (that is, the model specification does not involve the use of DEPLAG statements). If you use the DISTRIBUTE option in a MODEL statement, you cannot use the AGGREGATE option in the same statement or in another MODEL statement. For more information, see the section "Temporal Aggregation and Temporal Distribution" on page 2457.

PRINT=FILTER | SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests printing of the filtered or smoothed estimate of the specified response variable. The filtered estimate is produced during the filtering phase, and the smoothed estimate is produced by the smoothing phase of the Kalman filter and smoother algorithm. The filtered estimate is also called the one-step-ahead forecast of the response variable. The smoothed estimate corresponds to the full-sample prediction of the response variable. Since the full-sample prediction of a nonmissing response value is that value itself, full-sample predictions are printed only for the missing response values.

OUTPUT Statement

OUTPUT < *options* > **;**

The OUTPUT statement creates an optional output data set and also provides options to control certain aspects of the procedure output. If the OUT= option is specified, then an output data set is created to store estimates of the model components and series forecasts. If the OUT= option is omitted, then no data set is created by the OUTPUT statement. Other options in the OUTPUT statement produce additional information in the printed output generated by the procedure. For example, the AO and BREAK options control the search for additive outliers and structural breaks in the data, respectively.

AO(< ALPHA=*number* **> < MAXNUM=***number* **> < MAXPCT=***number* **>)**
controls the additive outlier search (see the section "Delete-One Cross Validation and the Additive Outlier Detection" on page 2443 for more information). The ALPHA= suboption specifies the significance level for reporting the outliers. The default is ALPHA=0.05. The MAXNUM= suboption limits the number of outliers to search. The default is MAXNUM=5. The MAXPCT= suboption is similar to the MAXNUM= suboption. In the MAXPCT= option you can limit the number of outliers to search for according to a percentage of the series length. The default is MAXPCT=1. When you specify both of these options, the lesser of the two search numbers is used.

ALPHA=*number*
specifies the significance level of the forecast confidence intervals. For example, ALPHA=0.05, which is the default, results in a 95% confidence interval.

BREAK(< ALPHA=*number* **> < MAXNUM=***number* **> < MAXPCT=***number* **>)**
controls the structural break search (for more information, see the section "Structural Breaks in the State Evolution" on page 2444). In order for this option to have any effect, the CHECKBREAK option in one of the STATE or TREND statements, or the MAXSHOCK option in the OUTPUT statement, must be turned on. The ALPHA= suboption specifies the significance level for reporting the breaks. The default is ALPHA=0.05. The MAXNUM= suboption limits the number of breaks to search. The default is MAXNUM=5. The MAXPCT= suboption is similar to the MAXNUM= suboption. In the MAXPCT= option, you can limit the number of breaks to search for according to a percentage of the number of distinct time points in the data. The default is MAXPCT=1. When you specify both of these options, the lesser of the two search numbers is used.

MAXSHOCK
causes the computation of the maximal state shock chi-square statistic at each distinct time point in the input data set. These statistics are output to the data set that is specified in the OUT= option. A time series plot of these statistics is produced if the PLOTS=MAXSHOCK option is specified in the PROC SSM statement. These statistics are useful for detecting structural breaks in the state evolution process. This option can be computationally expensive for a model with large state size. For more information, see the section "Structural Breaks in the State Evolution" on page 2444.

OUT=*SAS-data-set*
specifies an output data set for the forecasts. The output data set contains the ID variable (if specified), the response variables, the one-step-ahead and out-of-sample response variable forecasts, the forecast confidence intervals, the smoothed values of the response series, and the one-step-ahead and smoothed estimates of the model components—including expressions that are defined by using the EVAL statement. For more information, see the section "OUT= Data Set" on page 2466.

PDV
causes the inclusion of the variables (variables in the program data vector) that are defined by using the programming statements in the SSM procedure in the OUT= data set. The parameters defined by the PARMS statement are also included. The output data set contains the values of these variables evaluated for all the rows in the input data set that is specified in the DATA= option. The parameters in the PARMS statement contain their estimated values.

PRESS

prints the prediction error sum of squares (PRESS) and the generalized cross validation error sum of squares (GCV). The PRESS table also reports the number of summands that are used in these sums of squares. For more information, see the section "Delete-One Cross Validation and the Additive Outlier Detection" on page 2443.

PARMS Statement

PARMS *variable< =number> variable< =number> < / options>* **;**

The PARMS statement declares the parameters of a model and optionally sets their initial values. You can also specify the lower and upper limits of their validity range. The parameters declared by using the PARMS statement are called *named parameters* throughout this chapter. A model can have additional parameters: any unspecified quantity in the model specification becomes part of the parameter vector. You can specify the following *options*:

LOWER=(*number1 number2* **...)**

LOWER=(*number***)**

specifies the lower bounds for the specified parameters. The list can contain exactly one number, which is taken to be the lower bound for all the listed parameters in the statement, or it must contain as many values as the number of parameters specified. A missing value, denoted by ., is a permissible value, which signifies that the parameter has no lower bound.

UPPER=(*number1 number2* **...)**

UPPER=(*number***)**

specifies the upper bounds for the specified parameters. The list can contain exactly one number, which is taken to be the upper bound for all the listed parameters in the statement, or it must contain as many values as the number of parameters specified. A missing value, denoted by ., is a permissible value, which signifies that the parameter has no upper bound.

Programming Statements

To define the model, you can use most of the programming statements that are allowed in the SAS DATA step. For more information, see the *SAS DATA Step Statements: Reference*. For the most part, the syntax of programming statements used in PROC SSM is identical to that used in the MODEL procedure (see Chapter 24, "The MODEL Procedure") and the NLMIXED procedure (see Chapter 89, "The NLMIXED Procedure" (*SAS/STAT User's Guide*)). However, there are some restrictions: the DATA step lagging and differencing functions are not allowed, and the use of character variables in the DATA step expressions is not permitted. These are not serious restrictions; usually you can overcome them by adding the variables that are created by such operations to the input data set before its use in the SSM procedure.

STATE Statement

STATE *name* **(***dim***)**< *options* > **;**

The STATE statement specifies a subsection of $\boldsymbol{\alpha}_t$, the overall state vector at time t (for more information, see the section "State Space Model and Notation" on page 2430). Consider the state equations that define the state space model:

$$\begin{aligned} \boldsymbol{\alpha}_{t+1} &= \mathbf{T}_t\boldsymbol{\alpha}_t + \mathbf{W}_{t+1}\boldsymbol{\gamma} + \mathbf{c}_{t+1} + \boldsymbol{\eta}_{t+1} \\ \boldsymbol{\alpha}_1 &= \mathbf{c}_1 + \mathbf{A}_1\boldsymbol{\delta} + \mathbf{W}_1\boldsymbol{\gamma} + \boldsymbol{\eta}_1 \end{aligned}$$

You can specify multiple STATE statements, each specifying a separate subsection. It is assumed that the subsections that are specified by using different STATE statements are mutually independent. This independence assumption implies a block-diagonal structure for the transition matrices $\mathbf{T}_t$ and the disturbance covariances $\mathbf{Q}_t$ for all $t \geq 1$. An appropriate block structure also applies to $\mathbf{W}_t$ and $\mathbf{A}_1$. The *options* in the STATE statement provide complete control over the description of the relevant blocks of $\mathbf{T}_t$, $\mathbf{Q}_t$, $\mathbf{W}_t$, and $\mathbf{A}_1$. The argument *dim* (a positive integer in *name* (*dim*)) specifies the nominal dimension of this subsection. In most situations, the nominal dimension and the actual dimension of the state subsection are the same. However, when you specify the TYPE= option, the actual dimension of the state subsection can be different from the nominal dimension. The TYPE= option simplifies the state specification task for some commonly needed models.

NOTE: The T, COV, W, and COV1 options, described later in this section, specify the relevant blocks of $\mathbf{T}_t$, $\mathbf{Q}_t$, $\mathbf{W}_t$, and $\mathbf{Q}_1$, respectively. The structure of these matrix blocks is described in a similar way in the option descriptions. For example, the specification COV(I) corresponds to the identity form, COV(D) corresponds to the diagonal form, and COV(G) corresponds to the general form of the $\mathbf{Q}_t$ block.

You can use the following *options* in the STATE statement to specify the system matrices $\mathbf{T}_t$, $\mathbf{Q}_t$, $\mathbf{W}_t$, and $\mathbf{A}_1$ and to request printing of their estimates when they contain unknown parameters. You can also request the checking of unexpected changes—structural breaks—in the evolution of this state subsection by using the CHECKBREAK option.

A1(*nd***)**
treats the last *nd* elements of the state subsection as diffuse. This becomes the dimension of the relevant subsection of the diffuse vector $\boldsymbol{\delta}$. The $\mathbf{A}_1$ block is created by using appropriate columns of the identity matrix. The value of *nd* must lie between 1 and the nominal dimension, *dim*. The absence of this option signifies that this subsection of $\boldsymbol{\alpha}_t$ is nondiffuse. If both the COV1 and A1 options are specified, the last *nd* rows and columns of the matrix specified in the COV1 option are taken to be 0. This option cannot be used together with the RANK= option of the COV1 option.

CHECKBREAK< **(ELEMENTWISE | OVERALL)** >
turns on the checking of breaks for this state subsection. The ELEMENTWISE suboption requests the elementwise checking of any unexpected change in the state subsection as it evolves from one time point to the next. The OVERALL suboption requests a similar check for the entire state subsection—that is, in this case the change is measured as a multidimensional change. The ELEMENTWISE suboption is the default. Unless the PRINT=BREAKDETAIL option is specified, only a summary of the most significant breaks is produced. If the PRINT=BREAKDETAIL is specified, tables that contain the break significance statistics at every distinct time point are produced—one for the ELEMENTWISE suboption and one for the OVERALL suboption. For more information about the structural break

detection process, see the section "Structural Breaks in the State Evolution" on page 2444. For an example of the use of the CHECKBREAK option, see Example 33.8.

COV(D) < = (*var1 var2 . . .***) | (***number1 number2 . . .***) >**

COV(G) < = (*var1 var2 . . .***) | (***number1 number2 . . .***) >**

COV(I) < = (*variable***) | (***number***) >**

COV(RANK=*integer* **)**

specifies the relevant block of the disturbance covariance Q_t (for $t \geq 2$) in the transition equation. As with the T option, the absence of this option signifies that this Q-block consists of only zeros. The structure of the Q-block is also similarly specified. However, the following differences exist:

- The list that is specified to form the covariance must result in a symmetric, positive semidefinite matrix. For an example, see Example 33.5.
- You can specify a rank constraint on the Q-block by specifying COV(RANK=*integer*), where the specified integer must lie between 1 and *dim*. A rank constraint is permissible only for the general form and only when its elements are not specified by using a list.
- The convention of treating unset variables as structural zeros, which is used in specifying sparsity of the T-block, is not used in the Q-block specification. Whenever you explicitly specify the entries of the Q-block by specifying a list of variables in parentheses, all variables in the list must evaluate to nonmissing values.

The following examples illustrate different ways of specifying a Q-block. It is assumed that *dim* = 2.

- COV(G) specifies a general-form Q-block, which contributes $(2 * (2 + 1))/2 = 3$ unspecified elements to the parameter vector $\boldsymbol{\theta}$.
- COV(RANK=1) specifies a rank-one Q-block.

COV1(D) < = (*var1 var2 . . .***) | (***number1 number2 . . .***) >**

COV1(G) < = (*var1 var2 . . .***) | (***number1 number2 . . .***) >**

COV1(I) < = (*variable***) | (***number***) >**

COV1(RANK=*integer* **)**

specifies the relevant block of the initial state covariance Q_1. The different options in this case have the same meaning as the options of the COV option. However, the following differences exist:

- If the elements of Q_1 are specified by a list of variables in parentheses, then these variables must evaluate to constant values. In particular, they can depend on parameters that are specified by the PARMS statements; however, they cannot depend on any of the input data columns.
- If the initial condition is partially diffuse (that is, the diffuse dimension *nd* specified in the A1 option is nonzero), the last *nd* rows and columns of the matrix specified in COV1 are taken to be zero. Moreover, if the elements of Q_1 are specified by a list, its number of elements must correspond to a matrix of dimension (*dim* – *nd*).

PRINT=AR | BREAKDETAIL | COV | COV1 | MA | T

PRINT=(< AR > < BREAKDETAIL > < COV > < COV1 > < MA > < T >)

requests printing of the respective system matrices and the printing of the break statistics at each distinct time point. You can specify PRINT=AR or PRINT=MA only if you specify the TYPE=VARMA option. If any of these matrices are time-varying, the matrix that corresponds to the first time instance is printed. For the BREAKDETAIL suboption to have any effect, the CHECKBREAK option must be turned on. If TYPE= option is used, the result of PRINT=COV can be different than the matrix supplied in the COV= option.

SINPUT = (*var1 var2 . . .***) | (***number1 number2 . . .***)**

specifies the relevant *dim*-dimensional block of the state input vector $\mathbf{c}_t$. The absence of this option signifies that this block of the $\mathbf{c}_t$ vector consists of only zeros. If the elements of $\mathbf{c}_t$ are specified by a list of variables in parentheses, then these variables must be independent of unknown parameters. In particular, they cannot be functions of parameters that are defined by the PARMS statements.

T(D) < = (*var1 var2 . . .***) | (***number1 number2 . . .***) >**

T(G) < = (*var1 var2 . . .***) | (***number1 number2 . . .***) >**

T(I) < = (*variable***) | (***number***) >**

specifies the relevant block of the transition matrix T_t. The absence of this option signifies that this block consists of only zeros. You can specify the structure of the T-block by specifying T(I) for the identity form, T(D) for the diagonal form, and T(G) for a general unstructured form. In addition, you can explicitly specify the entries of the T-block by specifying a list of numbers in parentheses, or by specifying in parentheses a list of variables that are defined by using the programming statements. The unspecified elements of the T-block are included in the list of parameters to be estimated from the data. If the elements of the T-block are supplied by a list in parentheses, the number of elements in the list depends on its structure. For the diagonal form, the list must contain exactly *dim* elements. In the case of the identity form—T(I)—the block is already fully specified; however, a specification T(I)=(*variable*) is understood to mean that the identity block is scaled by the specified *variable* (or a *number*). In the general case—T(G)—the list must consist of *dim* $*$ *dim* elements, specified in a rowwise fashion. An inappropriate number of elements in the list results in a syntax error.

The following examples illustrate different ways of specifying the transition matrix. It is assumed that *dim* = 2.

- T(I) specifies that the T-block is a two-dimensional identity matrix.
- T(D) specifies that the T-block is a two-dimensional diagonal matrix. The two unspecified diagonal entries become part of the parameter vector $\boldsymbol{\theta}$.
- T(D)=(1.1 2) fully specifies the two-dimensional diagonal T-block.
- T(D)=(X_1 X_2) specifies a two-dimensional diagonal T-block where the diagonal elements are dynamically calculated based on the values of the variables X_1 and X_2. In this case the T-block can change with time if X_1 or X_2 changes with time.
- T(G) specifies a general form T-block (with $2^2 = 4$ unspecified elements).
- T(G)=(X_1 X_2 X_3 X_4) specifies a general form T-block where the first row is formed by X_1 and X_2, and the second row is formed by X_3 and X_4.

In practice the transition matrix is often sparse—that is, many of its elements are 0. The algorithms in the SSM procedure exploit this sparsity structure for computational efficiency. Whenever you explicitly

specify the entries of the T-block by specifying a list of variables in parentheses, you can leave the variables that correspond to the zero elements *unset*. These unset variables are treated as structural zeros by the SSM procedure. The section "Sparse Transition Matrix Specification" on page 2436 further explains how to use this sparsity convention.

TYPE=WN

TYPE=RW

TYPE=LL <(SLOPECOV(I | D | G) <= (*var1, var2, . . .***) | (***number1, number2, . . .***)>)>**

TYPE=LL (SLOPECOV(RANK=*integer***))**

TYPE=SEASON (LENGTH=*integer* **<DROPH=***number-list***> <KEEPH=***number-list***>)**

TYPE=CYCLE <(<CT> <RHO=*variable* | *number***> <PERIOD=***variable* | *number***>)>**

TYPE=VARMA (<p <(I | D)> =*integer***> <q<(D)>=***integer***>)**

specifies a state subsection that corresponds to the specified type. You can specify either a number or a variable for the RHO= and PERIOD= suboptions. When TYPE=VARMA, the autoregressive and moving average orders can be at most 1 ($0 \leq p \leq 1$ and $0 \leq q \leq 1$). Moreover, by using the D and I flags with the order specification, you can impose additional structure on the autoregressive and moving average coefficient matrices—for example, specifying TYPE=VARMA(P=1) implies a VAR(1) model with general autoregressive coefficient matrix, whereas specifying TYPE=VARMA(P(D)=1) implies a VAR(1) model with diagonal autoregressive coefficient matrix. If you specify the TYPE= option, the T, COV1, SINPUT, and A1 options are not needed. In fact they are ignored, since the transition matrix $\mathbf{T}_t$ and the matrices in the initial condition ($\mathbf{Q}_1$ and $\mathbf{A}_1$) are implicitly defined by the choice of the type. However, the COV and W options can be useful. In fact, the specification of the COV option does play a key role in the eventual form of $\mathbf{Q}_t$—the covariance of the disturbance term in the transition equation. For the types LL, CYCLE, SEASON, and VARMA, the dimension of the resulting state subsection is a certain multiple of *dim*, the nominal dimension in the STATE statement. For example, the following specification results in a state subsection, named cycleState, of dimension 2**dim*:

```
state cycleState(dim) cov(g) type=cycle;
```

The name cycleState corresponds to the state underlying a *dim*-dimensional cycle component. All of these special state types require that the data be regular (replication is permissible); the only exception is TYPE=CYCLE(CT), which defines a continuous-time cycle and is applicable to any data type. Table 33.2 summarizes some of this information for easy reference. For more information about these state types, see the section "Predefined Structural Models" on page 2450.

The TYPE=LL specification results in a state that corresponds to a multivariate local linear trend. It is governed by two covariance matrices: the COV option specifies the covariance that corresponds to the level equation, and the SLOPECOV suboption specifies the covariance used in the slope equation. The omission of the SLOPECOV suboption signifies that the covariance used in the slope equation is zero. The form of the SLOPECOV suboption is exactly the same as that of the COV option.

The TYPE=CYCLE option results in a state that corresponds to a (stochastic) cycle. By default, this cycle is assumed to be for the regular data type. If TYPE=CYCLE(CT), the resulting cycle is applicable to any data type. The CT option is available only for *dim = 1*; that is, only a univariate cycle is available for the irregular data type. The cycle specification depends on a covariance matrix and two numbers: the damping factor RHO and the cycle period PERIOD. The covariance can be specified by the COV option. The damping factor is specified by the RHO= suboption; its value must lie between 0.0 and 1.0.

The cycle period can be specified by the PERIOD= suboption. If the CT suboption is not included, the period value must be larger than 2.0. On the other hand, if the CT suboption is included, its value must be strictly positive. If these parameters are not specified, they are estimated from the data.

The TYPE=SEASON(LENGTH=*integer*) specifies a multivariate trigonometric season that contains the full set of harmonics (for more information, see "Multivariate Season" on page 2453). In some cases, you might want to drop some of the harmonics from this complete set to obtain a more parsimonious trigonometric season specification. You can use the DROPH= (to drop) or KEEPH= (to keep) suboption to control the harmonics that are included in the season specification as follows:

TYPE=SEASON(
LENGTH=*integer*
<DROPH=*number-list* | *n* **TO** *m* **BY** *p***>**
<KEEPH=*number-list* | *n* **TO** *m* **BY** *p***>**
)

The DROPH= and KEEPH= lists can include any integer between 1 and *LENGTH*/2 if the season length is even and any integer between 1 and (*LENGTH* – 1)/2 if the season length is odd. For example, the following specification results in a specification of a trigonometric season with a season length 12 that consists of only the first four harmonics $\boldsymbol{\zeta}_j$, $j = 1, 2, 3, 4$:

```
type=season(length=12  DROPH=5 6) ...;
```

The last two *high*-frequency harmonics, $\boldsymbol{\zeta}_5$ and $\boldsymbol{\zeta}_6$, are dropped. The DROPH= suboption cannot be used with the KEEPH= suboption.

Table 33.2 Summary of Predefined State Types

Type	Description	Parameters	State Dimension
WN	*dim*-variate white noise	COV	*dim*
RW	*dim*-variate random walk	COV	*dim*
LL	*dim*-variate local linear	COV, SLOPECOV	2**dim*
SEASON(LENGTH=*length*)	*dim*-variate season	COV	(*length*–1)**dim*
CYCLE	*dim*-variate cycle	COV, RHO, PERIOD	2**dim*
VARMA(P=*p* Q=*q*)	*dim*-variate VARMA(*p*, *q*)	COV, AR, MA	*dim**max(*p*, *q*+1)

W(D)= (*var1 var2 . . .***) | (***number1 number2 . . .***)**

W(G)= (*var1 var2 . . .***) | (***number1 number2 . . .***)**

W(I) < = (*variable***) | (***number***) >**

specifies the relevant block of the design matrix $\mathbf{W}_t$ in the transition equation. The W-block is of dimension $sdim \times sg$, where *sdim* denotes the actual dimension of the state subsection (which can be the same as *dim*, the nominal dimension, or different if the TYPE= option is used) and *sg* denotes the desired size of the subsection of the overall state regression vector $\boldsymbol{\gamma}$. The absence of this option signifies that the state equation does not contain any regression effects. The number of variables supplied in the W(G)= list option must be a multiple of *sdim*. For example, if *sdim* = 4 and the W(G)= list contains 8 variables, then the implied size of $\boldsymbol{\gamma}$ subsection is 2. If the W(D)= or W(I)= option is used, then the W-block is assumed to be an $sdim$-dimensional diagonal matrix and the W(D)=

list must contain exactly *sdim* variables. For examples of the use of this option, see Example 33.8, Example 33.10, and Example 33.11.

TREND Statement

TREND *name* **(***type***)**< *options* > **;**

The TREND statement defines a term in the model that follows a stochastic pattern of a certain predefined type. The *options* in the TREND statement enable you to specify a wide variety of commonly used stochastic patterns. Each TREND statement in effect stands for a special pair of STATE and COMPONENT statements. You can specify more than one TREND statement. Each separate TREND statement defines a component that is assumed to be independent of all other component specifications in the model. Very often the TREND statement is used to specify a component that captures the time-varying level of the data. However, in many cases it is also used to define components of a more general nature; for example, it can be used to define a noise component that follows a stationary ARMA model.

You can refer to the state that is associated with a TREND statement by appending the string "_state_" to the end of its name. For example, name_state_ is the state that is associated with a trend named name. You can use name_state_ in a COMPONENT statement to define a linear combination of its elements. The estimate of this linear combination can then be printed or output to a data set. The nominal dimension of name_state_ is taken to be 1, or the number of variables in the list that is specified in the CROSS= option in the TREND statement that is used to define name (see Example 33.4 for an example of such use of the COMPONENT statement).

Some of these trend specifications are applicable to all the data types—that is, they can be used for both regular data types and irregular data types, whereas the others require that the data be regular or regular with replication. Of course, the trend specification is only part of the overall model specification. Therefore, the other parts of the model can imply additional constraints on the data type.

Table 33.3 lists the available trend models and their data requirements. The *type* column shows the admissible keywords that signify the particular trend type. For brevity, the Data Type column groups the data types regular and regular with replication into one category: regular. For more information about these trend models, see the section "Predefined Trend Models" on page 2446.

Table 33.3 Summary of Trend Types

type	Data Type	Description	Parameters
ARIMA(P=*integer* D=*integer* ...)	Regular	ARIMA model specification	AR and MA coefficients, and the error variance σ^2
DLL	Regular	Damped local linear	Level and slope σ_1^2, σ_2^2, damping factor ϕ
LL	Regular	Local linear	Level and slope σ_1^2, σ_2^2
RW	Regular	Random walk	Level σ^2
DECAY	Irregular	A type of decay pattern	Level σ^2, decay rate ϕ
DECAY(OU)	Irregular	Ornstein-Uhlenbeck decay pattern	Level σ^2, decay rate ϕ
GROWTH	Irregular	A type of growth pattern	Level σ^2, growth rate ϕ
GROWTH(OU)	Irregular	Ornstein-Uhlenbeck growth pattern	Level σ^2, growth rate ϕ
PS(*order*)	Irregular	Polynomial spline of a given order	Level σ^2

The keyword specification of different trend types, except possibly the ARIMA trend, is quite simple. For example, the following statement specifies polySpline as a trend of the type second-order polynomial spline:

```
trend polySpline(ps(2));
```

Similarly, the following statement defines dampedTrend as a damped local linear trend:

```
trend dampedTrend(dll) slopevar=x;
```

The variance parameter that governs the slope equation of this trend type is given by a variable x, which must be defined elsewhere in the program. The other parameters that define dampedTrend are left unspecified (and are estimated by using the data).

The ARIMA trend specification permits specification of trends that follow an ARIMA$(p,d,q)\times(P,D,Q)_s$ model. The specification of ARIMA models requires some notation, which is explained first.

Let B denote the backshift operator—that is, for any sequence ζ_t, $B\zeta_t = \zeta_{t-1}$. The higher powers of B represent larger shifts (for example, $B^3\zeta_t = \zeta_{t-3}$). A random sequence ζ_t follows an ARIMA$(p,d,q)\times(P,D,Q)_s$ model with nonseasonal autoregressive order p, seasonal autoregressive order P, nonseasonal differencing order d, seasonal differencing order D, nonseasonal moving average order q, and seasonal moving average order Q if it satisfies the following difference equation, which is specified in terms of the polynomials in the backshift operator, where a_t is a white noise sequence and s is the season length:

$$\phi(B)\Phi(B^s)(1-B)^d(1-B^s)^D\zeta_t = \theta(B)\Theta(B^s)a_t$$

The polynomials ϕ, Φ, θ, and Θ are of orders p, P, q, and Q, respectively, which can be any nonnegative integers. The season length s must be a positive integer. For example, ζ_t satisfies an ARIMA(1,0,1) model (that is, $p = 1, d = 0, q = 1, P = 0, D = 0$, and $Q = 0$) if

$$\zeta_t = \phi_1\zeta_{t-1} + a_t - \theta_1 a_{t-1}$$

for some coefficients ϕ_1 and θ_1 and a white noise sequence a_t. Similarly, ζ_t satisfies an ARIMA$(0,1,1)\times(0,1,1)_{12}$ model if

$$\zeta_t = \zeta_{t-1} + \zeta_{t-12} - \zeta_{t-13} + a_t - \theta_1 a_{t-1} - \Theta_1 a_{t-12} + \theta_1\Theta_1 a_{t-13}$$

for some coefficients θ_1 and Θ_1 and a white noise sequence a_t. An ARIMA process is zero-mean, stationary, and invertible if $d = 0$, $D = 0$, and the defining polynomials ϕ, Φ, θ, and Θ have all their roots outside the unit circle—that is, their absolute values are strictly larger than 1.0. It is assumed that the coefficients of the polynomials ϕ, Φ, θ, and Θ are constrained so that the stationarity and invertibility conditions are satisfied. The unknown coefficients of these polynomials become part of the model parameter vector that is estimated by using the data. The general form of the ARIMA trend specification is as follows:

ARIMA(< P=*integer* **> < D=***integer* **> < Q=***integer* **> < SP=***integer* **> < SD=***integer* **> < SQ=***integer* **> < S=***integer* **>)**

By default, the different orders are equal to 0 and the season length is equal to 1. The following examples illustrate a few different ARIMA trend specifications. The following statement defines ima as an integrated moving average trend:

```
trend ima(arima(d=1 q=1));
```

The following statement defines airTrend as a trend that satisfies the well-known airline model (ARIMA(0,1,1)(0,1,1)12 model) for monthly seasonal data:

```
trend airTrend(arima(d=1 q=1 sd=1 sq=1 s=12));
```

The following statement defines arma11 as a zero-mean ARMA(1,1) trend with autoregressive parameter fixed to 0.1:

```
trend arma11(arima(p=1 q=1)) ar=0.1;
```

For an example of the use of the ARIMA trend specification, see Example 33.6.

You can use the following *options* in the TREND statement to specify the trend parameters and to request printing of the trend estimates. In addition, you can create a custom combination of a given trend type by specifying the CROSS= option to create a more general trend. For an example of using the CROSS= option, see the section "Getting Started: SSM Procedure" on page 2398 and the discussion of the second model in Example 33.4. You can also check for the unexpected changes in the trend component by using the CHECKBREAK option.

AR=$\phi_1\ \phi_2\ \ldots\phi_p$
lists the values of the coefficients of the nonseasonal autoregressive polynomial

$$\phi(B) = 1 - \phi_1 B - \cdots - \phi_p B^p$$

where the order p is specified in the ARIMA trend specification. The coefficients ϕ_i must define a stationary autoregressive polynomial.

CHECKBREAK< (ELEMENTWISE | OVERALL) >
turns on the checking of breaks for this trend component. The ELEMENTWISE suboption requests the elementwise checking of any unexpected change in the state subsection that is associated with the trend component. The OVERALL suboption requests a similar check for the entire state subsection—that is, in this case the change is measured as a multidimensional change. The ELEMENTWISE suboption is the default. Unless the PRINT=BREAKDETAIL option is specified, only a summary of the most significant breaks is produced. If the PRINT=BREAKDETAIL is specified, tables that contain the break significance statistics at every distinct time point are produced—one for the ELEMENTWISE suboption and one for the OVERALL suboption. If the CROSS= option is specified and the CROSS= list contains more than one variable, the OVERALL suboption considers subsections that are associated with each CROSS= variable separately. For more information about the structural break detection process, see the section "Structural Breaks in the State Evolution" on page 2444.

CROSS=(*var1, var2, . . .***)**
CROSS(MATCHPARM)=(*var1, var2, . . .***)**
creates a linear combination of one or more independent trend components that is based on the variables in the list. If the parameters of the trend are specified by options such as the LEVELVAR= option or the PHI= option, these parameters are shared by these constituent trends. For example, suppose that the CROSS= list contains two variables (X_1 and X_2) and the trend specification is of the type RW. The effect of CROSS=(X_1, X_2) is to create a component $\mu_t = X_1\mu_{1,t} + X_2\mu_{2,t}$, where $\mu_{1,t}$ and $\mu_{2,t}$ are two independent random walk trends. Moreover, if the random walk trend specification uses the LEVELVAR= option to specify the variance parameter, $\mu_{1,t}$ and $\mu_{2,t}$ share the same variance parameter; otherwise, two separate variance parameters are assigned to these random walks. If the second form of the CROSS option, CROSS(MATCHPARM)=, is used, then the constituent trends share all the relevant parameters no matter how they are specified. The CROSS= option is useful for a variety of situations. For example, suppose X is an indicator variable that is 1 before a certain time

point t_0 and 0 thereafter. Then CROSS=(X) has the effect of turning off the trend component after time t_0. Similarly, suppose G_1 and G_2 are indicators for gender—for example, G_1 = (GENDER=1) and G_2 = (GENDER=0) for male and female cases, respectively. Then CROSS=(G_1, G_2) results in separate trends according to the gender. The variables in the CROSS= list must be free of unknown parameters.

The CROSS= option can be computationally expensive; computationally it is equivalent to specifying as many separate trends as the number of variables in the specified list.

LEVELVAR=*variable* | *number*

specifies the disturbance variance parameter for all the trend types. For trend types LL and DLL, this option specifies σ_1^2. Any nonnegative value, including 0, is permissible. If *variable* contains unknown parameters, they are estimated from the data. Similarly, if the LEVELVAR= option is not specified, σ^2 is estimated from the data.

MA=$\theta_1\ \theta_2\ \ldots\theta_q$

lists the values of the coefficients of the nonseasonal moving average polynomial,

$$\theta(B) = 1 - \theta_1 B - \cdots - \theta_q B^q$$

where the order q is specified in the ARIMA trend specification. The coefficients θ_i must define an invertible moving average polynomial.

NODIFFUSE

treats the diffuse elements in the initial state of the state subsection underlying the trend component as nondiffuse. This option is applicable to all trend types except ARIMA. For the ARIMA trend type, this option is ignored even if the nonseasonal or seasonal differencing orders are nonzero. The diffuse elements are assumed to be independent, zero-mean, Gaussian variables. Their variances become part of the parameter vector and are estimated by using the data. This option is useful for creating a trend component that can be interpreted as a deviation from an overall trend component (with diffuse initialization), which is defined separately.

PHI=*variable* | *number*

specifies the value of ϕ for trend types DLL, DECAY, DECAY(OU), GROWTH, and GROWTH(OU). For the type DLL, the specified value must be between 0.0 and 1.0. For types DECAY and DECAY(OU), ϕ must be strictly negative. For types GROWTH and GROWTH(OU), ϕ must be strictly positive. If *variable* contains unknown parameters, they are estimated from the data. Similarly, if the PHI= option is not specified, ϕ is estimated from the data.

PRINT=BREAKDETAIL | COV | COV1 | FILTER | SMOOTH | T

PRINT= (< BREAKDETAIL > < COV > < COV1 > < FILTER > < SMOOTH > < T >)

requests printing of the respective system matrices of the state equation that underlies the specified trend, the printing of its filtered and smoothed estimates, and the printing of the break statistics at each distinct time point. For the BREAKDETAIL suboption to have any effect, the CHECKBREAK option must be turned on. If any of these matrices are time-varying, the matrix that corresponds to the first time instance is printed.

SAR=$\Phi_1\ \Phi_2\ \ldots\ \Phi_P$
lists the values of the coefficients of the seasonal autoregressive polynomial

$$\Phi(B^s) = 1 - \Phi_1 B^s - \cdots - \Phi_P B^{sP}$$

where the order P is specified by using the SP= option in the ARIMA trend specification and the season length s is specified in the S= option. The coefficients Φ_i must define a stationary autoregressive polynomial.

SMA=$\Theta_1\ \Theta_2\ \ldots\ \Theta_Q$
lists the values of the coefficients of the seasonal moving average polynomial

$$\Theta(B^s) = 1 - \Theta_1 B^s - \cdots - \Theta_Q B^{sQ}$$

where the order Q is specified by using the SQ= option in the ARIMA trend specification and the season length s is specified in the S= option. The coefficients Θ_i must define an invertible moving average polynomial.

SLOPEVAR=*variable* | *number*
specifies the second disturbance variance parameter, σ_2^2, for trend types LL and DLL. Any nonnegative value, including 0, is permissible. If *variable* contains unknown parameters, they are estimated from the data. Similarly, if the SLOPEVAR= option is not specified, σ_2^2 is estimated from the data.

Details

Throughout this section, vectors and matrices are denoted by boldface letters. Generally, Greek letters (such as $\boldsymbol{\alpha}$, $\boldsymbol{\beta}$, and $\boldsymbol{\epsilon}$) denote unobserved or latent quantities—often estimated from the data—that represent model parameters, latent states, or noise variables. Capital letters such as X, Y, and Z are used to denote the observed data variables. Whenever there is no ambiguity, it is assumed that the matrices have appropriate dimensions when they are being multiplied—in particular, the vectors behave as column vectors or row vectors as the need arises. On many occasions, matrices are described inline—that is, they are described as parenthesized lists, in a rowwise fashion, with the rows separated by a comma. The term "dot product" is used to describe the scalar that results from the product of a row vector with a (conforming) column vector.

State Space Model and Notation

The (linear) state space model is described in the literature in a few different ways and with varying degree of generality. The description given in this section loosely follows the description given in Durbin and Koopman (2012, chap. 6, sec. 4). This formulation of SSM is quite general; in particular, it includes nonstationary SSMs with time-varying system matrices and state equations with a diffuse initial condition (these terms are defined later in this subsection).

Suppose that observations are collected in a sequential fashion (indexed by a numeric variable τ) on some variables: the vector $\mathbf{y} = (y_1, y_2, \ldots, y_q)$, which denotes the q-variate response values, and the k-dimensional vector $\mathbf{x}$, which denotes the predictors. Suppose that the observation instances are $\tau_1 < \tau_2 < \ldots < \tau_n$. The possibility that multiple observations are taken at a particular instance τ_i is not ruled out, and

the successive observation instances do not need to be regularly spaced—that is, $(\tau_2 - \tau_1)$ does not need to equal $(\tau_3 - \tau_2)$. For $t = 1, 2, \ldots, n$, suppose p_t (≥ 1) denotes the number of observations recorded at instance τ_t. For notational simplicity, an integer-valued secondary index t is used to index the data so that $t = 1$ corresponds to $\tau = \tau_1$, $t = 2$ corresponds to $\tau = \tau_2$, and so on. Consider the following model:

$$\begin{aligned} \mathbf{Y}_t &= \mathbf{Z}_t\boldsymbol{\alpha}_t + \mathbf{X}_t\boldsymbol{\beta} + \boldsymbol{\epsilon}_t && \text{Observation equation} \\ \boldsymbol{\alpha}_{t+1} &= \mathbf{T}_t\boldsymbol{\alpha}_t + \mathbf{W}_{t+1}\boldsymbol{\gamma} + \mathbf{c}_{t+1} + \boldsymbol{\eta}_{t+1} && \text{State transition equation} \\ \boldsymbol{\alpha}_1 &= \mathbf{c}_1 + \mathbf{A}_1\boldsymbol{\delta} + \mathbf{W}_1\boldsymbol{\gamma} + \boldsymbol{\eta}_1 && \text{Initial condition} \end{aligned}$$

The following list describes these equations:

- The *observation equation* describes the relationship between the $(p_t * q)$-dimensional response vector $\mathbf{Y}_t$ and the unobserved vectors $\boldsymbol{\alpha}_t$, $\boldsymbol{\beta}$, and $\boldsymbol{\epsilon}_t$. The q-variate responses are vertically stacked in a column to form this $(p_t * q)$-dimensional response vector $\mathbf{Y}_t$. The m-dimensional vectors $\boldsymbol{\alpha}_t$ are called *states*, the k-dimensional vector $\boldsymbol{\beta}$ is the regression coefficient vector associated with predictors $\mathbf{x}$, and the $(p_t * q)$-dimensional vectors $\boldsymbol{\epsilon}_t$ are called the *observation disturbances*. The matrices $\mathbf{Z}_t$ (of dimension $(q * p_t) \times m$) and $\mathbf{X}_t$ (of dimension $(q * p_t) \times k$) correspond to the *state effect* and the *regression effect*, respectively. The elements of $\mathbf{X}_t$ are assumed to be fully known. The states $\boldsymbol{\alpha}_t$ and the disturbances $\boldsymbol{\epsilon}_t$ are *random* sequences. It is assumed that $\boldsymbol{\epsilon}_t$ is a sequence of independent, zero-mean, Gaussian random vectors with diagonal covariances, with the diagonal elements denoted by $\sigma^2_{t,i}, i = 1, 2, \ldots, q * p_t$.

- The state sequence $\boldsymbol{\alpha}_t$ is assumed to follow a Markovian structure described by the state transition equation and the associated initial condition.

- The *state transition equation* postulates that a new instance of the state, $\boldsymbol{\alpha}_{t+1}$, is obtained by multiplying its previous instance, $\boldsymbol{\alpha}_t$, by an m-dimensional square matrix $\mathbf{T}_t$ (called the state transition matrix) and by adding three more terms: a known nonrandom vector $\mathbf{c}_{t+1}$ (called the state input); a regression term $\mathbf{W}_{t+1}\boldsymbol{\gamma}$, where $\mathbf{W}_{t+1}$ is an $m \times g$-dimensional design matrix with fully known elements and γ is the g-dimensional regression vector; and a random disturbance vector $\boldsymbol{\eta}_{t+1}$. The m-dimensional state disturbance vectors $\boldsymbol{\eta}_t$ are assumed to be independent, zero-mean, Gaussian random vectors with covariances Q_t (not necessarily diagonal).

- The *initial condition* describes the starting condition of the state evolution equation. The starting state vector $\boldsymbol{\alpha}_1$ is assumed to be partially diffuse: it is the sum of a known nonrandom vector $\mathbf{c}_1$, a mean-zero Gaussian vector $\boldsymbol{\eta}_1$, and the terms $\mathbf{A}_1\boldsymbol{\delta}$ and $\mathbf{W}_1\boldsymbol{\gamma}$. $\mathbf{A}_1\boldsymbol{\delta}$ represents the contribution from a d-dimensional diffuse vector $\boldsymbol{\delta}$ (a diffuse vector is a Gaussian vector with infinite covariance). The observation and state regression vectors $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ are also assumed to be diffuse. The $m \times d$ matrix $\mathbf{A}_1$ is assumed to be completely known.

- The observation disturbances $\boldsymbol{\epsilon}_t$ and the state disturbances $\boldsymbol{\eta}_t$ (for $t \geq 1$) are assumed to be mutually independent. Either the elements of the matrices $\mathbf{Z}_t$, $\mathbf{T}_t$, and Q_t and the diagonal elements of the observation disturbance covariances $\sigma^2_{t,i}$ are assumed to be completely known, or some of them can be functions of a small set of unknown parameters (to be estimated from the data). Suppose that this unknown set of parameters is denoted by $\boldsymbol{\theta}$.

- The d-dimensional diffuse vector $\boldsymbol{\delta}$ from the state initial condition together with the observation and state regression vectors $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ constitute the overall $(d + k + g)$-dimensional diffuse initial condition of the model. For more information, see the section "Filtering, Smoothing, Likelihood, and Structural Break Detection" on page 2438.

Although this description of the state space model might appear involved, it conveniently covers many variants of the SSMs that are encountered in practice and precisely describes the most general case that can be handled by the SSM procedure. An important restriction about the preceding description of the model formulation is that it assumes that the matrices $\mathbf{X}_t$ and $\mathbf{W}_t$ that appear in the observation equation and the state equation respectively are free of unknown parameters and that the covariances of the observation disturbances $\boldsymbol{\epsilon}_t$ are diagonal. In most practical situations, the model under consideration can be easily reformulated to a statistically equivalent form that conforms to this restriction.

NOTE: The transition matrix $\mathbf{T}_t$ in the state equation relates the state $\boldsymbol{\alpha}_t$ at time t with the state $\boldsymbol{\alpha}_{t+1}$ at time $t+1$. In many situations, such as when the observations are taken at irregular time intervals, $\mathbf{T}_t$ depends on information at both t and $t+1$. Therefore, it is more appropriate to denote the transition matrix as $\mathbf{T}_t^{t+1}$. However, for simplicity, the former notation is used throughout this chapter. The same comment applies to the covariance matrix $\mathbf{Q}_t$ of the disturbance term $\boldsymbol{\eta}_t$.

For easy reference, Table 33.4 summarizes the information contained in the SSM equations.

Table 33.4 State Space Model: Notation

Notation	Description
$\tau_1, \tau_2, \ldots, \tau_n$	Distinct index values at which the observations are recorded
n	Number of distinct index instances
p_t	Number of observations recorded at index τ_t, $t = 1, 2, \ldots, n$
q	Number of response variables in the model
$\mathbf{Y}_t = (y_{t,1}, y_{t,2}, \ldots, y_{t,p_t*q})$	Vertically stacked vector of response values recorded at τ_t
$N = q * \sum_{t=1}^{n} p_t$	Total number of response values in the data set
k	Number of predictor (regressor) variables in the observation equation
$\mathbf{X}_t$	$(p_t * q) \times k$ matrix of predictor values recorded at τ_t
$\boldsymbol{\beta}$	k-dimensional regression vector that is associated with the predictors
$\boldsymbol{\epsilon}_t \sim N(0, (\sigma^2_{t,1}, \ldots))$	$(q * p_t)$-dimensional observation disturbance vector with diagonal covariance
m	Dimension of the state vectors $\boldsymbol{\alpha}_t$
$\boldsymbol{\alpha}_t$	m-dimensional state vector
$\mathbf{Z}_t$	$(q * p_t) \times m$ matrix that is associated with $\boldsymbol{\alpha}_t$ in the observation equation
$\mathbf{T}_t$	$m \times m$ state transition matrix
$\mathbf{c}_t$	m-dimensional state input vector
$\mathbf{W}_t$	$m \times g$ design matrix associated with $\boldsymbol{\gamma}$, the state regression vector
$\boldsymbol{\gamma}$	g-dimensional state regression vector
$\boldsymbol{\eta}_t \sim N(0, Q_t)$	m-dimensional state disturbance vector
d	Dimension of the diffuse vector $\boldsymbol{\delta}$ in the state initial condition
$\boldsymbol{\delta} \sim N(0, \kappa\Sigma), \kappa \to \infty$	Diffuse vector in the state initial condition
$\mathbf{A_1}$	$m \times d$ constant matrix associated with $\boldsymbol{\delta}$
$\boldsymbol{\eta}_1 \sim N(0, Q_1)$	m-dimensional state disturbance vector in the initial condition
$\boldsymbol{\theta}$	Parameter vector

Types of Sequence Data

The state space model specification in the SSM procedure requires proper understanding of both the data organization and the form of the model. The SSMs that are appropriate for time series data might not be appropriate for irregularly spaced longitudinal data. The SSM procedure distinguishes three types of data organization based on the way the observations are sequenced by the index variable. If an index variable is not specified, it is assumed that the observations are sequenced according to the observation number.

Regular: The observations are recorded at regularly spaced intervals; that is, $\tau_1, \tau_2, \ldots, \tau_n$ are regularly spaced. Moreover, at each observation instance τ_i a single observation is recorded; that is, $p_t = 1$ for all t. The standard time series data (both univariate and multivariate) fall in this category.

Regular with Replication: The observations are recorded at regularly spaced intervals, but $p_t > 1$ for at least one t. Here the word replication is used loosely—it does not mean that the multiple observations at τ_t are replications in the precise statistical sense. The panel or cross-sectional data types fall into this category. In the panel data case with p cross sections, $p_t = p$ for all t.

Irregular: The observations are not recorded at regular intervals, and the number of observations p_t at each index instance can be different. The longitudinal data fall into this category.

It is not always easy to decide whether the specified model is appropriate for the given data type. Whenever possible, the SSM procedure issues a note regarding the possible mismatch between the specified model and the data type being analyzed.

Overview of Model Specification Syntax

An SSM specification involves the description of the terms in the observation equation, the state transition equation, and the initial condition. For example, the response variables, the predictor variables, and the elements of the state transition matrix $\mathbf{T}_t$ must somehow be specified. The SSM procedure syntax is designed so that little effort is needed to specify the more commonly needed models, while a highly flexible language is available for specifying more complex models. Two syntax features help achieve this goal: the ability to build a complex specification by combining simpler subspecifications, and a programming language for creating lists of variables to be used later in the model specification.

The SSM procedure statements can be divided into two classes:

- programming statements, which are used to create lists of variables that can be used for a variety purposes (for example, as the elements of the model system matrices)
- statements specific to the SSM procedure that formulate the state space model and control its other aspects such as the input data specification and the resulting output

Since the matrices involved in the model specification can be specified as lists of variables, which you separately create by using the programming statements, you can finely control all aspects of the model specification. These programming statements permit the use of most DATA step language features such as the conditional logic (IF-THEN-ELSE), array type variables, and all the mathematical functions available in the DATA step. You can also use programming statements to define predictor variables on the fly.

Building a Complex Model Specification

In addition to being able to specify the system matrices in a flexible way, you can also build a complex model specification in a modular way by combining simpler subspecifications. Suppose that the state vector for the model to be specified is composed of subsections that are statistically independent, which is a common scenario in practical modeling situations. For example, suppose that $\boldsymbol{\alpha}_t$ can be divided into two disjoint subsections $\boldsymbol{\alpha}_t^a$ and $\boldsymbol{\alpha}_t^b$, which are statistically independent. This entails a corresponding block-diagonal structure to the system matrices $\mathbf{T}_t$, $\mathbf{W}_t$, and $\mathbf{Q}_t$ that govern the state equations. In this case the term $\mathbf{Z}_t\boldsymbol{\alpha}_t$ that appears in the observation equation also splits into the sum $\mathbf{Z}_t^a\boldsymbol{\alpha}_t^a + \mathbf{Z}_t^b\boldsymbol{\alpha}_t^b$ for appropriately partitioned matrices $\mathbf{Z}_t^a$ and $\mathbf{Z}_t^b$. The model specification syntax of the SSM procedure makes building an SSM from such smaller pieces easy. Throughout this chapter, the linear combinations of the state subsections (such as $\mathbf{Z}_t^a\boldsymbol{\alpha}_t^a$) that appear in the observation equation are called *components*. An SSM specification in the SSM procedure is created by combining separate component specifications. In general, you specify a component in two steps: first you define a state subsection $\boldsymbol{\alpha}_t^a$, and then you define a matching linear combination $\mathbf{Z}_t^a\boldsymbol{\alpha}_t^a$. For some special components, such as some commonly needed *trend* components, you can combine these two steps into one keyword specification.

The following list summarizes the (nonprogramming) SSM procedure syntax statements used for model specification:

- The ID statement specifies the index variable (τ). It is assumed that the data within each BY group are ordered (in ascending order) according to the ID variable. The SSM procedure automatically creates a variable, _ID_DELTA_, which contains the difference between the successive ID values. This variable is available for use by the programming statements to define time-varying system matrices. For example, in the case of SSMs used for modeling the longitudinal data, the $\mathbf{T}_t$ and $\mathbf{Q}_t$ matrices often depend on _ID_DELTA_ (see Example 33.5).

- The PARMS statement specifies variables that serve as the parameters of the model. That is, it partially defines the model parameter vector $\boldsymbol{\theta}$. Other elements of $\boldsymbol{\theta}$ are implicitly defined if your specification of the system matrices is not fully complete.

- The STATE statement specifies a subsection of the model state vector. Multiple STATE statements can be used in the model specification; each one defines a statistically independent subsection of the model state vector. For full customization, $\mathbf{T}_t$, $\mathbf{W}_t$, and $\mathbf{Q}_t$ blocks that govern this subsection can be specified as lists of variables that are created by programming statements. However, you can obtain many commonly needed state subsection types simply by using the TYPE= option in this statement. For example, the use of TYPE=SEASON(LENGTH=12) results in a state subsection that can be used to define a monthly seasonal component.

- The COMPONENT statement specifies a linear combination that matches a state subsection that is previously defined in a STATE statement. Thus, a matching pair of STATE and COMPONENT statements define a component.

- The TREND statement is used for easy specification of some commonly needed components that follow stochastic patterns of certain predefined types.

- The IRREGULAR statement specifies the observation disturbance for a particular response variable.

- The DEPLAG statement specifies the terms in the model that involve lagged response variables.

- The MODEL statement specifies the observation equation for one of the response variables. A separate MODEL statement is needed for each response variable in the multivariate case. The MODEL statement specifies an equation in which the left-hand side is the response variable and the right-hand side is a list that contains components and regression variables.

Model Specification Steps

To illustrate the model specification steps, suppose y is a response variable and variables x1 and x2 are predictors. The following statements specify a model for y that includes two components named cycle and randomWalk, predictors x1 and x2, and an observation disturbance named whiteNoise:

```
parms lambda / lower=(1.e-6) upper=(3.14);
parms cycleVar / lower=(1.e-6);
array cycleT{4} c1-c4;
c1 = cos(lambda);
c2 = sin(lambda);
c3 = -c2;
c4 = c1;
state s_cycle(2) T(g)=(cycleT) cov(I)=(cycleVar) a1(2);
component cycle=(1 0)*s_cycle;
trend randomWalk(rw);
irregular whiteNoise;
model y = x1 x2 randomWalk cycle whiteNoise;
```

The specification begins with a PARMS statement that defines two parameters, lambda and cycleVar, along with their lower and upper bounds (essentially 0 and π for lambda, and 0 and infinity for cycleVar). Next, programming statements define an array of variables, cycleT, which contains four variables, c1–c4; these variables are used later for defining the elements of the transition matrix of a state subsection. The STATE statement specifies the two-dimensional subsection s_cycle; the dimension appears within the parentheses after the name (`s_cycle(2)`). The T= option specifies the transition matrix for the s_cycle (`T(g)=(cycleT)`); the `g` in `T(g)` signifies that the form of the T matrix is *general*. The COV= option (`cov(I)=(cycleVar)`) specifies the covariance of the state disturbance ($\mathbf{Q}_t$ for $t \geq 2$); because of the use of `I` in `cov(I)`, the covariance is of the form scaled identity, essentially a two-dimensional diagonal matrix with both diagonal elements equal to cycleVar. The initial condition for s_cycle is completely diffuse because the A1= option, which specifies $\mathbf{A}_1$, specifies that the dimension of the diffuse vector $\boldsymbol{\delta}$ is 2: `a1(2)`. In this case there is no need to specify the covariance $\mathbf{Q}_1$ in the initial condition. The COMPONENT statement specifies the component cycle. It specifies cycle as a dot product of two vectors—(1 0) and s_cycle, which merely selects the first element of s_cycle: `component cycle=(1 0)*s_cycle`. The TREND statement defines a component named randomWalk; its type is *rw*, which signifies random walk. The IRREGULAR statement defines an observation disturbance named whiteNoise. Both the randomWalk and whiteNoise specifications are only partially complete—for example, the disturbance variance of whiteNoise is not specified. These unspecified variances, trendVar, which corresponds to randomWalk, and wnVar, which corresponds to whiteNoise, are automatically included in the list of unknown parameters, $\boldsymbol{\theta}$, along with the parameters that are defined by the PARMS statements. Thus, the parameter vector for this model is $\boldsymbol{\theta}$ = (lambda cycleVar trendVar wnVar). Finally, the model specification is completed by the MODEL statement, which specifies the components of the observation equation: the response variable y, the predictors x1 and x2, the components randomWalk and cycle, and the irregular term whiteNoise.

The preceding statements result in an SSM with a three-dimensional state vector, which is the result of combining the two-dimensional state subsection, s_cycle, and a one-dimensional subsection underlying the

trend, randomWalk. In this specification, the initial state is completely diffuse with $\mathbf{Q}_1$ a null matrix, and $\mathbf{A}_1$ equal to the three-dimensional identity. The other state system matrices $\mathbf{T}_t$ and $\mathbf{Q}_t$ are time-invariant:

$$\mathbf{T} = \begin{bmatrix} \cos(\text{lambda}) & \sin(\text{lambda}) & 0 \\ -\sin(\text{lambda}) & \cos(\text{lambda}) & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad \mathbf{Q} = \begin{bmatrix} \text{cycleVar} & 0 & 0 \\ 0 & \text{cycleVar} & 0 \\ 0 & 0 & \text{trendVar} \end{bmatrix}$$

The observation equation is obvious with $\mathbf{Z} = [1\ 0\ 1]$.

Sparse Transition Matrix Specification

It often happens that the transition matrix $\mathbf{T}$ (or $\mathbf{T}_t$ in the time-varying case) specified in a STATE statement is sparse—that is, many of its elements are zero. The algorithms in the SSM procedure exploit this sparsity for computational efficiency. In most cases the sparsity of a T-block can be inferred from the context. However, if the elements of the T-block are supplied by a list of variables in parentheses, it can be difficult to recognize elements that are structurally zero (this is because of the generality of the DATA step language used for defining the variables). To simplify the specification of such sparse transition matrix, SSM procedure has adopted a convention: the variables that correspond to structural zeros can (and should) be left *unset*—that is, these variables are declared, but no value is assigned to them. As an example, suppose that a three-dimensional state subsection has the following form of transition matrix for some variables X1, X2, and X3 defined elsewhere in the program:

$$\mathbf{T} = \begin{bmatrix} \text{X1} & 0 & 0 \\ \text{X2} & \text{X1} & 0 \\ \text{X3} & 0 & \text{X1} \end{bmatrix}$$

The following (incomplete) statements show how to specify such a T-block:

```
array tMat{3,3};
do i=1 to 3;
   tMat[i, i] = x1;
end;
tMat[2,1] = x2;
tMat[3,1] = x3;
state foo(3) T(g)=(tMat) ...;
```

In this specification only the nonzero elements of the tMat array, which contains $3 \times 3 = 9$ elements, are assigned a value. On the other hand, the following statements show an alternate way of specifying the same T-block. This specification explicitly sets the zeros in the T-block (the elements above the diagonal and tMat[3,2]) to 0.

```
array tMat{3,3};
do i=1 to 3;
   do j=1 to 3;
       if i=j then tMat[i, j] = x1;
       else if j > i then tMat[i, j] = 0;
   end;
end;
tMat[2,1] = x2;
tMat[3,1] = x3;
tMat[3,2] = 0;
state foo(3) T(g)=(tMat) ...;
```

The first specification is simpler, and is preferred. The second specification is mathematically equivalent (and generates the same output) but is computationally less efficient since its sparsity structure cannot always be reliably inferred due to the generality of the DATA step language. In the first specification, the unset elements are recognized to be *structural* zeros while the set elements are treated as nonzero for sparsity purposes. For a simple illustration, see Example 33.5. Proper sparsity specification can lead to significant computational savings for larger matrices.

Regression Variable Specification in Multivariate Models

Suppose that a regression variable in a multivariate model affects two or more response variables. For example, suppose that response variables y1 and y2 depend on a regression variable x. This dependence can be categorized as one of two types:

- In the more common case, the regression coefficient of x for y1 and the regression coefficient of x for y2 are different. The relationship can be described as follows:

$$\begin{aligned} y1 &= \beta_1 x + \text{other terms} \\ y2 &= \beta_2 x + \text{other terms} \end{aligned}$$

  In the SSM procedure you can specify this type of relationship in two equivalent ways:

  – You can specify the variable x in the MODEL statement for y1 and specify the variable x_copy (a copy of x) in the MODEL statement for y2 as follows:

```
x_copy = x;             /* create a copy of x */
model y1 = x ...;
model y2 = x_copy ...;
```

  – You can specify the variable x in MODEL statements for both y1 and y2 as follows:

```
model y1 = x ...;
model y2 = x ...;
```

    This specification avoids creating x_copy.

  Of these two alternate ways, the first is preferred because x and x_copy can then be unambiguously used in an EVAL statement to refer to the terms $\beta_1 x$ and $\beta_2 x$, respectively.

- In the less common case, y1 and y2 share a common regression coefficient.The relationship can be described as follows:

$$\begin{aligned} y1 &= \beta x + \text{other terms} \\ y2 &= \beta x + \text{other terms} \end{aligned}$$

  You can specify this type of relationship by placing the regression coefficient in the model state vector as follows:

```
state beta(1) T(I) A1(1) ;        /* beta is a constant state */
comp xeffect = beta*(x) ;
model y1 =  xeffect ...;
model y2 =  xeffect ...;
```

Here the STATE statement defines beta as a one-dimensional, time-invariant constant (because the transition matrix is identity, the disturbance covariance is 0 and the initial state is diffuse). Next, the COMP statement defines xeffect as the product between beta and the variable x. Subsequently, both y1 and y2 use xeffect in their respective MODEL statements.

Filtering, Smoothing, Likelihood, and Structural Break Detection

The Kalman filter and smoother (KFS) algorithm is the main computational tool for using SSM for data analysis. This subsection briefly describes the basic quantities generated by this algorithm and their relationship to the output generated by the SSM procedure. For proper treatment of SSMs with a diffuse initial condition or when regression variables are present, a modified version of the traditional KFS, called diffuse Kalman filter and smoother (DKFS), is needed. A good discussion of the different variants of the traditional and diffuse KFS can be found in Durbin and Koopman (2012). The DKFS implemented in the SSM procedure closely follows the treatments in De Jong and Chu-Chun-Lin (2003) and Francke, Koopman, and de Vos (2010). Additional details can be found in these references.

The state space model equations (see the section "State Space Model and Notation" on page 2430) imply that the combined response data vector $\mathbf{Y} = (\mathbf{Y}_1, \mathbf{Y}_2, \ldots, \mathbf{Y}_n)$ has a Gaussian probability distribution. This probability distribution is *proper* if d, the dimension of the diffuse vector $\boldsymbol{\delta}$ in the initial condition, is 0 and if $(k + g)$, the total number of regression variables in the observation and state equations, is also 0 (the regression vectors $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ are also treated as a diffuse vectors). Otherwise, this probability distribution is *improper*. The KFS algorithm is a combination of two iterative phases: a forward pass through the data, called *filtering*, and a backward pass through the data, called *smoothing*, that uses the quantities generated during filtering. One of the advantages of using the SSM formulation to analyze the time series data is its ability to handle the missing values in the response variables. The KFS algorithm appropriately handles the missing values in $\mathbf{Y}$. For additional information about how PROC SSM handles missing values, see the section "Missing Values" on page 2461.

Filtering Pass

The filtering pass sequentially computes the quantities shown in Table 33.5 for $t = 1, 2, \ldots, n$ and $i = 1, 2, \ldots, q * p_t$.

Table 33.5 KFS: Filtering Phase

Quantity	Description
$\hat{y}_{t,i} = \mathrm{E}(y_{t,i} \mid y_{t,i-1}, \ldots y_{t,1}, \mathbf{Y}_{t-1}, \ldots, \mathbf{Y}_1)$	One-step-ahead prediction of the response values
$v_{t,i} = y_{t,i} - \hat{y}_{t,i}$	One-step-ahead prediction residuals
$F_{t,i} = \mathrm{Var}(y_{t,i} \mid y_{t,i-1}, \ldots y_{t,1}, \mathbf{Y}_{t-1}, \ldots, \mathbf{Y}_1)$	Variance of the one-step-ahead prediction
$\hat{\boldsymbol{\alpha}}_{t,i} = \mathrm{E}(\boldsymbol{\alpha}_t \mid y_{t,i-1}, \ldots y_{t,1}, \mathbf{Y}_{t-1}, \ldots, \mathbf{Y}_1)$	One-step-ahead prediction of the state vector
$\mathbf{P}_{t,i} = \mathrm{Cov}(\boldsymbol{\alpha}_t \mid y_{t,i-1}, \ldots y_{t,1}, \mathbf{Y}_{t-1}, \ldots, \mathbf{Y}_1)$	Covariance of $\hat{\boldsymbol{\alpha}}_{t,i}$

Table 33.5 *continued*

Quantity	Description
$\mathbf{b}_{t,i}$	$(d+k+g)$-dimensional vector
$\mathbf{S}_{t,i}$	$(d+k+g)$-dimensional symmetric matrix
$\left(\hat{\boldsymbol{\delta}}\ \hat{\boldsymbol{\beta}}\ \hat{\boldsymbol{\gamma}}\right)'_{t,i} = \mathbf{S}_{t,i}^{-1}\mathbf{b}_{t,i}$	Estimates of $\boldsymbol{\delta}$, $\boldsymbol{\beta}$, and $\boldsymbol{\gamma}$ by using the data up to (t,i)
$\mathbf{S}_{t,i}^{-1}$	Covariance of $\left(\hat{\boldsymbol{\delta}}\ \hat{\boldsymbol{\beta}}\ \hat{\boldsymbol{\gamma}}\right)'_{t,i}$
$\mathbf{S}_{t,i}^{*}$	$(d+k+g)$-dimensional symmetric matrix needed in the marginal likelihood computation

Here the notation $\mathrm{E}(y_{t,i}|y_{t,i-1},\ldots,y_{t,1},\mathbf{Y}_{t-1},\ldots,\mathbf{Y}_1)$ denotes the *conditional expectation* of $y_{t,i}$ given the history up to the index $(t,i-1)$: $(y_{t,i-1},\ldots,y_{t,1},\mathbf{Y}_{t-1},\ldots,\mathbf{Y}_1)$. Similarly $\mathrm{Var}(y_{t,i}|y_{t,i-1},\ldots,y_{t,1},\mathbf{Y}_{t-1},\ldots,\mathbf{Y}_1)$ denotes the corresponding conditional variance. The quantity $v_{t,i} = y_{t,i} - \hat{y}_{t,i}$ is set to missing whenever $y_{t,i}$ is missing. Note that $\hat{y}_{t,i}$ are *one-step-ahead* forecasts only when the model has only one response variable and the data are a time series; in all other cases it is more appropriate to call them *one-measurement-ahead* forecasts (since the next measurement might be at the same time point). Despite this, $\hat{y}_{t,i}$ are called one-step-ahead predictions (and $v_{t,i}$ are called one-step-ahead residuals) throughout this document. In the diffuse case, the conditional expectations must be appropriately interpreted. The vector $\mathbf{b}_{t,i}$ and the matrix $\mathbf{S}_{t,i}$ contain some accumulated quantities that are needed for the estimation of $\boldsymbol{\delta}$, $\boldsymbol{\beta}$, and $\boldsymbol{\gamma}$. Of course, when $(d+k+g)=0$ (the nondiffuse case), these quantities are not needed. In the diffuse case, because the matrix $\mathbf{S}_{t,i}$ is sequentially accumulated (starting at $t=1,i=1$), it might not be invertible until some $t=t_*,i=i_*$. The filtering process is called *initialized* after $t=t_*,i=i_*$. In some situations, this initialization might not happen even after the entire sample is processed—that is, the filtering process remains *uninitialized*. This can happen if the regression variables are collinear or if the data are not sufficient to estimate the initial condition $\boldsymbol{\delta}$ for some other reason. In the diffuse case if the marginal likelihood is to be computed (see the section "Likelihood Computation and Model-Fitting Phase" on page 2439), an additional matrix ($\mathbf{S}_{t,i}^{*}$) is computed at each step by sequential accumulation.

The filtering process is used for a variety of purposes. One important use of filtering is to compute the likelihood of the data. In the model-fitting phase, the unknown model parameters $\boldsymbol{\theta}$ are estimated by maximum likelihood. This requires repeated evaluation of the likelihood at different trial values of $\boldsymbol{\theta}$. After $\boldsymbol{\theta}$ is estimated, it is treated as a known vector. The filtering process is used again with the fitted model in the forecasting phase, when the one-step-ahead forecasts and residuals based on the fitted model are provided. In addition, this filtering output is needed by the smoothing phase to produce the full-sample component estimates and for the structural break analysis.

Likelihood Computation and Model-Fitting Phase

Because of the Gaussian nature of the response vector, the likelihood of $\mathbf{Y}$ can be computed by using the prediction-error decomposition. The desired prediction-error decomposition is obtained by the filtering pass described in the previous section ("Filtering Pass" on page 2438). When the state space model under consideration has a nondiffuse initial condition and no regression effects are present in the observation and state equations, $\mathbf{Y}$ has a proper Gaussian distribution and its likelihood is defined unambiguously. Otherwise, the definition of the likelihood depends on the treatment of the diffuse quantities—$\boldsymbol{\delta}$, $\boldsymbol{\beta}$, and $\boldsymbol{\gamma}$. Francke, Koopman, and de Vos (2010) describe three variants of the likelihood function—*diffuse*-likelihood,

marginal-likelihood, and *profile*-likelihood—that are commonly considered for state space models that have a diffuse initial condition. In the SSM procedure, you can either use diffuse likelihood ($\mathbf{L}_d(\mathbf{Y},\boldsymbol{\theta})$) or marginal likelihood ($\mathbf{L}_m(\mathbf{Y},\boldsymbol{\theta})$) for parameter estimation. By default, diffuse likelihood is used for parameter estimation.

In terms of the quantities described in Table 33.5, diffuse, marginal, and profile likelihoods are defined as follows:

$$-2\log \mathbf{L}_d(\mathbf{Y},\boldsymbol{\theta}) = N_0 \log 2\pi + \sum_{t=1}^{n}\sum_{i=1}^{q*p_t}(\log F_{t,i} + \frac{v_{t,i}^2}{F_{t,i}}) - \mathbf{b}_{n,p_n}^{'}\mathbf{S}_{n,p_n}^{-1}\mathbf{b}_{n,p_n} + \log(|\mathbf{S}_{n,p_n}|)$$

$$-2\log \mathbf{L}_m(\mathbf{Y},\boldsymbol{\theta}) = N_0 \log 2\pi + \sum_{t=1}^{n}\sum_{i=1}^{q*p_t}(\log F_{t,i} + \frac{v_{t,i}^2}{F_{t,i}}) - \mathbf{b}_{n,p_n}^{'}\mathbf{S}_{n,p_n}^{-1}\mathbf{b}_{n,p_n} + \log(|\mathbf{S}_{n,p_n}|) - \log(|\mathbf{S}^*_{n,p_n}|)$$

$$-2\log \mathbf{L}_p(\mathbf{Y},\boldsymbol{\theta}) = N \log 2\pi + \sum_{t=1}^{n}\sum_{i=1}^{q*p_t}(\log F_{t,i} + \frac{v_{t,i}^2}{F_{t,i}}) - \mathbf{b}_{n,p_n}^{'}\mathbf{S}_{n,p_n}^{-1}\mathbf{b}_{n,p_n}$$

In the preceding formulas, the terms that are associated with the missing response values $y_{t,i}$ are excluded and N denotes the total number of nonmissing response values in the sample. In addition, $N_0 = (N-k-g-d)$; $|\mathbf{S}_{n,p_n}|$ and $|\mathbf{S}^*_{n,p_n}|$ denote the determinants of $\mathbf{S}_{n,p_n}$ and $\mathbf{S}^*_{n,p_n}$, respectively; and $\mathbf{b}^{'}_{n,p_n}$ denotes the transpose of the column vector $\mathbf{b}_{n,p_n}$. If $\mathbf{S}_{n,p_n}$ is not invertible, then a generalized inverse is used in place of $\mathbf{S}^{-1}_{n,p_n}$, and $|\mathbf{S}_{n,p_n}|$ and $|\mathbf{S}^*_{n,p_n}|$ are computed based on the nonzero eigenvalues of $\mathbf{S}_{n,p_n}$ and $\mathbf{S}^*_{n,p_n}$, respectively. Moreover, in this case, $N_0 = N - \mathrm{Rank}(\mathbf{S}_{n,p_n})$. When $(d+k+g) = 0$, the terms that involve $\mathbf{S}_{n,p_n}$, $\mathbf{S}^*_{n,p_n}$, and $\mathbf{b}_{n,p_n}$ are absent.

The expression for marginal likelihood is derived by treating the diffuse quantities as fixed but unknown parameters. The expression can be shown to be based on a linear transformation of the N-dimensional response vector $\mathbf{Y}$. For a suitably chosen $N \times N$ matrix $\mathbf{H}$, let $\mathbf{U} = \mathbf{HY}$. $\mathbf{H}$ is chosen such that the N-dimensional transformed vector $\mathbf{U}$ partitions into two uncorrelated (and independent because of their Gaussian nature) subvectors: an N_0-dimensional vector $\mathbf{U}_1$ and a $(d+k+g)$-dimensional vector $\mathbf{U}_2$. Furthermore, the distribution of $\mathbf{U}_1$ does not depend on the diffuse vectors ($\boldsymbol{\delta}$, $\boldsymbol{\beta}$, and $\boldsymbol{\gamma}$), and $\mathbf{U}_2$ stores the generalized least squares estimates of the diffuse vectors: $\mathbf{U}_2^{'} = (\hat{\boldsymbol{\delta}} \quad \hat{\boldsymbol{\beta}} \quad \hat{\boldsymbol{\gamma}})^{'}$. It turns out that the N_0-dimensional vector, $\mathbf{U}_1$, has a proper Gaussian distribution and the marginal likelihood, $\log \mathbf{L}_m(\mathbf{Y},\boldsymbol{\theta})$, is the proper likelihood of $\mathbf{U}_1$. The diffuse likelihood, $\log \mathbf{L}_d(\mathbf{Y},\boldsymbol{\theta})$, is also based on $\mathbf{U}_1$. However, rather than assuming the diffuse quantities as unknown parameters, the expression of the diffuse likelihood is derived by assuming that $\boldsymbol{\delta}$, $\boldsymbol{\beta}$, and $\boldsymbol{\gamma}$ are random vectors with diffuse priors. Even though the marginal and diffuse likelihoods are based on different interpretations of the diffuse quantities, their expressions differ by only one term: the diffuse likelihood does not have the term $-\log(|\mathbf{S}^*_{n,p_n}|)$. Since the marginal likelihood is the proper likelihood of $\mathbf{U}_1$, the diffuse likelihood can be interpreted as a quasi-likelihood of $\mathbf{U}_1$. Apart from being essential to make it a proper likelihood, the extra term in the marginal likelihood plays another useful role: it makes the marginal likelihood invariant to linear rescaling of the diffuse effects, a desirable property in a likelihood. The diffuse likelihood is not invariant to linear rescaling of the diffuse effects. The profile likelihood, $\log \mathbf{L}_p(\mathbf{Y},\boldsymbol{\theta})$, is the likelihood of the response vector $\mathbf{Y}$ evaluated at the generalized least squares estimates of the diffuse vectors: $(\boldsymbol{\delta} \quad \boldsymbol{\beta} \quad \boldsymbol{\gamma})^{'} = (\hat{\boldsymbol{\delta}} \quad \hat{\boldsymbol{\beta}} \quad \hat{\boldsymbol{\gamma}})^{'}$. It is derived by treating the diffuse quantities as fixed but unknown parameters and, like the marginal likelihood, is invariant to linear rescaling of the diffuse effects. For an illustration of this invariance property, see Example 33.18.

In the literature, the marginal likelihood (in addition to the diffuse likelihood) is also called the *restricted*-likelihood, and the estimate of the parameter vector $\boldsymbol{\theta}$ that is obtained by maximizing $\log \mathbf{L}_m(\mathbf{Y},\boldsymbol{\theta})$ (or

$\log \mathbf{L}_d(\mathbf{Y}, \boldsymbol{\theta})$) is called the restricted maximum likelihood estimate (REML). In this section, the REML estimate that is based on marginal likelihood is denoted by REML_M and the REML estimate that is based on diffuse likelihood is denoted by REML_D. In addition, the estimate of $\boldsymbol{\theta}$ that is obtained by maximizing the profile likelihood is called the maximum likelihood estimate (ML). In the absence of the diffuse quantities, all three likelihoods are the same and the REML_M, REML_D, and ML estimates coincide. When diffuse quantities are present, there is some evidence to prefer REML_M, the estimate of $\boldsymbol{\theta}$ that is based on the marginal likelihood. For more information, see Francke, Koopman, and de Vos (2010) and the references therein. By default, the SSM procedure uses diffuse likelihood for parameter estimation. You can switch to marginal likelihood by using the LIKE=MARGINAL option in the PROC SSM statement. In the current release of the SSM procedure, you cannot request parameter estimation by using profile likelihood.

Interestingly, for many types of state space models, REML_M and REML_D coincide even when diffuse effects are present. This is because for these models the extra term in the marginal likelihood, $-\log(|\mathbf{S}^*_{n,p_n}|)$, turns out to be independent of the parameter vector $\boldsymbol{\theta}$. Specifically, for models that are specified by using the PROC SSM syntax, REML_M and REML_D differ only if at least one of the following conditions hold:

- The transition matrix ($\mathbf{T}_t$) that is implied by a STATE statement depends on at least one unknown parameter and the diffuse dimension of the associated state subsection is nonzero.
- The list of variables that is specified in a COMPONENT statement depends on at least one unknown parameter and the diffuse dimension of the associated state subsection is nonzero.
- At least one lag term in a DEPLAG statement depends on an unknown parameter.
- A TREND statement with GROWTH or GROWTH(OU) type is present and the growth parameter, ϕ, is unknown.

In particular, if the parameter vector affects only the disturbance covariances (Q_t) in the state equation and the error variances ($\sigma^2_{t,i}$) in the observation equation (see Table 33.4), REML_M and REML_D coincide. These observations also imply that REML_M and REML_D coincide for the most commonly used univariate and multivariate unobserved component models and for ARIMA models, with or without regression effects.

NOTE: For many examples in the section "Examples: SSM Procedure" on page 2467, one of the preceding conditions does hold and the REML_M and REML_D estimates do differ. However, in all these cases, it turns out that the differences in REML_M and REML_D are not large enough to change the overall conclusions of the analysis. As verification, you can rerun the analyses that are described in Example 33.10, Example 33.13, and Example 33.14 by using the LIKE=MARGINAL option in the PROC SSM statement. Of course, this will not be true in general.

The REML_D and REML_M estimates of the unknown parameter vector $\boldsymbol{\theta}$ (each denoted as $\hat{\boldsymbol{\theta}}$), are computed by maximizing the diffuse (or marginal) likelihood. This is done by using a nonlinear optimization process that involves repeated evaluations of $\mathbf{L}_d(\mathbf{Y}, \boldsymbol{\theta})$ (or $\mathbf{L}_m(\mathbf{Y}, \boldsymbol{\theta})$) at different values of $\boldsymbol{\theta}$. Approximate standard errors of $\hat{\boldsymbol{\theta}}$ are computed by taking the square root of the diagonal elements of its (approximate) covariance matrix. This covariance is computed as $-\mathbf{H}^{-1}$, where $\mathbf{H}$ is the Hessian (the matrix of the second-order partials) of $\log \mathbf{L}_d(\mathbf{Y}, \boldsymbol{\theta})$ (or $\log \mathbf{L}_m(\mathbf{Y}, \boldsymbol{\theta})$) evaluated at the optimum $\hat{\boldsymbol{\theta}}$. It is known that under mild regularity assumptions (as the number of distinct time points tends toward infinity), $\hat{\boldsymbol{\theta}}$ is consistent and efficient. For good discussions about REML_D, REML_M, and ML estimates, see Searle, Casella, and McCulloch (1992); Laird (2004); Francke, Koopman, and de Vos (2010).

If the marginal likelihood is used for parameter estimation, the SSM procedure reports the values of all three likelihoods at the parameter estimate $\hat{\boldsymbol{\theta}}$. Otherwise, PROC SSM reports the values of the diffuse and profile

likelihoods that are calculated at the parameter estimate $\hat{\boldsymbol{\theta}}$. Let $\dim(\theta)$ denote the dimension of the parameter vector $\boldsymbol{\theta}$. After PROC SSM completes the parameter estimation, it prints the "Likelihood Computation Summary" table, which summarizes the likelihood calculations at $\hat{\boldsymbol{\theta}}$, as shown in Table 33.6.

Table 33.6 Likelihood Computation Summary

Quantity	Formula
Nonmissing response values used	N
Estimated parameters	$\dim(\theta)$
Initialized diffuse state elements	$\mathrm{rank}(\mathbf{S}_{n,p_n})$
Normalized residual sum of squares	$\sum_{t=1}^{n}\sum_{i=1}^{q*p_t}(\frac{v_{t,i}^2}{F_{t,i}}) - \mathbf{b}_{n,p_n}^{'}\mathbf{S}_{n,p_n}^{-1}\mathbf{b}_{n,p_n}$
Diffuse log likelihood	$\log \mathbf{L}_d(\mathbf{Y},\hat{\boldsymbol{\theta}})$
Marginal log likelihood	$\log \mathbf{L}_m(\mathbf{Y},\hat{\boldsymbol{\theta}})$
Profile log likelihood	$\log \mathbf{L}_p(\mathbf{Y},\hat{\boldsymbol{\theta}})$

In addition to the likelihood computation summary, PROC SSM also reports the information criteria that are based on the diffuse and profile likelihoods. It also reports the information criteria that are based on the marginal likelihood if marginal likelihood is used for parameter estimation. A variety of information criteria are reported. All these criteria are functions of twice the negative likelihood ($-2\log\mathbf{L}$, where the likelihood can be diffuse, marginal, or profile), N_* (the effective sample size), and $nparm$ (the effective number of model parameters). For information criteria that are based on the diffuse and marginal likelihoods, the effective sample size, N_*, is equal to N_0 and the effective number of model parameters, $nparm$, is equal to $\dim(\theta)$. For information criteria that are based on the profile likelihood, the effective sample size, N_*, is equal to N and the effective number of model parameters, $nparm$, is equal to $\dim(\theta) + d + k + g$. Table 33.7 summarizes the reported information criteria in smaller-is-better form.

Table 33.7 Information Criteria

Criterion	Formula	Reference
AIC	$-2\log\mathbf{L} + 2nparm$	Akaike (1974)
AICC	$-2\log\mathbf{L} + 2nparm N_*/(N_* - nparm - 1)$	Hurvich and Tsai (1989) Burnham and Anderson (1998)
HQIC	$-2\log\mathbf{L} + 2nparm\log\log(N_*)$	Hannan and Quinn (1979)
BIC	$-2\log\mathbf{L} + nparm\log(N_*)$	Schwarz (1978)
CAIC	$-2\log\mathbf{L} + nparm(\log(N_*) + 1)$	Bozdogan (1987)

Forecasting Phase

After the model-fitting phase, the filtering process is repeated again to produce the model-based one-step-ahead response variable forecasts ($\hat{y}_{t,i}$), residuals ($v_{t,i}$), and their standard errors ($\sqrt{F_{t,i}}$). In addition, one-step-ahead forecasts of the components that are specified in the MODEL statements, and any other user-defined linear combinations of $\boldsymbol{\alpha}_t$, are also produced. These forecasts are set to missing as long as the index $t < t_*$ (that is, until the filtering process is initialized). If the filtering process remains uninitialized, then all the quantities that are related to the one-step-ahead forecast (such as $\hat{y}_{t,i}$ and $v_{t,i}$) are reported

as missing. When the fitted model is appropriate, the one-step-ahead residuals $v_{t,i}$ form a sequence of uncorrelated normal variates. This fact can be used during model diagnostic process.

Smoothing Phase

After the filtering phase of KFS produces the one-step-ahead predictions of the response variables and the underlying state vectors, the smoothing phase of KFS produces the full-sample versions of these quantities—that is, rather than using the history up to $(t, i-1)$, the entire sample $\mathbf{Y}$ is used. The smoothing phase of KFS is a backward algorithm, which begins at $t = n$ and $i = q * p_n$ and goes back toward $t = 1$ and $i = 1$. It produces the following quantities:

Table 33.8 KFS: Smoothing Phase

Quantity	Description
$\tilde{y}_{t,i} = \mathrm{E}(y_{t,i}\|\mathbf{Y})$	Interpolated response value
$\tilde{F}_{t,i} = \mathrm{Var}(y_{t,i}\|\mathbf{Y})$	Variance of the interpolated response value
$\tilde{\boldsymbol{\alpha}}_t = \mathrm{E}(\boldsymbol{\alpha}_t\|\mathbf{Y})$	Full-sample estimate of the state vector
$\tilde{\mathbf{P}}_t = \mathrm{Cov}(\boldsymbol{\alpha}_t\|\mathbf{Y})$	Covariance of $\tilde{\boldsymbol{\alpha}}_t$
$\left(\hat{\boldsymbol{\delta}}\ \ \hat{\boldsymbol{\beta}}\ \ \hat{\boldsymbol{\gamma}}\right)' = \mathbf{S}_{n,p_n}^{-1}\mathbf{b}_{n,p_n}$	Full-sample estimates of $\boldsymbol{\delta}$, $\boldsymbol{\beta}$, and $\boldsymbol{\gamma}$
$\mathbf{S}_{n,p_n}^{-1}$	Covariance of $\left(\hat{\boldsymbol{\delta}}\ \ \hat{\boldsymbol{\beta}}\ \ \hat{\boldsymbol{\gamma}}\right)'$

Note that if $y_{t,i}$ is not missing, then $\tilde{y}_{t,i} = \mathrm{E}(y_{t,i}|\mathbf{Y}) = y_{t,i}$ and $\tilde{F}_{t,i} = \mathrm{Var}(y_{t,i}|\mathbf{Y}) = 0$ because $y_{t,i}$ is completely known, given $\mathbf{Y}$. Therefore, $\tilde{y}_{t,i}$ provides nontrivial information only when $y_{t,i}$ is missing—in which case $\tilde{y}_{t,i}$ represents the best estimate of $y_{t,i}$ based on the available data. The full-sample estimates of components that are specified in the model equations are based on the corresponding linear combinations of $\tilde{\boldsymbol{\alpha}}_t$. Similarly, their standard errors are computed by using appropriate functions of $\tilde{\mathbf{P}}_t$.

If the filtering process remains uninitialized until the end of the sample (that is, if $\mathbf{S}_{n,p_n}$ is not invertible), some linear combinations of $\boldsymbol{\delta}$, $\boldsymbol{\beta}$, and $\boldsymbol{\gamma}$ are not estimable. This, in turn, implies that some linear combinations of $\boldsymbol{\alpha}_t$ are also inestimable. These inestimable quantities are reported as missing. For more information about the estimability of the state effects, see Selukar (2010).

Delete-One Cross Validation and Structural Breaks

In addition to the interpolation of missing response values and the full-sample estimation of components in the model, the smoothing phase can also produce several useful diagnostic measures that can indicate outlying observations and breaks in the state evolution process. The treatment of additive outliers and structural breaks that is described in this section is based on De Jong and Penzer (1998). Also see Selukar (2017) for illustrative examples.

Delete-One Cross Validation and the Additive Outlier Detection

Let $\mathrm{AO}_{t,i} = y_{t,i} - \mathrm{E}(y_{t,i}|\mathbf{Y}^{t,i})$ denote the difference between the observed response value $y_{t,i}$ and its estimate or prediction by using all the data except $y_{t,i}$, which is denoted by $\mathbf{Y}^{t,i}$. The smoothing phase of DKFS can generate $\mathrm{AO}_{t,i}$ (and its variance) at all (t, i). A large value of $\mathrm{AO}_{t,i}$ signifies that the observed response value $(y_{t,i})$ is unusual relative to the rest of the sample (according to the postulated model). Such values are called additive outliers. In the literature, $\mathrm{AO}_{t,i}$ are referred by a few different names. Sometimes

they are called *delete-one cross validation errors* or simply *prediction errors*. In this chapter, these names are used interchangeably. Like the one-step-ahead residuals, $v_{t,i}$, the prediction errors can be used in checking the adequacy of the model. The prediction errors are normally distributed; however, unlike $v_{t,i}$, they are not serially uncorrelated. $\mathrm{AO}_{t,i}$ is set to missing when $y_{t,i}$ is missing. The SSM procedure prints a summary table of extreme additive outliers by default. In addition, you can request the plotting of the standardized prediction errors, and they can be output to a data set.

The prediction error sum of squares (PRESS)

$$\sum_{t,i} AO_{t,i}^2$$

can be a useful measure of fit to compare different models. It is also called the *cross validation error sum of squares*. An additional measure of fit based on the prediction errors is called the *generalized* cross validation error sum of squares (GCV). Denoting the variance of $\mathrm{AO}_{t,i}$ by $\mathrm{VAR\_AO}_{t,i}$, it is defined as

$$\frac{\sum_{t,i}(\mathrm{AO}_{t,i}^2/\mathrm{VAR\_AO}_{t,i}^2)}{[\,\sum_{t,i}(1/\mathrm{VAR\_AO}_{t,i})\,]^2}$$

You can request the printing of PRESS and GCV by specifying the PRESS option in the OUTPUT statement.

After inspecting the reported additive outliers, you can adjust the model to account for the effects of some of the extreme outlying observations. This can be done by including appropriate dummy variables in the observation equation.

Structural Breaks in the State Evolution

The additive outliers that are discussed in the preceding section are diagnostic measures associated with the measurement equation. The smoothing phase of DKFS can generate diagnostic measures that are also associated with the state equation.

For simplicity of notation and exposition, initially assume that the state equation has the following form:

$$\boldsymbol{\alpha}_{t+1} = \mathbf{T}_t\boldsymbol{\alpha}_t + \mathbf{c}_{t+1} + \boldsymbol{\eta}_{t+1}$$

That is, the state regression term $\mathbf{W}_{t+1}\boldsymbol{\gamma}$ is absent in the postulated model. Suppose that an unanticipated change of unknown size takes place in the i_0th element of the state at time $(t_0 + 1)$. The model can then be adjusted to account for this change by including a suitable dummy regressor in the state equation as follows:

$$\boldsymbol{\alpha}_{t+1} = \mathbf{T}_t\boldsymbol{\alpha}_t + \mathbf{W}_{t+1}\boldsymbol{\gamma} + \mathbf{c}_{t+1} + \boldsymbol{\eta}_{t+1}$$

Here $\mathbf{W}_t$ is a sequence of m-dimensional column vectors such that $\mathbf{W}_{t_0+1}[i_0] = 1$ and $\mathbf{W}_t[i] = 0$ for all other t and i. The estimate of the regression coefficient $\boldsymbol{\gamma}$ provides information about the size of the unanticipated change in the i_0th element of $\boldsymbol{\alpha}_t$ at time $t = t_0 + 1$. Similarly, an unanticipated change in a subsection of $\boldsymbol{\alpha}_t$ at a time $t = t_0 + 1$ can be estimated by using a set of appropriate dummies (the number of dummies equals the number of elements in the state subsection) in the state equation. The algorithm of De Jong and Penzer (1998) efficiently generates the estimates of such one-time changes in the state at all distinct time points in the sample in one smoothing pass. A statistically significant value of $\boldsymbol{\gamma}$ at a time point t_0 indicates an unanticipated change in the relevant element (or the subsection) of $\boldsymbol{\alpha}_{t_0}$. Note that the change associated with an additive outlier is temporary: the previous or the subsequent measurements are not affected. On the other hand, because of the evolutionary nature of the state equation, a one-time change in the state affects all the subsequent states, which in turn affect the subsequent observations. In this sense, a significant unanticipated change in the state is a *structural break*.

In the preceding discussion, the absence of the state regression variables in the postulated model was assumed only for notational simplicity. If the postulated model does contain some state regression variables, the dummy variable that is associated with the one-time state change is simply added to the existing set of state regression variables, and the interpretation of its regression coefficient as the measure of unanticipated change in the state remains unaffected.

In the SSM procedure, you can request the computation of significance statistics that are associated with one-time changes in the state subsections specified by using the STATE statement in addition to the state subsections that are associated with the components specified by using the TREND statements. This is done by using the CHECKBREAK option in these statements. In addition, you can request the computation of such statistics for the entire state $\boldsymbol{\alpha}_t$ by using the MAXSHOCK option in the OUTPUT statement. The significance statistics can be computed for both elementwise change and subsectionwise change. The computation of subsectionwise change statistics can be computationally expensive for large subsections (an inversion of a $p \times p$-dimensional matrix at each distinct time point in the sample is needed for the computation of significance statistics for a state subsection of size p). For an example of structural break analysis, see Example 33.8.

Estimation of User-Specified Linear Combination of State Elements

By default, the SSM procedure computes the estimates of all the components that are specified in the MODEL statements (you can print these estimates by using the PRINT= option in the respective TREND and COMPONENT statements, or you can output these estimates to a data set by specifying it in the OUT= option in the OUTPUT statement). However, in many cases it is desirable to obtain the estimates of additional linear combinations of the state elements and the regression effects. The SSM procedure provides two statements, the COMPONENT statement and the EVAL statement, that are useful for specifying virtually any desired linear combination of the elements of the state vector and the regression effects in the observation equation. After a desired linear combination is specified, you can print or output its estimate as you would for a component that is used in the MODEL statement. This feature of the SSM procedure is illustrated in many examples in the section "Examples: SSM Procedure" on page 2467. For example, in the second part of Example 33.4, the COMPONENT and EVAL statements are used to define the contrasts between the growth profiles of cows that are receiving different treatments. Similarly, in Example 33.7, the EVAL statement is used to define the yield curve as a sum of the components that are used in the MODEL statement.

Contrasting PROC SSM with Other SAS Procedures

The SSM procedure complements several SAS/ETS procedures and the MIXED procedure in SAS/STAT software (see Chapter 84, "The MIXED Procedure" (*SAS/STAT User's Guide*)). The statistical models underlying all these procedures can be formulated as state space models; however, in many cases this formulation effort can be considerable. Generally speaking, when a problem can be formulated and satisfactorily solved either by using the SSM procedure or by using one of these other procedures, the other procedures are likely to be more efficient. However, in many instances, the SSM procedure can solve more general problems or offer more detailed analysis, or both. Throughout this discussion, it is assumed that the problem being solved can be modeled as a linear statistical model with Gaussian response variables. In particular, situations that require models such as autoregressive conditional heteroscedasticity (ARCH) models, and models with categorical response variables are not considered. The following list provides a more specific comparison of the SSM procedure with different procedures:

- All the SAS/ETS time series analysis procedures (the ARIMA, ESM, UCM, VARMAX, STATESPACE, and PANEL procedures) require time series data and are not applicable to the longitudinal data.
- For univariate time series analysis, the modeling facilities provided by the ARIMA, ESM, and UCM procedures are adequate in most cases. The SSM procedure can handle cases that do not fit neatly into one of these categories.
- For multivariate time series data analysis, you can use the VARMAX procedure for vector ARIMA modeling and the STATESPACE procedure for state space modeling. The capabilities of the SSM procedure are complementary to these procedures. In particular, the predefined multivariate structural models available in the SSM procedure cannot be specified by either of these procedures. In addition, you can formulate a much wider range of multivariate models—for example, models for series with different frequencies, by using the SSM procedure.
- When the $\mathbf{R}$ side effects are not too complicated (for example, if $\mathbf{R}$ is diagonal), the model considered by the MIXED procedure is a special case of the model considered by the SSM procedure. In the case of diagonal $\mathbf{R}$, it is easy to see that the state vector $\boldsymbol{\alpha}_t$ is equal to $\boldsymbol{\gamma}$, the MIXED random-effects vector, for all $t \geq 1$ (that is, $\boldsymbol{\alpha}_t$ is *time invariant*). Therefore, the random-effects MIXED model is obtained by setting $\mathbf{T} = \text{Identity}$, $\mathbf{Q}_t = \mathbf{0}, t \geq 2$, $\mathbf{Q}_1 = \mathbf{G}$ (the MIXED $\mathbf{G}$ matrix), and $\mathbf{A}_1 = \mathbf{0}$.
- For the analysis of cross-sectional data, you can use the PANEL procedure. In this case, the SSM procedure capabilities are complementary. PROC SSM can provide alternate models, REML estimates, richer missing value support, and the estimates of the unobserved components (see the section "Getting Started: SSM Procedure" on page 2398 and the examples Example 33.2 and Example 33.11 for more information). In some situations the cross-sectional studies contain many panels but very few distinct time points. The PANEL procedure based analysis is better suited in such settings. In order for the analysis based on PROC SSM to be valid, the cross-sectional study must contain an adequate number of distinct time points.

Predefined Trend Models

The statistical models that govern the predefined trend components available in the SSM procedure are divided into two groups: models that are applicable to equally spaced data (possibly with replication), and models that are applicable more generally (the irregular data type). Each trend component can be described as a dot product $\mathbf{Z}\boldsymbol{\alpha}_t$ for some (time-invariant) vector $\mathbf{Z}$ and a state vector $\boldsymbol{\alpha}_t$. The component specification is complete after the vector $\mathbf{Z}$ is specified and the system matrices that govern the equations of $\boldsymbol{\alpha}_t$ are specified. For trend models for regular data, all the system matrices are time-invariant. For irregular data, $\mathbf{T}_t$ and $\mathbf{Q}_t$ depend on the spacing between the distinct time points: $(\tau_{t+1} - \tau_t)$.

Trend Models for Regular Data

These models are applicable when the data type is either regular or regular with replication. A good reference for these models is Harvey (1989).

Random Walk Trend

This model provides a trend pattern in which the level of the curve changes with time. The rapidity of this change is inversely proportional to the disturbance variance σ^2 that governs the underlying state. It can be

described as $\mathbf{Z}\alpha_t$, where $Z = (1)$ and the (one-dimensional) state α_t follows a random walk:

$$\alpha_{t+1} = \alpha_t + \eta_{t+1}, \quad \eta_t \sim N(0, \sigma^2)$$

Here $\mathbf{T} = 1$ and $\mathbf{Q} = \sigma^2$. The initial condition is fully diffuse. Note that if $\sigma^2 = 0$, the resulting trend is a fixed constant.

Local Linear Trend

This model provides a trend pattern in which both the level and the slope of the curve change with time. This variation in the level and the slope is controlled by two parameters: σ_1^2 controls the level variation, and σ_2^2 controls the slope variation. If $\sigma_1^2 = 0$, the resulting trend is called an *integrated random walk*. If both $\sigma_1^2 = 0$ and $\sigma_2^2 = 0$, then the resulting model is the deterministic linear time trend. Here $\mathbf{Z} = (1\ 0)$, $\mathbf{T} = (1\ 1,\ 0\ 1)$, and $\mathbf{Q} = \mathrm{Diag}(\sigma_1^2,\ \sigma_2^2)$. The initial condition is fully diffuse.

Damped Local Linear Trend

This trend pattern is similar to the local linear trend pattern. However, in the DLL trend the slope follows a first-order autoregressive model, whereas in the LL trend the slope follows a random walk. The autoregressive parameter or the damping factor, ϕ, must lie between 0.0 and 1.0, which implies that the long-run forecast according to this pattern has a slope that tends to 0. Here $\mathbf{Z} = (1\ 0)$, $\mathbf{T} = (1\ 1,\ 0\ \phi)$, and $\mathbf{Q} = \mathrm{Diag}(\sigma_1^2,\ \sigma_2^2)$. The initial condition is partially diffuse with $\mathbf{Q_1} = \mathrm{Diag}(0,\ \sigma_2^2/(1 - \phi * \phi))$.

ARIMA Trend

This section describes the state space form for a component that follows an ARIMA(*p,d,q*)×(*P,D,Q*)$_s$ model. The notation for ARIMA models is explained in the TREND statement.

First the state space form for the stationary case—that is, when $d = 0$ and $D = 0$, is explained. A number of alternate state space forms are possible in this case; the one described here is based on Jones (1980). With slight abuse of notation, let $p = p + s * P$ denote the effective autoregressive order, and let $q = q + sQ$ denote the effective moving average order of the model. Similarly, let ϕ be the effective autoregressive polynomial, and let θ be the effective moving average polynomial in the backshift operator with coefficients $\phi_1, \ldots, \phi_p$ and $\theta_1, \ldots, \theta_q$, obtained by multiplying the respective nonseasonal and seasonal factors. Then, a random sequence ξ_t that follows an ARMA(*p,q*)×(*P,Q*)$_s$ model with a white noise sequence a_t has a state space form with state vector of size $m = \max(p, q+1)$. The system matrices are as follows: $\mathbf{Z} = [1\ 0\ \ldots\ 0]$, and the transition matrix $\mathbf{T}$, in a blocked form, is given by

$$\mathbf{T} = \begin{bmatrix} 0 & I_{m-1} \\ \phi_m\ \ldots & \phi_1 \end{bmatrix}$$

where $\phi_i = 0$ if $i > p$ and I_{m-1} is an $(m-1)$ dimensional identity matrix. The covariance of the state disturbance matrix $\mathbf{Q} = \sigma^2 \psi \psi'$, where σ^2 is the variance of the white noise sequence a_t and the vector $\psi = [\psi_0 \ldots \psi_{m-1}]'$ contains the first m values of the impulse response function—that is, the first m coefficients in the expansion of the ratio θ/ϕ. The covariance matrix of the initial state, $\mathbf{Q}_1$, is computed as

$$vec(\mathbf{Q}_1) = (\mathbf{I} - \mathbf{T} \bigotimes \mathbf{T})^{-1} vec(\mathbf{Q})$$

where $\bigotimes$ denotes the Kronecker product and the vec operation on a matrix creates a vector formed by vertically stacking the rows of that matrix.

A number of alternate state space forms are possible in the nonstationary case also. The form used by the SSM procedure utilizes the state space form for the stationary case as a building block. Suppose that a random

sequence ξ_t follows an ARIMA(*p,d,q*)×(*P,D,Q*)$_s$ model with a white noise sequence a_t. As in the notation for the stationary case, with slight abuse of notation, let $d = d + s * D$ denote the effective differencing order, and let Δ be the effective differencing polynomial in the backshift operator with coefficients $\Delta_1, \ldots, \Delta_d$. It can be shown that ξ_t has a state space form with state vector size $m^\dagger = m + d$. In what follows, the system matrices and related quantities in the nonstationary case are described in terms of similar entities in the stationary case. A superscript dagger (†) has been added to distinguish the entities from the nonstationary case. $\mathbf{Z}^\dagger = [0\ 0\ \ldots\ 1\ \ldots\ 0]$ where the only nonzero value, 1, is at the index $m + 1$, and the transition matrix, $\mathbf{T}^\dagger$, in a blocked form, is given by

$$\mathbf{T}^\dagger = \begin{bmatrix} \mathbf{T} & 0 & 0 \\ \mathbf{ZT} & \Delta_1 \ldots & \Delta_d \\ 0 & I_{d-1} & 0 \end{bmatrix}$$

The state disturbance matrix $\mathbf{Q}^\dagger$ is given by

$$\mathbf{Q}^\dagger = \begin{bmatrix} \mathbf{Q} & \mathbf{QZ}' & 0 \\ \mathbf{ZQ} & \mathbf{ZQZ}' & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

Finally, the initial state is partially diffuse: the first m elements are nondiffuse and the last d elements are diffuse. The covariance matrix of the first m elements is $\mathbf{Q}_1$.

Trend Models for Irregular Data

A good reference for these models is De Jong and Mazzi (2001). Throughout this section $h_t = (\tau_{t+1} - \tau_t)$ denotes the difference between the successive time points. The system matrices $\mathbf{T}_t$ and $\mathbf{Q}_t$ that govern these models depend on h_t. However, whenever the notation is unambiguous, the subscript t is omitted.

Polynomial Spline Trend

This model is a general-purpose tool for extracting a smooth trend from the noisy data. The order of the spline governs the order of the local polynomial that defines the spline. The order-1 spline corresponds to Brownian motion (continuous-time random walk), the order-2 spline corresponds to integrated Brownian motion (continuous-time integrated random walk), and the order-3 spline provides a locally quadratic trend; the default order is 1. The dimension of the state underlying this component is the same as the order of the spline. The system matrices for the orders up to 3 are described as follows (in all the cases the initial condition is fully diffuse):

- order-1 spline: $\mathbf{Z} = (1)$, $\mathbf{T} = (1)$, and $\mathbf{Q} = \sigma^2(h)$
- order-2 spline: $\mathbf{Z} = (1\ 0)$, $\mathbf{T} = (1\ h,\ 0\ 1)$, and $\mathbf{Q} = \sigma^2 \begin{pmatrix} \frac{h^3}{3} & \frac{h^2}{2}, \frac{h^2}{2} & h \end{pmatrix}$
- order-3 spline: $\mathbf{Z} = (1\ 0\ 0)$, $\mathbf{T} = \begin{pmatrix} 1 & h & \frac{h^2}{2}, 0 & 1 & h, 0 & 0 & 1 \end{pmatrix}$, and

$$\mathbf{Q}[i, j] = \sigma^2 * \frac{h^{6-i-j+1}}{(6 - i - j + 1)(3 - i)!(3 - j)!} \quad 1 \le i, j \le 3$$

The system matrices for higher orders are similarly defined (for more information, see De Jong and Mazzi (2001)).

Note that, in addition to providing an estimate of the trend, this methodology can provide estimates of the higher-order derivatives of the trend. If $\boldsymbol{\alpha}$ denotes the k-dimensional subsection that is associated with a polynomial spline of order k, then its jth element ($1 \leq j \leq k$), $\boldsymbol{\alpha}[j]$, corresponds to the derivative of order $(j-1)$ of this polynomial spline. For an example of the estimation of the first derivative of a trend component, see Example 33.12. For additional information about using these types of trend patterns in data analysis, see Eubank, Huang, and Wang (2003); Kohn, Ansley, and Tharm (1991); Selukar (2015).

Decay and Growth Trends

There are two choices for the decay trend: DECAY and DECAY(OU). Similarly, there are two choices for the growth trend: GROWTH and GROWTH(OU). The "OU" stands for the Ornstein-Uhlenbeck form of these models. The decay trend is a sum of two correlated components: one component is a random walk, and the other component is a stationary autoregression. In its Ornstein-Uhlenbeck form, the random walk component is replaced by a constant. The growth trend (and its Ornstein-Uhlenbeck variant) has the same form as the decay trend except that the autoregression is nonstationary (in fact, it is explosive). For growth trend models, floating-point errors can result for even moderately long forecast horizons because of the explosive growth in the trend values.

The system matrices for the decay and the growth types in their respective cases are identical, except for the sign of the rate parameter ϕ: $\phi < 0.0$ for the decay type, and $\phi > 0.0$ for the growth type. In addition, the initial conditions for the growth models are fully diffuse; they are only partially diffuse for the decay models. The underlying state vector for all these models is two-dimensional.

The system matrices for the DECAY type are

$$\begin{aligned}
\mathbf{Z} &= (1\ 1) \\
\mathbf{T} &= \mathrm{Diag}(1,\ \exp(h\phi)) \\
\mathbf{Q} &= \frac{\sigma^2}{\phi^3}\left(h\phi \ \ 1-\exp(h\phi),\ \ 1-\exp(h\phi) \ \ (\exp(2h\phi)-1)/2 \right)
\end{aligned}$$

The initial condition is partially diffuse with $\mathbf{Q_1} = \mathrm{Diag}(0,\ \frac{-\sigma^2}{2\phi^3})$. The system matrices for the GROWTH type are the same (with $\phi > 0.0$), except that the initial condition is fully diffuse; so $\mathbf{Q_1} = 0$.

For the DECAY(OU) type, $\mathbf{Z}$ and $\mathbf{T}$ are the same as DECAY, whereas

$$\mathbf{Q} = \mathrm{Diag}\left(0,\ \sigma^2 \frac{(\exp(2h\phi)-1)}{2\phi} \right) \ \text{ and } \ \mathbf{Q_1} = \mathrm{Diag}(0,\ \frac{-\sigma^2}{2\phi})$$

The system matrices for the GROWTH(OU) type are the same (with $\phi > 0.0$), except that the initial condition is fully diffuse; so $\mathbf{Q_1} = 0$.

Predefined Structural Models

A set of predefined models is available in the SSM procedure for models called structural models in the time series literature. These predefined models can be used to model trend, seasonal, and cyclical patterns in the univariate and multivariate time series. For the most part, the multivariate models are straightforward generalizations of the corresponding univariate models—for example, the multivariate random walk trend described later in this section generalizes the univariate random walk trend that is described in the section "Random Walk Trend" on page 2446. All of these models, with the exception of the continuous-time cycle model, are applicable only to the regular data type. The continuous-time cycle model is applicable to all the data types; however, it is available for the univariate case only.

To specify these models, you must first use the STATE statement with the correct TYPE= option. When you specify the TYPE=option, you do not need to specify other options of the STATE statement (for example, the T option, the COV1 option, and the A1 option). However, you must specify the COV option, which describes the covariance of the disturbance term that drives the state equation. Throughout this section, the symmetric matrix specified by using the COV option is denoted by $\mathbf{\Sigma}$. For TYPE= LL, an additional matrix, specified by using the SLOPECOV suboption, also plays a role; it is denoted by $\mathbf{\Sigma}_{\text{slope}}$. Subsequently you must specify one or more COMPONENT statements to define the (univariate) components that are based on this state subsection for their inclusion in the MODEL statement. These univariate components exhibit interesting behavior based on the structure of $\mathbf{\Sigma}$ (and $\mathbf{\Sigma}_{\text{slope}}$, whenever applicable)—for example, imposing rank restrictions on $\mathbf{\Sigma}$ in the multivariate random walk results in these univariate trends moving together. For additional information about these models, see Harvey (1989).

The following example summarizes the steps needed to define a multivariate structural model by using a sequence of STATE and COMPONENT statements. For a full example, see Example 33.1. Suppose that a three-dimensional time series is being studied with response variables y1, y2, and y3. Suppose you want to specify the trivariate structural model

$$\mathbf{y}_t = \boldsymbol{\mu}_t + \boldsymbol{\psi}_t + \boldsymbol{\epsilon}_t$$

where $\mathbf{y}_t = (y_{1,t},\ y_{2,t},\ y_{3,t})$ denotes the response series, and $\boldsymbol{\mu}_t$, $\boldsymbol{\psi}_t$, and $\boldsymbol{\epsilon}_t$ denote the trivariate components, trend, cycle, and white noise, respectively. The three components of $\boldsymbol{\epsilon}_t$, the observation noise in the model, are not assumed to be independent. Therefore, you cannot specify them by using three IRREGULAR statements; you must include them in the state specification. The following (incomplete) statements show how to specify this model:

```
state whiteNoise(3)  type=wn ...;
component wn1 =  whiteNoise[1];
component wn2 =  whiteNoise[2];
component wn3 =  whiteNoise[3];

state randomWalk(3)  type=rw ...;
component rw1 =  randomWalk[1];
component rw2 =  randomWalk[2];
component rw3 =  randomWalk[3];

state cycleState(3)  type=cycle ...;
component c1 = cycleState[1];
component c2 = cycleState[2];
component c3 = cycleState[3];
```

```
model y1 = rw1 c1 wn1;
model y2 = rw2 c2 wn2;
model y3 = rw3 c3 wn3;
```

The first STATE statement defines whiteNoise, a state subsection that is needed for defining a three-dimensional white noise component. In turn, whiteNoise is used to define the three univariate white noise components: wn1, wn2, and wn3. The components wn1, wn2, and wn3 are correlated—their correlation structure is controlled by the covariance specification of whiteNoise. The second set of STATE and COMPONENT statements result in three correlated random walk trend components: rw1, rw2, and rw3. Finally, the last set of STATE and COMPONENT statements result in three correlated cycle components: c1, c2, and c3. In the end, the desired multivariate model is defined by including these (univariate) components in the appropriate MODEL statements.

In the preceding example, it is important to note the relationship between the nominal dimension (denoted by *dim* throughout this section) that is specified in the STATE statement and the actual dimension of the resulting state subsection. Note that the three state subsections, whiteNoise, randomWalk, and cycleState, are defined by using the same *dim* specification: 3. However, the actual dimensions of these state subsections depend on their type; they do not need to equal this specified dimension. Here, whiteNoise and randomWalk do have the same size, 3, as the specified *dim*. However, the size of cycleState, which is of TYPE=CYCLE, is $2 * dim = 6$. Another important point to note: no matter what the underlying size of the state subsection, the desired univariate components were obtained by using an identical specification scheme in the COMPONENT statement. This happens because the component specification style that is based on the element operator—[]—in the COMPONENT statement behaves differently when the TYPE= option is used to define the state subsection (for an illustration, see the section "Multivariate Season" on page 2453).

The system matrices for all these models are time-invariant, with the exception of the continuous-time cycle model. In this section, $\boldsymbol{\alpha}_t$ denotes the subsection of the overall model state $\boldsymbol{\alpha}_t$, and $\mathbf{T}$, $\mathbf{Q}$, and $\mathbf{A}_1$ denote the corresponding blocks of the larger system matrices.

For the multivariate cycle system matrices described in the section "Multivariate Cycle" on page 2452, the Kronecker product notation is useful: if $\mathbf{A}$ is an $m \times n$ matrix and $\mathbf{B}$ is a $p \times q$ matrix, then the Kronecker product $\mathbf{A} \bigotimes \mathbf{B}$ is an $mp \times nq$ block matrix:

$$\mathbf{A} \bigotimes \mathbf{B} = \begin{bmatrix} a_{11}B & \cdots & a_{1n}B \\ \vdots & \ddots & \vdots \\ a_{m1}B & \cdots & a_{mn}B \end{bmatrix}$$

Multivariate White Noise

The STATE statement option TYPE=WN specifies white noise of dimension *dim*—that is, a sequence of zero mean, independent, Gaussian vectors with covariance $\boldsymbol{\Sigma}$. The specification of the associated system matrices is trivial: $\mathbf{T}$ is zero, $\mathbf{Q} = \boldsymbol{\Sigma}$, and the initial condition is nondiffuse ($\mathbf{Q}_1 = \boldsymbol{\Sigma}$ and $\mathbf{A}_1 = 0$).

Multivariate white noise is needed to specify the observation equation noise term for the multivariate models for the time series data. Since the state space formulation for the SSM procedure requires the observation equation noise vector to have the diagonal form, you need to include the noise vector in the state. The noise term for the *i*th response variable is defined by a component that simply picks the *i*th element of this multivariate white noise. For example, the component wn_i defined as follows can be used as a noise term in the MODEL statement of the *i*th response variable:

```
state white(dim) type=wn ...;
component wn_3 = white[3];
```

Multivariate Random Walk Trend

The STATE statement option TYPE=RW specifies a *dim*-dimensional random walk

$$\boldsymbol{\alpha}_{t+1} = \boldsymbol{\alpha}_t + \boldsymbol{\eta}_{t+1}$$

where $\boldsymbol{\eta}_t$ is a sequence of zero mean, independent, Gaussian vectors with covariance $\boldsymbol{\Sigma}$. The specification of the associated system matrices is trivial: $\mathbf{T}$ is a *dim*-dimensional identity matrix, $\mathbf{I}_{dim}$, $\mathbf{Q} = \boldsymbol{\Sigma}$, and the initial condition is fully diffuse ($\mathbf{Q}_1 = 0$ and $\mathbf{A}_1 = \mathbf{I}_{dim}$).

The multivariate random walk is a useful trend model for multivariate time series data. The trend term for the *i*th response variable is defined by a component that simply picks the *i*th ($1 \leq i \leq dim$) element of $\boldsymbol{\alpha}_t$. For example, the component rw_i defined as follows can be used as a trend term in the MODEL statement of the *i*th response variable:

```
state randomWalk(3) type=rw ...;
component rw_2 = randomWalk[2];
```

Multivariate Local Linear Trend

The STATE statement option TYPE=LL specifies a *(2*dim)*-dimensional $\boldsymbol{\alpha}_t$, needed for defining a *dim*-dimensional local linear trend. The first *dim* elements of $\boldsymbol{\alpha}_t$ correspond to the needed multivariate trend, and the subsequent *dim* elements are needed to capture the slope vector of this trend. $\boldsymbol{\alpha}_t$ can be defined as

$$\boldsymbol{\alpha}_{t+1} = \mathbf{T}\boldsymbol{\alpha}_t + \boldsymbol{\eta}_{t+1}$$

where $\boldsymbol{\eta}_t$ is a sequence of zero mean, independent, Gaussian vectors with covariance $\mathrm{Diag}(\boldsymbol{\Sigma},\ \boldsymbol{\Sigma}_{\mathrm{slope}})$ and $\mathbf{T}$ is a 2**dim*-dimensional block matrix $\mathbf{T} = (\mathbf{I}_{dim}\ \mathbf{I}_{dim},\ \mathbf{0}\ \mathbf{I}_{dim})$. The initial condition is fully diffuse ($\mathbf{Q}_1 = 0$ and $\mathbf{A}_1 = \mathbf{I}_{2*dim}$). This is a multivariate generalization of the univariate local linear trend.

The multivariate local linear trend is a useful trend model for multivariate time series data. The trend term for the *i*th response variable is defined by a component that simply picks the *i*th element ($1 \leq i \leq dim$) of $\boldsymbol{\alpha}_t$. For example, the component ll_i defined as follows can be used as a trend term in the MODEL statement of the *i*th response variable:

```
state localLin(dim) type=ll(slopecov..) ...;
component ll_3 = localLin[3];
```

Multivariate Cycle

The STATE statement option TYPE=CYCLE specifies a *(2*dim)*-dimensional $\boldsymbol{\alpha}_t$, needed for defining a *dim*-dimensional cycle. As in the LL case, the first *dim* elements of $\boldsymbol{\alpha}_t$ correspond to the needed *dim*-dimensional cycle, and the remaining *dim* elements contain some auxiliary quantities. The cycle model defined in this subsection requires a regular data type—that is, the CT option is not included. Let ρ denote the damping factor, and let $\lambda = 2\pi/\mathit{period}$ be the frequency associated with the cycle. The admissible parameter ranges are $0 < \rho \leq 1$ and $\mathit{period} > 2$, which implies that $0 < \lambda < \pi$. Let $\mathbf{C} = \rho(\cos(\lambda)\ \sin(\lambda),\ -\sin(\lambda)\ \cos(\lambda))$, a 2×2 matrix, and let $\mathbf{T} = \mathbf{C} \bigotimes \mathbf{I}_{dim}$, a $2 * dim \times 2 * dim$ matrix. With this notation, the transition equation associated with $\boldsymbol{\alpha}_t$ is

$$\boldsymbol{\alpha}_{t+1} = \mathbf{T}\boldsymbol{\alpha}_t + \boldsymbol{\eta}_{t+1}$$

where $\boldsymbol{\eta}_t$ is a sequence of zero mean, independent, $(2 * dim)$-dimensional Gaussian vectors with covariance $\mathrm{Diag}(\boldsymbol{\Sigma},\ \boldsymbol{\Sigma})$. If $\rho = 1$, the initial condition is fully diffuse ($\mathbf{Q}_1 = 0$ and $\mathbf{A}_1 = \mathbf{I}_{2*dim}$). Otherwise, it is nondiffuse: $\mathbf{Q}_1 = \frac{1}{(1-\rho^2)}\mathrm{Diag}(\boldsymbol{\Sigma},\ \boldsymbol{\Sigma})$ and $\mathbf{A}_1 = 0$.

The multivariate cycle is useful for capturing periodic behavior for multivariate time series data. The cycle term for the *i*th response variable is defined by a component that simply picks the *i*th element of $\boldsymbol{\alpha}_t$. For example, the component cycle_i defined as follows can be used as a cycle term in the MODEL statement of the *i*th response variable:

```
state cycleState(dim) type=cycle  ...;
component cycle_2 = cycleState[2];
```

Multivariate Season

The STATE statement option TYPE=SEASON(LENGTH=*s*) specifies a *((s–1)*dim)*-dimensional $\boldsymbol{\alpha}_t$, needed for defining a *dim*-dimensional trigonometric season component with season length *s*. A (multivariate) trigonometric season component, $\boldsymbol{\zeta}$, is a sum of (multivariate) cycles of different frequencies,

$$\boldsymbol{\zeta} = \sum_{j=1}^{[s/2]} \boldsymbol{\zeta}_j$$

where the constituent cycles $\boldsymbol{\zeta}_j$, called harmonics, have frequencies $\lambda_j = 2\pi j/s$. All the harmonics are assumed to be statistically independent, have the same damping factor $\rho = 1$, and are governed by the disturbances with the same covariance matrix $\boldsymbol{\Sigma}$. The number of harmonics, $[s/2]$, equals $s/2$ if s is even and $(s-1)/2$ if it is odd. This means that specifying TYPE=SEASON(LENGTH=*s*) is equivalent to specifying $[s/2]$ cycle specifications with correct frequencies, damping factor $\rho = 1$, and the COV option restricted to the same covariance $\boldsymbol{\Sigma}$. The resulting $\boldsymbol{\alpha}_t$ is necessarily *((s–1)*dim)*-dimensional. When the season length *s* is even, the last harmonic cycle, $\boldsymbol{\zeta}_{s/2}$, has frequency π and requires special attention. It is of dimension *dim* rather than *2*dim* because its underlying state equation simplifies to a *dim*-variate autoregression with autoregression coefficient $-\mathbf{I}_{dim}$. As a result of this discussion, it is clear that the system matrices $\mathbf{T}$ and $\mathbf{Q}$ associated with the *((s–1)*dim)*-dimensional $\boldsymbol{\alpha}_t$ are block-diagonal with the blocks corresponding to the harmonics. The initial condition is fully diffuse.

For all the models discussed so far, the first *dim* elements of $\boldsymbol{\alpha}_t$ provided the needed (multivariate) component. This is not the case for the (multivariate) season component. Extracting the *i*th seasonal component from $\boldsymbol{\alpha}_t$ requires accumulating the contributions from the $[s/2]$ harmonics that are associated with this *i*th seasonal, which are not organized contiguously in $\boldsymbol{\alpha}_t$. For example, suppose that *dim* is 2 and the season length *s* is 4. In this case $[s/2]$ is 2, and the bivariate seasonal component is a sum of two independent bivariate cycles, $\boldsymbol{\zeta}_1$ and $\boldsymbol{\zeta}_2$. The cycle $\boldsymbol{\zeta}_1$ has frequency $\pi/2$ and its underlying state, say $\boldsymbol{\alpha}_t^a$, has dimension $2 * dim = 4$. The last harmonic, $\boldsymbol{\zeta}_2$, has frequency π, and therefore its underlying state, say $\boldsymbol{\alpha}_t^b$, has dimension 2. The combined state $\boldsymbol{\alpha}_t = (\boldsymbol{\alpha}_t^a, \boldsymbol{\alpha}_t^b)$ has dimension $6 = 4 + 2$. In order to extract the first bivariate seasonal component, you must extract the first components of bivariate cycles $\boldsymbol{\zeta}_1$ and $\boldsymbol{\zeta}_2$, which in turn implies the first elements of $\boldsymbol{\alpha}_t^a$ and $\boldsymbol{\alpha}_t^b$, respectively. Thus, obtaining the first bivariate seasonal component requires extracting the first and the fifth elements of the combined state $\boldsymbol{\alpha}_t$. Similarly, obtaining the second bivariate seasonal component requires extracting the second and the sixth elements of the combined state $\boldsymbol{\alpha}_t$. All this can be summarized by the dot product expressions

$$\begin{aligned} s_{1t} &= (1\,0\,0\,0\,1\,0)\,\boldsymbol{\alpha}_t \\ s_{2t} &= (0\,1\,0\,0\,0\,1)\,\boldsymbol{\alpha}_t \end{aligned}$$

where s_{1t} and s_{2t} denote the first and second components, respectively, of the bivariate seasonal component. Note that s_{1t} and s_{2t} are univariate seasonal components, each of season length 4, in their own right. They are correlated components; their correlation structure depends on $\mathbf{\Sigma}$.

Obtaining the desired components of the multivariate seasonal component is made easy by a special syntax convention of the COMPONENT statement. Continuing with the previous example, the following examples illustrate two equivalent ways of obtaining s_{1t} and s_{2t}. The first set of statements explicitly specify the linear combinations needed for defining s_{1t} and s_{2t}:

```
state seasonState(2) type=season(length=4)  ...;
component s_1 =( 1  0  0  0  1  0 ) * seasonState;
component s_2 =( 0  1  0  0  0  1 ) * seasonState;
```

The following simpler specification achieves the same result:

```
state seasonState(2) type=season(length=4)  ...;
component s_1 = seasonState[1];
component s_2 = seasonState[2];
```

In the latter specification, the meaning of the element operator [] changes if the state in question is defined by using the TYPE= option.

Multivariate ARMA

You can specify a state vector that follows a multivariate autoregressive, moving average (VARMA) model by using the STATE statement option TYPE=VARMA. The autoregressive and moving average orders can be either 0 or 1 ($0 \leq p \leq 1$ and $0 \leq q \leq 1$)—that is, only VAR(1), MA(1), and VARMA(1,1) models can be specified. The notation and the state space form of the VARMA model described here is taken from Reinsel (1997), which is a good reference for VARMA modeling.

A *dim*-dimensional vector process $\boldsymbol{\zeta}_t$ follows a zero-mean, autoregressive order p, moving average order q (VARMA(p, q)) model if it satisfies the following matrix difference equation:

$$\boldsymbol{\zeta}_t = \sum_{i=1}^{p} \mathbf{\Phi}_i \boldsymbol{\zeta}_{t-i} + \boldsymbol{\epsilon}_t - \sum_{j=1}^{q} \mathbf{\Theta}_j \boldsymbol{\epsilon}_{t-j}$$

Here $\mathbf{\Phi}_i$ and $\mathbf{\Theta}_j$ are *dim*-dimensional square matrices and $\boldsymbol{\epsilon}_t$ is a *dim*-dimensional, Gaussian, white noise sequence with covariance matrix $\mathbf{\Sigma}$. If autoregressive order p is 0, the term that involves $\mathbf{\Phi}_i$ is absent; similarly, if the moving average order q is 0, the term that involves $\mathbf{\Theta}_j$ is absent. Since AR and MA orders can be at most 1, the subscripts of $\mathbf{\Phi}_i$ and $\mathbf{\Theta}_j$ can be ignored in this discussion—when applicable, an AR coefficient matrix is denoted by $\mathbf{\Phi}$ and an MA coefficient matrix is denoted by $\mathbf{\Theta}$. The unknown elements of $\mathbf{\Phi}$, $\mathbf{\Theta}$, and $\mathbf{\Sigma}$ constitute the parameter vector that is associated with a VARMA state. The process $\boldsymbol{\zeta}_t$ defined by the VARMA difference equation is stationary and invertible (Reinsel 1997) if and only if the eigenvalues of $\mathbf{\Phi}$ and $\mathbf{\Theta}$ are strictly less than 1 in magnitude. By default, the SSM procedure imposes these stationarity and invertibility restrictions on $\mathbf{\Phi}$ and $\mathbf{\Theta}$. However, you can specify $\mathbf{\Phi}$ to be an identity matrix, in which case the resulting process is nonstationary.

A VARMA model can be cast into a state space form. The state space form used by the SSM procedure is described in Reinsel (1997, pp. 52–53). The system matrices for the supported VARMA models are as follows:

- The VAR(1) form is the simplest. In this case, the underlying state $\boldsymbol{\alpha}_t$ is the same as the VAR(1) process $\boldsymbol{\zeta}_t$. Therefore, $\mathbf{T} = \mathbf{\Phi}$ and $\mathbf{Q_t} = \mathbf{\Sigma}$.

- Taking $\mathbf{\Phi}$ equal to the zero matrix if $p = 0$, the VARMA(1,1) and MA(1) cases can be treated together. In this case, the underlying state $\boldsymbol{\alpha}_t$ is *2*dim* dimensional and the desired VARMA process $\boldsymbol{\zeta}_t$ corresponds to its first *dim* elements. Let $\mathbf{\Psi} = \mathbf{\Phi} - \mathbf{\Theta}$. Then, in the blocked form,

$$\mathbf{T} = \begin{bmatrix} \mathbf{0} & \mathbf{I}_{dim} \\ \mathbf{0} & \mathbf{\Phi} \end{bmatrix} \quad \text{and} \quad \mathbf{Q}_t = \mathbf{Q} = \begin{bmatrix} \mathbf{\Sigma} & \mathbf{\Sigma\Psi}' \\ \mathbf{\Psi\Sigma} & \mathbf{\Psi\Sigma\Psi}' \end{bmatrix}$$

Unless $\mathbf{\Phi}$ is restricted to be identity, the underlying state $\boldsymbol{\alpha}_t$ is stationary and the covariance of the initial condition is computed by

$$vec(\mathbf{Q}_1) = (\mathbf{I} - \mathbf{T} \bigotimes \mathbf{T})^{-1} vec(\mathbf{Q})$$

where $\bigotimes$ denotes the Kronecker product and the vec operation on a matrix creates a vector formed by vertically stacking the rows of that matrix. If $\mathbf{\Phi}$ is restricted to be identity, the initial condition is fully diffuse.

Continuous-Time Cycle

The STATE statement option TYPE=CYCLE(CT) specifies a two-dimensional $\boldsymbol{\alpha}_t$, needed for defining a univariate continuous time cycle. In this case the nominal dimension, *dim*, must be 1. In particular, $\mathbf{\Sigma}$ becomes one-dimensional, which is denoted by σ^2. This cycle can be used for any data type. As before, the parameters of the cycle are a damping factor ρ, $0 < \rho \leq 1$, and *period* > 0. Unlike in the discrete-time cycle described in the section "Multivariate Cycle" on page 2452, the *period* is not required to be larger than 2. Let $\lambda = 2\pi/$*period*, and let $h_t = (\tau_{t+1} - \tau_t)$ denote the difference between successive time points. In this case, the system matrices $\mathbf{T}$ and $\mathbf{Q}$ that govern $\boldsymbol{\alpha}_t$ depend on h_t. They are as follows:

$$\begin{aligned} \mathbf{T} &= \rho^h \left(\cos(\lambda h)\ \sin(\lambda h),\ -\sin(\lambda h)\ \cos(\lambda h)\right) \\ \mathbf{Q} &= \frac{\sigma^2(1-\rho^{2h})}{-2\ln(\rho)} * \mathbf{I}_2 \qquad \text{if } \rho < 1 \\ \mathbf{Q} &= \sigma^2 h \mathbf{I}_2 \qquad \text{if } \rho = 1 \end{aligned}$$

If $\rho < 1$, the initial condition is nondiffuse: $\mathbf{Q}_1 = \frac{\sigma^2}{-2\ln(\rho)}\mathbf{I}_2$. For $\rho = 1$, the initial condition is fully diffuse.

The first element of $\boldsymbol{\alpha}_t$ corresponds to the needed cycle, and the second element is an auxiliary quantity. You can define a cycle term based on this state as follows:

```
state cycleState(1) type=cycle(CT)  ...;
component cycle = cycleState[1];
```

The CT option must be included in the use of TYPE=CYCLE.

Models with Dependent Lags

Many useful time series models relate the present value of a response variable to its own lagged values and, in the multivariate case, the lagged values of other response variables in the model. In the SSM procedure, you can use the DEPLAG statement to specify the terms in the model that involve lagged response variables. These models apply only to the regular data type. This section describes the state space form of such models; for more information, see Harvey (1989, sec. 7.1.1). As an illustration, consider the following model, where the q-dimensional coefficient matrices $\mathbf{\Phi}_1$ and $\mathbf{\Phi}_2$ are either fully or partially known:

$$\begin{aligned} \mathbf{Y}_t &= \mathbf{\Phi}_1 \mathbf{Y}_{t-1} + \mathbf{\Phi}_2 \mathbf{Y}_{t-2} + \mathbf{Z}_t \boldsymbol{\alpha}_t + \mathbf{X}_t \boldsymbol{\beta} + \boldsymbol{\epsilon}_t \\ \boldsymbol{\alpha}_{t+1} &= \mathbf{T}_t \boldsymbol{\alpha}_t + \mathbf{W}_{t+1} \boldsymbol{\gamma} + \mathbf{c}_{t+1} + \boldsymbol{\eta}_{t+1} \\ \boldsymbol{\alpha}_1 &= \mathbf{c}_1 + \mathbf{A}_1 \boldsymbol{\delta} + \boldsymbol{\eta}_1 \end{aligned}$$

Except for the presence of the terms that involve lagged response vectors ($\mathbf{\Phi}_1 \mathbf{Y}_{t-1}$ and $\mathbf{\Phi}_2 \mathbf{Y}_{t-2}$) in the observation equation, the form of this model is the same as the standard state space form that is described in the section "State Space Model and Notation" on page 2430. It turns out that this model can be expressed in the standard state space form by suitably enlarging the latent vectors in the state equation and by appropriately reorganizing the system matrices. The enlarged latent vectors and the corresponding system matrices are distinguished by the presence of dagger (†) as a superscript in the following reformulated model,

$$\begin{aligned} \mathbf{Y}_t &= \mathbf{Z}_t^{\dagger} \boldsymbol{\alpha}_t^{\dagger} \\ \boldsymbol{\alpha}_{t+1}^{\dagger} &= \mathbf{T}_t^{\dagger} \boldsymbol{\alpha}_t^{\dagger} + \mathbf{W}_{t+1}^{\dagger} \boldsymbol{\gamma}^{\dagger} + \mathbf{c}_{t+1}^{\dagger} + \boldsymbol{\eta}_{t+1}^{\dagger} \\ \boldsymbol{\alpha}_1^{\dagger} &= \mathbf{c}_1^{\dagger} + \mathbf{A}_1^{\dagger} \boldsymbol{\delta}^{\dagger} + \boldsymbol{\eta}_1^{\dagger} \end{aligned}$$

where the following conditions are true (column vectors are displayed horizontally to save space):

- The enlarged state vector ($\boldsymbol{\alpha}_t^{\dagger}$) is formed by vertically stacking the old state vector ($\boldsymbol{\alpha}_t$), the observation disturbance vector ($\boldsymbol{\epsilon}_t$), and the present and lagged response vectors ($\mathbf{Y}_t$ and $\mathbf{Y}_{t-1}$, respectively). That is, $\boldsymbol{\alpha}_t^{\dagger} = [\boldsymbol{\alpha}_t \;\; \boldsymbol{\epsilon}_t \;\; \mathbf{Y}_t \;\; \mathbf{Y}_{t-1}]$. Because $\boldsymbol{\alpha}_t$ is m-dimensional and $\boldsymbol{\epsilon}_t$, $\mathbf{Y}_t$, and $\mathbf{Y}_{t-1}$ are q-dimensional, the dimension of $\boldsymbol{\alpha}_t^{\dagger}$ is $m^{\dagger} = (m + 3 * q)$.
- The new state regression vector ($\boldsymbol{\gamma}^{\dagger}$) is formed by vertically stacking the old state regression vector ($\boldsymbol{\gamma}$) and the observation equation regression vector ($\boldsymbol{\beta}$). That is, $\boldsymbol{\gamma}^{\dagger} = [\boldsymbol{\gamma} \;\; \boldsymbol{\beta}]$.
- The enlarged disturbance vector ($\boldsymbol{\eta}_t^{\dagger}$) is formed by vertically stacking the old state disturbance vector ($\boldsymbol{\eta}_t$), the observation disturbance vector ($\boldsymbol{\epsilon}_t$), the vector sum ($\mathbf{Z}_t \boldsymbol{\eta}_t + \boldsymbol{\epsilon}_t$), and filling the rest of the vector with zeros. That is, $\boldsymbol{\eta}_t^{\dagger} = [\boldsymbol{\eta}_t \;\; \boldsymbol{\epsilon}_t \;\; (\mathbf{Z}_t \boldsymbol{\eta}_t + \boldsymbol{\epsilon}_t) \;\; \mathbf{0}]$.
- The deterministic vector $\mathbf{c}_{t+1}^{\dagger} = [\mathbf{c}_{t+1} \;\; \mathbf{0} \;\; \mathbf{Z}_{t+1} \mathbf{c}_{t+1} \;\; \mathbf{0}]$.
- The last $2q$ elements of the initial state vector ($\boldsymbol{\alpha}_1^{\dagger}$), which correspond to $\mathbf{Y}_1$, and $\mathbf{Y}_0$, are taken to be diffuse (which means that the diffuse vector $\boldsymbol{\delta}^{\dagger}$ has $2q$ additional elements compared to $\boldsymbol{\delta}$).

The new system matrices can be described in blockwise form in terms of the old system matrices as follows:

- The $q \times (m + 3 * q)$-dimensional $\mathbf{Z}_t^{\dagger} = [\mathbf{0}\ \mathbf{0}\ \mathbf{I}\ \mathbf{0}]$, where $\mathbf{0}$ is either a $q \times m$-dimensional or $q \times q$-dimensional matrix of zeros and $\mathbf{I}$ is a q-dimensional identity matrix.
- The $m^{\dagger} \times m^{\dagger}$ matrices $\mathbf{T}_t^{\dagger}$ (transition matrix) and $\mathbf{Q}_t^{\dagger}$ (covariance of $\boldsymbol{\eta}_{t+1}^{\dagger}$) are

$$\mathbf{T}_t^{\dagger} = \begin{bmatrix} \mathbf{T}_t & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{Z}_{t+1}\mathbf{T}_t & \mathbf{0} & \boldsymbol{\Phi}_1 & \boldsymbol{\Phi}_2 \\ \mathbf{0} & \mathbf{0} & \mathbf{I} & \mathbf{0} \end{bmatrix} \quad \text{and} \quad \mathbf{Q}_t^{\dagger} = \begin{bmatrix} \mathbf{Q}_t & \mathbf{0} & \mathbf{Q}_t\mathbf{Z}_{t+1}^{'} & \mathbf{0} \\ \mathbf{0} & \boldsymbol{\Sigma}_{t+1} & \boldsymbol{\Sigma}_{t+1} & \mathbf{0} \\ \mathbf{Z}_{t+1}\mathbf{Q}_t & \boldsymbol{\Sigma}_{t+1} & (\mathbf{Z}_{t+1}\mathbf{Q}_t\mathbf{Z}_{t+1}^{'} + \boldsymbol{\Sigma}_{t+1}) & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{0} \end{bmatrix}$$

  where $\boldsymbol{\Sigma}_t$ denotes the covariance matrix (which is diagonal by design) of the observation error vector $\boldsymbol{\epsilon}_t$. Recall that the system matrices in the transition equation can depend on both t and $t + 1$ even if the subscripts of $\mathbf{T}$ and $\mathbf{Q}$ show dependence on t alone.
- The $m^{\dagger} \times (k + g)$ matrix $\mathbf{W}_t^{\dagger}$ is

$$\mathbf{W}_{t+1}^{\dagger} = \begin{bmatrix} \mathbf{W}_{t+1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \\ \mathbf{Z}_{t+1}\mathbf{W}_{t+1} & \mathbf{X}_{t+1} \\ \mathbf{0} & \mathbf{0} \end{bmatrix}$$

This state space form can be easily extended to account for higher-order lags.

Models that contain dependent lag terms must be used with care. Because the SSM procedure does not impose any special constraints on the lag coefficients (the elements of coefficient matrices $\boldsymbol{\Phi}_1, \boldsymbol{\Phi}_2$, and so on), the resulting models can often be explosive. For an example of a model with lagged response variables, see Example 33.13.

PROC SSM and PROC UCM (see Chapter 41, "The UCM Procedure") handle models that contain dependent lags in essentially the same way. However, there is one difference: if the model parameter vector contains unknown lag parameters, PROC UCM parameters are estimated by optimizing the nondiffuse part of the likelihood, whereas PROC SSM continues to use the full diffuse likelihood for parameter estimation.

Temporal Aggregation and Temporal Distribution

The response variables in time series analysis are often classified as either stock variables or flow variables. Stock variables, such as interest rates or temperatures, are measured at a particular point in time. Flow variables, such as monthly income or weekly sales, are defined with respect to an interval of time. Flow variables have the property that they remain meaningful under the operations of temporal aggregation and temporal distribution—for example, aggregation of daily sales to weekly sales and distribution (or disaggregation) of weekly sales to daily sales are quite natural, whereas the same cannot be said of temperature readings. This section explains how you can use the SSM procedure to do model-based temporal aggregation and distribution of flow variables. State space models are often used to carry out model-based temporal aggregation and distribution. Two properties of state space models make them particularly suitable for this purpose:

- If a variable is modeled by a state space model at a particular time interval, its aggregated form—for example, daily to monthly—also follows a state space model. Moreover, the state space forms of these two models have a simple relationship.

- State space models can easily handle missing response values.

The discussion in this section, which is based on Harvey (1989, chap. 6, sec. 3), is limited to regular data types—that is, the data must be either univariate or multivariate time series.

Temporal Distribution

For the sake of simplicity, consider a simple case of distributing weekly observations of a flow variable, y, at a daily interval. Even though the values of y are observed weekly (suppose they are recorded each Sunday), in this case it is necessary to treat the observations $y_t, t \geq 1$, as a daily time series such that y_t equals the weekly total when t corresponds to the end of the week (Sunday), and y_t is missing on other days of the week. In addition, suppose that $y_t^\dagger$ denotes the unobserved time series of daily values of y. In other words, if t corresponds to a Sunday, then

$$y_t = \sum_{s=t-6}^{t} y_s^\dagger$$

Suppose that the unobserved daily series $y_t^\dagger$ can be modeled by a state space model. For example, suppose the model for $y_t^\dagger$ is

$$\begin{aligned} y_t^\dagger &= \mathbf{Z}_t \boldsymbol{\alpha}_t + \epsilon_t \\ \boldsymbol{\alpha}_{t+1} &= \mathbf{T}_t \boldsymbol{\alpha}_t + \boldsymbol{\eta}_{t+1} \end{aligned}$$

Then it is easy to see that the aggregated series y_t follows a state space model of the form

$$\begin{aligned} y_t &= \mathbf{Z}_t^\dagger \boldsymbol{\alpha}_t^\dagger \\ \boldsymbol{\alpha}_{t+1}^\dagger &= \mathbf{T}_t^\dagger \boldsymbol{\alpha}_t^\dagger + \boldsymbol{\eta}_{t+1}^\dagger \end{aligned}$$

where the following are true (both the row and column vectors are displayed horizontally to save space):

- The new state vector ($\boldsymbol{\alpha}_t^\dagger$) is formed by augmenting the old state vector ($\boldsymbol{\alpha}_t$) with a latent variable, y_t^f. That is, $\boldsymbol{\alpha}_t^\dagger = [\boldsymbol{\alpha}_t \; y_t^f]$. In fact, y_t^f represents the within-week running total of $y_t^\dagger$, so that when t corresponds to a Sunday, $y_t^f = y_t$.

- The new transition matrix $\mathbf{T}_t^\dagger$ is

$$\mathbf{T}_t^\dagger = \begin{bmatrix} \mathbf{T}_t & \mathbf{0} \\ \mathbf{Z}_{t+1}\mathbf{T}_t & \psi_{t+1} \end{bmatrix}$$

  where ψ_t is a dummy variable that equals 1 when t is not the start of the week (not Monday) and equals 0 when t is the start of the week (Monday).

- The new disturbance vector ($\boldsymbol{\eta}_t^\dagger$) is formed by augmenting the old disturbance vector ($\boldsymbol{\eta}_t$) by ($\mathbf{Z}_t\boldsymbol{\eta}_t + \epsilon_t$). That is, $\boldsymbol{\eta}_t^\dagger = [\boldsymbol{\eta}_t \;\; \mathbf{Z}_t\boldsymbol{\eta}_t + \epsilon_t]$.

- The new design matrix for the state effect ($\mathbf{Z}_t^\dagger$) is $\mathbf{Z}_t^\dagger = [\mathbf{0}\ 1]$, where $\mathbf{0}$ is a zero vector of the same size as the old state vector $\boldsymbol{\alpha}_t$.

This shows that you can do model-based distribution of y values by carrying out the following steps:

1 Organize the y values as a daily time series.

2 Define a dummy variable, startWeek, that flags the start of the week—that is, startWeek is 1 when the day is Monday and 0 otherwise. Note that $\psi_t = 1 - \text{startWeek}_t$.

3 Specify a suitable state space model for the unobserved daily series $y_t^\dagger$. This specification in turn implies a state space model specification for y.

4 Carry out the analysis—model fitting, component estimation, and forecasting—of y in the usual fashion by using this implied model specification.

5 The smoothed values of y from the previous step provide the estimates of y_t^f. In addition, the estimates of $y_t^\dagger$ can be obtained as the smoothed estimates of appropriate linear combination of the elements of $\boldsymbol{\alpha}_t$ and ϵ_t.

The SSM procedure enables you to carry out the key steps—Step 3 to Step 5—in this process quite easily. The usual model specification syntax that uses the STATE, COMPONENT, and TREND statements to define the terms in a MODEL statement is used to define a model for the unobserved daily series $y_t^\dagger$ (the first part of Step 3). Then, the use of the DISTRIBUTE(START=*startWeek*) option in the MODEL statement causes the SSM procedure to use the implied model to analyze the observed y values. As a brief illustration, suppose that a data set Test contains two variables: date, a SAS date variable that indexes the daily observations, and y, the values of the weekly variable arranged as a daily series. Then the following PROC SSM statements show you how to distribute y at the daily interval:

```
proc ssm data=test;
    id date interval=day;
    startWeek = (weekday(date) = 2); /* indicator of Monday */
    state ...;
    comp term1 = ...;
    ...;
    state noise(1) type=wn ...;
    comp wnoise = noise[1];
    model y = term1 term2 ... wnoise / distribute(start=startWeek);
    /* daily_Y = sum of all terms in the MODEL statement */
    eval daily_Y = term1 + term2 + ...+ wnoise;
    output out=...;
 run;
```

Here are a few comments about this program:

- The terms in the MODEL statement correspond to the observation equation for the unobserved daily series $y_t^\dagger$. However, the DISTRIBUTE(START=*startWeek*) option causes the SSM procedure to use the implied model (with the augmented state vector) to analyze y—the weekly variable arranged as a daily series.
- Because wnoise—the white noise term (ϵ_t) in the observation equation of $y_t^\dagger$—is subsequently to be used in an EVAL statement, this program specifies it by using the STATE statement rather than by using the IRREGULAR statement.
- Because daily_Y (the component specified in the EVAL statement) is the sum of all the terms in the MODEL statement, it corresponds to the unobserved daily series $y_t^\dagger$. Therefore, the smoothed estimate of daily_Y (smoothed_daily_Y) provides the needed distribution of y at the daily interval.

In this release of the SSM procedure, the last element of the augmented state vector, y^f, is always initialized with diffuse distribution. A more flexible specification of the initial distribution of y^f might become possible in a future release.

To keep the explanation simple, the preceding discussion was confined to a single response variable. In fact, you can use the SSM procedure for temporal distribution in more general settings—for example, you can consider temporal distribution of one or more flow variables in a multivariate model that includes one or more response variables of stock type, one or more response variables of flow type, and one or more explanatory variables. An illustration of such modeling is shown in Example 33.16. The modeling of a response variable as a temporal aggregate of some unobserved latent variable is also needed in a process known as benchmarking; see Durbin and Koopman (2012, chap. 3, sec. 10.2) and Pelagatti (2015, chap. 9, sec. 2). You can use the SSM procedure in such benchmarking situations as well.

NOTE: Model specification in the temporal distribution setting requires some care. The model for the lower-frequency observed series, y_t, is based on the model specified for the unobserved higher-frequency series $y_t^\dagger$. Because aggregation from higher frequency to lower frequency involves loss of information, an otherwise identifiable model for $y_t^\dagger$ can lead to unidentifiable model for y_t.

Temporal Aggregation

Temporal aggregation is the reverse of temporal distribution. In this case, the observations are available on a finer time scale, and you are interested in estimating the aggregated values on some coarser time scale—for example, estimating weekly totals from daily data. Of course, the aggregation is trivial in the historical region where the observations on the finer scale are known—in fact, in this case the estimation of the aggregate values is done with no estimation error. However, when the aggregate values are to be estimated in the region where the observations on the finer scale are missing—for example, in the forecast region—the problem becomes nontrivial. It is easier to explain the situation by using a simple example. Suppose $y_t, 1 \le t \le 100$, denote the daily observations of a response variable, y. Let $wy_t, t \ge 1$, denote the within-week daily running totals—that is, wy_t represents the total of y values up to the day t in the week that contains the day t. Clearly, given the daily values $y_t, 1 \le t \le 100$, the aggregate values $wy_t, 1 \le t \le 100$, are fully known. The question is, assuming that y follows a state space model, how do you estimate and obtain appropriate confidence intervals for wy_t in the forecast region ($t = 101, 102, \ldots$)? In this section you have already seen that when a variable is modeled by a state space model at a particular time interval, its aggregated form also follows a state space model. The AGGREGATE(START=) option in the MODEL statement of the SSM procedure enables you to perform temporal aggregation for a response variable. An illustration of such aggregation is shown in Example 33.17.

Covariance Parameterization

The covariance matrices specified by the COV and COV1 options in the STATE statement must be positive semidefinite. When these matrices are of general form and are not user-specified, they are internally parameterized by their Cholesky root. Suppose that Σ, an $m \times m$ positive semidefinite matrix of rank r, is such a covariance matrix. Then, Σ can always be written as

$$\Sigma = RR'$$

where the (generalized) Cholesky root, R, is an $m \times r$ lower triangular matrix with nonnegative diagonal elements (that is, $R[i,j] = 0$ if $j > i$ and $R[i,i] \ge 0,\ 1 \le i \le r$). The SSM procedure parameterizes Σ by the elements of its Cholesky root, which adds $r * (r+1)/2 + r * (m-r)$ elements to the parameter vector $\boldsymbol{\theta}$.

Missing Values

For a variety of reasons the data might contain missing response and predictor values. Before starting the analysis of a particular BY group, SSM procedure makes an internal copy of the data. The actual analysis is done by using this copy. The data in the copy are first examined for missing values in the response, predictor, and the ID variables. No missing values are permitted in the ID variable (if it is specified). If all the missing values are associated with only the response variables, then the internal copy of the data is not altered. However, if any of the predictors in the observation equation—the elements of $\mathbf{X}$ matrix—are found to contain missing values, the internal copy of the data is altered as follows: any missing predictor value is replaced by 0, and the response values that are dependent on that predictor in the corresponding row are set to missing. These missing response values are called the *induced missing values*. The reported analysis is based on the (possibly altered) internal copy of the BY group.

Missing values are not permitted in any of the other system matrices that define the state space model. In particular, missing values are not permitted in $\mathbf{Z}$, $\mathbf{T}$, $\mathbf{W}$, and $\mathbf{Q}$ matrices. In some cases the elements of these matrices depend on the data values. In such cases, care must be taken to ensure that these data values are not missing.

Computational Issues

A Well-Behaved Model

The model defined by the state space model equations (see the section "State Space Model and Notation" on page 2430) is very general. This generality is quite useful because it encompasses a wide variety of data generation processes. On the other hand, it also makes it easy to specify overly complex and numerically unstable models. If a suitable model is not already known and you are in the early phases of modeling, it is important to start with models that are relatively simple and well-behaved from the numerical standpoint. From the numerical and statistical considerations, two aspects of model formulation are particularly important: identifiability and numerical stability. A model is identifiable if the observed data has a distinct probability distribution for each admissible parameter vector. Unless proper care is taken, it is easy to specify an unidentifiable state space model. Similarly, predictions according to some types of state space models can display explosive growth or wild oscillations. This behavior is primarily governed by the transition matrix $\mathbf{T}$ (or $\mathbf{T}_t$ in the time-varying case). Unidentifiable models can run into difficulties during parameter estimation, and explosive growth (and wild oscillation) causes numerical problems associated with finite-precision arithmetic. Unfortunately, no simple identifiability check is available for a general state space model, and it is difficult to decide at the outset whether a specified model might suffer from numerical instability. For a discussion of identifiability issues, see Harvey (1989, chap. 4, sec. 4). For a discussion of the stability properties of time-invariant state space models, see Harvey (1989, chap. 3, sec. 3). The following guidelines are likely to result in models that are identifiable and numerically stable:

- Build models by composing submodels that are known to be well-behaved. The predefined models provided by the SSM procedure are good submodel candidates (see the sections "Predefined Trend Models" on page 2446 and "Predefined Structural Models" on page 2450).
- Pay careful attention to the way the variety of system matrices are defined. The behavior of their elements, as functions of model parameters and other variables, must be well-understood. If these

elements are defined by using DATA steps, you can validate their behavior by running these DATA steps outside of the SSM procedure. In particular, note the following:

- The transition matrix $\mathbf{T}$ (or $\mathbf{T}_t$ in the time-varying case) determines the explosiveness characteristics of the model; it must be well-behaved for all parameters.
- The disturbance covariances $\mathbf{Q}_t$ must be positive semidefinite for all parameters.
- If the system matrices in the state equation, such as the transition matrix $\mathbf{T}_t$ or the disturbance covariance $\mathbf{Q}_t$, are time-varying and the data contain replicate observations (observations with the same ID value), check that the elements of these matrices do not vary during replicate observations. This follows from the fact that the underlying state does not vary during replications (see the state equation in the section "State Space Model and Notation" on page 2430 and the section "Types of Sequence Data" on page 2433).

Convergence Problems

As explained in the section "Likelihood Computation and Model-Fitting Phase" on page 2439, the model parameters are estimated by nonlinear optimization of the likelihood. This process is not guaranteed to succeed. For some data sets, the optimization algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data. It is also possible for the algorithm to converge to a point that is not the global optimum of the likelihood.

If you experience convergence problems, consider the following:

- Data that are extremely large or extremely small can adversely affect results because of the internal tolerances used during the filtering steps of the likelihood calculation. Rescaling the data can improve stability.
- Whenever possible, parameterize the disturbance variances in the model on the exponential scale. For illustrations of parameterizing disturbance variances in this manner, see Example 33.12 and Example 33.14.
- Examine your model for redundancies in the included components and regressors. The components or regressors that are nearly collinear to each other can cause the optimization process to become unstable.
- Lack of convergence can indicate model misspecification such as unidentifiable model or a violation of the normality assumption.

Computer Resource Requirements

The computing resources required for the SSM procedure depend on several factors. The memory requirement for the procedure is largely dependent on the number of observations to be processed and the size of the state vector underlying the specified model. If n denotes the sample size and m denotes the size of the state vector, the memory requirement for the smoothing phase of the Kalman filter is of the order of $6 \times 8 \times n \times m^2$ bytes, ignoring the lower-order terms. If the smoothed component estimates are not needed, then the memory requirement is of the order of $6 \times 8 \times (m^2 + n)$ bytes. Besides m and n, the computing time for the parameter estimation depends on the size of the parameter vector $\boldsymbol{\theta}$ and how many likelihood evaluations are needed to reach the optimum.

Displayed Output

The default printed output produced by the SSM procedure contains the following information:

- brief information about the input data set, including the data set name and label
- summary statistics for the response variables in the model, including the names of the variables, the total number of observations and the number of missing observations, the smallest and largest measurements, and the mean and standard deviation
- information about the index variable, including the index value of the first and the last observation, the maximum difference between the successive index values, the number of distinct index values, and the categorization of the data into regular, regular with replication, or irregular types
- estimates of the regression parameters if the model contains any predictors, including their standard errors, t statistics, and p-values
- convergence status of the likelihood optimization process if any parameters are estimated
- estimates of the free parameters at the end of the model-fitting phase, including the parameter estimates and their approximate standard errors
- the likelihood-based goodness-of-fit statistics, including the full likelihood, the sum of squares of residuals normalized by their standard errors, and the information criteria: AIC, AICC, HQIC, BIC, and CAIC
- summary of most significant additive outliers

ODS Table Names

The SSM procedure assigns a name to each table it creates. You can use these names to refer to the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 33.9.

Table 33.9 ODS Tables Produced by PROC SSM

ODS Table Name	Description	Statement	Option
Tables That Summarize the Model Information			
ModelSummary	Summary information about the underlying state space model		Default
IdInformation	Summary information about the ID variable		Default
ResponseInfo	Summary information about the response variables		Default
StateSummary	Summary information about the model state vector	PROC SSM	STATEINFO

Table 33.9 *continued*

ODS Table Name	Description	Statement	Option
DiffuseStateSummary	Summary information about the diffuse initial state	PROC SSM	STATEINFO
Tables Related to Model Parameters and the Likelihood			
ConvergenceStatus	Convergence status of the estimation process		Default
RegressionEstimates	Estimates of the regression parameters	MODEL	Default
StateRegressionEstimates	Estimates of the state regression parameters	STATE	W
FixedStateEstimates	Estimates of time-invariant, non-stochastic state subsections		Default
NamedParameterEstimates	Estimates of the parameters specified in the PARMS statement	PARMS	Default
ParameterEstimates	Estimates of the unknown elements in the model system matrices		Default
DisturbanceCovariance	Estimate of the disturbance covariance	STATE	PRINT=COV
InitialCovariance	Estimate of the initial state covariance	STATE	PRINT=COV1
ARCoefficient	Estimate of the autoregressive coefficient matrix	STATE	PRINT=AR
MACoefficient	Estimate of the moving-average coefficient matrix	STATE	PRINT=MA
TransitionMatrix	Estimate of the state transition matrix	STATE	PRINT=T
FitSummary	Summary of the likelihood-based fit-statistics		Default
InformationCriteria	Likelihood-based information criteria		Default
Tables Related to Series and Component Forecasts			
Forecasts	Series forecasts	MODEL	PRINT=FILTER
SmoothedResponse	Smoothed series values	MODEL	PRINT=SMOOTH
FilteredComponent	Component forecasts	COMPONENT	PRINT=FILTER
SmoothedComponent	Smoothed component	COMPONENT	PRINT=SMOOTH
Tables Related to Outlier Detection and Model Quality			
AOSummary	Summary of additive outliers	Default	Default

Table 33.9 *continued*

PRESS	Prediction error sum of squares	OUTPUT	PRESS

ODS Graph Names

You can refer to every graph produced through ODS Graphics with a name. The names of the graphs that PROC SSM generates are listed in Table 33.10, along with the required statements and options.

Table 33.10 ODS Graphs Produced by PROC SSM

ODS Graph Name	Description	Statement	Option
Graphs for One-Step-Ahead Residual Analysis			
ResidualNormalityPlot	Normality check	PROC SSM	PLOTS=RESIDUAL(NORMAL)
ResidualHistogram	Residual histogram	PROC SSM	PLOTS(UNPACK)=RESIDUAL
ResidualQQPlot	Residual Q-Q plot	PROC SSM	PLOTS(UNPACK)=RESIDUAL
StdResidualPlot	Time series plot of standardized residuals	PROC SSM	Default
Graphs Related to Outlier Detection and Structural Break			
PredErrorNormalityPlot	Normality check	PROC SSM	PLOTS=AO(NORMAL)
PredErrorHistogram	Prediction error histogram	PROC SSM	PLOTS(UNPACK)=AO
PredErrorQQPlot	Prediction error Q-Q plot	PROC SSM	PLOTS(UNPACK)=AO
StdPredErrorPlot	Time series plot of standardized additive-outlier statistics	PROC SSM	PLOTS=AO(STD)
MaximalShockPlot	Time series plot of maximal state shock chi-square statistics	PROC SSM	PLOTS=MAXSHOCK

OUT= Data Set

You can use the OUT= option in the OUTPUT statement to store the series and component forecasts that are produced by PROC SSM. Which columns are included in the data set depends on the model specification. The model can have one or more response variables, a variety of components that appear in the MODEL statement, and components specified by the EVAL statement. The OUT= data set contains the one-step-ahead and full-sample estimates of the response variables, and all these components.

The following list describes the columns of the data set:

- the BY variables
- the ID variable, if specified by the ID statement
- Obs, a variable that contains the observation number
- the response series (more than one in the multivariate case)
- the following columns associated with the response series (the wildcard * is substituted by the name of one of the response variables):
  - FORECAST_* contains the one-step-ahead predicted values and the multistep forecasts of the response series.
  - RESIDUAL_* contains the difference between the actual and forecast values.
  - StdErr_* contains the standard error of prediction.
  - Lower_* and Upper_* contain the lower and upper forecast confidence limits.
  - Smoothed_* contains the smoothed values of the response variable.
  - StdErr_Smoothed_* contains standard errors of the smoothed values of the response variable.
  - AO_* contains the additive outlier estimate.
  - StdErr_AO_* contains the standard error of the additive outlier estimate.
- the following columns associated with the components (the wildcard * is substituted by the name of one of the components):
  - FORECAST_* contains the one-step-ahead predicted values and the multistep forecasts of the component.
  - StdErr_* contains the standard error of prediction.
  - Smoothed_* contains the smoothed values of the component.
  - StdErr_Smoothed_* contains standard errors of the smoothed values of the component.
  - Smoothed_Lower_* and Smoothed_Upper_* contain the lower and upper confidence limits of the smoothed component.
- the maximal state shock chi-square statistics at distinct time points (this column is present only if the MAXSHOCK option is used in the OUTPUT statement)

Confidence limits are not produced for the smoothed series values or for the component forecasts; they are produced for the smoothed components.

Examples: SSM Procedure

Example 33.1: Bivariate Basic Structural Model

This example illustrates how you can use the SSM procedure to analyze a bivariate time series. The following data set contains two variables, f_KSI and r_KSI, which are measured quarterly, starting the first quarter of 1969. The variable f_KSI represents the quarterly average of the log of the monthly totals of the front-seat passengers killed or seriously injured during the car accidents, and r_KSI represents a similar number for the rear-seat passengers. The data set has been extended at the end with eight missing values, which represent four quarters, to cause the SSM procedure to produce model forecasts for this span.

```
data seatBelt;
input f_KSI r_KSI @@;

run;
```

These data have been analyzed in Durbin and Koopman (2012, chap. 8, sec. 3). The analysis presented here is similar. To simplify the illustration, the monthly data have been converted to quarterly data and two predictors (the number of kilometers traveled and the real price of petrol) are excluded from the analysis. You can also use PROC SSM to carry out the more elaborate analysis in Durbin and Koopman (2012).

One of the original reasons for studying these data was to assess the effect on f_KSI of the enactment of a seat-belt law in February 1983 that compelled the front seat passengers to wear seat belts. A simple graphical inspection of the data (not shown here) reveals that f_KSI and r_KSI do not show a pronounced

upward or downward trend but do show seasonal variation, and that these two series seem to move together. Additional inspection also shows that the seasonal effect is relatively stable throughout the data span. These considerations suggest the following model for $\mathbf{y}$ = (f_KSI, r_KSI):

$$\mathbf{y}_t = \begin{pmatrix} X_t \\ 0 \end{pmatrix} \beta + \boldsymbol{\mu}_t + \boldsymbol{\zeta}_t + \boldsymbol{\xi}_t$$

All the terms on the right-hand side of this equation are assumed to be statistically independent. These terms are as follows:

- The predictor X_t (defined as Q1_83_Shift later in the program) denotes a variable that is 0 before the first quarter of 1983, and 1 thereafter. X_t is supposed to affect only f_KSI (the first element of $\mathbf{y}$); it represents the enactment of the seat-belt law of 1983.
- $\boldsymbol{\mu}_t$ denotes a bivariate random walk. It is supposed to capture the slowly changing level of the vector $\mathbf{y}_t$. To capture the fact that f_KSI and r_KSI move together (that is, they are co-integrated), the covariance of the disturbance term of this random walk is assumed to be of lower than full rank.
- $\boldsymbol{\zeta}_t$ denotes a bivariate trigonometric seasonal term. In this model, it is taken to be fixed (that is, the seasonal effects do not change over time).
- $\boldsymbol{\xi}_t$ denotes a bivariate white noise term, which captures the residual variation that is unexplained by the other terms in the model.

The preceding model is an example of a (bivariate) basic structural model (BSM). The following statements specify and fit this model to f_KSI and r_KSI:

```
proc ssm data=seatBelt stateinfo;
   id date interval=quarter;
   Q1_83_Shift = (date >= '1jan1983'd);
   state error(2) type=WN cov(g) print=cov;
   component wn1 = error[1];
   component wn2 = error[2];
   state level(2) type=RW cov(rank=1) print=cov;
   component rw1 = level[1];
   component rw2 = level[2];
   state season(2) type=season(length=4);
   component s1 = season[1];
   component s2 = season[2];
   model f_KSI = Q1_83_Shift rw1 s1  wn1 / print=(smooth);
   model r_KSI = rw2 s2 wn2;
   eval f_KSI_sa = rw1 + Q1_83_Shift;
   output out=For1;
run;
```

The PROC SSM statement specifies the input data set, seatBelt. The use of the STATEINFO option in the PROC SSM statement produces additional information about the model state vector and its diffuse initial state. The optional ID statement specifies an index variable, date. The INTERVAL=QUARTER option in the ID statement indicates that the measurements were collected on a quarterly basis. Next, a programming statement defines Q1_83_Shift, the predictor that represents the enactment of the seat-belt law of 1983. It is used later in the MODEL statement for f_KSI. Separate STATE statements specify the terms $\boldsymbol{\mu}_t$, $\boldsymbol{\zeta}_t$, and $\boldsymbol{\xi}_t$ because they are statistically independent. Each model that governs them (white noise for $\boldsymbol{\xi}_t$, random

walk for $\boldsymbol{\mu}_t$, and trigonometric seasonal for $\boldsymbol{\zeta}_t$) can be specified by using the TYPE= option of the STATE statement. When you use the TYPE= option, you can use the COV option to specify the information about the disturbance covariance in the state transition equation. The other details, such as the transition matrix specification and the specification of $\mathbf{A}_1$ in the initial condition, are inferred from the TYPE= option. The use of PRINT=COV in the STATE statement causes the estimated disturbance covariance to be printed. For $\boldsymbol{\xi}_t$ (a white noise), $\mathbf{A}_1$ is zero and $\mathbf{Q}_t = \mathbf{Q}$ for all $t \geq 1$, where $\mathbf{Q}$ is specified by the COV option. For $\boldsymbol{\mu}_t$ and $\boldsymbol{\zeta}_t$ the initial condition is fully diffuse—that is, $\mathbf{A}_1$ is an identity matrix of appropriate order and $\mathbf{Q}_1 = 0$. The total diffuse dimension of this model, $(d + k)$, is $9 = 8 + 1$ as a result of one predictor, Q1_83_Shift, and two fully diffuse state subsections, $\boldsymbol{\mu}_t$ and $\boldsymbol{\zeta}_t$. The components in the model are defined by suitable linear combinations of these different state subsections. The program statements define the model as follows:

- **`state error(2) type=WN cov(g);`** defines $\boldsymbol{\xi}_t$ as a two-dimensional white noise, named error, with the covariance of general form. Then two COMPONENT statements define wn1 and wn2 as the first and second elements of error, respectively.

- **`state level(2) type=RW cov(rank=1);`** defines $\boldsymbol{\mu}_t$ as a two-dimensional random walk, named level, with covariance of general form whose rank is restricted to 1. Then two COMPONENT statements define rw1 and rw2 as the first and second elements of level, respectively.

- **`state season(2) type=season(length=4);`** defines $\boldsymbol{\zeta}_t$ as a two-dimensional trigonometric seasonal of season length 4, named season, with zero covariance—signified by the absence of the COV option. Then two COMPONENT statements define s1 and s2 as appropriate linear combinations of season so that s1 represents the seasonal for f_KSI and s2 represents the seasonal for r_KSI. Because TYPE=SEASON in the STATE statement, the COMPONENT statement appropriately interprets **`component s1 = season[1];`** as s1 being a dot product: $(1\ 0\ 0\ 0\ 1\ 0) * \text{season}$. For more information, see the section "Multivariate Season" on page 2453.

- **`model f_KSI = Q1_83_Shift rw1 s1 wn1;`** defines the model for f_KSI, and **`model r_KSI = rw2 s2 wn2;`** defines the model for r_KSI.

The SSM procedure fits the model and reports the parameter estimates, their approximate standard errors, and the likelihood-based goodness-of-fit measures by default. In order to output the one-step-ahead and full-sample estimates of the components in the model, you can either use the PRINT= options in the MODEL statement and the respective COMPONENT statements or you can specify an output data set in the OUTPUT statement. In addition, you can use the EVAL statement to define specific linear combinations of the underlying state that should also be estimated. The statement **`eval f_KSI_sa = rw1 + Q1_83_Shift;`** is an example of one such linear combination. It defines f_KSI_sa, a linear combination that represents the seasonal adjustment of f_KSI. The output data set, For1 (named in the OUTPUT statement) contains estimates of all the model components in addition to the estimate of f_KSI_sa.

The model summary table, shown in Output 33.1.1, provides basic model information, such as the dimension of the underlying state equation ($m = 10$), the diffuse dimension of the model ($(d + k) = 9$), and the number of parameters (5) in the model parameter vector $\boldsymbol{\theta}$.

Output 33.1.1 Bivariate Basic Structural Model

The SSM Procedure

Model Summary	
Model Property	**Value**
Number of Model Equations	2
State Dimension	10
Dimension of the Diffuse Initial Condition	9
Number of Parameters	5

Additional details about the role of different components in forming the model state and its diffuse initial condition are shown in Output 33.1.2 and Output 33.1.3. They show that the 10-dimensional model state vector is made up of subsections that are associated with error and level (each of dimension 2) and season (of dimension 6). Similarly, the nine-dimensional diffuse vector in the initial condition is made up of subsections that correspond to level, season, and the regression variable, Q1_83_Shift. Note that error does not contribute to the diffuse initial vector because it has a fully nondiffuse initial state.

Output 33.1.2 Bivariate Basic Structural Model State Vector Summary

State Vector Composition	
Subsection	**Dimension**
error	2
level	2
season	6

Output 33.1.3 Bivariate Basic Structural Model Initial Diffuse State Vector Summary

Diffuse Initial State Composition (Including Regressors)	
Subsection	**Dimension**
level	2
season	6
Q1_83_Shift	1

The index variable information is shown in Output 33.1.4.

Output 33.1.4 Index Variable Information

ID Variable Information					
Name	**Start**	**End**	**Max Delta**	**NDistinct**	**Type**
date	1969:1	1985:4	1	68	Regular

Output 33.1.5 provides simple summary information about the response variables. It shows that f_KSI and r_KSI have four missing values each and no induced missing values because the predictor in the model, Q1_83_Shift, has no missing values.

Output 33.1.5 Response Variable Summary

Response Variable Information

Name	Number of Observations Total	Missing	Induced Missing	Minimum	Maximum	Mean	Std Deviation
f_KSI	68	4	0	6.16	7.09	6.71	0.206
r_KSI	68	4	0	5.56	6.41	5.97	0.186

The regression coefficient of Q1_83_Shift, shown in Output 33.1.6, is negative and is statistically significant. This is consistent with the expected drop in f_KSI after the enactment of the seat-belt law.

Output 33.1.6 Regression Coefficient of Q1_83_Shift

Regression Parameter Estimates

Response Variable	Regression Variable	Estimate	Standard Error	t Value	Pr > |t|
f_KSI	Q1_83_Shift	-0.408	0.0259	-15.74	<.0001

Output 33.1.7 shows the estimates of the elements of $\boldsymbol{\theta}$. The five parameters in $\boldsymbol{\theta}$ correspond to unknown elements that are associated with the covariance matrices in the specifications of error and level. Whenever a covariance specification is of a general form and is not defined by a user-specified variable list, it is internally parameterized as a product of its Cholesky root: $\mathrm{Cov} = \mathrm{Root}\ \mathrm{Root}'$. This ensures that the resulting covariance is positive semidefinite. The Cholesky root is constrained to be lower triangular, with positive diagonal elements. If rank constraints (such as the rank-one constraint on the covariance in the specification of level) are imposed, the number of free parameters in the Cholesky factor is reduced appropriately. For more information, see the section "Covariance Parameterization" on page 2460. In view of these considerations, the five parameters in $\boldsymbol{\theta}$ are a result of three parameters from the Cholesky root of error and two parameters that are associated with the Cholesky root of level.

Output 33.1.7 Parameter Estimates

Model Parameter Estimates

Component	Type	Parameter	Estimate	Standard Error	t Value
error	Disturbance Covariance	RootCov[1, 1]	0.0361	0.00736	4.91
error	Disturbance Covariance	RootCov[2, 1]	0.0338	0.01131	2.99
error	Disturbance Covariance	RootCov[2, 2]	0.0462	0.00470	9.84
level	Disturbance Covariance	RootCov[1, 1]	0.0375	0.00843	4.45
level	Disturbance Covariance	RootCov[2, 1]	0.0223	0.00569	3.92

Output 33.1.8 shows the resulting covariance estimate of error after multiplying the Cholesky factors.

Output 33.1.8 White Noise Covariance Estimate

Disturbance Covariance for error	Col1	Col2
Row1	0.001307	0.001222
Row2	0.001222	0.003277

Similarly, Output 33.1.9 shows the covariance estimate of level disturbance. Note that because of the rank-one constraint, the determinant of this matrix is 0.

Output 33.1.9 Covariance Estimate of the Random Walk Disturbance

Disturbance Covariance for level		
	Col1	Col2
Row1	0.001408	0.000837
Row2	0.000837	0.000497

Output 33.1.10 shows the likelihood computation summary. This table is produced by using the fitted model to carry out the filtering operation on the data. For more information, see the section "Likelihood Computation and Model-Fitting Phase" on page 2439.

Output 33.1.10 Likelihood Computation Summary of the Fitted Model

Likelihood Computation Summary	
Statistic	Value
Nonmissing Response Values Used	128
Estimated Parameters	5
Initialized Diffuse State Elements	9
Normalized Residual Sum of Squares	119.00002
Diffuse Log Likelihood	166.15755
Profile Log Likelihood	199.91165

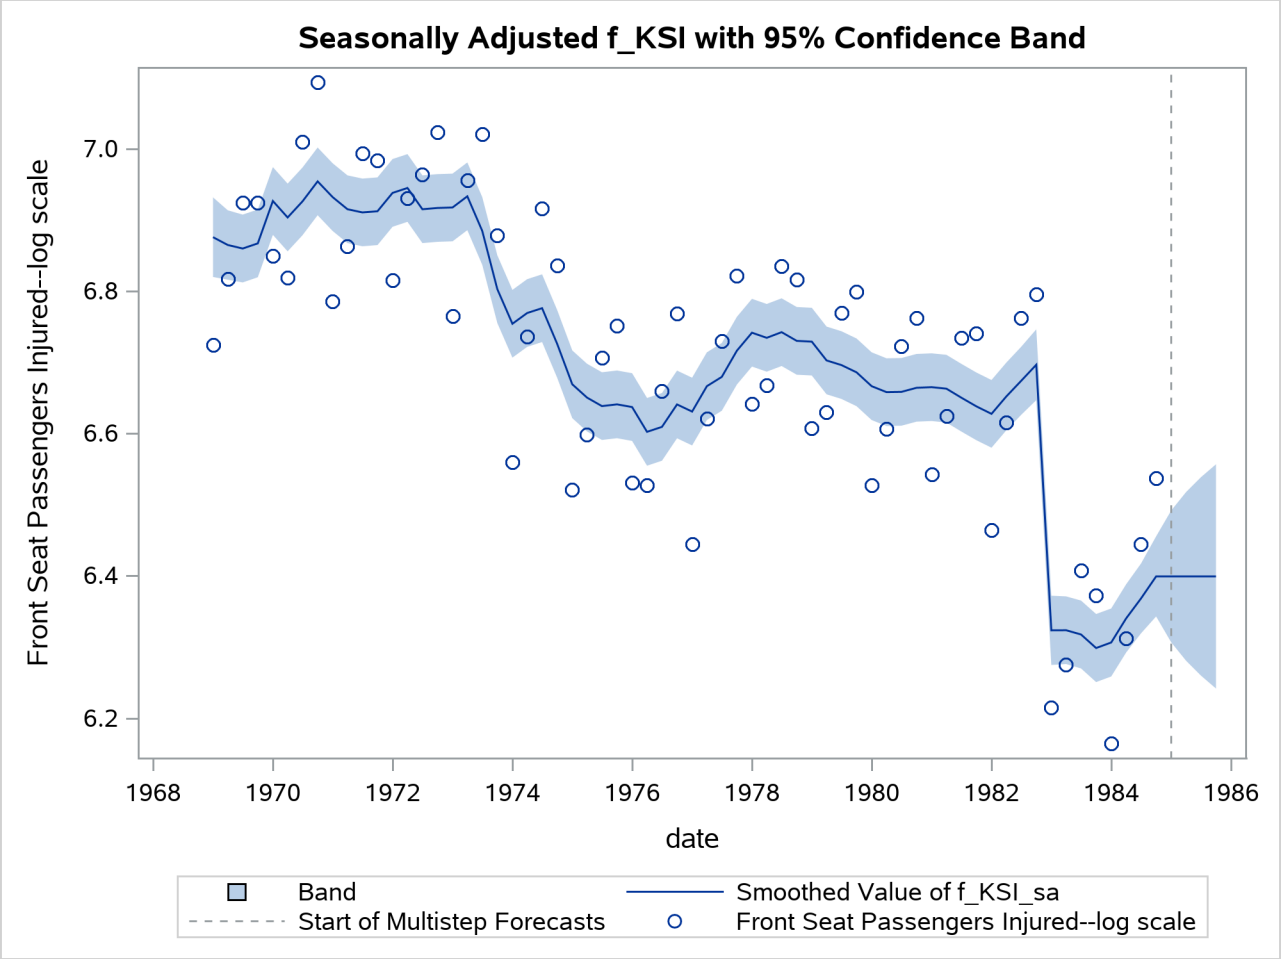
The output data set, For1, specified in the OUTPUT statement contains one-step-ahead and full-sample estimates of all the model components and the user-specified components (defined by the EVAL statement). Their standard errors and the upper and lower confidence limits (by default, 95%) are also produced.

The following statements use the For1 data set to produce a time series plot of the seasonally adjusted f_KSI:

```
proc sgplot data=For1;
   title "Seasonally Adjusted f_KSI with 95% Confidence Band";
   band x=date lower=smoothed_lower_f_KSI_sa
      upper=smoothed_upper_f_KSI_sa ;
   series x=date y=smoothed_f_KSI_sa;
   refline '1jan1985'd / axis=x lineattrs=(pattern=shortdash)
      LEGENDLABEL= "Start of Multistep Forecasts"
      name="Forecast Reference Line";
   scatter x=date y=f_KSI ;
run;
```

The generated plot is shown in Output 33.1.11.

Output 33.1.11 Plot of Seasonally Adjusted f_KSI



Example 33.2: Panel Data: Random-Effects and Autoregressive Models

This example shows how you can use the SSM procedure to specify and fit the two-way random-effects model and the autoregressive model to analyze a panel of time series. The fitting of dynamic panel model for such data is illustrated in Example 33.11. These (and a few other) model types can also be fitted by the PANEL procedure, a SAS/ETS procedure that is specially designed to efficiently handle the cross-sectional time series data. However, because of the differences in their model fitting algorithms, generally the parameter estimates and other fit statistics produced by the SSM and PANEL procedures do not match. The SSM procedure always uses the (restricted) maximum likelihood for parameter estimation. The estimation method used by the PANEL procedure depends on the model type and the particular estimation options.

The cross-sectional data, Cigar, that are used in the section "Getting Started: SSM Procedure" on page 2398 are reused in this example. The output shown here is less extensive than the output shown in that section. The main emphasis of this example is how you can specify the two-way random effects model and the autoregressive model in the SSM procedure.

According to the two-way random effects model, the cigarette sales, lsales, can be described by the following

equation:

$$\text{lsales}_{i,t} = \boldsymbol{\mu} + \text{lprice}\,\boldsymbol{\beta}_1 + \text{lndi}\,\boldsymbol{\beta}_2 + \text{lpimin}\,\boldsymbol{\beta}_3 + \boldsymbol{\zeta}_i + \boldsymbol{\eta}_t + \boldsymbol{\epsilon}_{i,t}$$

This model represents lsales in region i and in year t as a sum of an overall intercept $\boldsymbol{\mu}$, the regression effects due to lprice, lndi, and lpimin, a zero-mean, random effect $\boldsymbol{\zeta}_i$ associated with region i, a zero-mean, random effect $\boldsymbol{\eta}_t$ associated with year t, and the observation noise $\boldsymbol{\epsilon}_{i,t}$. The region-specific random effects $\boldsymbol{\zeta}_i$ and the year-specific random effects $\boldsymbol{\eta}_t$ are assumed to be independent, Gaussian sequences with variances σ_ζ^2 and σ_η^2, respectively. In addition, they are assumed to be independent of the observation noise, which is also assumed to be a sequence of independent, zero-mean, Gaussian variables with variance σ_ϵ^2.

You can specify and fit this model by using the following statements:

```
proc ssm data=Cigar;
   id year interval=year;
   parms s2g/ lower=(1.e-6);
   array RegionArray{46} region1-region46;
   do i=1 to 46;
      RegionArray[i] = (region=i);
   end;
   /* region-specific random effects */
   state zeta(46) T(I) cov1(I)=(s2g);
   component regionEffect = zeta * (RegionArray);
   /* year-specific random effect */
   state eta(1) type=wn cov(D);
   component timeEffect = eta[1];
   irregular wn;
   intercept = 1.0;
   model lsales = intercept lprice lndi lpimin
       timeEffect regionEffect wn;
run;
```

The PARMS statement defines s2g, a parameter that is restricted to be positive and is used later as the variance parameter for the region effect. Similarly the 46-dimensional array, RegionArray, of region-specific dummy variables is defined to be used later. The state subsection zeta corresponds to $\boldsymbol{\zeta}$, which is the 46-dimensional vector of region-specific, zero-mean, random effects. The component regionEffect extracts the proper element of $\boldsymbol{\zeta}$ by using the array RegionArray. A constant column, intercept, is defined to be used later as an intercept term. The component timeEffect corresponds to η_t, and wn specifies the observation noise $\boldsymbol{\epsilon}_{it}$. Finally the MODEL statement defines the model. Some of the tables that are produced by running these statements are shown in Output 33.2.1 through Output 33.2.5.

The model summary, shown in Output 33.2.1, shows that the model is defined by one MODEL statement, the dimension of the underlying state vector is 47 (because $\boldsymbol{\zeta}$ is 46-dimensional and η_t is one-dimensional), the diffuse dimension is 4 (because of the four predictors in the model), and there are three parameters to be estimated.

Output 33.2.1 Two-Way Random-Effects Model: Model Summary

The SSM Procedure

Model Summary	
Model Property	**Value**
Number of Model Equations	1
State Dimension	47
Dimension of the Diffuse Initial Condition	4
Number of Parameters	3

Output 33.2.2 provides the likelihood information about the fitted model.

Output 33.2.2 Two-Way Random-Effects Model: Likelihood Summary

Likelihood Computation Summary	
Statistic	**Value**
Nonmissing Response Values Used	1380
Estimated Parameters	3
Initialized Diffuse State Elements	4
Normalized Residual Sum of Squares	1376.0001
Diffuse Log Likelihood	1459.0277
Profile Log Likelihood	1470.8628

Output 33.2.3 shows the regression estimates.

Output 33.2.3 Two-Way Random-Effects Model: Regression Estimates

Regression Parameter Estimates					
Response Variable	**Regression Variable**	**Estimate**	**Standard Error**	**t Value**	**Pr > |t|**
lsales	**intercept**	2.798	0.1136	24.62	<.0001
lsales	**lprice**	-0.903	0.0365	-24.73	<.0001
lsales	**lndi**	0.592	0.0246	24.08	<.0001
lsales	**lpimin**	0.127	0.0398	3.18	0.0015

The ML estimate of s2g, a parameter specified in the PARMS statement, is shown in Output 33.2.4. It corresponds to σ_ξ^2, the variance of the region effect.

Output 33.2.4 Two-Way Random-Effects Model: Estimate of σ_ξ^2

Estimates of Named Parameters			
Parameter	**Estimate**	**Standard Error**	**t Value**
s2g	0.0241	0.00512	4.70

Output 33.2.5 Variance Estimates of η_t and ϵ_{it}

Model Parameter Estimates

Component	Type	Parameter	Estimate	Standard Error	t Value
eta	Disturbance Covariance	Cov[1, 1]	0.000681	0.000264	2.58
wn	Irregular	Variance	0.005698	0.000224	25.40

The estimates of the other unknown parameters in the model are shown in Output 33.2.5. It shows the estimate of the variance of the irregular component wn and the estimate of the variance of the time effect η_t.

The remainder of this example describes how you can specify and fit the following first-order vector autoregessive model to the cigarette data:

$$\begin{aligned} \text{lsales}_{i,t} &= \boldsymbol{\mu} + \text{lprice}\,\boldsymbol{\beta}_1 + \text{lndi}\,\boldsymbol{\beta}_2 + \text{lpimin}\,\boldsymbol{\beta}_3 + \boldsymbol{\zeta}_t[i] \\ \boldsymbol{\zeta}_t &= \boldsymbol{\Phi}\,\boldsymbol{\zeta}_{t-1} + \boldsymbol{\eta}_t \end{aligned}$$

This model represents lsales in region i and in year t as a sum of an overall intercept $\boldsymbol{\mu}$, the regression effects due to lprice, lndi, and lpimin, and the ith element of a vector error term $\boldsymbol{\zeta}_t[i]$. The multidimensional error sequence $\boldsymbol{\zeta}_t$ is assumed to follow a first-order autoregression with a diagonal autoregressive coefficient matrix $\boldsymbol{\Phi}$ and with a multivariate, white noise sequence $\boldsymbol{\eta}_t$ as its disturbance sequence. The covariance matrix of $\boldsymbol{\eta}_t$, $\boldsymbol{\Sigma}$, is assumed to be dense. Note that the dimension of the vectors $\boldsymbol{\zeta}_t$ is the same as the number of cross sections in the study (the number of regions in this example). Therefore, even for a relatively modest panel study, the total number of parameters to be estimated can get quite large. Therefore, in this example only the first three regions are considered in the analysis. The following statements specify and fit this model to the Cigar data set:

```
proc ssm data=Cigar;
   where region <= 3;
   id year interval=year;
   array RegionArray{3} region1-region3;
   do i=1 to 3;
      RegionArray[i] = (region=i);
   end;
   state zeta(3) type=varma(p(d)=1) cov(g) print=(ar cov);
   component eta = zeta*(RegionArray);
   intercept = 1.0;
   model lsales = intercept lprice lndi lpimin eta;
run;
```

The vectors $\boldsymbol{\zeta}_t$ are specified in the STATE statement. The TYPE= specification signifies that the three-dimensional state subsection, zeta, follows a vector AR(1) model with a diagonal transition matrix and a disturbance covariance of a general form. The PRINT=(AR COV) option causes the SSM procedure to print the estimated AR coefficient matrix, $\boldsymbol{\Phi}$, and the disturbance error covariance $\boldsymbol{\Sigma}$, respectively. The COMPONENT statement defines the appropriate error contribution (named eta), $\boldsymbol{\zeta}_t[i]$. Output 33.2.6 shows the estimated regression coefficients, Output 33.2.7 shows the estimate of $\boldsymbol{\Phi}$, and Output 33.2.8 shows the estimate of $\boldsymbol{\Sigma}$:

Output 33.2.6 Autoregressive Model: Regression Estimates

Example 33.3: Backcasting, Forecasting, and Interpolation

This example illustrates how you can do model-based extrapolation—backcasting, forecasting, or interpolation—of a response variable. All you need is to appropriately augment the input data set with the relevant ID and predictor information and assign missing values to the response variable in these places. The following DATA step creates one such augmented data set by using a well-known data set that contains recordings of the Nile River water level measured between the years 1871 and 1970. Suppose you want to backcast the Nile water level for two years before 1871, forecast it for two years after 1970, and interpolate its value for the year 1921—for illustration purposes, this value is assumed to be missing in the available data set.

```
data Nile;
   input level @@;
   year = intnx( 'year', '1jan1869'd, _n_-1 );
   format year year4.;
   if year = '1jan1921'd then level=.;
datalines;
. .
1120  1160  963  1210  1160  1160  813  1230   1370  1140
995   935   1110 994   1020  960   1180 799    958   1140
```

```
1100  1210  1150 1250  1260  1220  1030 1100   774   840
874   694   940  833   701   916   692  1020   1050  969
831   726   456  824   702   1120  1100 832    764   821
768   845   864  862   698   845   744  796    1040  759
781   865   845  944   984   897   822  1010   771   676
649   846   812  742   801   1040  860  874    848   890
744   749   838  1050  918   986   797  923    975   815
1020  906   901  1170  912   746   919  718    714   740
. .
;
```

It is also known that for this time span the Nile water level can be reasonably modeled as a sum of a random walk trend, a level shift in the year 1899, and the observation error. The following statements fit this model to the data:

```
proc ssm data=Nile;
    id year interval=year;
    shift1899 = ( year >= '1jan1899'd );
    trend rw(rw);
    irregular wn;
    model level = shift1899 RW wn  / print=smooth;
    output out=nileOut;
quit;
```

The model-based interpolated and extrapolated values of the Nile water level are shown in Output 33.3.1, which is produced by using the PRINT=SMOOTH option in the MODEL statement.

Output 33.3.1 Interpolated and Extrapolated Nile Water Level

The SSM Procedure

Full-Sample Prediction of Missing Values for level

Obs	ID	Estimate	Standard Error	95% Confidence Limits	
1	1869	1098	130	843	1353
2	1870	1098	130	843	1353

103	1971	851	129	599	1104
104	1972	851	129	599	1104

Example 33.4: Longitudinal Data: Smoothing of Repeated Measures

This example of a repeated measures study is taken from Diggle, Liang, and Zeger (1994, p. 100). The data consist of body weights of 27 cows, measured at 23 unequally spaced time points over a period of approximately 22 months. Following Diggle, Liang, and Zeger (1994), one animal is removed from the analysis, one observation is removed according to their Figure 5.7, and the time is shifted to start at 0 and is measured in 10-day increments. The design is a 2×2 factorial, and the factors are the infection of an animal with M. paratuberculosis and whether the animal is receiving iron dosing. The data set contains five variables: cow assigns a unique identification number—from 1 to 26—to each cow in the study, tpoint denotes the time of the growth measurement, weight denotes the growth measurement, iron is a dummy variable that indicates whether the animal is receiving iron or not, and infection is a dummy variable that indicates whether the animal is infected or not. The goal of the study is to assess the effect of iron and infection—and their possible interaction—on weight. The following DATA steps create this data set:

```
data times;
  input time1-time23;
  datalines;
 122  150  166  179  219  247  276  296  324  354  380  445
 478  508  536  569  599  627  655  668  723  751  781
;

data Cows;
  if _n_ = 1 then merge times;
  array t{23} time1   - time23;
  array w{23} weight1 - weight23;
  input cow iron infection weight1-weight23 @@;
  do i=1 to 23;
     weight = w{i};
     tpoint = (t{i}-t{1})/10;
     output;
  end;
  keep cow iron infection tpoint weight;
  datalines;
  1 0 0  4.7    4.905  5.011  5.075  5.136  5.165  5.298  5.323
         5.416  5.438  5.541  5.652  5.687  5.737  5.814  5.799

   ... more lines ...
```

The following DATA step adds ironInf, a grouping variable that is used later during the plotting of the results. In the next step, the data are sorted by the index variable, tpoint.

```
data Cows;
   set Cows;
   ironInf = "No Iron and No Infection";
   if iron=1 and infection=1 then ironInf = "Iron and Infection";
   else if iron=1 and infection=0 then ironInf = "Iron and No Infection";
   else if iron=0 and infection=1 then ironInf = "No Iron and Infection";
   else ironInf = "No Iron and No Infection";
   run;
```

```
proc sort data=Cows;
    by tpoint ;
run;
```

To assess the effect of iron and infection on weight, the natural growth profile of the animals must also be accounted for. Here two alternate models for this problem are considered. The first model assumes that the observed weight of an animal is the sum of a common growth profile, which is modeled by a polynomial spline trend of order 2, the regression effects of iron and infection, and the observation error—modeled as white noise. An interaction term, for interaction between iron and infection, was found to be insignificant and is not included. In the second model, the common growth profile and the regression variables of the first model are replaced by four environment specific growth profiles.

The following statements fit the first model:

```
proc ssm data=Cows;
   id tpoint;
   trend growth(ps(2));
   irregular wn;
   model weight = iron infection growth wn;
   eval pattern = iron + infection + growth;
   output out=For;
quit;
```

Output 33.4.1 shows that the state dimension of this model is 2 (corresponding to the polynomial trend specification of order 2), the number of diffuse elements in the initial condition is 4 (corresponding to the trend and the two regressors iron and infection), and the number of unknown parameters is 2 (corresponding to the variance parameters of trend and irregular).

Output 33.4.1 Model1: Model Summary Information

The SSM Procedure

Model Summary	
Model Property	**Value**
Number of Model Equations	1
State Dimension	2
Dimension of the Diffuse Initial Condition	4
Number of Parameters	2

Output 33.4.2 shows that the ID variable is irregularly spaced with replication.

Output 33.4.2 ID Variable Information

ID Variable Information					
Name	**Start**	**End**	**Max Delta**	**NDistinct**	**Type**
tpoint	0	65.9	6.5	23	Irregular with Replication

The estimated regression coefficients of iron and infection, shown in Output 33.4.3, are significant and negative. This implies that both iron and infection adversely affect the response variable, weight.

Output 33.4.3 Model 1: Regression Estimates

Regression Parameter Estimates

Response Variable	Regression Variable	Estimate	Standard Error	t Value	Pr > |t|
weight	iron	-0.0748	0.00761	-9.82	<.0001
weight	infection	-0.1292	0.00859	-15.04	<.0001

The variance estimates of the trend component and the irregular component are shown in Output 33.4.4.

Output 33.4.4 Model 1: Estimates of Unnamed Parameters

Model Parameter Estimates

Component	Type	Parameter	Estimate	Standard Error	t Value
growth	PS(2) Trend	Level Variance	0.0000162	9.01E-06	1.80
wn	Irregular	Variance	0.0085849	5.03E-04	17.06

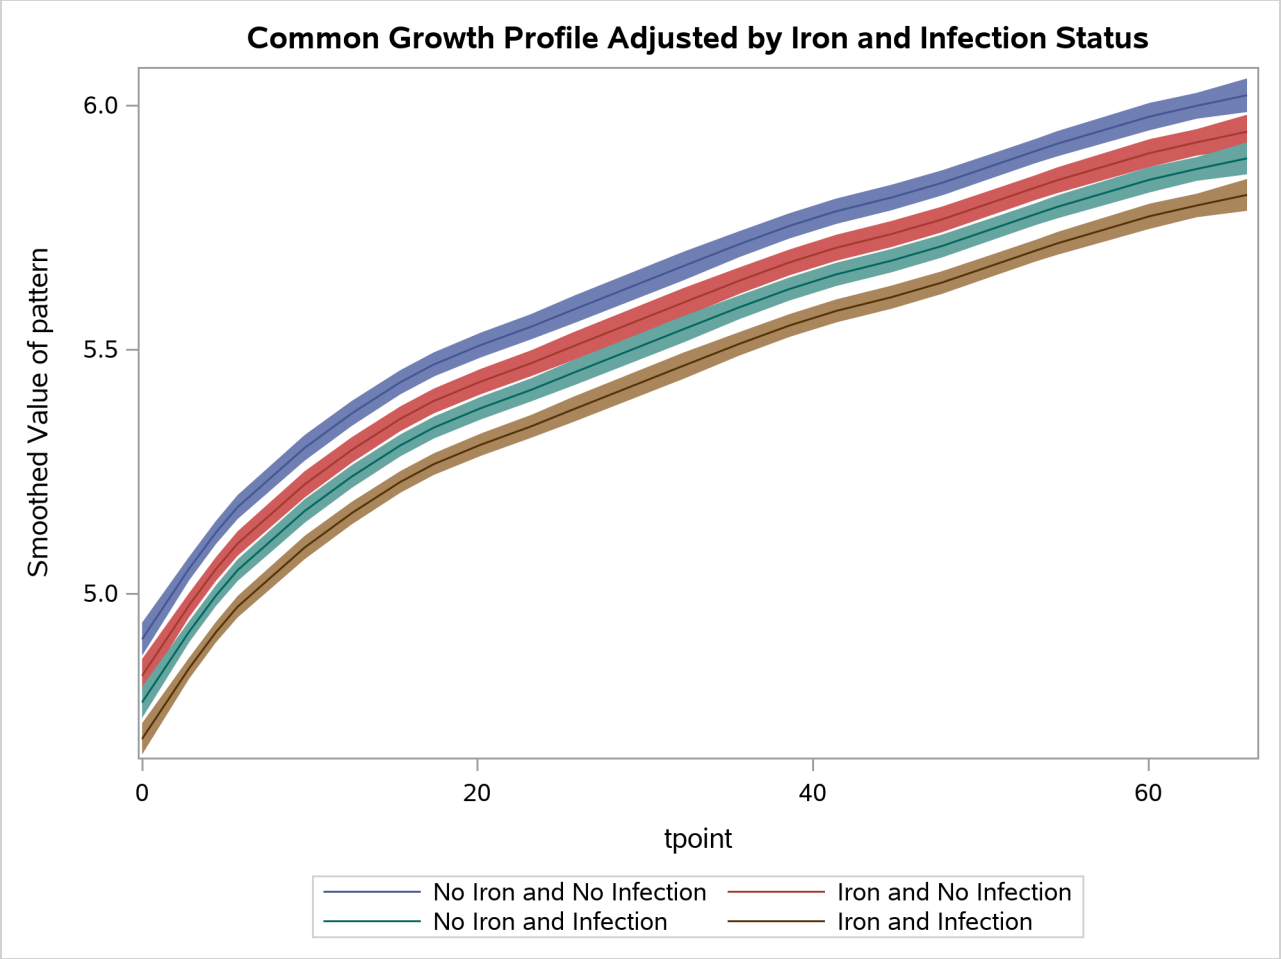
After examining the model fit, it is useful to study how well the patterns implied by the model follow the data. pattern, defined by the EVAL statement, is a sum of the trend component and the regression effects. A graphical examination of the smoothed estimate of pattern is done next. The following DATA step merges the output data set specified in the OUTPUT statement, For, with the input data set, Cows. In particular, this adds ironInf (a grouping variable from Cows) to For.

```
data For;
    merge for Cows;
    by tpoint;
run;
```

The following statements produce the graphs of smoothed_pattern, grouped according to the environment condition (see Output 33.4.5). The plot clearly shows that the control group "No Iron and No Infection" has the best growth profile, while the worst growth profile is for the group "Iron and Infection."

```
proc sgplot data=For noautolegend;
    title 'Common Growth Profile Adjusted by Iron and Infection Status';
    band x=tpoint lower=smoothed_lower_pattern
       upper=smoothed_upper_pattern / group=ironInf name="band";
    series  x=tpoint y=smoothed_pattern / group=ironInf name="series";
    keylegend "series";
run;
```

Output 33.4.5 Model 1: Growth Profile Comparison with 95% Confidence Bands

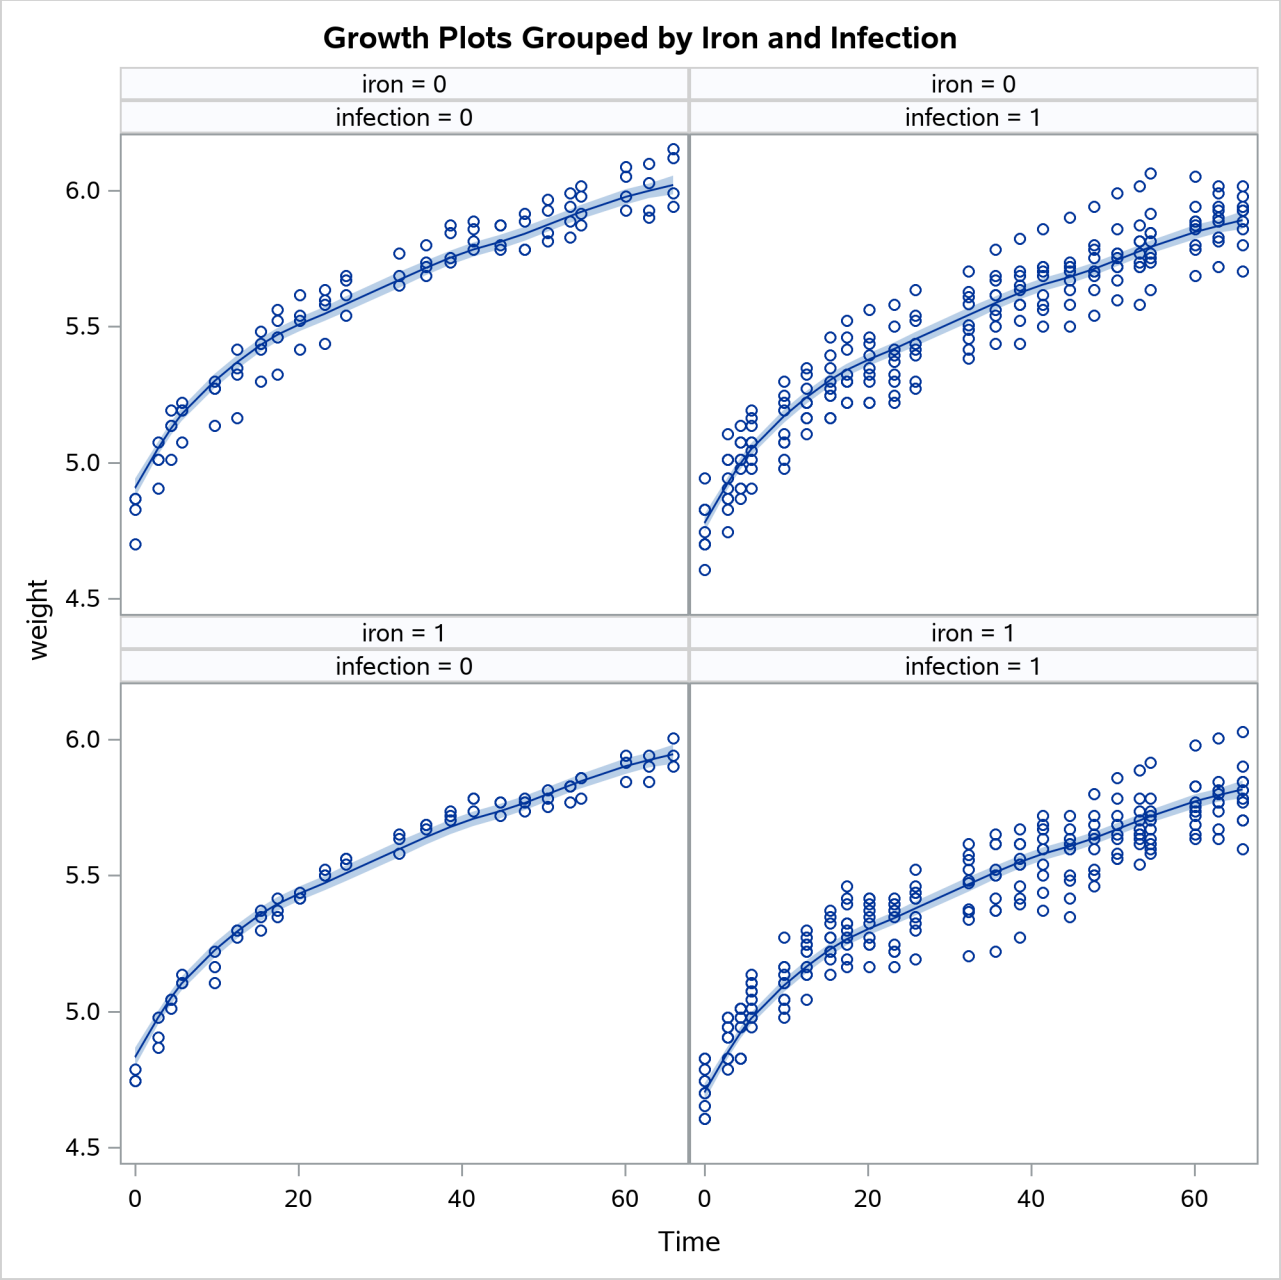


The following statements produce a panel of plots that show how well smoothed_pattern follows the observed data:

```
proc sgpanel data=For noautolegend;
  title 'Growth Plots Grouped by Iron and Infection';
   label tpoint='Time' ;
   panelby iron infection / columns=2;
   band x=tpoint lower=smoothed_lower_pattern
      upper=smoothed_upper_pattern ;
   scatter x=tpoint y=weight;
   series  x=tpoint y=smoothed_pattern ;
run;
```

Output 33.4.6 shows that the model fits the data reasonably well.

Output 33.4.6 Model 1: Smoothed Model Fit Lines



The following statements fit the second model. In this model separate polynomial trends are fit according to different settings of iron and infection by specifying an appropriate list of (dummy) variables in the CROSS= option of the trend specification.

```
proc ssm data=Cows;
    id tpoint;
    a1 = (iron=1 and infection=1);
    a2 = (iron=1 and infection=0);
    a3 = (iron=0 and infection=1);
    a4 = (iron=0 and infection=0);
```

```
    trend growth(ps(2)) cross=(a1-a4);
    irregular wn;
    model weight = growth wn;
    /* Define contrasts between a1 and other treatments  */
    comp a1Curve = growth_state_[1];
    comp a2Curve = growth_state_[2];
    comp a3Curve = growth_state_[3];
    comp a4Curve = growth_state_[4];
    eval contrast21 = a2Curve - a1Curve;
    eval contrast31 = a3Curve - a1Curve;
    eval contrast41 = a4Curve - a1Curve;
    output out=for1;
quit;
```

As a result of the CROSS= option, the trend component growth is actually a sum of four separate trends that correspond to the different iron-infection settings. Denoting growth by μ_t and the four independent trends by $\mu_{1,t}$, $\mu_{2,t}$, $\mu_{3,t}$, and $\mu_{4,t}$,

$$\mu_t = a1 * \mu_{1,t} + a2 * \mu_{2,t} + a3 * \mu_{3,t} + a4 * \mu_{4,t}$$

where a1, a2, a3, and a4 are the dummy variables specified in the CROSS= option. This shows that, for any given setting (say, the one for a4) μ_t is simply the corresponding trend $\mu_{4,t}$. In addition, note the form of the COMPONENT statements that define the components a1Curve, a2Curve, a3Curve, and a4Curve. This form of the COMPONENT statement treats the state that is associated with growth, named growth_state_ by convention, as a state of nominal dimension 4—the number of variables in the CROSS= list. This, in turn, implies that a1Curve, which is defined as growth_state_[1], refers to $\mu_{1,t}$. These components are subsequently used in the EVAL statements to define contrasts between the trends—for example, contrast21 corresponds to the difference between the trends $\mu_{2,t}$ and $\mu_{1,t}$. The estimates of these components (a1Curve, a2Curve, ..., contrast41) are output to the data set For1 named in the OUT= option of the OUTPUT data set.

The model summary, shown in Output 33.4.7, reflects the increased state dimension and the increased number of parameters.

Output 33.4.7 Model2: Model Summary Information

The SSM Procedure

Model Summary	
Model Property	**Value**
Number of Model Equations	1
State Dimension	8
Dimension of the Diffuse Initial Condition	8
Number of Parameters	5

Output 33.4.8 shows the parameter estimates for this model.

Output 33.4.8 Model2: Estimates of Unnamed Parameters (Partial Output)

Component	Parameter	Estimate	StdErr	tValue
growth(Cross = a1)	Level Variance	1.28E-05	6.83E-06	1.87
growth(Cross = a2)	Level Variance	8.72E-06	3.81E-06	2.29
growth(Cross = a3)	Level Variance	9.07E-06	4.23E-06	2.14
growth(Cross = a4)	Level Variance	8.45E-06	3.40E-06	2.49
wn	Variance	8.39E-03	4.98E-04	16.84

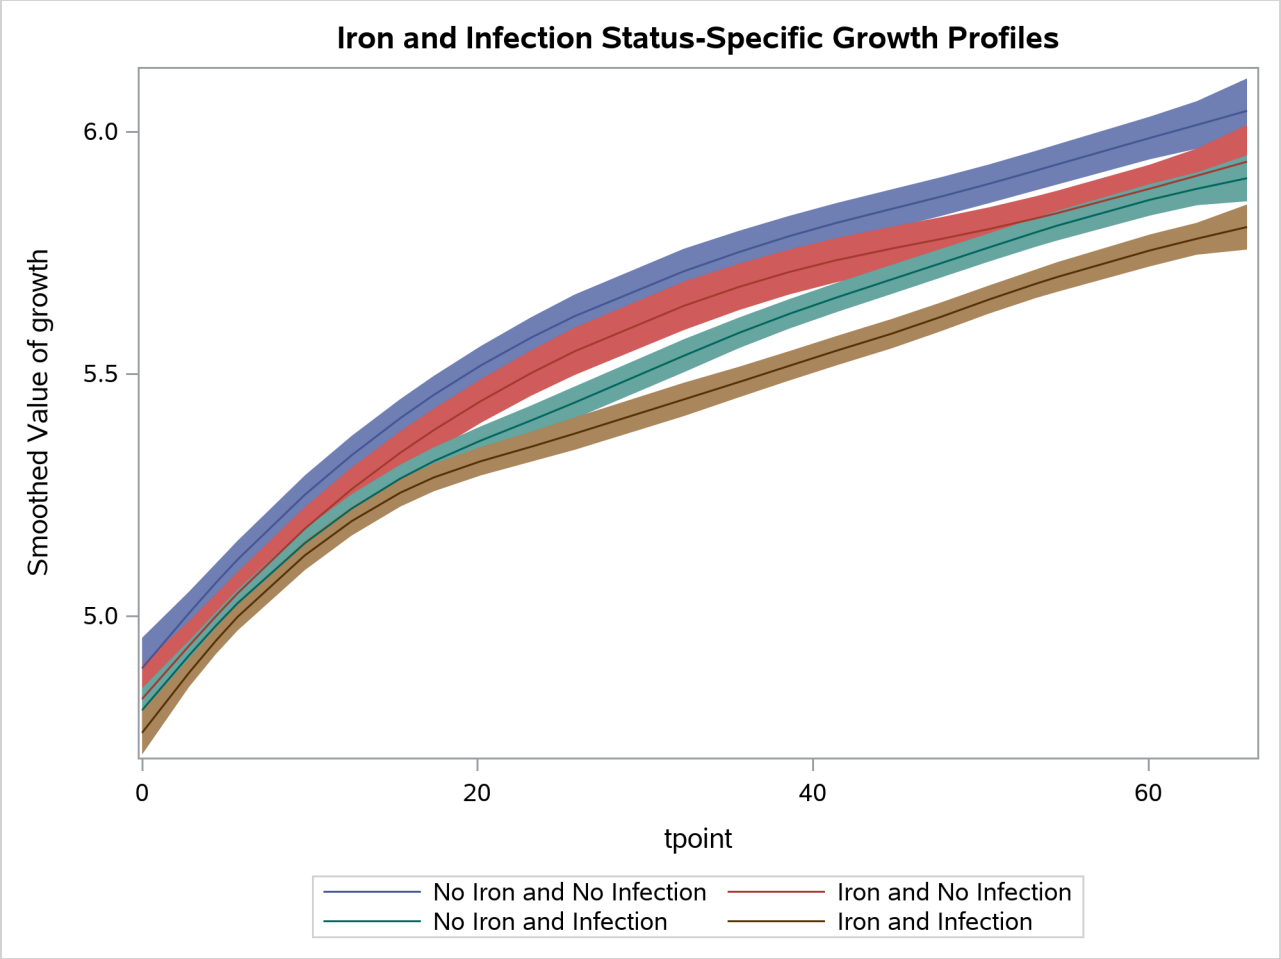
Next, the smoothed estimate of trend (growth) is graphically studied. The following DATA step prepares the data for the grouped plots of smoothed_growth by merging For1 with the input data set Cows. As before, the reason is merely to include ironInf (the grouping variable).

```
data For1;
    merge For1 Cows;
    by tpoint;
run;
```

The following statements produce the graphs of smoothed μ_t for the desired settings (since the grouping variable ironInf exactly corresponds to these settings). Once again, the plot in Output 33.4.9 clearly shows that the control group "No Iron and No Infection" has the best growth profile, while the worst growth profile is for the group "Iron and Infection." However, unlike the first model, the profile curves are not merely shifted versions of a common profile.

```
proc sgplot data=For1 noautolegend;
   title 'Iron and Infection Status-Specific Growth Profiles';
    band x=tpoint lower=smoothed_lower_growth
      upper=smoothed_upper_growth / group=ironInf name="band";
    series  x=tpoint y=smoothed_growth / group=ironInf name="series";
    keylegend "series";
run;
```

Output 33.4.9 Model 2: Growth Profile Comparison with 95% Confidence Bands

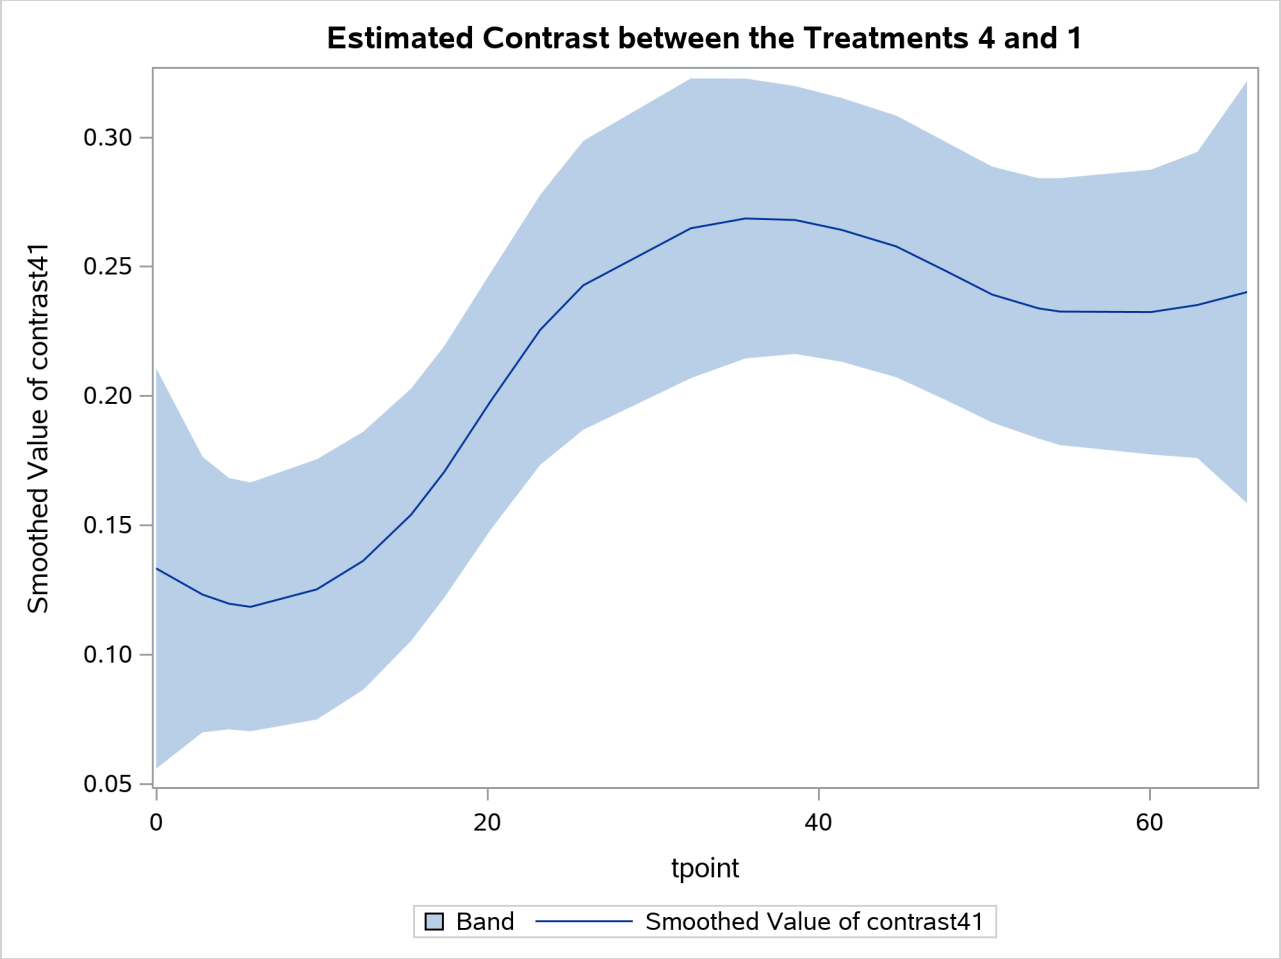


The following statements produce the plot of smoothed $(\mu_{4,t} - \mu_{1,t})$—contrast between the best and the worst growth profiles:

```
proc sgplot data=For1;
   title "Estimated Contrast between the Treatments 4 and 1 ";
    band x=tpoint lower=smoothed_lower_contrast41
       upper=smoothed_upper_contrast41;
    series x=tpoint y=smoothed_contrast41;
run;
```

Output 33.4.10 shows that the growth pattern of the control group "No Iron and No Infection" consistently remains above the growth pattern of the treatment group "Iron and Infection."

Output 33.4.10 Estimated Contrast between the Treatments 4 and 1 with 95% Confidence Bands



Example 33.5: A User-Defined Trend Model

This example shows how to specify a continuous-time trend model discussed in Harvey (1989, chap. 9, sec. 9.2.1). This model is not one of the predefined trend models in the SSM procedure. The system matrices that govern the two-dimensional state of this model are

$$\mathbf{T} = \begin{bmatrix} 1 & h \\ 0 & 1 \end{bmatrix}$$

$$\mathbf{Q} = \begin{bmatrix} h\sigma_1^2 + \frac{h^3\sigma_2^2}{3} & \frac{h^2\sigma_2^2}{2} \\ \frac{h^2\sigma_2^2}{2} & h\sigma_2^2 \end{bmatrix}$$

where $h = h_t = (\tau_{t+1} - \tau_t)$ denotes the difference between the successive time points, and the parameters σ_1^2 and σ_2^2 are called the level variance and the slope variance, respectively. The initial condition is fully diffuse. The trend component corresponds to the first element of this state vector. The second element of the state vector corresponds to the slope of this trend component. This model reduces to the polynomial spline model of order 2 if the level variance $\sigma_1^2 = 0$. (See the section "Polynomial Spline Trend" on page 2448.)

The following statements specify a trend-plus-noise model to model the growth of cows in the previous example (Example 33.4). The only cows that are considered are the ones that received iron and are infected.

```
proc ssm data=Cows;
   where iron=1 and infection=1;
   id tpoint;
   parms var1 var2 / lower=(1.e-8 1.e-8);
   array tMat{2,2};
   tMat[1,1] = 1;
   tMat[2,2] = 1;
   tMat[1,2] = _ID_DELTA_;
   array covMat{2,2};
   covMat[1,1] = var1*_ID_DELTA_ + var2*_ID_DELTA_**3/3;
   covMat[1,2] = var2*_ID_DELTA_**2/2;
   covMat[2,1] = covMat[1,2] ;
   covMat[2,2] = var2*_ID_DELTA_;
   state harveyLL(2) T(g)=(tMat) cov(g)=(covMat) a1(2);
   component trend = harveyLL[1];
   component slope = harveyLL[2];
   irregular wn;
   model  weight = trend  wn;
   output out=for;
run;
```

The program is easy to follow. The PARMS statement declares var1 and var2 as positive parameters, which correspond to σ_1^2 and σ_2^2, respectively. The programming statements define arrays tMat and covMat, which later become the matrices $\mathbf{T}$ and $\mathbf{Q}$, respectively. Note that the element tMat[2,1] is left unassigned, since it is a structural zero of $\mathbf{T}$ (see the section "Sparse Transition Matrix Specification" on page 2436 for more information). Recall that the predefined variable _ID_DELTA_ contains the value of h_t, which is needed for defining the elements of $\mathbf{T}$ and $\mathbf{Q}$ (see the section "ID Statement" on page 2416). The STATE statement defines the trend state vector, harveyLL, and the COMPONENT statement defines the trend component, trend, by selecting the first element of harveyLL. An additional COMPONENT statement defines the slope component, slope, as the second element of harveyLL. The slope component (which represents the cow's growth rate) is not part of the observation equation; it is specified so that its estimate is output to For (the OUT= data set specified in the OUTPUT statement). The IRREGULAR statement defines the observation noise, and the MODEL statement defines the trend-plus-noise model.

The estimates of var1 and var2 are shown in Output 33.5.1. It shows that the estimate of the level variance is nearly 0, implying that the fitted trend model is identical to the polynomial spline trend of order 2.

Output 33.5.1 Estimates of the Named Parameters

The SSM Procedure

Estimates of Named Parameters

Parameter	Estimate	Standard Error	t Value
var1	1.00E-08	0.000849	0.00
var2	1.24E-05	.	.

The estimate of the noise variance is shown in Output 33.5.2.

Output 33.5.2 Estimates of the Unnamed Parameters

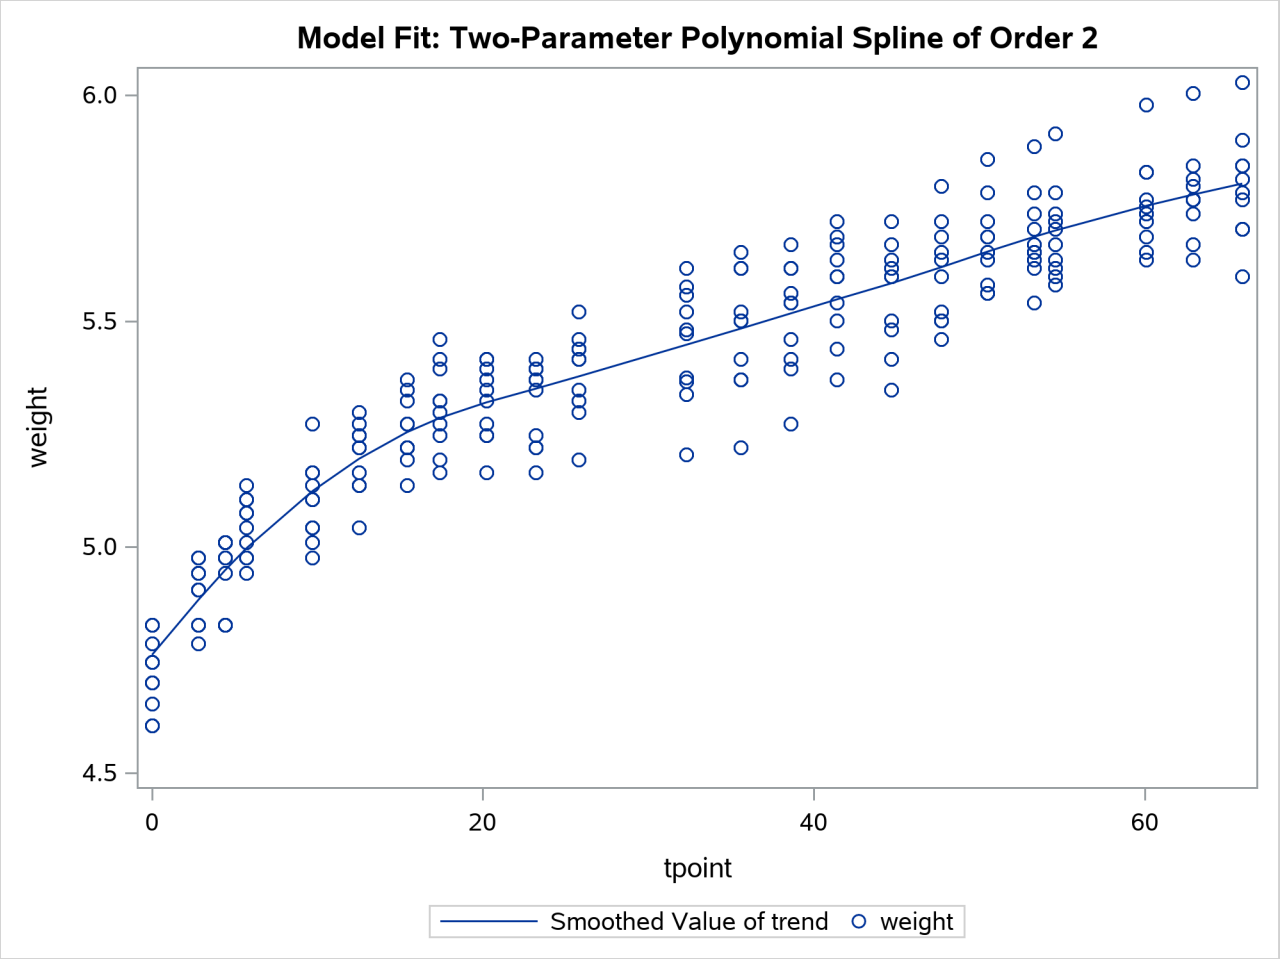
Model Parameter Estimates

Component	Type	Parameter	Estimate	Standard Error	t Value
wn	Irregular	Variance	0.00954	0.000909	10.49

The following statements produce the plot of the fit of this trend model (shown in Output 33.5.3):

```
proc sgplot data=For;
    title "Model Fit: Two-Parameter Polynomial Spline of Order 2";
    series x=tpoint y=smoothed_trend;
    scatter x=tpoint y=weight;
run;
```

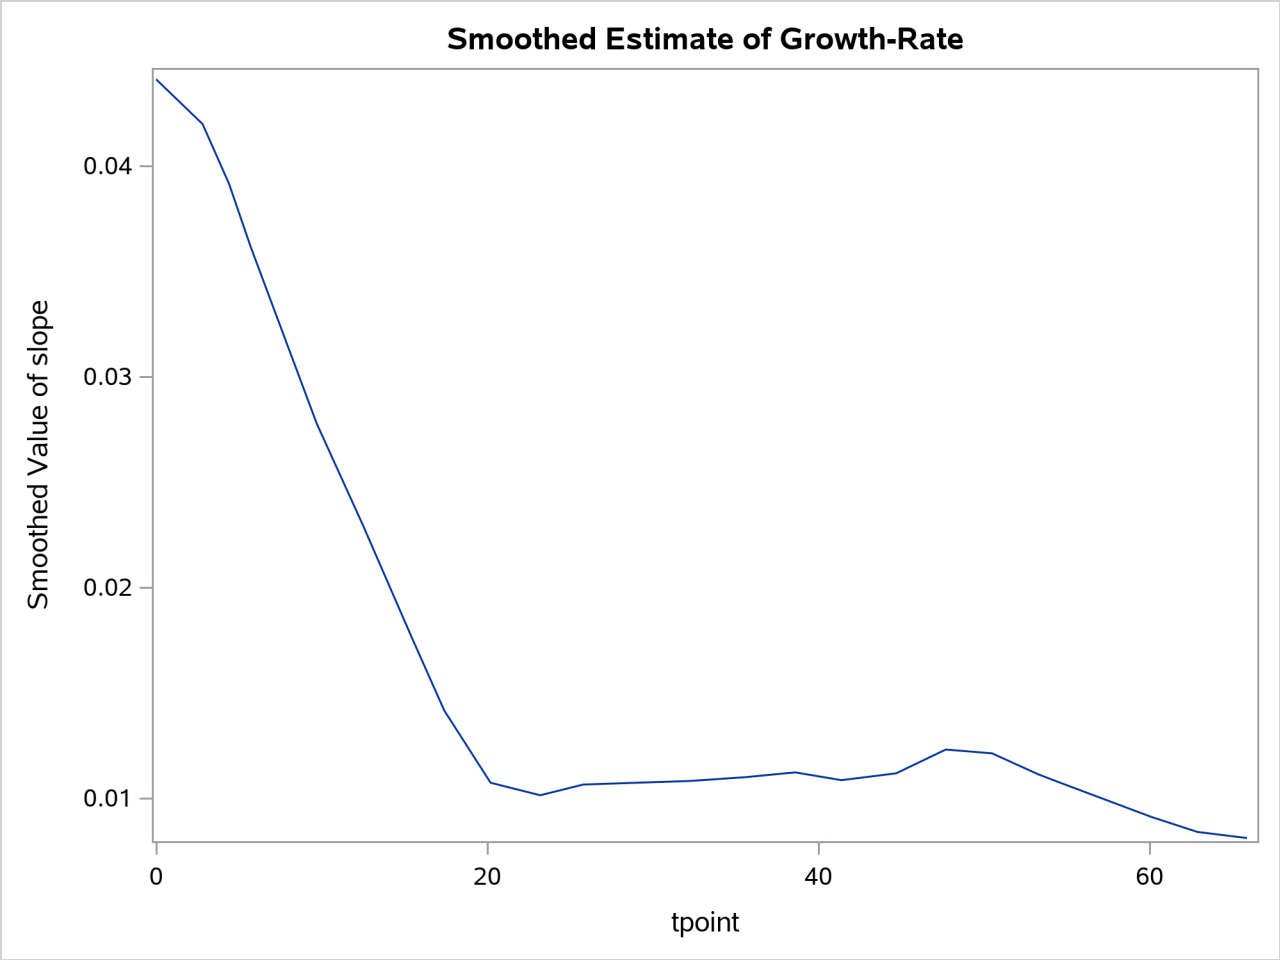
Output 33.5.3 A User-Defined Trend Model



The following statements produce the plot of the estimate of the slope component (shown in Output 33.5.4). This plot complements the preceding plot of trend; it shows the pattern of decline in the growth rate as the animals age.

```
proc sgplot data=For;
    title "Smoothed Estimate of Growth-Rate";
    series x=tpoint y=smoothed_slope;
run;
```

Output 33.5.4 Estimate of the slope Component



Example 33.6: Model with Multiple ARIMA Components

This example shows how you can fit the REGCOMPONENT models in Bell (2011) by using the SSM procedure. The following DATA step generates the data used in the last example of this article (Example 6: "Modeling a Time Series with a Sampling Error Component"). The variable y in this data set contains monthly values of the VIP series (value of construction put in place), a US Census Bureau publication that measures the value of construction installed or erected at construction sites during a given month. The values of y are known to be contaminated with heterogeneous sampling errors; the variable hwt in the data set is a proxy for this sampling error in the log scale. The variable hwt is treated as a weight variable for the noise component in the model.

```
data Test;
  input y hwt;
  date = intnx('month', '01jan1997'd, _n_-1 );
  format date date.;
  logy = log(y);
  label logy = 'Log value of construction put in place';
  datalines;
115.2    0.042
110.4    0.042
111.5    0.067
127.9    0.122
150.0    0.129
149.5    0.135
139.5    0.152
144.6    0.168
176.0    0.173

   ... more lines ...
```

The article proposes the following model for the log VIP series:

$$\log(y) = \mu_t + hwt * \eta_t$$

where μ_t follows an ARIMA$(0,1,1)\times(0,1,1)_{12}$ model and η_t is a zero-mean, AR(2) error process. In addition, the article fixes the values of some of the model parameters to known values in order to use the known background information. The following statements specify the model in the article:

```
proc ssm data=Test;
   id date interval=month;
   parm var1=0.016565 / lower=1.e-8;
   trend airlineTrend(arma(d=1 sd=1 q=1 sq=1 s=12)) variance=var1;
   trend ar2Noise(arma(p=2)) cross=(hwt) ar=0.600 0.246 variance=0.34488;
   model logy = airlineTrend ar2Noise;
   output outfor=For;
run;
```

Output 33.6.1 Estimates of the MA Parameters in the airlineTrend Model

The SSM Procedure

Model Parameter Estimates

Component	Type	Parameter	Estimate	Standard Error	t Value
airlineTrend	ARMA Trend	MA_1	0.466	0.280	1.67
airlineTrend	ARMA Trend	SMA_1	0.430	0.344	1.25

Output 33.6.2 Estimate of the Error Variance in the airlineTrend Model

Estimates of Named Parameters

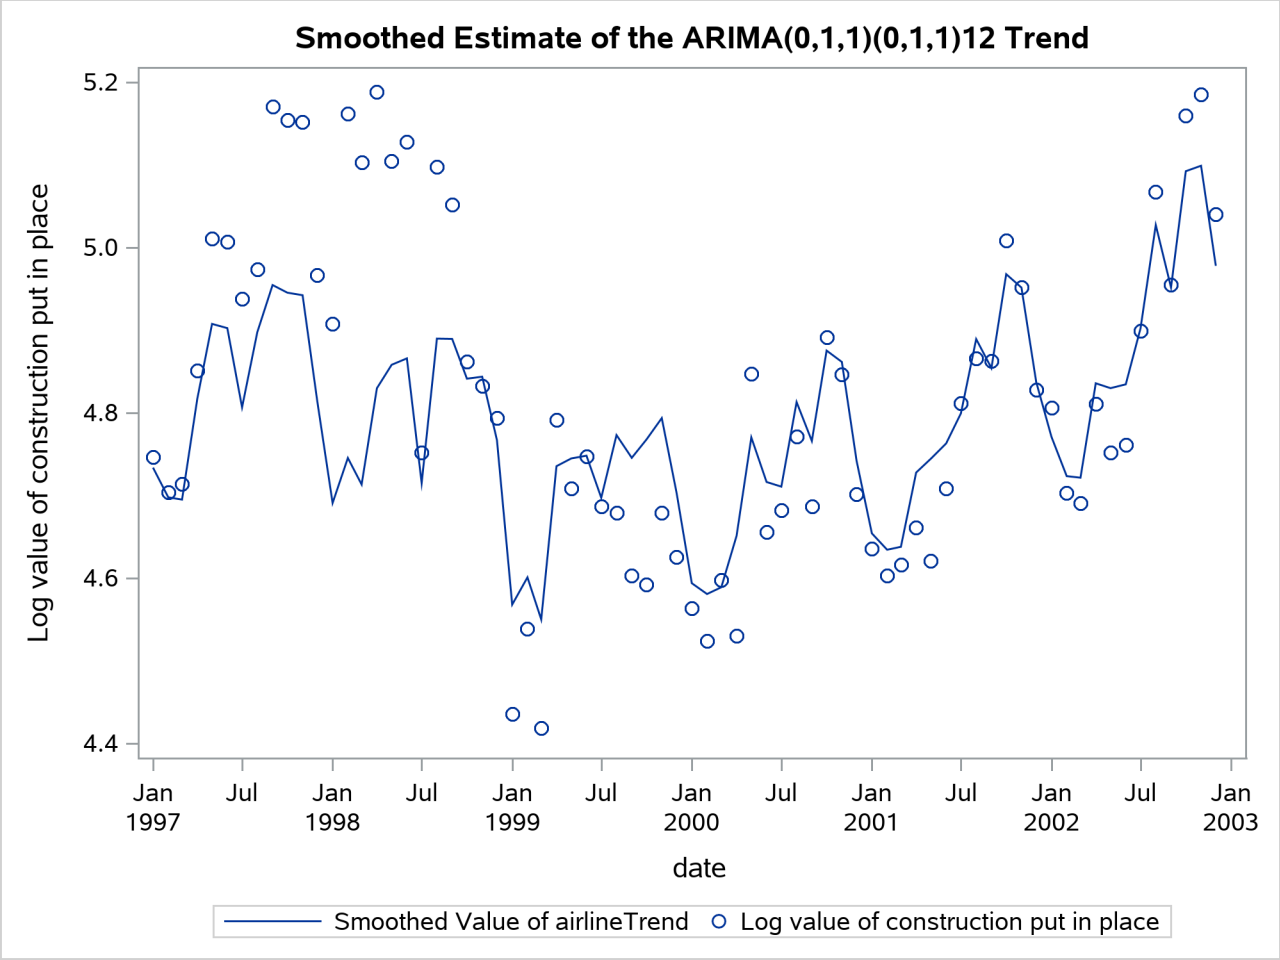
Parameter	Estimate	Standard Error	t Value
var1	0.00533	0.00306	1.74

The ARIMA$(0,1,1)\times(0,1,1)_{12}$ trend μ_t is named airlineTrend and the zero-mean, AR(2) error process η_t is named ar2Noise. For more information about the ARIMA notation, see the TREND statement. The estimates of model parameters are shown in Output 33.6.1 and Output 33.6.2. These estimates are quite close to the estimates given in the article, and the estimated trend and noise series are also very similar to those in the article.

The following statements produce the plot of the estimate of the airlineTrend component (shown in Output 33.6.3). This plot is very similar to the trend plot shown in the article (the article plots are in the antilog scale).

```
proc sgplot data=For;
    title "Smoothed Estimate of the ARIMA(0,1,1)(0,1,1)12 Trend";
    series x= date y=smoothed_airlineTrend;
    scatter x= date y=logy;
run;
```

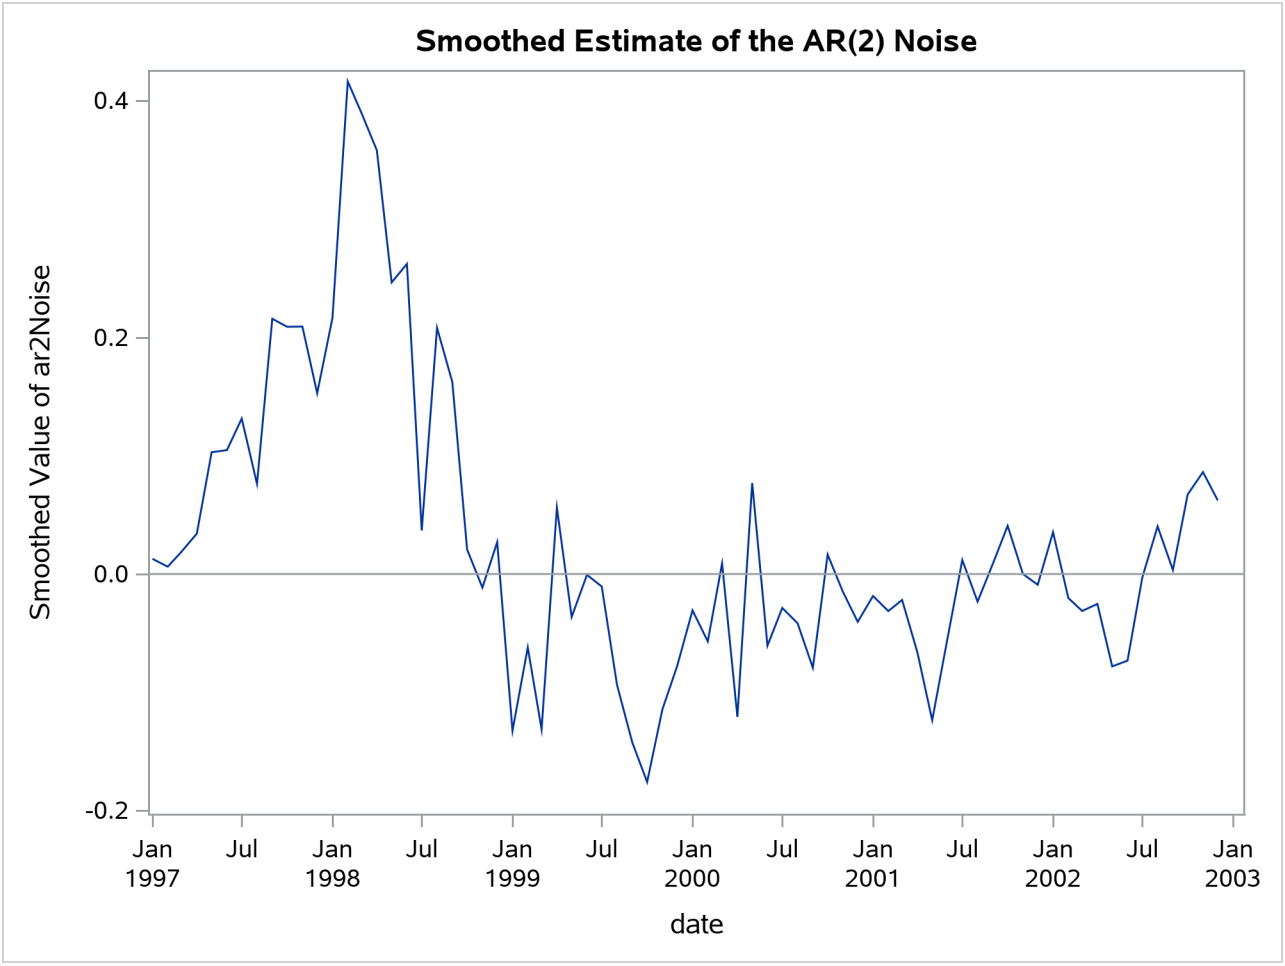
Output 33.6.3 Estimate of the airlineTrend Component



The following statements produce the plot of the estimate of the ar2Noise component (shown in Output 33.6.4). This plot is also very similar to the noise plot shown in the article (once again, the article plots are in the antilog scale).

```
proc sgplot data=For;
    title "Smoothed Estimate of the AR(2) Noise";
    series x= date y=smoothed_ar2Noise;
    refline 0;
run;
```

Output 33.6.4 Estimate of the ar2Noise Component



Example 33.7: A Dynamic Factor Model for the Yield Curve

This example shows how you can fit a variant of the dynamic Nelson-Siegel (DNS) factor model discussed in Koopman, Mallee, and van der Wel (2010). Also see the example in Durbin and Koopman (2012, chap. 8, sect. 6). The following DATA step creates the yield-curve data set, Dns, that is used in Koopman, Mallee, and van der Wel. The data are monthly bond yields that were recorded between the start of 1970 and the end of 2000 for 17 bonds of different maturities; the maturities range from three months to 10 years (120 months). The variable date contains the observation date, yield contains the bond yield, maturity contains the associated bond maturity, and mtype contains an index (ranging from 1 to 17) that sequentially labels bonds of increasing maturity. The data have been extended for two more years by adding missing yields for the years 2001 and 2002, which causes the SSM procedure to produce model forecasts for this span.

```
data Dns;
input date : date. yield maturity mtype;
format date date.;
datalines;
1-Jan-70    8.019    3    1
1-Jan-70    8.091    6    2
1-Jan-70    8.108    9    3

   ... more lines ...
```

In addition, suppose you are interested in extrapolating the fitted model to predict the yield of a hypothetical bond that has a maturity of 42 months and is not traded on the general exchange. The following DATA step creates the necessary missing values for this new bond, which is assigned the index of 18—that is, the value of mtype is 18:

```
data tmp1;
   set dns(keep=date);
   by date;
   if first.date then do;
       yield = .;
       maturity = 42;
       mtype = 18;
       output;
   end;
run;

 proc append data=tmp1 base=dns; run;
 proc sort data=dns;
 by date;
 run;
```

Suppose that $\theta_t(\tau)$ denotes the (idealized) yield at time t that is associated with a bond of maturity τ (in months). Even if time is not measured continuously and the bonds of only certain maturities are traded, $\theta_t(\tau)$ is treated as a smooth function of two continuous variables, time t and maturity τ. Koopman, Mallee, and van der Wel (2010) discuss a variety of models for $\theta_t(\tau)$, which is called the yield surface. One of these models depends on a positive, time-varying, scalar parameter λ_t and a time-varying three-dimensional vector

parameter $\boldsymbol{\beta}_t$. This model can be described as follows:

$$\begin{aligned}\theta_t(\tau) &= \theta(\tau;\lambda_t,\boldsymbol{\beta}_t)\\ &= \beta_{1t}+\beta_{2t}\left(\frac{1-\exp(-\lambda_t\tau)}{\lambda_t\tau}\right)+\beta_{3t}\left(\frac{1-\exp(-\lambda_t\tau)}{\lambda_t\tau}-\exp(-\lambda_t\tau)\right)\end{aligned}$$

This model is a dynamic version of a static model discussed in Nelson and Siegel (1987), where λ_t and $\boldsymbol{\beta}_t$ are time invariant. For fixed time period t, the three terms in this model have relatively simple interpretation. The first term β_{1t} can be thought of as the overall yield level because it does not depend on τ, the bond maturity. It can also be thought of as the long term yield because as $\tau \uparrow \infty$ the other two terms vanish; the coefficients of both β_{2t} and β_{3t} converge to 0 as $\tau \uparrow \infty$ (recall that λ_t is positive). Next, note that as $\tau \downarrow 0$ the coefficient of β_{2t} in the second term converges to 1 while that of β_{3t} in the third term converges to 0; therefore the second term can be thought of as a correction to the overall yield that is associated with the short term bonds. Finally, note that the coefficient of β_{3t} in the third term is a unimodal function of τ that decays monotonically to 0 as $\tau \downarrow 0$ and as $\tau \uparrow \infty$; therefore the third term is associated with the medium term bond yields. It is postulated that the observed yield, denoted by $y_t(\tau)$, is a noisy version of this unobserved (true) yield $\theta_t(\tau)$. The observed yield can be modeled as

$$\begin{aligned}y_t(\tau) &= \theta(\tau;\lambda_t,\boldsymbol{\beta}_t)+\epsilon_{t,\tau}\\ &= \beta_{1t}+\beta_{2t}\left(\frac{1-\exp(-\lambda_t\tau)}{\lambda_t\tau}\right)+\beta_{3t}\left(\frac{1-\exp(-\lambda_t\tau)}{\lambda_t\tau}-\exp(-\lambda_t\tau)\right)+\epsilon_{t,\tau}\\ (\boldsymbol{\beta}_t-\boldsymbol{\mu}) &= \boldsymbol{\Phi}(\boldsymbol{\beta}_{t-1}-\boldsymbol{\mu})+\boldsymbol{\eta}_t\end{aligned}$$

where $\epsilon_{t,\tau}$ are zero-mean, independent, Gaussian variables with variance σ_τ^2, and $\boldsymbol{\eta}_t$ is a three-dimensional, Gaussian white noise. That is, $\boldsymbol{\beta}_t$ is a VAR(1) process with mean vector $\boldsymbol{\mu}$. The remainder of this example explains how to use the SSM procedure to fit this model to the yield data in the Dns data set.

Suppose that variables Z1, Z2, and Z3 are defined as the coefficients of β_{1t}, β_{2t}, and β_{3t}, respectively. That is,

$$\begin{aligned}Z1 &= 1\\ Z2 &= \frac{1-\exp(-\lambda_t\tau)}{\lambda_t\tau}\\ Z3 &= \frac{1-\exp(-\lambda_t\tau)}{\lambda_t\tau}-\exp(-\lambda_t\tau)\end{aligned}$$

In this case,

$$\theta_t(\tau) = Z1*\beta_{1t}+Z2*\beta_{2t}+Z3*\beta_{3t}$$

Let $\boldsymbol{\zeta}_t = \boldsymbol{\beta}_t - \boldsymbol{\mu}$. Then $\boldsymbol{\zeta}_t$ is a zero-mean VAR(1) process and $\boldsymbol{\beta}_t = \boldsymbol{\zeta}_t + \boldsymbol{\mu}$. In particular,

$$\begin{aligned}\theta_t(\tau) &= Z1*\beta_{1t}+Z2*\beta_{2t}+Z3*\beta_{3t}\\ &= Z1*\zeta_{1t}+Z2*\zeta_{2t}+Z3*\zeta_{3t}+Z1*\mu_1+Z2*\mu_2+Z3*\mu_3\end{aligned}$$

This shows that the model for $y_t(\tau)$ can be cast into a state space form with the following observation equation:

$$y_t(\tau) = \mathbf{Z}\boldsymbol{\zeta}_t + \mathbf{Z}\boldsymbol{\mu} + \epsilon_{t,\tau}$$

The underlying six-dimensional state vector $\boldsymbol{\alpha}_t$ is formed by joining the two independent subvectors, $\boldsymbol{\zeta}_t$ (which is a zero-mean, VAR(1) process) and the constant mean vector $\boldsymbol{\mu}$. That is, $\boldsymbol{\alpha}_t = (\zeta_{1t}\ \zeta_{2t}\ \zeta_{3t}\ \mu_1\ \mu_2\ \mu_3)'$.

Note that the variables Z2 and Z3 depend on the time varying parameter λ_t, which is unknown. λ_t is assumed to be a smooth and positive function of time t. In what follows λ_t is represented as an exponential of a cubic spline—a B-spline— in time with four evenly spaced interior knots between January 1970 and December 2002. A cubic spline with four interior knots can be represented as a sum of seven (number of knots + spline degree + 1) B-spline basis functions, $c_{1t}, c_{2t}, \ldots, c_{7t}$, for example. More specifically, λ_t can be expressed as

$$\lambda_t = \exp(v1 * c_{1t} + \ldots + v7 * c_{7t})$$

for some parameters $v1, v2, \ldots, v7$ and the B-spline basis functions (of time) $c_{1t}, c_{2t}, \ldots, c_{7t}$. Thus, the variables Z2 and Z3 become known functions of time, except for the parameters $v1, v2, \ldots, v7$, which are estimated from the data. The following statements augment the Dns data set with the B-spline basis columns in two steps. First a data set that contains the basis columns, c1–c7, is created by using the BSPLINE function in the IML procedure. This data set is then merged with the Dns data set.

```
proc iml;
   use dns;
   read all var {date} into x;
   bsp = bspline(x, 2, ., 4);
   create spline var{c1 c2 c3 c4 c5 c6 c7};
   append from bsp;
quit;
data dns;
   merge dns spline;
run;
```

The following statements use the SSM procedure to perform the model fitting and forecasting calculations. The variance of the observation equation disturbance for the hypothetical bond (mtype = 18) is taken to be the average of the neighboring bonds (mtype = 10 and 11), whose maturities are 36 and 48 months, respectively.

```
 proc ssm data=Dns optimizer(technique=dbldog maxiter=400);
      id date interval=month;

     /* Time-varying parameter lambda */
     parms v1-v7;
     lambda = exp(v1*c1 + v2*c2 + v3*c3 + v4*c4
          + v5*c5 + v6*c6 + v7*c7);

     /* Observation equation disturbance -- separate variance for each maturity */
     parms sigma1-sigma17 / lower=1.e-4;
     array s_array(17) sigma1-sigma17;
      do i=1 to 17;
         if (mtype=i) then sigma = s_array[i];
      end;
      if (mtype=18) then sigma = (sigma10+sigma11)/2;
      irregular wn variance=sigma;

      /* Variables Z1, Z2, Z3 needed in the observation equation */
      Z1= 1.0;
      tmp = lambda*maturity;
      Z2 = (1-exp(-tmp))/tmp;
      Z3 = ( 1-exp(-tmp)-tmp*exp(-tmp) )/tmp;
```

```
    /* Zero-mean VAR(1) factor zeta and the associated component */
   state zeta(3) type=VARMA(p(d)=1) cov(g) print=(cov ar);
   comp zetaComp = (Z1-Z3)*zeta;

   /* Constant mean vector mu and the associated component */
    state mu(3) type=rw;
    comp muComp = (Z1-Z3)*mu;

    /* Observation equation */
    model yield = muComp zetaComp wn;

    /* Various components defined only for output purposes  */
    eval yieldSurface = muComp + zetaComp;

    comp zeta1 = zeta[1];
    comp zeta2 = zeta[2];
    comp zeta3 = zeta[3];
    comp mu1 = mu[1];
    comp mu2 = mu[2];
    comp mu3 = mu[3];

    comp z2zeta = (Z2)*zeta[2];
    comp z3zeta = (Z3)*zeta[3];
    comp z2Mu =  (Z2)*mu[2];
    comp z3Mu =  (Z3)*mu[3];

    eval beta1 = mu1 + zeta1;
    eval beta2 = mu2 + zeta2;
    eval beta3 = mu3 + zeta3;

    eval shortTem = z2zeta + z2Mu;
    eval medTerm = z3zeta + z3Mu;

    /* output the component estimates and the forecasts */
    output out=dnsFor pdv;
run;
```

The DBLDOG optimization technique is used for parameter estimation since it is computationally more efficient in this example. The transition matrix, $\mathbf{\Phi}$, in the VAR(1) specification of $\boldsymbol{zeta}$ is taken to be diagonal (TYPE=VARMA(P(D)=1)) because the use of more general square matrix did not improve the model fit significantly. The mean vector $\boldsymbol{mu}$ (recall that $\boldsymbol{beta}_t = \boldsymbol{zeta}_t + \boldsymbol{mu}$) is specified as a three-dimensional random walk with zero disturbance covariance (signified by the absence of COV= option). The model specification part of the program ends with the MODEL statement; the subsequent COMP and EVAL statements define some useful linear combinations of the underlying state. Their estimates are computed after the model fit is completed and are output to the output data set dnsFor. The dnsFor data set also contains all the program variables and the parameters defined in the PARMS statement because the OUTPUT statement contains the PDV option.

Output 33.7.1 shows the estimated mean vector ($\boldsymbol{\mu}$). It shows that the mean long-term yield is 7.64. Output 33.7.2 shows the estimates of v1–v7 (used for defining time-varying λ_t) and the maturity specific observation variances. Output 33.7.3 shows the estimate of the VAR(1) transition matrix $\mathbf{\Phi}$, and Output 33.7.4

shows the associated disturbance covariance matrix $\mathbf{\Sigma}$. The model fit summary is shown in Output 33.7.5.

Output 33.7.1 Estimate of the Mean Vector (μ)

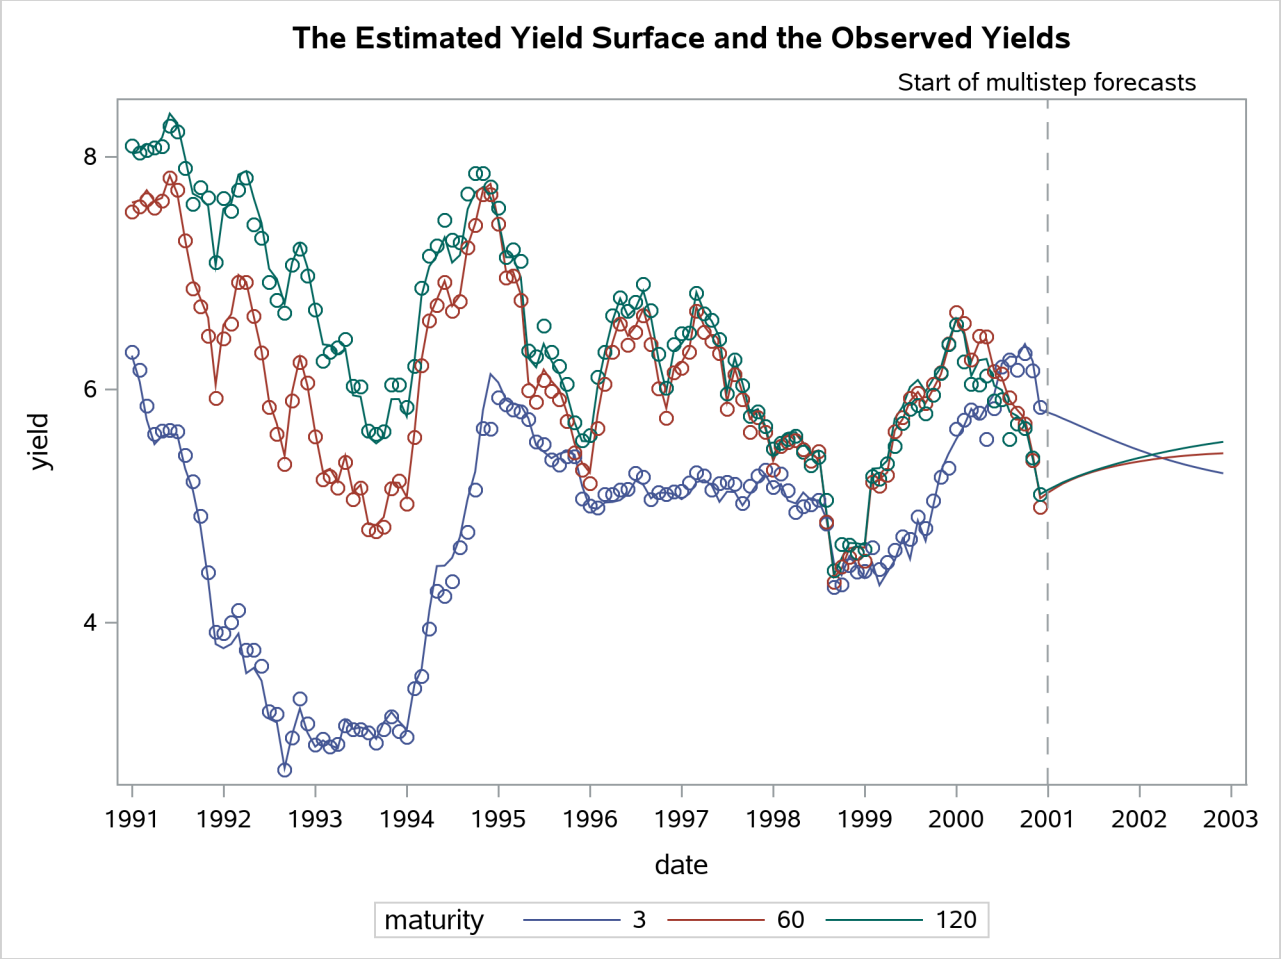
The following statements produce the time series plots of the smoothed estimate of the idealized bond yield ($\theta_t(\tau)$) for bonds with maturities 30, 60, and 120 months (shown in Output 33.7.6). To simplify the display, the plots exclude the time span prior to 1991.

```
proc sgplot data= dnsFor;
    title "The Estimated Yield Surface and the Observed Yields ";
    where maturity in (3 60 120) and date >= '31dec1990'd;
    series x=date y=smoothed_yieldSurface / group=maturity;
    scatter x=date y=yield / group=maturity;
    refline '31dec2000'd / axis=x lineattrs=GraphReference(pattern = Dash)
        name="RefLine"   label="Start of multistep forecasts";
run;
```

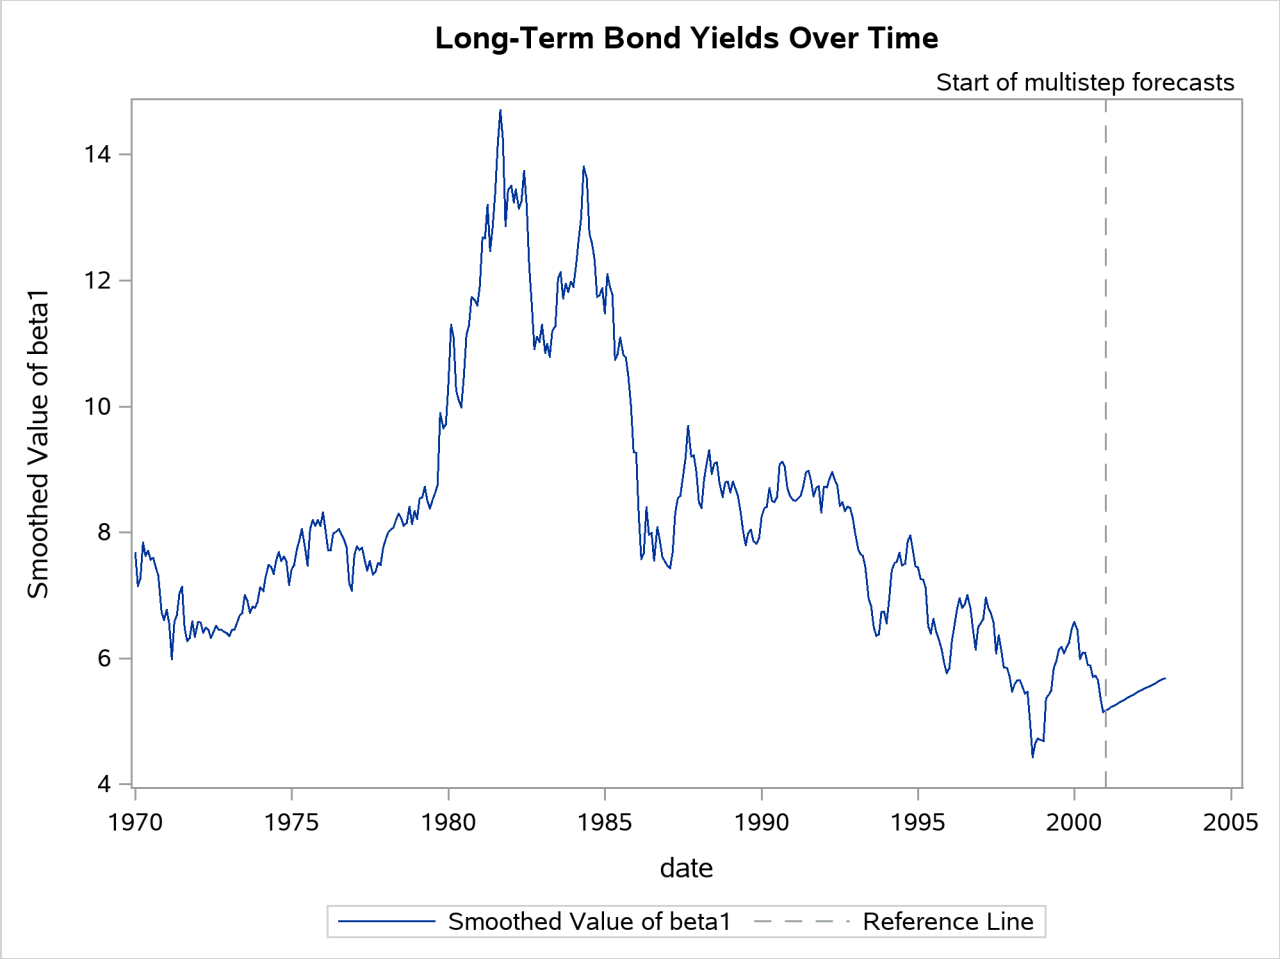
Output 33.7.6 Smoothed Estimate of $\theta_t(\tau)$ for $\tau = 3, 60, 120$



The plots indicate that the DNS model is a reasonable description of the yield data. Similar plots (not shown here) for other maturities also indicate the adequacy of the DNS model. The following statements produce the time series plot of the smoothed estimate of β_{1t}, the long-term bond yield (shown in Output 33.7.7) :

```
proc sgplot data=dnsFor;
   title "Long-Term Bond Yields Over Time ";
   series x=date y=smoothed_beta1 ;
   refline '31dec2000'd / axis=x lineattrs=GraphReference(pattern = Dash)
        name="RefLine"   label="Start of multistep forecasts";
run;
```

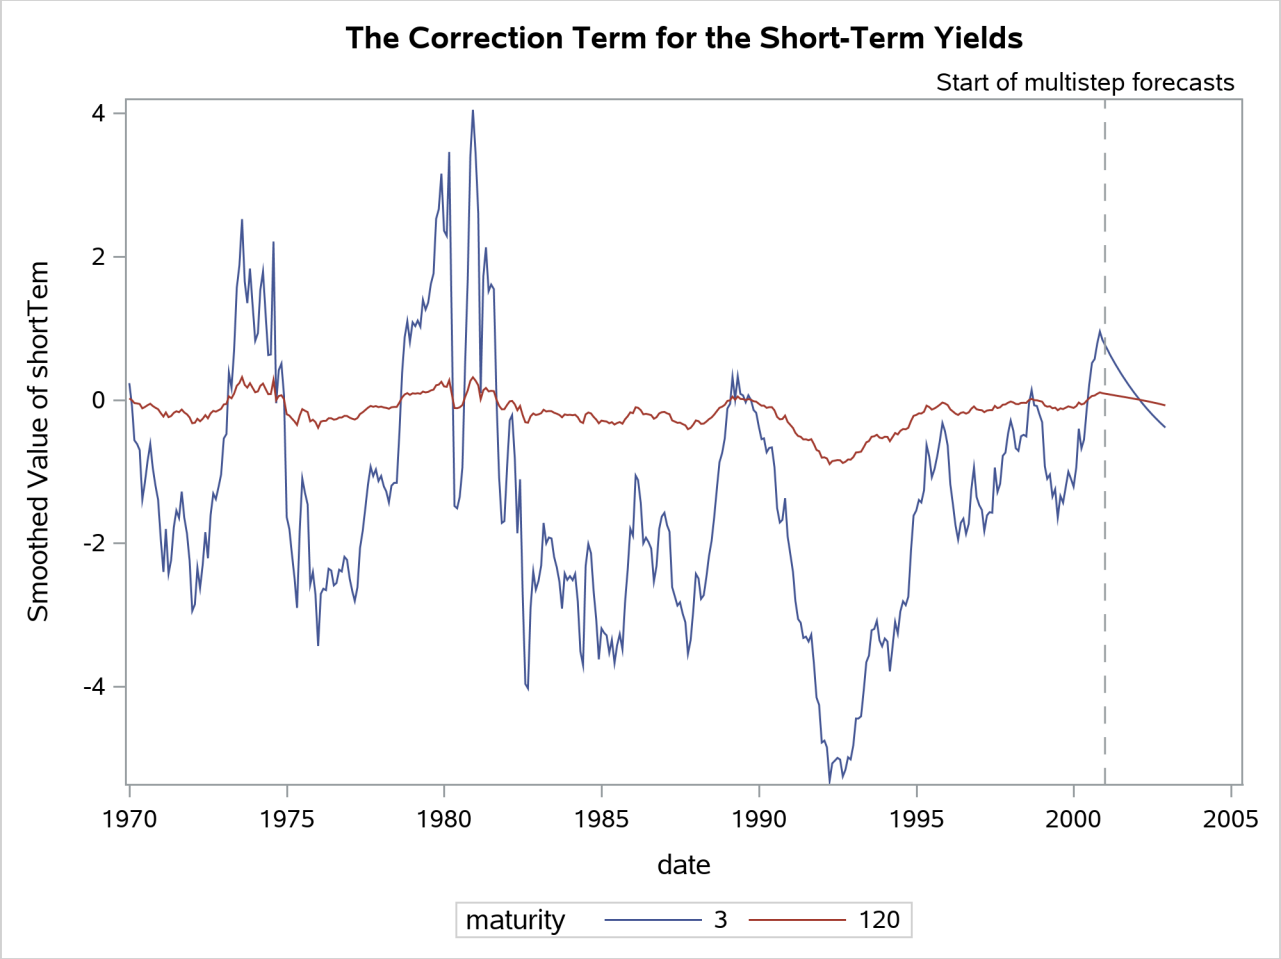
Output 33.7.7 Smoothed Estimate of β_{1t}, the Long-Term Yield



Similarly, Output 33.7.8, which is produced by the following statements, shows the smoothed estimate of the correction to the overall yield that is provided by the second term ($Z2 * \beta_{2t}$) for maturities of 3 months and 120 months. As expected, the correction for the (long-term) maturity of 120 months is negligible compared to the (short-term) maturity of 3 months.

```
proc sgplot data=dnsFor;
  title "The Correction Term for the Short-Term Yields ";
  where maturity in (3 120);
  series x=date y=smoothed_shortTem / group=maturity;
  refline '31dec2000'd / axis=x lineattrs=GraphReference(pattern = Dash)
        name="RefLine"   label="Start of multistep forecasts";
run;
```

Output 33.7.8 Smoothed Estimate of $Z2 * \beta_{2t}$, the Correction Term for the Short-Term Yields



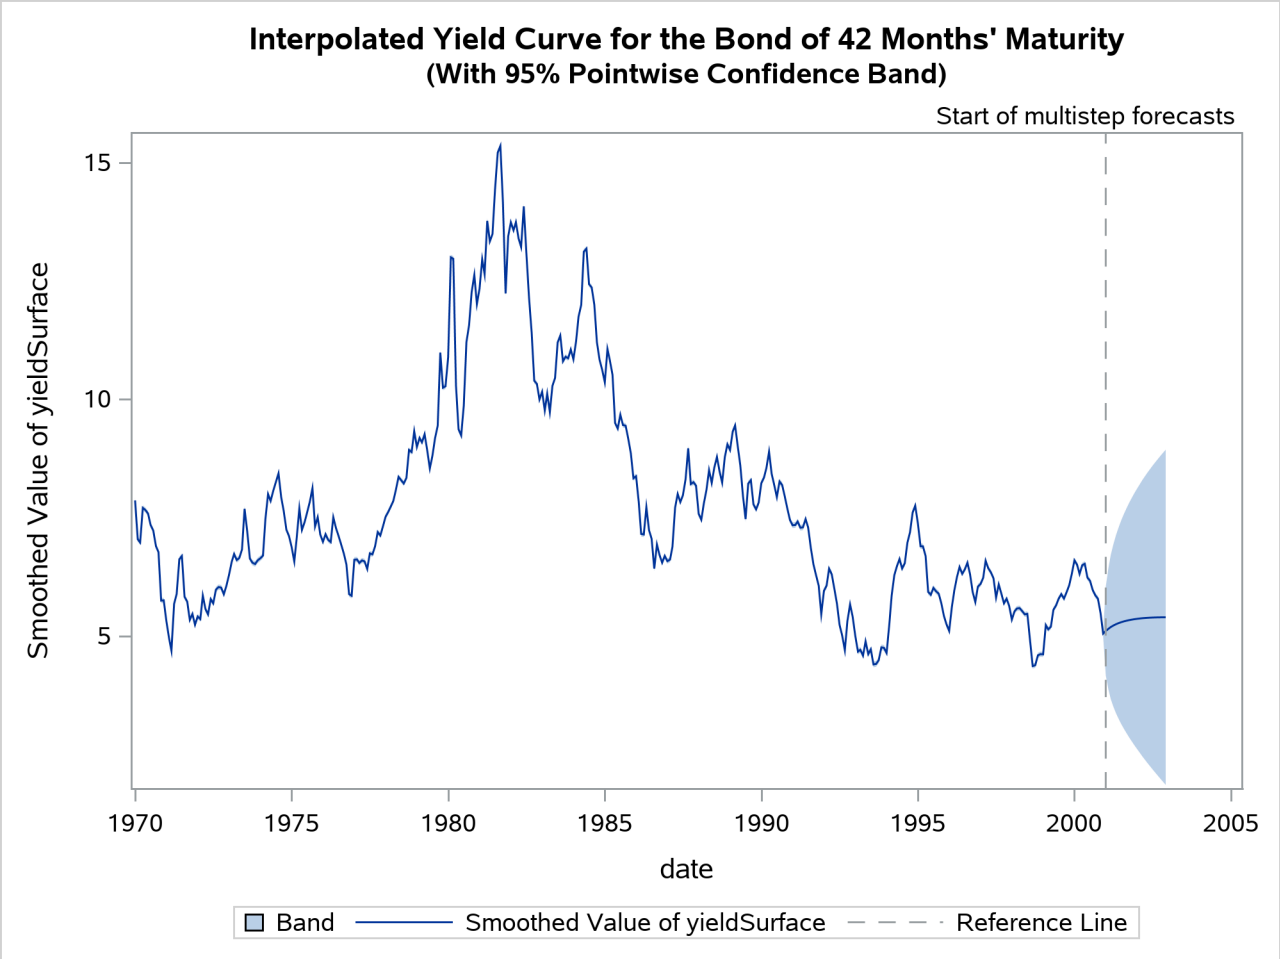
The following statements create plots that show the estimated yield for the hypothetical bond whose maturity is 42 months:

```
proc sgplot data=dnsFor;
   title "Interpolated Yield Curve for the Bond of 42 Months' Maturity";
   title2 "(With 95% Pointwise Confidence Band)";
   where maturity in (42);
   band x=date lower=smoothed_lower_yieldSurface upper=smoothed_upper_yieldSurface;
   series x=date y=smoothed_yieldSurface;
   refline '31dec2000'd / axis=x lineattrs=GraphReference(pattern = Dash)
      name="RefLine"   label="Start of multistep forecasts";
run;

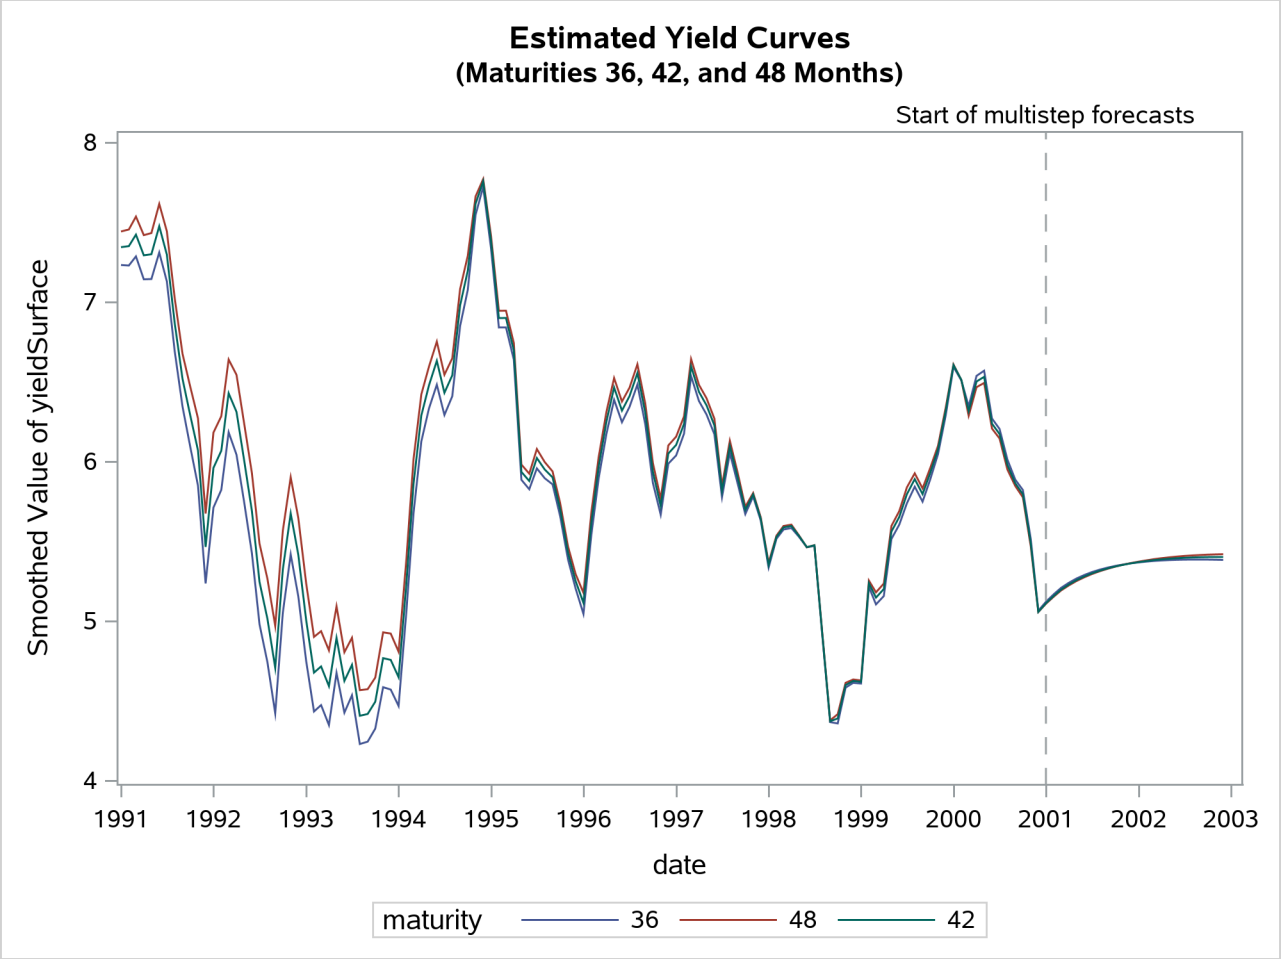
proc sgplot data= dnsFor;
  title "Estimated Yield Curves";
  title2 "(Maturities 36, 42, and 48 Months)";
  where maturity in (36 42 48) and date >= '31dec1990'd;
  series x=date y=smoothed_yieldSurface / group=maturity;
  refline '31dec2000'd / axis=x lineattrs=GraphReference(pattern = Dash)
      name="RefLine"   label="Start of multistep forecasts";
run;
```

Output 33.7.9 shows the interpolated yield curve with a pointwise 95% confidence band. In the historical period, the confidence band appears too tight, mostly because of graphical scaling.

Output 33.7.9 Interpolated Yield Curve for 42 Months' Maturity



Output 33.7.10 Estimated Yield Curves



Output 33.7.10 shows the estimates of $\theta_t(\tau)$ for $\tau = 36$, 42, and 48 months. As expected, the estimated $\theta_t(42)$ lies between the estimates of $\theta_t(36)$ and $\theta_t(48)$.

Example 33.8: Diagnostic Plots and Structural Break Analysis

This example provides information about the diagnostic plots that the SSM procedure produces. In addition, a simple illustration of structural break analysis is also provided. For additional examples of structural break analysis, see Selukar (2017). The following plots are available in the SSM procedure:

- a panel of two plots—a histogram and a Q-Q plot—for the normality check of the one-step-ahead residuals $v_{t,i}$. A separate panel is produced for each response variable.
- a time series plot of standardized residuals, one per response variable
- a panel of two plots—a histogram and a Q-Q plot—for the normality check of the prediction errors $\mathrm{AO}_{t,i}$. A separate panel is produced for each response variable.
- a time series plot of standardized prediction errors, one per response variable

- a time series plot of maximal state shock chi-square statistics

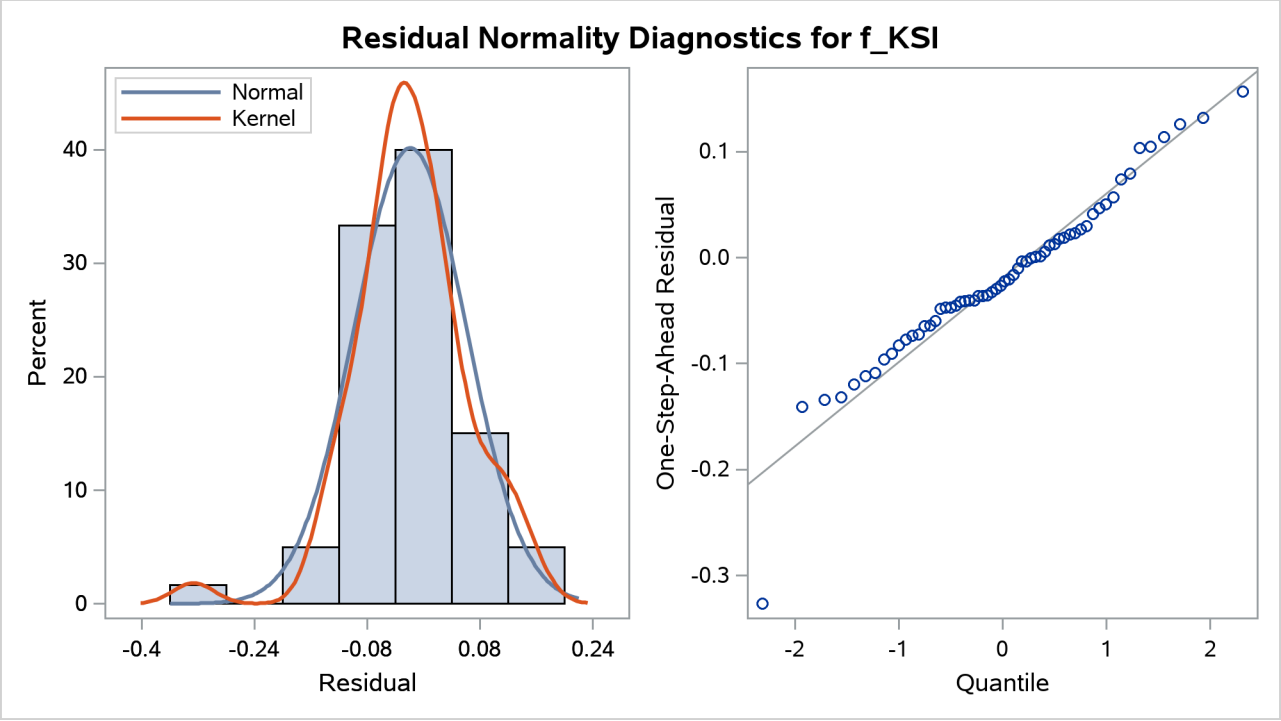
All these plots are used primarily for model diagnostics. In this example, the automobile seat-belt data that are discussed in Example 33.1 are revisited. In Example 33.1, the question under consideration is whether the data show evidence of the effectiveness of the seat-belt law that was introduced in the first quarter of 1983. An intervention variable, Q1_83_Shift, was used in the model to measure the effect of this law on the drivers and front-seat passengers who were killed or seriously injured in car accidents (f_KSI). In the current example, the analysis of these data begins without the knowledge of this seat-belt law. In effect, the same model is fitted without the use of the intervention variable Q1_83_Shift.

The following statements specify the model (without the intervention variable):

```
proc ssm data=seatBelt optimizer(tech=interiorpoint) plots=all;
   id date interval=quarter;
   state error(2) type=WN cov(g);
   component wn1 = error[1];
   component wn2 = error[2];
   state level(2) type=RW cov(rank=1) checkbreak;
   component rw1 = level[1];
   component rw2 = level[2];
   state season(2) type=season(length=4);
   component s1 = season[1];
   component s2 = season[2];
   model f_KSI = rw1 s1  wn1;
   model r_KSI = rw2 s2 wn2;
run;
```

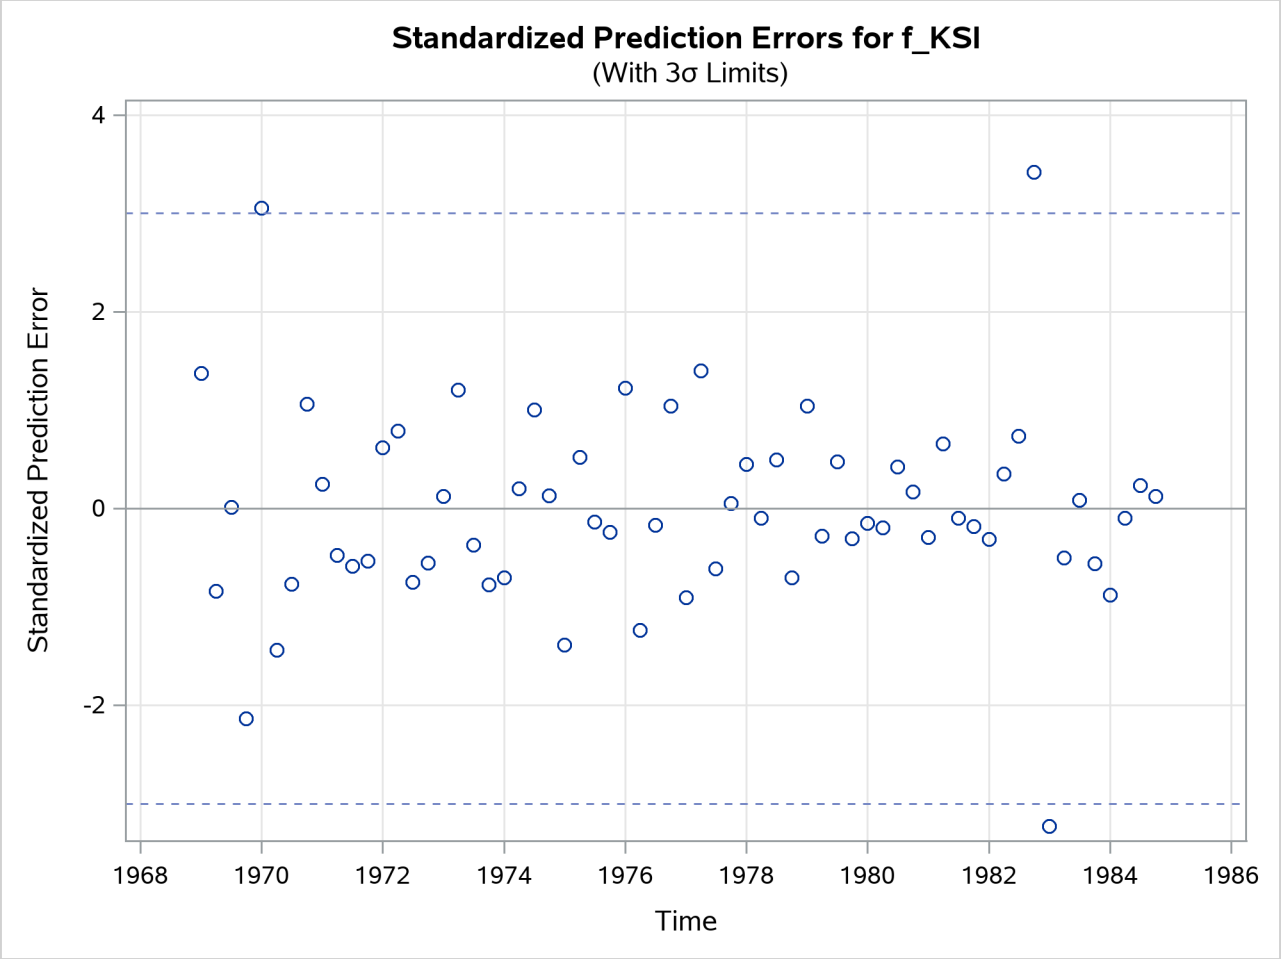
The PLOTS=ALL option in the PROC SSM statement turns on all the plotting options. Because there are two response variables, nine plots in total are produced: a separate set of four plots—two residual and two prediction error—is produced for f_KSI and r_KSI, and one maximal shock plot is produced. Only three of these plots are shown here. Output 33.8.1 shows the normality check for the one-step-ahead residuals for f_KSI. It shows some evidence of lack of normality.

Output 33.8.1 Normality Check of One-Step-Ahead Residuals for f_KSI



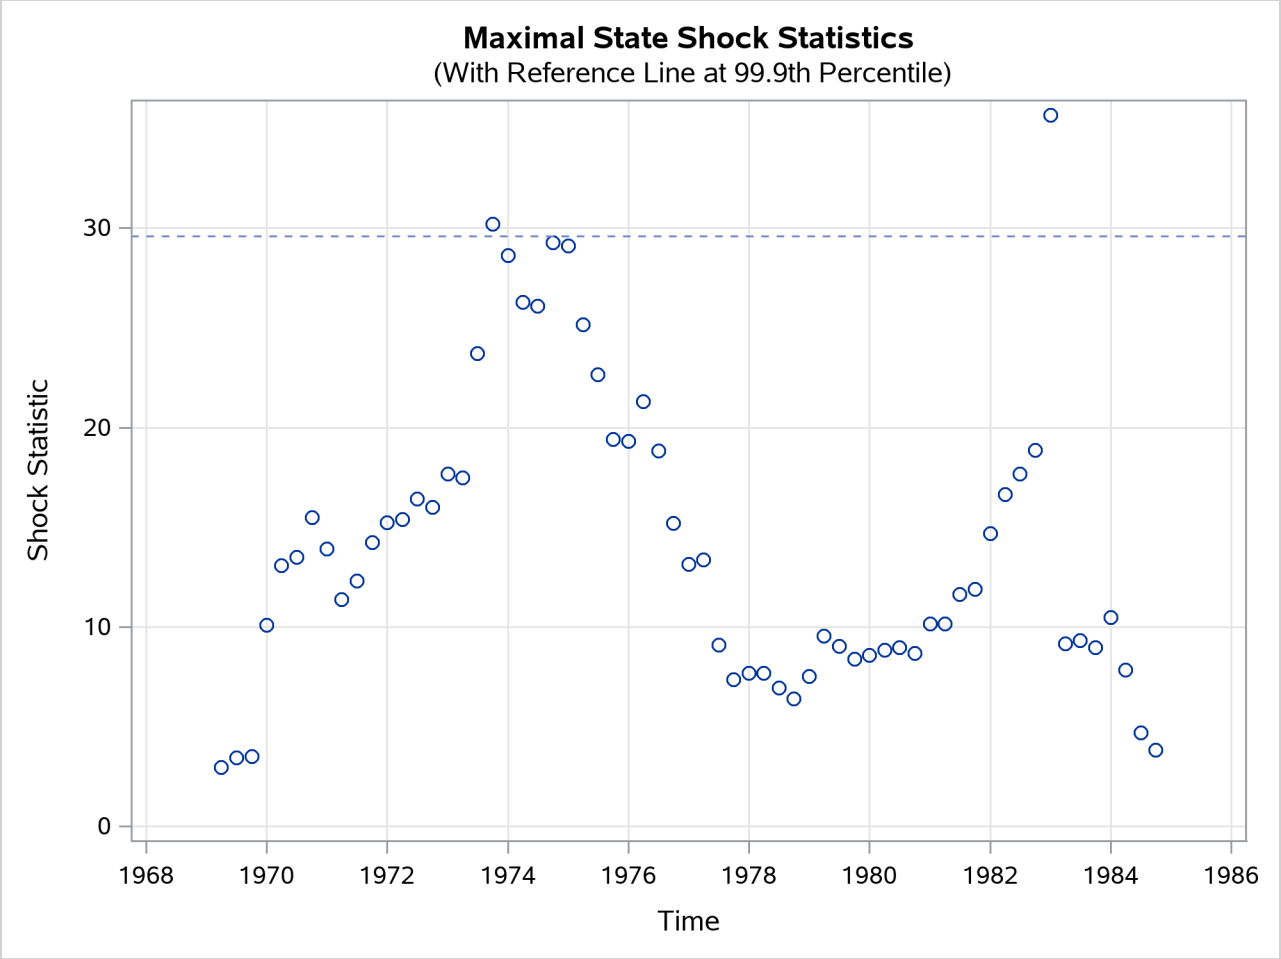
Output 33.8.2 shows the time series plot of standardized prediction errors for f_KSI. It identifies some extreme observations (additive outliers): two near 1983 and one near 1970.

Output 33.8.2 Time Series Plot of Standardized Prediction Errors for f_KSI



Output 33.8.3 shows the time series plot of maximal shock statistics. This plot can be very informative in showing the temporal locations of the structural changes in the overall observation-generation process (treating the fitted model as the reference). It can indicate locations of shifts in the process level or shifts in other characteristics, such as its slope. The precise nature of the shift (whether the shift occurs in the level or in some other aspects) can be determined by using the CHECKBREAK option in the appropriate STATE and TREND statements (as is done in the STATE statement in this example that defines the bivariate state level). In this example, the maximal shock statistics plot indicates two locations—the last quarter of 1973 and the first quarter of 1983—as likely locations for the structural breaks that are associated with the traffic accident process. These are indeed reasonable findings, because the last quarter of 1973 (beginning in October 1973) is associated with the start of the oil crisis that severely curtailed worldwide automobile traffic, and the first quarter of 1983 is associated with the introduction of the seat-belt law that might have improved the safety of drivers and front-seat passengers. In addition, Output 33.8.4 shows the summary of most likely break locations for the bivariate state level. It identifies a break in the first element of level (which corresponds to the drivers and front-seat passengers) in the first quarter of 1983.

Output 33.8.3 Time Series Plot of Maximal Shock Statistics



Output 33.8.4 Elementwise Break Summary for the Bivariate State: level

Elementwise Break Summary for level

Element ID	Index	Z Value	Pr > |z|
1983:1	1	-5.85	<.0001

The following statements fit a revised model that accounts for the break in the first element of level by introducing a dummy variable, Q1_83_Pulse, in the state equation:

```
ods output ElementStateBreakDetails=stateBreak;
proc ssm data=seatBelt optimizer(tech=interiorpoint) plots=all;
   id date interval=quarter;
   Q1_83_Pulse = (date = '1jan1983'd);
   zero = 0;
   state error(2) type=WN cov(g);
   component wn1 = error[1];
   component wn2 = error[2];
```

```
   state level(2) type=RW cov(rank=1) W(g)=(Q1_83_Pulse zero)
       checkbreak print=breakdetail;
   component rw1 = level[1];
   component rw2 = level[2];
   state season(2) type=season(length=4);
   component s1 = season[1];
   component s2 = season[2];
   model f_KSI =  rw1 s1  wn1;
   model r_KSI = rw2 s2 wn2;
run;
```

Note that using Q1_83_Pulse in the definition of level is equivalent to using Q1_83_Shift in the MODEL statement for f_KSI in Example 33.1. Output 33.8.5 shows the estimated change in the first element of the state level, which is the same as the estimated level shift shown in Output 33.1.6 (this is not surprising, because these two models are statistically equivalent).

Output 33.8.5 Estimate of the Regression Coefficient of Q1_83_Pulse

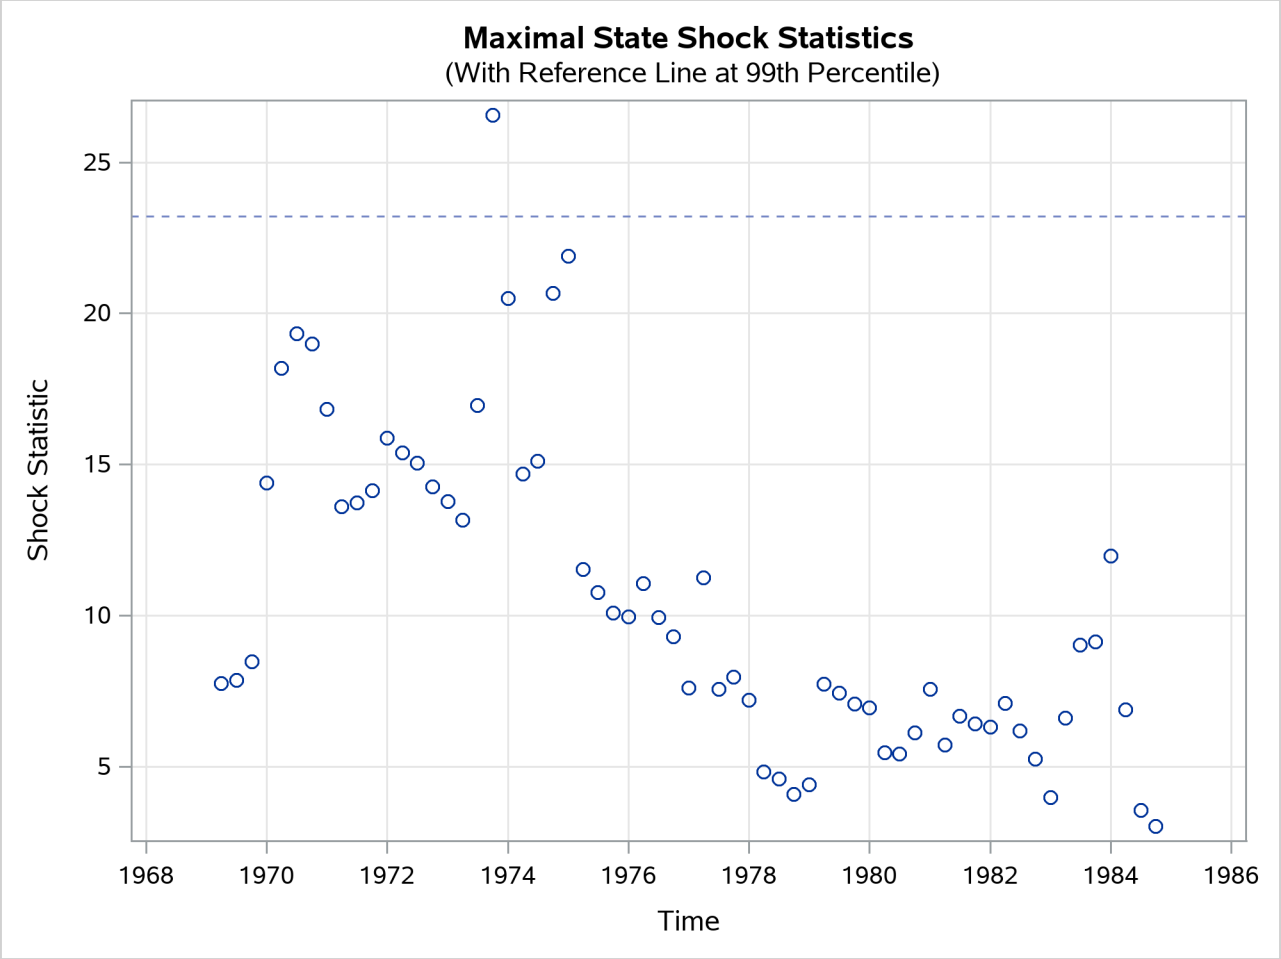
The SSM Procedure

Estimate of the State Equation Regression Vector

State	Element Index	Estimate	Standard Error	t Value	Pr > |t|
level	1	-0.408	0.0259	-15.74	<.0001

In the preceding SSM procedure statements, the CHECKBREAK option is used along with the PRINT=BREAKDETAIL option, which produces a table that contains the break statistics at every distinct time point (this table, in turn, is captured in the output data set stateBreak for later use). Output 33.8.6 shows the time series plot of maximal shock statistics for this revised model. As expected, the plot no longer shows the first quarter of 1983 as a structural break location. It continues to show the last quarter of 1973 as a structural break location, because the fitted model does not try to explicitly account for this shift.

Output 33.8.6 Time Series Plot of Maximal Shock Statistics for the Model with Q1_83_Pulse

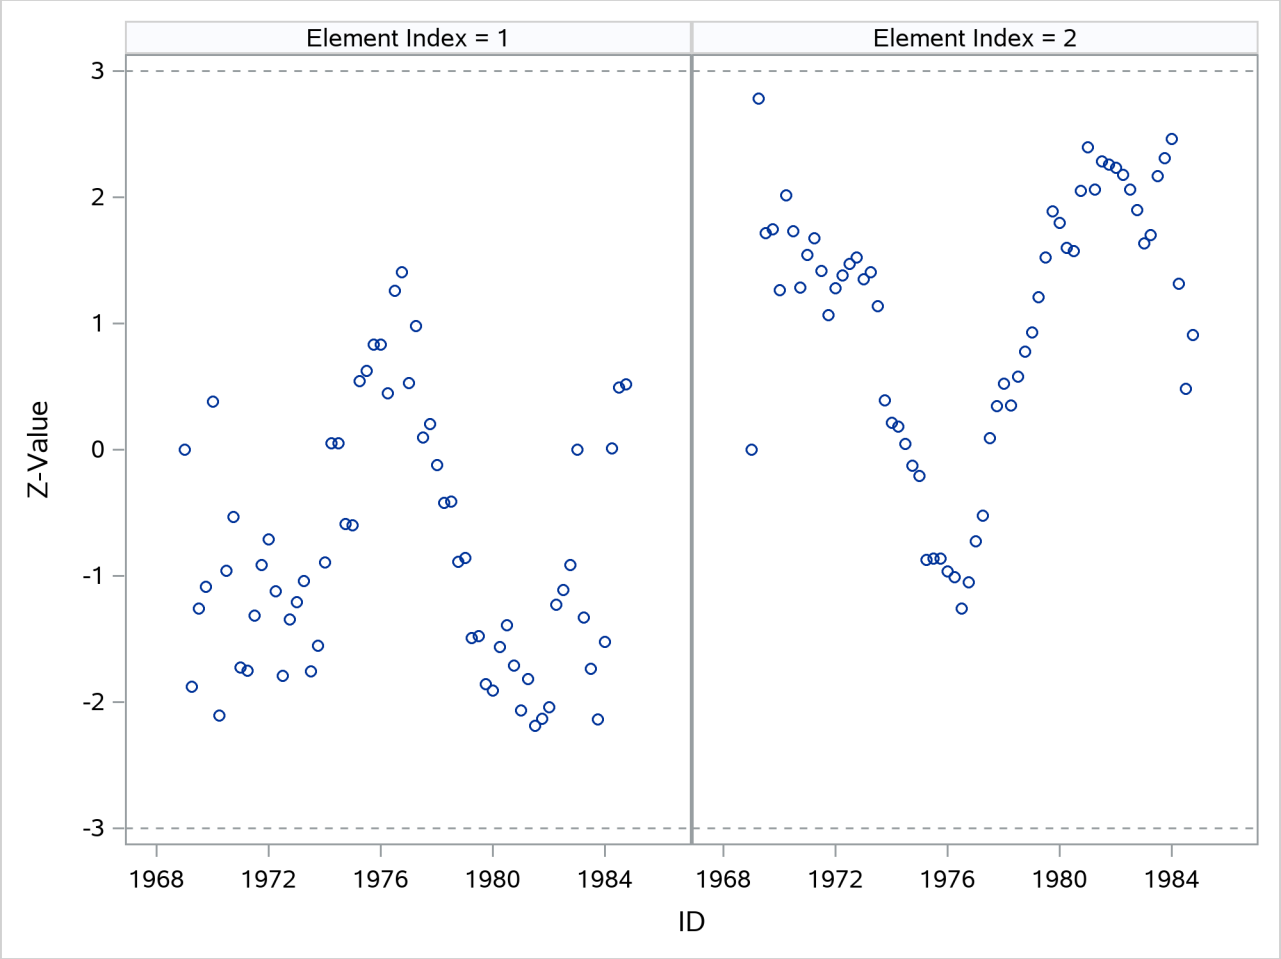


Note that the reference line in Output 33.8.3 is drawn at the 99.9th percentile, whereas the reference line in Output 33.8.6 is drawn at the 99th percentile. The reference line location in the maximal state shock chi-square statistics plot is based on the points in the plot. A reference line is drawn at percentile 80, 90, 99, or 99.9 based on the largest maximal shock statistic that is shown.

The detailed information in the data set stateBreak can be used to further investigate the possibility of significant breaks in the trend in and around 1973. The following statements produce scatter plots for the break statistics for both the drivers and front passengers and the rear passengers (reference lines are also drawn at –3 and 3 to check for extreme Z values):

```
proc sgpanel data=stateBreak;
    panelby elementIndex;
    scatter x=time y=zValue;
    refline 3 / axis=y lineattrs=(pattern=shortdash) noclip;
    refline -3 / axis=y lineattrs=(pattern=shortdash) noclip;
run;
```

Output 33.8.7 Elementwise Structural Break Statistics for level



The resulting graph, shown in Output 33.8.7, shows possible breaks in the second element—rear side passengers—around 1969. In general, however, the evidence of breaks in the elements of level is not very strong. This means that you must look elsewhere to explain the extreme point in Output 33.8.6.

Example 33.9: Longitudinal Data: Variable Bandwidth Smoothing

The data for this example, taken from Givens and Hoeting (2005, chap. 11, Example 11.8), contain two variables, x and y. The variable y represents noisy evaluation of an unknown smooth function at x. The data are sorted by x.

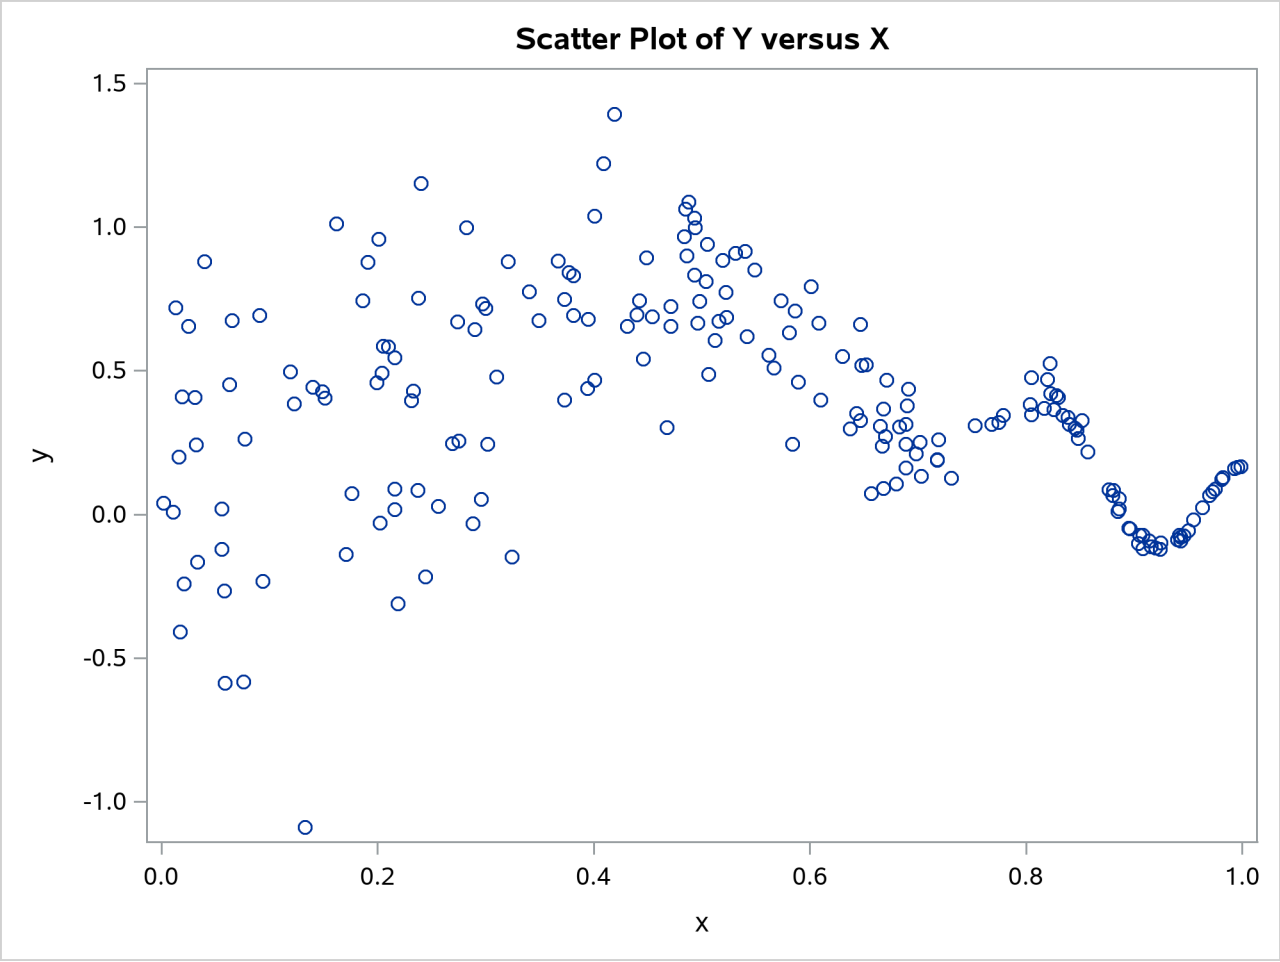
```
data Difficult;
input x y;
datalines;
0.002 0.040
0.011 0.009
0.013 0.719
0.016 0.199
0.017 -0.409
```

```
... more lines ...
```

Output 33.9.1 shows the scatter plot of y against x that is generated by the following statements:

```
proc sgplot data=Difficult;
   title "Scatter Plot of Y versus X";
   scatter x=x y=y ;
run;
```

Output 33.9.1 Scatter Plot of Y versus X



The plot clearly shows that the variance of y values varies considerably over the range of x values—the variance is larger for x values around 0.2 and gets increasingly smaller as the x values get closer to 1. Givens and Hoeting (2005) discuss the difficulties of extracting a smooth pattern from such data. Consider the following model for y:

$$\mathrm{y}(x) = \boldsymbol{\mu}_x + \boldsymbol{\epsilon}_x$$

where $\boldsymbol{\mu}_x$ is a smooth trend component and $\boldsymbol{\epsilon}_x$ is the observation noise with variance, $h(x)$, which changes with x: $\boldsymbol{\epsilon}_x \sim N(0, h(x))$. It is known (Durbin and Koopman 2012, chap. 3, sect. 9 and chap. 8, sect. 5) that modeling the trend $\boldsymbol{\mu}_x$ as a polynomial smoothing spline (for example, the way the growth curves are

modeled in Example 33.4) and taking the variance function of the observation noise ϵ_x a constant results in a trend estimate that can be termed a fixed-bandwidth-smoother. The optimal bandwidth turns out to be a function of the signal-to-noise ratio: the ratio of the observation noise variance and the disturbance variance of the trend component. On the other hand, allowing the variance function of the observation noise to change with the x values results in a trend estimate that can be termed a variable-bandwidth-smoother. The rest of this example shows how to use the SSM procedure to create a data-dependent variance function $h(x)$ and to extract the associated (variable-bandwidth) smooth trend from such data. Suppose that the (unknown) variance function $h(x)$ can be approximated as

$$h(x) = \exp(\sum_{i=1}^{7} v_i \ \mathrm{SplineBasis}_i(x))$$

where $v_i, i = 1, 2, \ldots, 7$ are unknown parameters and $\mathrm{SplineBasis}_i(x), i = 1, 2, \ldots, 7$, are the full set of cubic spline basis functions (B-splines) with four evenly spaced internal knots between the range of x values—essentially, four equispaced points between 0.0 and 1.0. Note that the number of basis functions in the full set, 7, is the sum of the number of internal knots, 4, and the degree of the polynomial, 3. The following statements create a data set, Combined, that contains the variables x and y, along with the desired spline basis functions (col1–col7) that are created by using the BSPLINE function in PROC IML:

```
proc iml;
   use difficult;
   /* read x and y from difficult into temp */
   read all var _num_ into temp;
   x = temp[,1];
   /* generate B-spline basis for a cubic spline
      with 4 evenly spaced internal knots in the x-range */
   bsp = bspline(x, 2, ., 4);
   Combined = temp || bsp;
   /* create a merged data set with x, y, and
      spline basis columns                    */
   create Combined var {x y col1 col2 col3 col4 col5 col6 col7};
   append from Combined;
quit;
```

The following statements specify and fit the desired model to the data:

```
proc ssm data=Combined opt(tech=dbldog);
   id x;
   /* parameters needed to define h(x) */
   parms v1-v7;
   /* defining h(x) */
   var = exp(v1*col1 + v2*col2 + v3*col3 + v4*col4
      + v5*col5 + v6*col6 + v7*col7);
   /* defining the polynomial spline trend */
   trend trend(ps(2));
   /* defining the observation noise with variance h(x) */
   irregular wn variance=var;
   model y = trend wn;
   output out=For pdv;
run;
```

Output 33.9.2 shows the estimates of $v_i, i = 1, 2, \ldots, 7$, and Output 33.9.3 shows the estimate of the disturbance variance associated with the polynomial spline trend that is specified in the TREND statement.

Output 33.9.2 Estimates of v1–v7

The SSM Procedure

Estimates of Named Parameters

Parameter	Estimate	Standard Error	t Value
v1	-3.302	1.501	-2.20
v2	-0.826	0.619	-1.33
v3	-2.234	0.453	-4.93
v4	-3.130	0.412	-7.60
v5	-4.306	0.415	-10.38
v6	-6.901	0.588	-11.73
v7	-19.514	2.306	-8.46

Output 33.9.3 Estimate of the Disturbance Variance Associated with the Trend

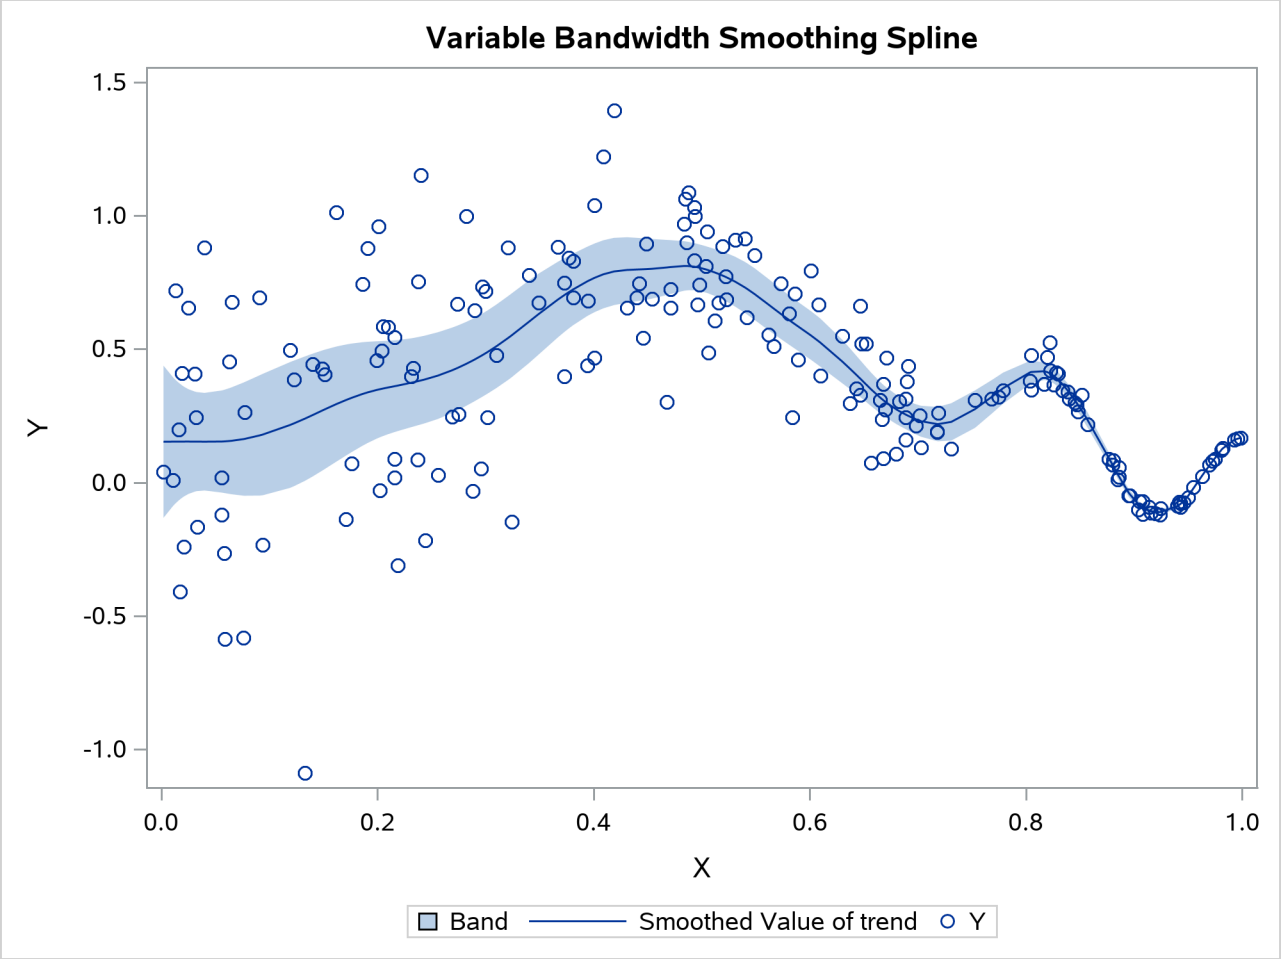
Model Parameter Estimates

Component	Type	Parameter	Estimate	Standard Error	t Value
trend	**PS(2) Trend**	**Level Variance**	339	110	3.07

The following statements produce a plot, shown in Output 33.9.4, of the fitted trend with 95% confidence band:

```
proc sgplot data=For;
   title "Variable Bandwidth Smoothing Spline";
   band x=x lower=smoothed_lower_trend
      upper=smoothed_upper_trend ;
   series x=x y=smoothed_trend;
   scatter x=x y=y;
run;
```

Output 33.9.4 Fitted Trend with 95% Confidence Band

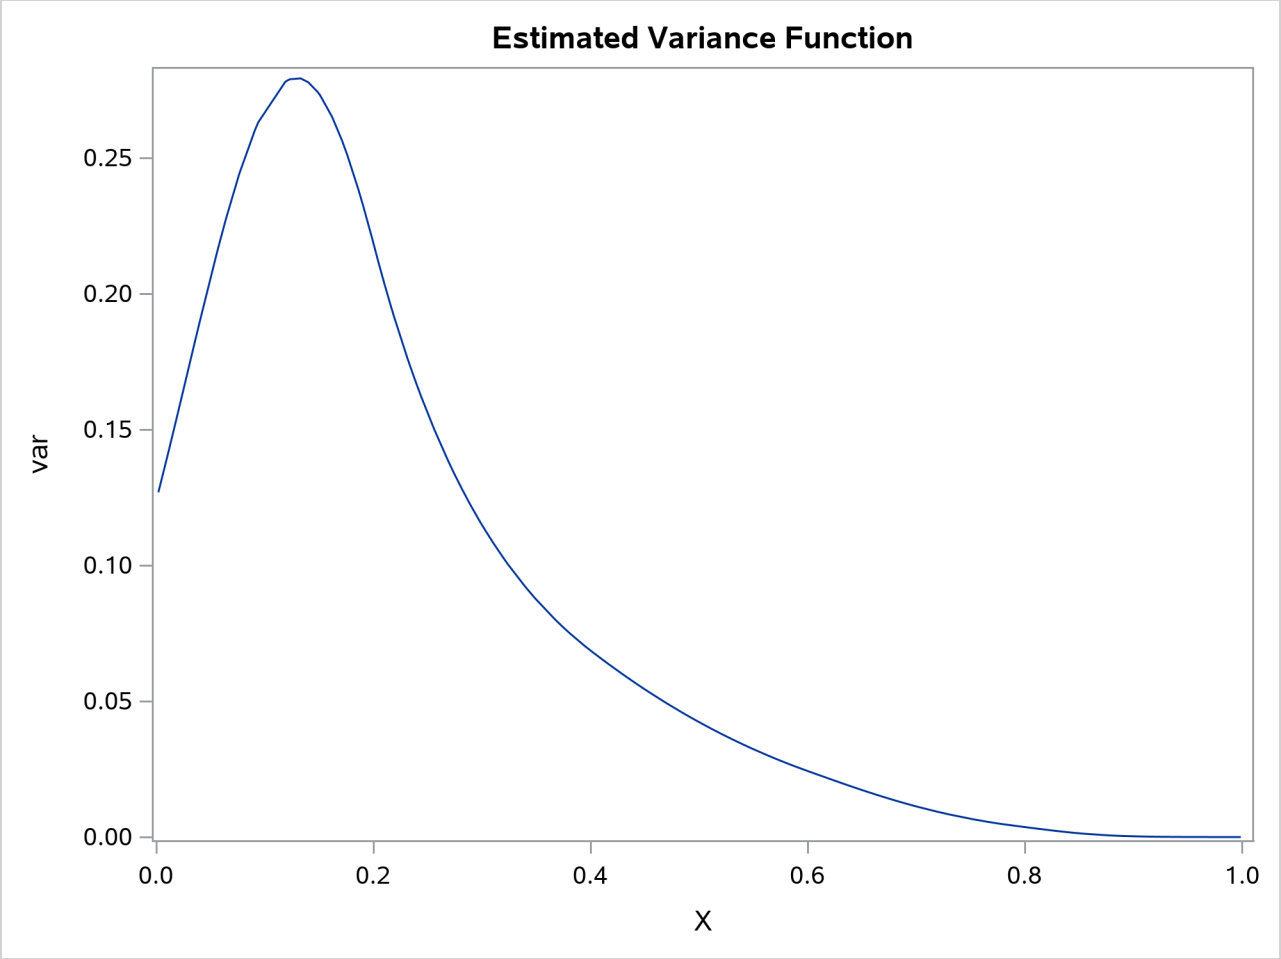


Clearly the fitted curve tracks the data quite well. Lastly, Output 33.9.5 (produced by using the following statements) shows the estimated variance function $h(x)$.

```
proc sgplot data=For;
   title "Estimated Variance Function";
   series x=x y=var;
run;
```

As expected, the curve attains its peak at an x value around 0.18 and decays to nearly 0 as x values reach 1.0.

Output 33.9.5 Estimated Variance Function $h(x) = \exp(\sum_{i=1}^{7} \hat{\nu}_i \ \mathrm{SplineBasis}_i(x))$



Example 33.10: A Transfer Function Model for the Gas Furnace Data

This example describes how you can include components in your model that follow a transfer function model. Transfer function models, a generalization of distributed lag models, are useful for capturing the contributions from lagged values of the predictor series. Box and Jenkins popularized ARIMA models with transfer function inputs in their famous book (Box and Jenkins 1976). This example shows how you can specify an ARIMA model that is suggested in that book to analyze the data collected in an experiment at a chemical factory. The data set, called Series J by Box and Jenkins, contains sequentially recorded measurements of two variables: x, the input gas rate, and y, the output CO_2. For the output CO_2, Box and Jenkins suggest the model

$$y_t = \mu + f_t + \zeta_t$$

where μ is the intercept, ζ_t is a zero-mean noise term that follows a second-order autoregressive model (that is, $\zeta_t \sim \mathrm{AR}(2)$), and f_t follows a transfer function model

$$f_t = \frac{(\gamma_1 B^3 + \gamma_2 B^4 + \gamma_3 B^5)}{(1 - \delta B)} x_t$$

The model for f_t is specified by using the ratio of two polynomials in the backshift operator B. Alternatively, this model can also be described as follows:

$$f_t = \delta f_{t-1} + \gamma_1 x_{t-3} + \gamma_2 x_{t-4} + \gamma_3 x_{t-5}$$

In this alternate form, it is easy to see that the equation for f_t can also be seen as a state evolution equation for a one-dimensional state with a (1×1) transition matrix δ and state regression variables x_{t-3}, x_{t-4}, and x_{t-5} (lagged values of x). This state equation has no disturbance term.

The following statements define the data set Seriesj. The variables x3, x4, and x5, which denote the appropriately lagged values of x, are also created. These variables are used later in the STATE statement that is used to specify f_t.

```
data Seriesj;
   input x y @@;
   label x = 'Input Gas Rate'
         y = 'Output CO2';
   x3 = lag3(x);
   x4 = lag4(x);
   x5 = lag5(x);
   obsIndex = _n_;
   label obsIndex = 'Observation Index';
datalines;
-0.109  53.8  0.000  53.6  0.178  53.5  0.339  53.5
 0.373  53.4  0.441  53.1  0.461  52.7  0.348  52.4
 0.127  52.2 -0.180  52.0 -0.588  52.0 -1.055  52.4

   ... more lines ...
```

The following SSM procedure statements carry out the modeling of y, the output CO_2, according to the preceding model:

```
proc ssm data=Seriesj(firstobs=6);
    id obsIndex;
    parms delta /lower=-0.9999 upper=0.9999;
    state tfstate(1) T(g)=(delta) W(g)=(x3 x4 x5) a1(1) checkbreak;
    comp tfinput = tfstate[1];
    trend ar2(arma(p=2)) ;
    intercept = 1;
    model y = intercept tfinput ar2 ;
    eval modelCurve = intercept + tfinput;
    forecast out=For;
run;
```

The coefficient of the denominator polynomial, δ, is specified in a PARMS statement. It is constrained to be less than 1 in magnitude, which ensures that the transfer function term does not have explosive growth. The transfer function model for f_t is specified in a STATE statement that defines a one-dimensional state named tfstate. In this statement, the transition matrix (which contains only one element, δ) is specified by using the T(g)= option; the state regression variables x3, x4, and x5 are specified by using the W(g)= option; and the CHECKBREAK option is used to turn on the search for unexpected changes in the behavior of f_t. The COV option is absent from this STATE statement because the disturbance term is absent from the state equation for f_t. Moreover, because nothing can be assumed about the initial condition of this state equation, it is taken to be diffuse (as signified by the A1 option). Note that the first five observations of the input data

set, Seriesj, are excluded from the analysis to ensure that the state regression variables x3, x4, and x5 do not contain any missing values. The component that is associated with tfstate, named tfinput, is specified in a COMPONENT statement that follows the STATE statement. A zero-mean, second-order autoregressive noise term, named ar2, is specified by using a TREND statement. Next, a constant regression variable, intercept, is defined to be used in the MODEL statement to capture the intercept term μ. Finally, the model specification is completed by specifying the response variable, y, and the three right-hand terms in the MODEL statement. Next, an EVAL statement is used to specify a component, modelCurve, which is the sum of the intercept and the transfer function input ($\mu + f_t$). The modelCurve component represents the structural part of the model and is defined only for output purposes: its estimate is output (along with the estimates of other components) to the data set that is specified in the OUT= option of the OUTPUT statement.

Note that the modeling of output CO_2 according to this model is also illustrated in Example 7.3 of the PROC ARIMA documentation (see Chapter 7, "The ARIMA Procedure"). The ARIMA procedure handles the computation of the transfer function f_t slightly differently than the way it is estimated by the SSM procedure. However, despite this algorithmic difference in the modeling procedures, for this example the estimated parameters agree quite closely (barring the sign conventions that are used to specify the model parameters).

Output 33.10.1 shows the estimate of μ, the intercept in the model. Output 33.10.2 shows the estimate of δ, the coefficient in the denominator polynomial of the transfer function. Output 33.10.3 shows the regression estimates of the state regression variables x3, x4, and x5 (which correspond to the coefficients of the numerator polynomial). Output 33.10.4 shows the estimates of the parameters of the AR(2) noise term.

Output 33.10.1 Estimate of μ

The SSM Procedure

Regression Parameter Estimates

Response Variable	Regression Variable	Estimate	Standard Error	t Value	Pr > |t|
y	intercept	53.4	0.145	368.20	<.0001

Output 33.10.2 Estimate of δ, the Coefficient of the Denominator Polynomial in the Transfer Function

Estimates of Named Parameters

Parameter	Estimate	Standard Error	t Value
delta	0.548	0.0398	13.78

Output 33.10.3 Regression Estimates of the State Regression Variables x3, x4, and x5

Estimate of the State Equation Regression Vector

State	Element Index	Estimate	Standard Error	t Value	Pr > |t|
tfstate	1	-0.530	0.0743	-7.13	<.0001
tfstate	2	-0.380	0.1022	-3.72	0.0002
tfstate	3	-0.519	0.0743	-6.99	<.0001

Output 33.10.4 Estimates of the Parameters of the Autoregressive Term

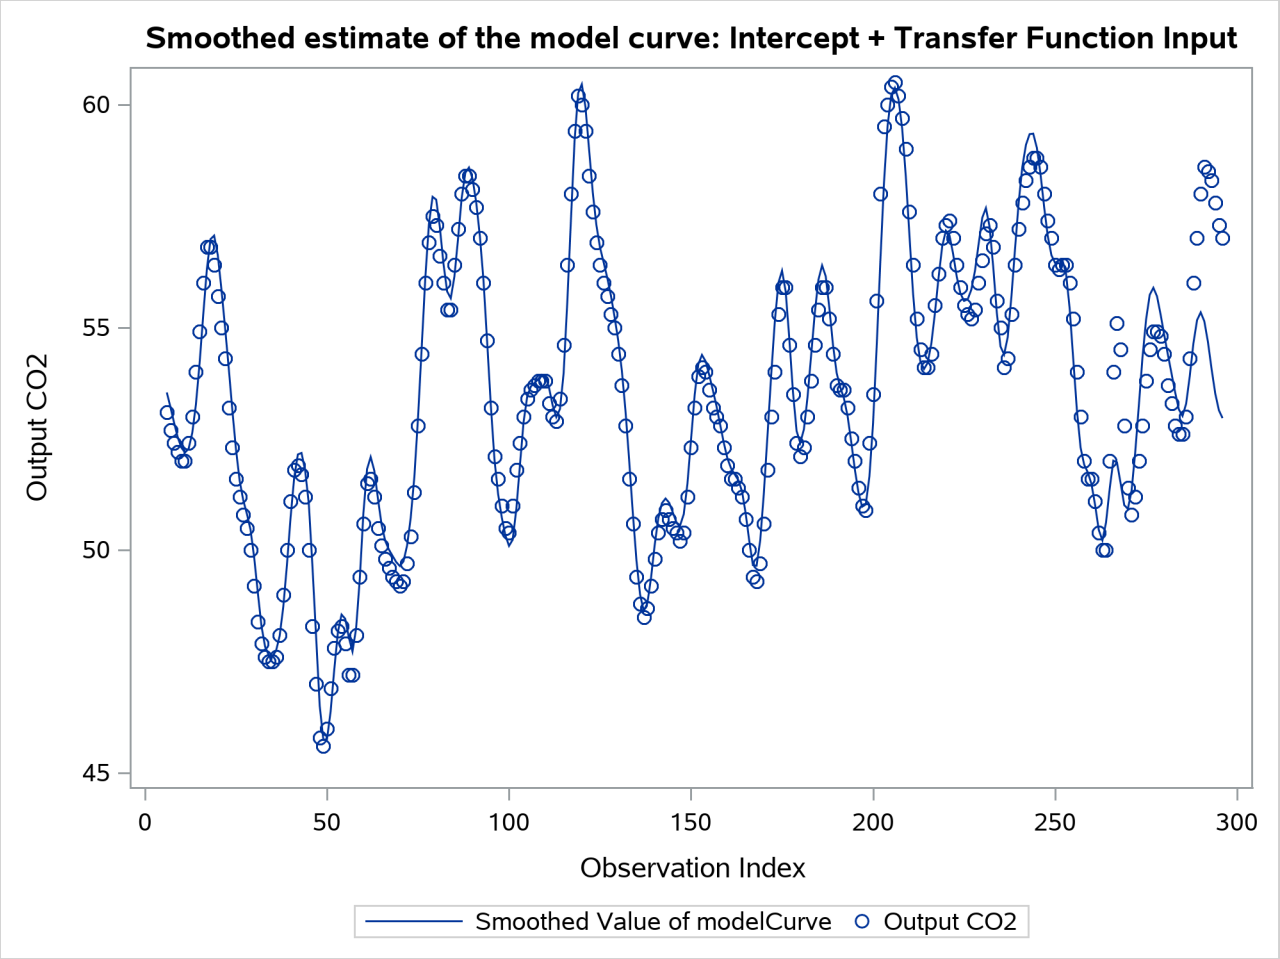
Model Parameter Estimates

Component	Type	Parameter	Estimate	Standard Error	t Value
ar2	ARMA Trend	Error Variance	0.0581	0.00486	11.96
ar2	ARMA Trend	AR_1	1.5319	0.04700	32.60
ar2	ARMA Trend	AR_2	-0.6291	0.04973	-12.65

The following statements produce a time series plot of the estimate of modelCurve—that is, the estimate of the structural part of the model ($\mu + f_t$)—along with the scatter plot of the observed values of the output CO_2. The plot, shown in Output 33.10.5, seems to indicate that the model captures the relationship between the input gas rate and the output CO_2 quite well, at least up to the observation index 250.

```
proc sgplot data=For;
   title "Smoothed estimate of the model curve: Intercept + Transfer Function Input";
   series x=obsIndex y=smoothed_modelCurve;
   scatter x=obsIndex y=y;
run;
```

Output 33.10.5 Smoothed Estimate of $\mu + f_t$

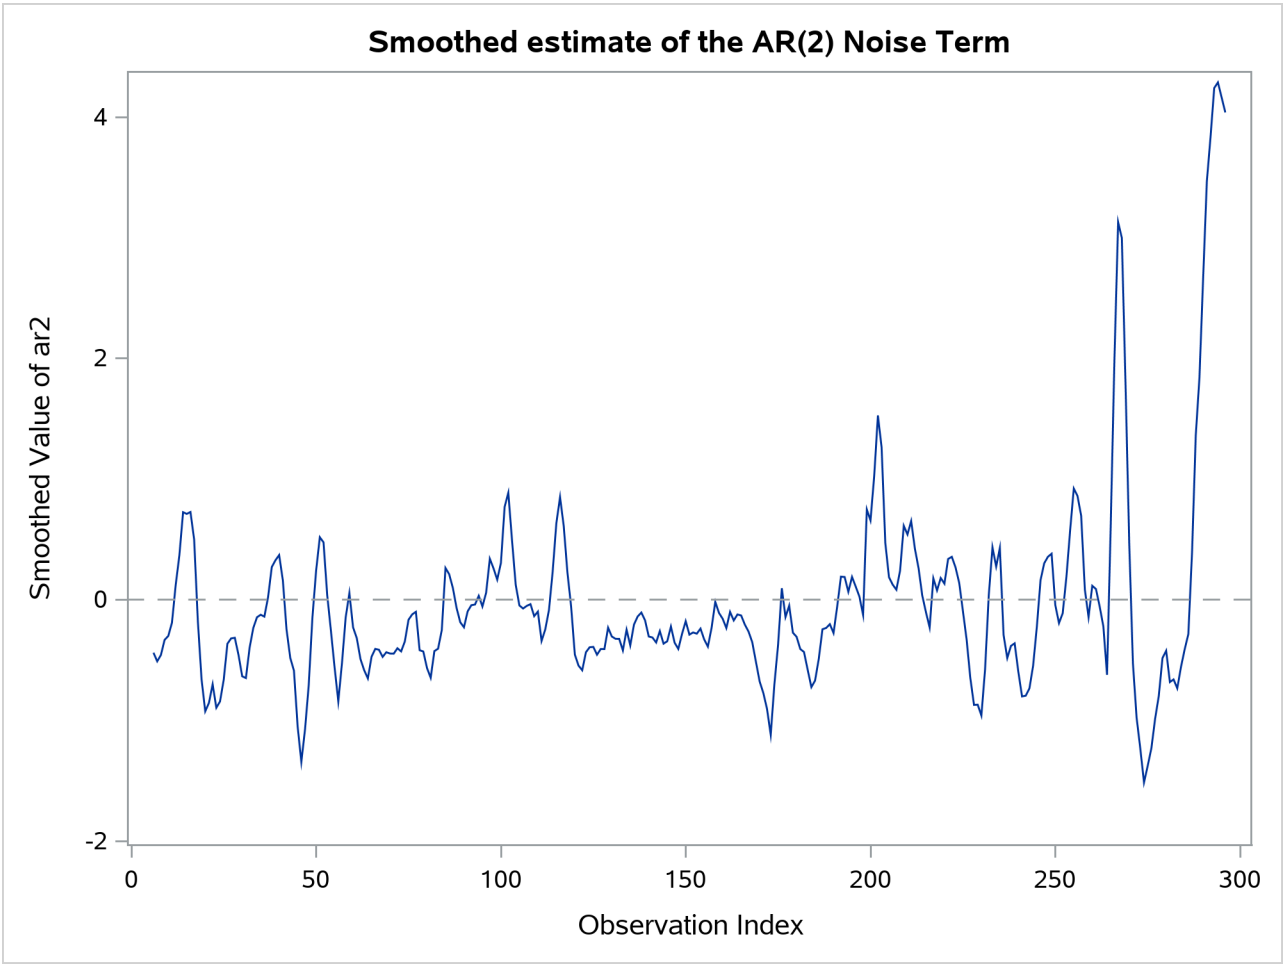


The plot shown in Output 33.10.6 shows the estimate of the noise term, ar2, which is produced by the following statements:

```
proc sgplot data=For;
   title "Smoothed estimate of the AR(2) Noise Term";
   series x=obsIndex y=smoothed_ar2;
   refline 0 / axis=y lineattrs=GraphReference(pattern = Dash);
run;
```

If you compare the scales of these two plots, it appears that the noise term is relatively small and that most of the variation in output CO_2 can be explained by the structural part of the model. It does, however, appear that the model fit deteriorates toward the latter part of the sample. The structural break analysis summary, shown in Output 33.10.7, indicates strong evidence of structural break in the behavior of f_t at or near the observation index 264. Obviously, this type of structural break analysis can be quite useful in industrial quality-control applications.

Output 33.10.6 Smoothed Estimate of the AR(2) Noise Term



Output 33.10.7 Summary of Breaks in f_t

Elementwise Break Summary for tfstate

264	1	-5.03	<.0001
199	1	4.62	<.0001
198	1	-3.15	0.0016

Example 33.11: Panel Data: Dynamic Panel Model for the Cigar Data

This example shows how you can use the SSM procedure to specify and fit the so-called dynamic panel model, which is commonly used to analyze a panel of time series. Suppose that a panel of time series $y_{t,i}$ follows the model

$$y_{t,i} = \rho y_{(t-1),i} + \mu_i + \beta X_{t,i} + \zeta_t + \epsilon_{t,i}$$

where t denotes the time index (for example, $t = 1, \ldots, T$); i denotes the panel index (for example, $i = 1, \ldots, P$); ρ is the autoregression coefficient; μ_i denote the panel-specific intercepts; $X_{t,i}$ are observations on a regression variable with regression coefficient β (the same for all panels); ζ_t are unobserved, random time effects; and $\epsilon_{t,i}$ are the observation errors. The sequences ζ_t and $\epsilon_{t,i}$ are assumed to be independent, zero-mean Gaussian variables with variances σ_1^2 and σ_0^2, respectively. This is an example of a dynamic panel model that contains one regressor variable. It is easy to formulate this model equation as a state equation with state $\boldsymbol{\alpha}_t$ of size P—the number of panels. Taking $y_{t,i} = \boldsymbol{\alpha}_t[i]$, it is easy to see that the states $\boldsymbol{\alpha}_t$ evolve according to the equation

$$\boldsymbol{\alpha}_{t+1} = \mathbf{T}\boldsymbol{\alpha}_t + \mathbf{W}_{t+1}\boldsymbol{\beta} + \boldsymbol{\eta}_{t+1}$$

where $\mathbf{T} = \rho I_P$ (a P-dimensional, diagonal matrix with all its diagonal elements equal to ρ); $\mathbf{W}_t = (\mathbf{X}_t \;\; I_P)$ is a $P \times (1 + P)$-dimensional matrix (in a block form) of state regression variables, where the first block is a column that includes all the values $X_{t,i}$ that are associated with a given time index (t) and the second block is a P-dimensional identity matrix; $\boldsymbol{\beta} = (\beta \; \mu_1, \ldots, \mu_P)'$ is the $(1 + P)$-dimensional column vector of regression coefficients; and $\boldsymbol{\eta}_t = (\zeta_t + \epsilon_{t,1}, \ldots, \; \zeta_t + \epsilon_{t,P})'$ is a P-dimensional column vector of all the disturbances that are associated with time index t. Because ζ_t and $\epsilon_{t,i}$ are independent, the covariance matrix of $\boldsymbol{\eta}_t$—for example, $\mathbf{Q}_t$—is easy to calculate: $\mathbf{Q}_t[i,i] = \sigma_0^2 + \sigma_1^2$ and, for $i \neq j$, $\mathbf{Q}_t[i,j] = \sigma_1^2$. This formulation can be easily extended to multiple regression variables, such as r variables, by appropriately modifying the term that is associated with the state regression variables—$\mathbf{W}_t\boldsymbol{\beta}$: the new $\mathbf{W}_t$ matrix becomes $P \times (r + P)$-dimensional and the new regression vector $\boldsymbol{\beta}$ becomes $(r + P)$-dimensional.

The cross-sectional data, Cigar, that are used in the section "Getting Started: SSM Procedure" on page 2398 are reused in this example. In order to use the SSM procedure to perform the dynamic panel model–based analysis, the input data set must be reorganized so that it contains the variables that form the $P \times (r + P)$-dimensional matrix $\mathbf{W}_t$. For the Cigar data, the number of panels $P = 46$ (the number of regions considered in the study), and the number of regression variables $r = 3$. Therefore, the input data set needs to be augmented by $46 * (3 + 46) = 2{,}254$ variables that constitute the matrix $\mathbf{W}_t = (\mathbf{X}_t \;\; I_{46})$—the first 46×3-dimensional block $\mathbf{X}_t$ contains the values of the three regression variables, lprice, lndi, and lpimin, at a given time index (a particular year in this case). The following DATA steps accomplish this task in two steps. In the first step, the raw data that form the rows of the Cigar data set are read into a temporary data set,

Tmp, such that all 6*46 = 276 values that are associated with a given year (values of six variables—year, region, lsales, lprice, lndi, and lpimin for 46 panels in a given year) are read in a single row that consists of 276 columns. In the second step, the final input data set is formed by rearranging Tmp so that it contains the necessary variables in the proper order—year (the time index), region (the panel index), lsales (the response variable), and the variables that form the 46×49-dimensional $\mathbf{W}$ matrix (w1, . . . , w2254).

```
data Tmp;

              if k=3 then wmat[j,k] = ivar[j, 6];
          end;
      end;
      output;
   end;
run;
```

The following statements specify and fit the dynamic panel model:

```
 proc ssm data=Cigar opt(tech=dbldog maxiter=75);
     id year interval=year;
     parms rho / lower=-0.9999 upper=0.9999;
     parms sigma0 sigma1 / lower=1.e-8;
     array RegionArray{46} region1-region46;
     do i=1 to 46;
        RegionArray[i] = (region=i);
     end;
     array cov{46,46};
     do i=1 to 46;
         do j=1 to 46;
            if(i=j) then cov[i,j] = sigma0 + sigma1;
            else cov[i,j] = sigma1;
         end;
```

```
    end;
    state panelState(46) T(I)=(rho) W(g)=(w1-w2254)
      cov(g)=(cov) a1(46) checkbreak;
    comp dynPanel = (RegionArray)*panelState;
    model lsales = dynPanel;
    output out=for1 press;
run;
```

The estimates of the regression coefficients and the regional intercepts, which are all statistically significant, are shown in Output 33.11.1. In particular, the estimated coefficients of lprice, lndi, and lpimin, are –0.26, 0.13, and 0.07, respectively.

Output 33.11.1 Estimates of β_1, β_2, β_3 and the Regional Intercepts

sigma0	0.001231	0.0000491	25.08
sigma1	0.000213	0.0000662	3.22

Finally, you can compare the fit of the dynamic panel model with the fit of the model that is discussed in the section "Getting Started: SSM Procedure" on page 2398. Output 33.11.3 shows the likelihood-based information criteria for the dynamic panel model, and Output 33.11.4 shows the same information for the other model.

Output 33.11.3 Likelihood-Based Information Criteria: Dynamic Panel Model

Information Criteria

Statistic	Diffuse Likelihood Based	Profile Likelihood Based
AIC (lower is better)	-4732.722	-4856.398
BIC (lower is better)	-4717.247	-4343.874
AICC (lower is better)	-4732.704	-4841.250
HQIC (lower is better)	-4726.913	-4664.667
CAIC (lower is better)	-4714.247	-4245.874

Output 33.11.4 Likelihood-Based Information Criteria: Getting Started Example

Information Criteria		
Statistic	Diffuse Likelihood Based	Profile Likelihood Based
AIC (lower is better)	-4488.093	-4145.246
BIC (lower is better)	-4477.776	-3637.952
AICC (lower is better)	-4488.084	-4130.417
HQIC (lower is better)	-4484.220	-3955.472
CAIC (lower is better)	-4475.776	-3540.952

Similarly, Output 33.11.5 shows fit criteria based on the delete-one cross validation error for the dynamic panel model, and Output 33.11.6 shows the same information for the other model.

Output 33.11.5 Delete-One Cross Validation Criteria: Dynamic Panel Model

Delete-One Cross Validation Error Criteria			
Variable	N	PRESS	Generalized Cross-Validation
lsales	1380	1.115309	5.62798E-7

Output 33.11.6 Delete-One Cross Validation Criteria: Getting Started Example

Delete-One Cross Validation Error Criteria			
Variable	N	PRESS	Generalized Cross-Validation
lsales	1380	1.290420	6.18144E-7

On the basis of both these considerations, the dynamic panel model appears to provide a better fit for the Cigar data than the model that is fit in the section "Getting Started: SSM Procedure" on page 2398.

Example 33.12: Multivariate Modeling: Long-Term Temperature Trends

In a presentation by Ansley and de Jong (2015), three monthly time series are jointly modeled to obtain long-term—several decades long—temperature predictions for certain regions of the northern hemisphere. This example shows how you can specify and fit the final model that this presentation proposed. The following data set, Temp, contains four variables: date dates the monthly observations; UAH contains monthly satellite global temperature readings, starting in December 1978; CRU contains monthly temperature data, starting in January 1850 (from a different source); and GISS contains monthly temperature data, starting in January 1880 (from yet another source). All these temperature data are scaled suitably so that the numbers represent temperature readings in centigrade.

```
data Temp;
input UAH CRU GISS @@;
date = intnx('month', '01jan1850'd, _n_-1);
format date date.;
```

```
datalines;
.    8.243    .
.    9.733    .

   ... more lines ...
```

The following statements produce scatter plots of these three series in a single graph:

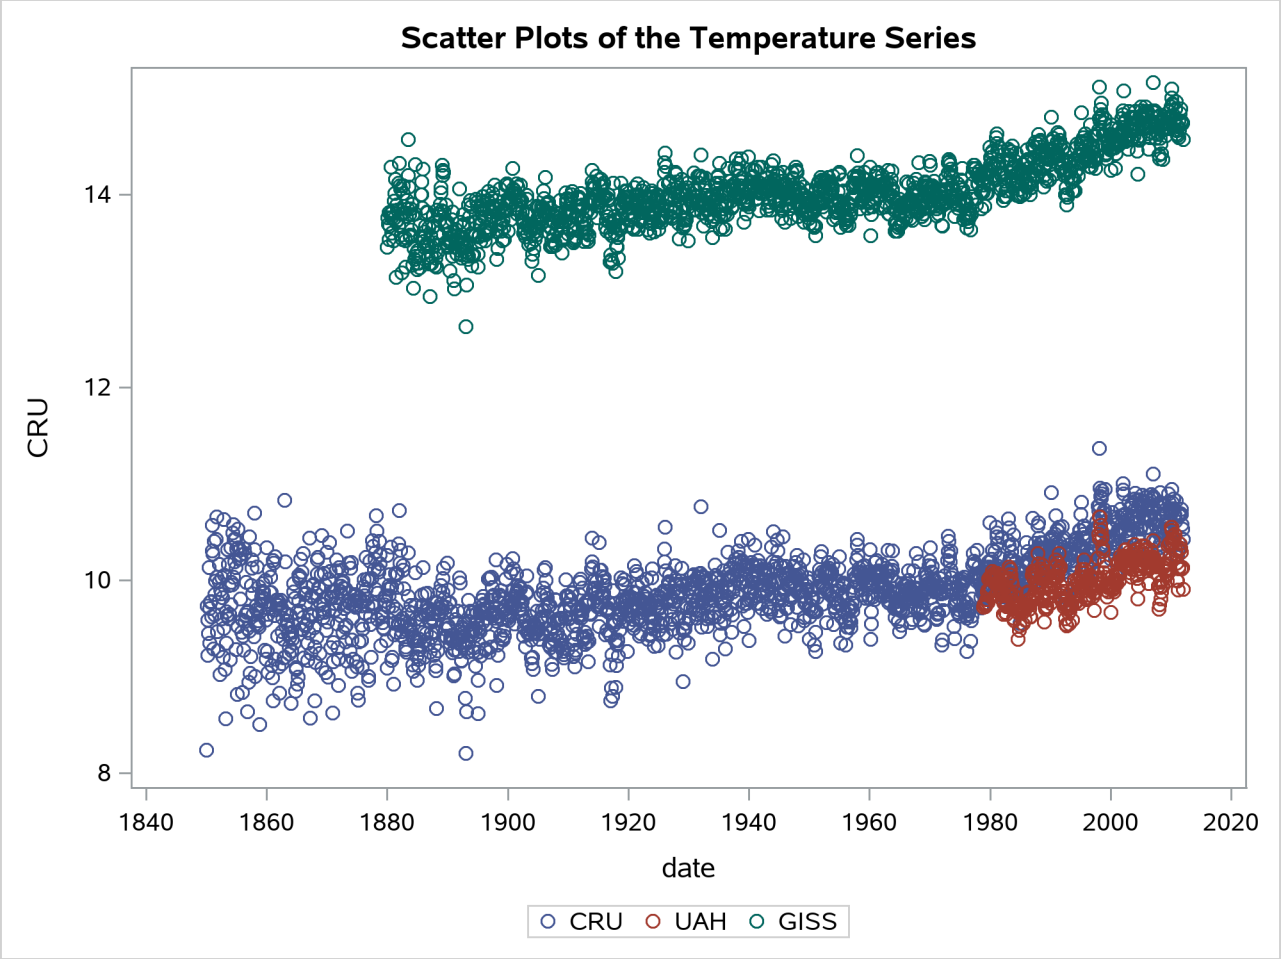
```
 proc sgplot data=Temp;
       title "Scatter Plots of the Temperature Series";
       scatter x=date y=cru;
       scatter x=date y=uah ;
       scatter x=date y=giss;
  run;
```

Output 33.12.1 shows the resulting graph. As already noted, these three series start at different points in the past. However, they all end at the same time: they all have measurements until January 2012, which is the last month in the data set. The mean levels of these series are different: the GISS measurements are generally larger than CRU and UAH by about 4 degrees. In addition, the variability in the CRU values seems to decrease with time (this is more apparent when the series is plotted by itself). The goal of the analysis is to use these data to make long-term predictions about future temperature levels. The following statements append 1,200 missing measurements to Temp, so that the model fitted by using the SSM procedure can be extrapolated to obtain temperature forecasts 100 years in the future:

```
data append(keep=date cru giss uah);
    do i=1 to 1200;
        cru = .; giss=.; uah=.;
        date = intnx('month','01jan2012'D, i);
    format date monyy7.;
    output;
    end;
run;

 proc append base=Temp data=Append; run;
```

Output 33.12.1 Scatter Plots of CRU, UAH, and GISS



Ansley and de Jong propose a parsimonious model that links these three time series. It can be described as

$$
\begin{aligned}
\mathrm{GISS}_t &= \mu_t + a\,\zeta_t + a\,r_1\,\epsilon_{1t} \\
\mathrm{CRU}_t &= \beta_{cru} + \mu_t + a\,\zeta_t + a\,\epsilon_{2t} \\
\mathrm{UAH}_t &= \beta_{uah} + \mu_t + a\,\zeta_t + a\,r_3\,\epsilon_{3t}
\end{aligned}
$$

where β_{cru} and β_{uah} are intercepts that are associated with CRU and UAH, respectively; μ_t is an integrated random walk trend; ζ_t is a zero-mean, autoregressive noise term (which is scaled by an unknown scaling factor a); and ϵ_{it} $(i = 1, 2, 3)$ are independent observation errors with different variances that are also scaled suitably. Note that the trend μ_t and the autoregressive noise term ζ_t are shared by the models of the three series, and, for identification purposes, the intercept for GISS is taken to be zero. In addition, the model parameters are assumed to be interrelated and are parameterized in a particular way (which leads to fewer parameters to estimate, and their relative scaling helps in parameter estimation). This special parameterization can be expressed as a function of seven basic parameters: *loga1*, *logr1*, *logr3*, *logsigma*, *b*, *c*, and *rhoParm* (this naming convention is different from that used by Ansley and de Jong (2015)).

Let $\sigma^2 = \exp(2\mathrm{logsigma})$, and let the scaling factors $a = \exp(\mathrm{loga1})$, $r_1 = \exp(\mathrm{logr1})$, and $r_3 = \exp(\mathrm{logr3})$. Then the model parameters can be described as follows:

- The parameters that are associated with the autoregression ζ_t: the damping factor $\rho = \frac{\exp(\text{rhoParm})-1}{\exp(\text{rhoParm})+1}$, the variance of the disturbance term = $a^2\sigma^2$, and the variance of the initial state = $a^2\sigma^2/(1-\rho^2)$
- The parameters that are associated with the integrated random walk trend: the variance of the disturbance term in the slope equation = σ^2
- The variance of the observation errors for GISS = $a^2 r_1^2 \sigma^2$
- The variance of the observation errors for UAH = $a^2 r_3^2 \sigma^2$
- The variance of the observation errors for CRU is taken to be time-varying with the following form: for $t \leq nobs$,

  $$\sigma_{2,t}^2 = a^2\sigma^2 \exp(2b + 2c\ t/nobs)$$

  where $nobs$ = 1,945 (the number of observations in the unappended data set). For $t >$ 1,945, it is fixed at its last value: $\sigma_{2,t}^2 = a^2\sigma^2 \exp(2b + 2c)$.

The following DATA step adds an observation index, tindex, to Temp, which is used in the SSM procedure to define the time-varying observation error variance for CRU:

```
data temp;
   set temp;
   tindex = _n_;
run;
```

The following statements fit the preceding model to the Temp data:

```
 ods output RegressionEstimates=regEst;
 proc ssm data=Temp;
     id date interval=month;
     parms loga1 logr1 logr3  logsigma;
     parms b=0 c=0;
     parms rhoParm;
     rho = (exp(rhoParm)-1)/(exp(rhoParm)+1);
     sigmaSq = exp(2*logsigma);
     initSigmaSq = sigmaSq/(1-rho*rho);
     a1 = exp(loga1);
     a1Sq = a1*a1;
     r1sq  = exp(2*logr1);
     r3sq  = exp(2*logr3);
     giss_var = a1Sq*r1sq*sigmaSq;
     nobs=1945;
     if tindex <= nobs then
         cru_var = a1Sq*exp(2*b + 2*c*tindex/nobs)*sigmaSq;
     else cru_var = a1Sq*exp(2*b + 2*c)*sigmaSq;
     uah_var = a1Sq*r3sq*sigmaSq;
     UAH_Intercept=1.0;
     CRU_Intercept=1.0;
     trend level(ll) variance=0 slopevar=sigmaSq;
     state auto(1) T(g)=(rho) cov(g)=(sigmaSq)  cov1(g)=(initSigmaSq);
     comp auto_common = auto*(a1);
     state wn(3) type=wn cov(d)=(giss_var cru_var uah_var);
     comp wn_giss = wn[1];
```

```
      comp wn_cru = wn[2];
      comp wn_uah = wn[3];
      model GISS = level auto_common  wn_giss;
      model CRU = CRU_Intercept level auto_common  wn_cru;
      model UAH = UAH_Intercept level auto_common  wn_uah;
      comp slope = level_state_*(0 1);
      output out=For pdv press;
  run;
```

Output 33.12.2 shows the estimated intercepts $\hat{\beta}_{cru}$ and $\hat{\beta}_{uah}$. As expected, they are quite close (see the scatter plots of CRU and UAH in Output 33.12.1).

Output 33.12.2 Estimated Intercepts for CRU and UAH

The SSM Procedure

Regression Parameter Estimates

Response Variable	Regression Variable	Estimate	Standard Error	t Value	Pr > |t|
CRU	CRU_Intercept	-4.09	0.00359	-1139.0	<.0001
UAH	UAH_Intercept	-4.48	0.00671	-666.54	<.0001

The estimates of the basic parameters that underlie the model parameters are shown in Output 33.12.3.

Output 33.12.3 Estimates of Basic Model Parameters

Estimates of Named Parameters

Parameter	Estimate	Standard Error	t Value
loga1	7.779	0.3899	19.95
logr1	-1.005	0.0884	-11.36
logr3	-0.230	0.0453	-5.09
logsigma	-9.641	0.3885	-24.81
b	0.737	0.0502	14.68
c	-1.402	0.0690	-20.34
rhoParm	1.429	0.0766	18.66

The following DATA steps add two variables (CRU_ADJ = CRU – $\hat{\beta}_{cru}$ and UAH_ADJ = UAH – $\hat{\beta}_{uah}$) to the output data set For. These adjusted versions of CRU and UAH have the same mean level as GISS—estimated μ_t.

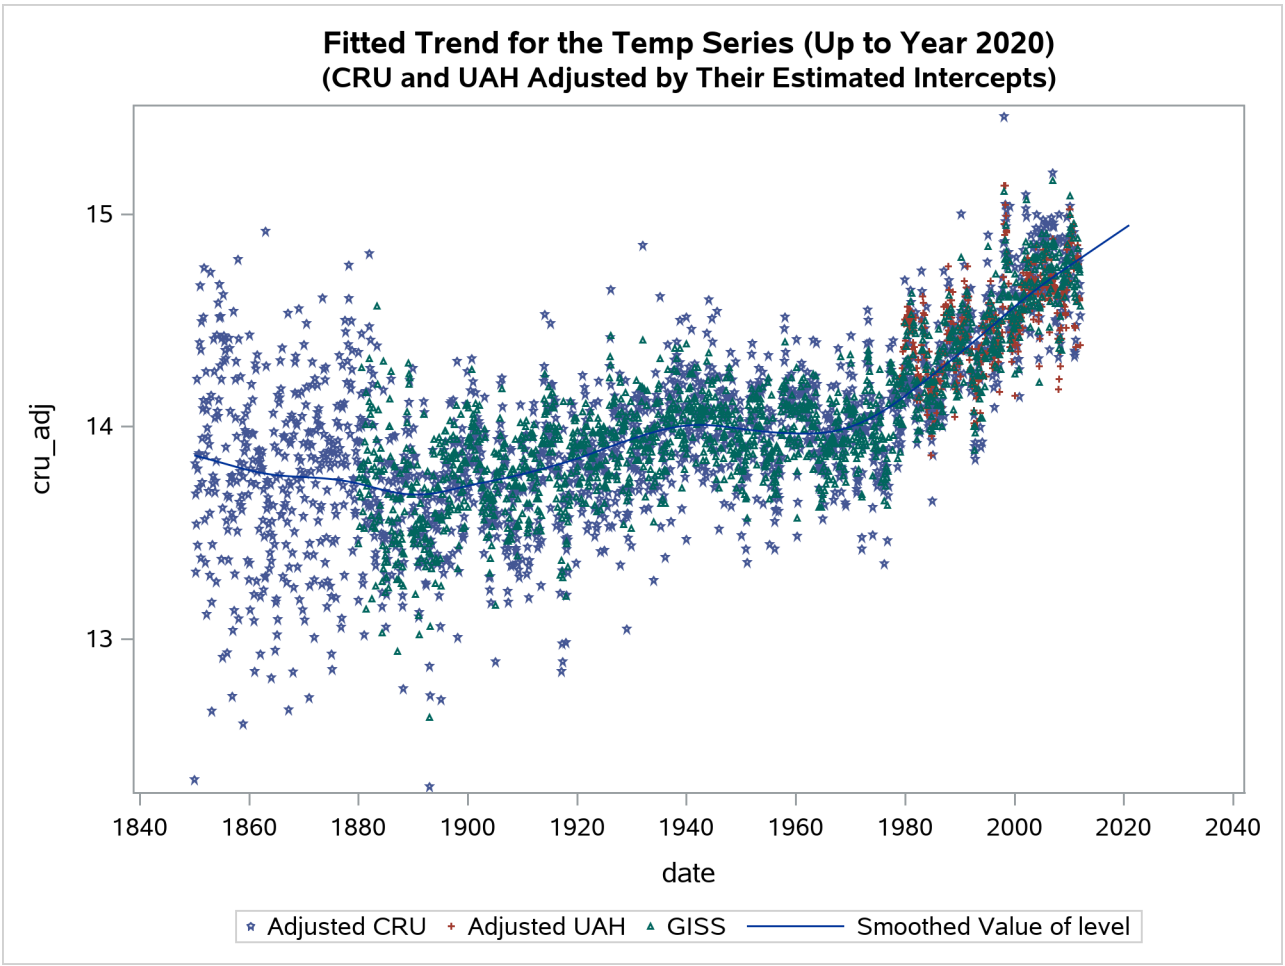
```
data _NULL_;
   set regEst;
   if _n_ = 1 then call symput('intercept1',trim(left(estimate)));
   else call symput('intercept2',trim(left(estimate)));
run;
data for;
    set For;
    cru_adj = cru - &intercept1;
    uah_adj = uah - &intercept2;
run;
```

The following statements produce a graph that contains four plots: scatter plots of GISS, CRU_ADJ, and UAH_ADJ and a series plot of the estimated μ_t.

```
proc sgplot data=For;
   where date < '01feb2021'd;
   title "Fitted Trend for the Temp Series (Up to Year 2020) ";
   title2 "(CRU and UAH Adjusted by Their Estimated Intercepts) ";
   scatter x=date y=cru_adj / LEGENDLABEL="Adjusted CRU"
       MARKERATTRS=GraphData1(symbol=star size=3);
   scatter x=date y=uah_adj / LEGENDLABEL="Adjusted UAH"
       MARKERATTRS=GraphData2(symbol=plus size=3);
   scatter x=date y=giss /
       MARKERATTRS=GraphData3(symbol=triangle size=3);
   series x=date y=smoothed_level / MARKERATTRS=GraphData4;
run;
```

Output 33.12.4 shows the resulting graph. It shows that the estimated mean level μ_t tracks the observed data quite well.

Output 33.12.4 Fitted Trend μ_t

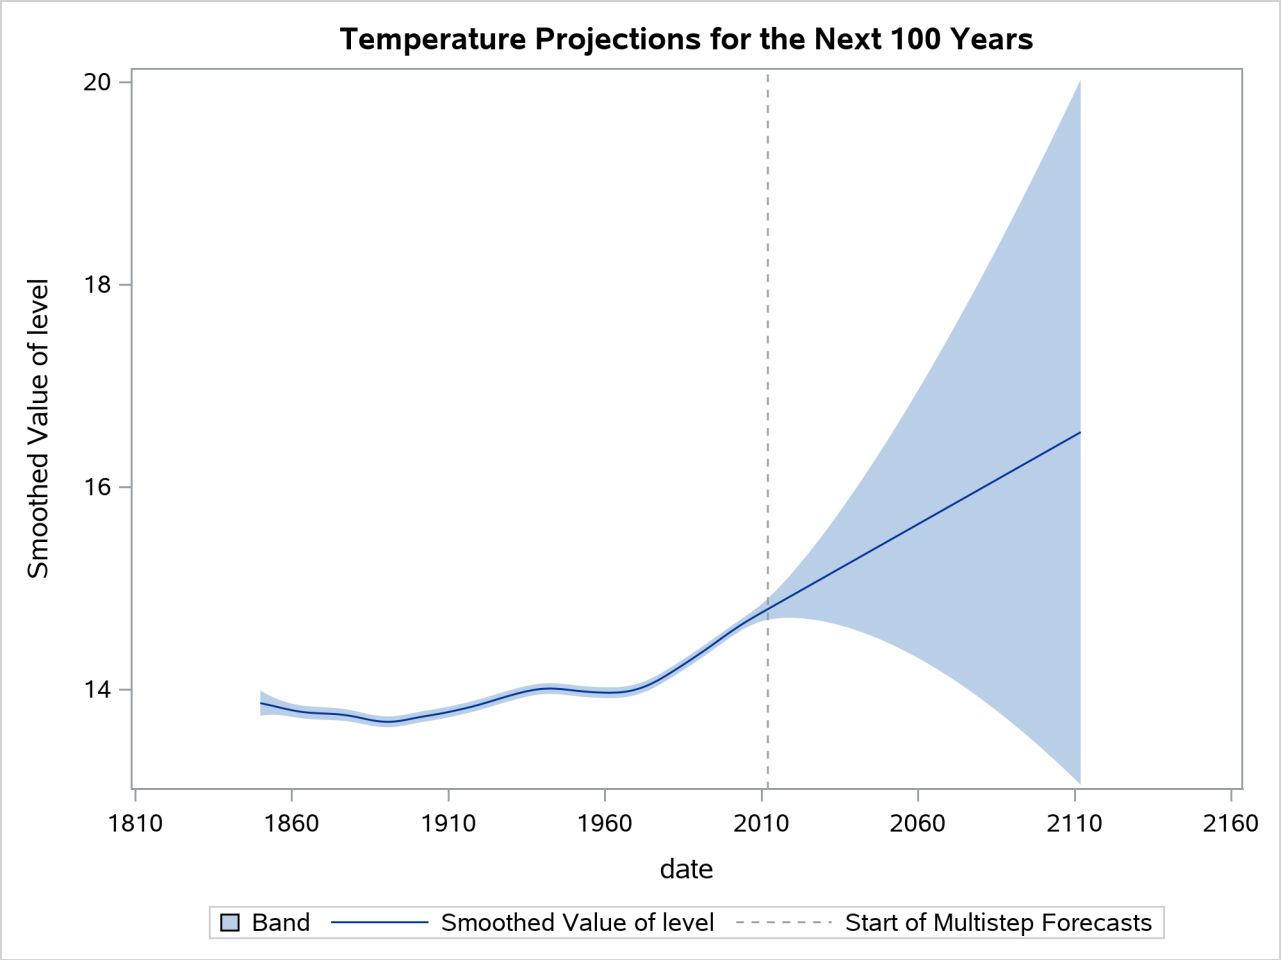


The following statements produce the time series plot of the estimated μ_t along with the 95% confidence band:

```
proc sgplot data=For;
   title "Temperature Projections for the Next 100 Years";
   band x=date lower=smoothed_lower_level upper=smoothed_upper_level;
   series x=date y=smoothed_level;
   refline '01feb2012'd / axis=x lineattrs=(pattern=shortdash)
      LEGENDLABEL= "Start of Multistep Forecasts"
      name="Forecast Reference Line";
run;
```

Output 33.12.5 shows the resulting graph.

Output 33.12.5 Long-Term Forecasts of μ_t



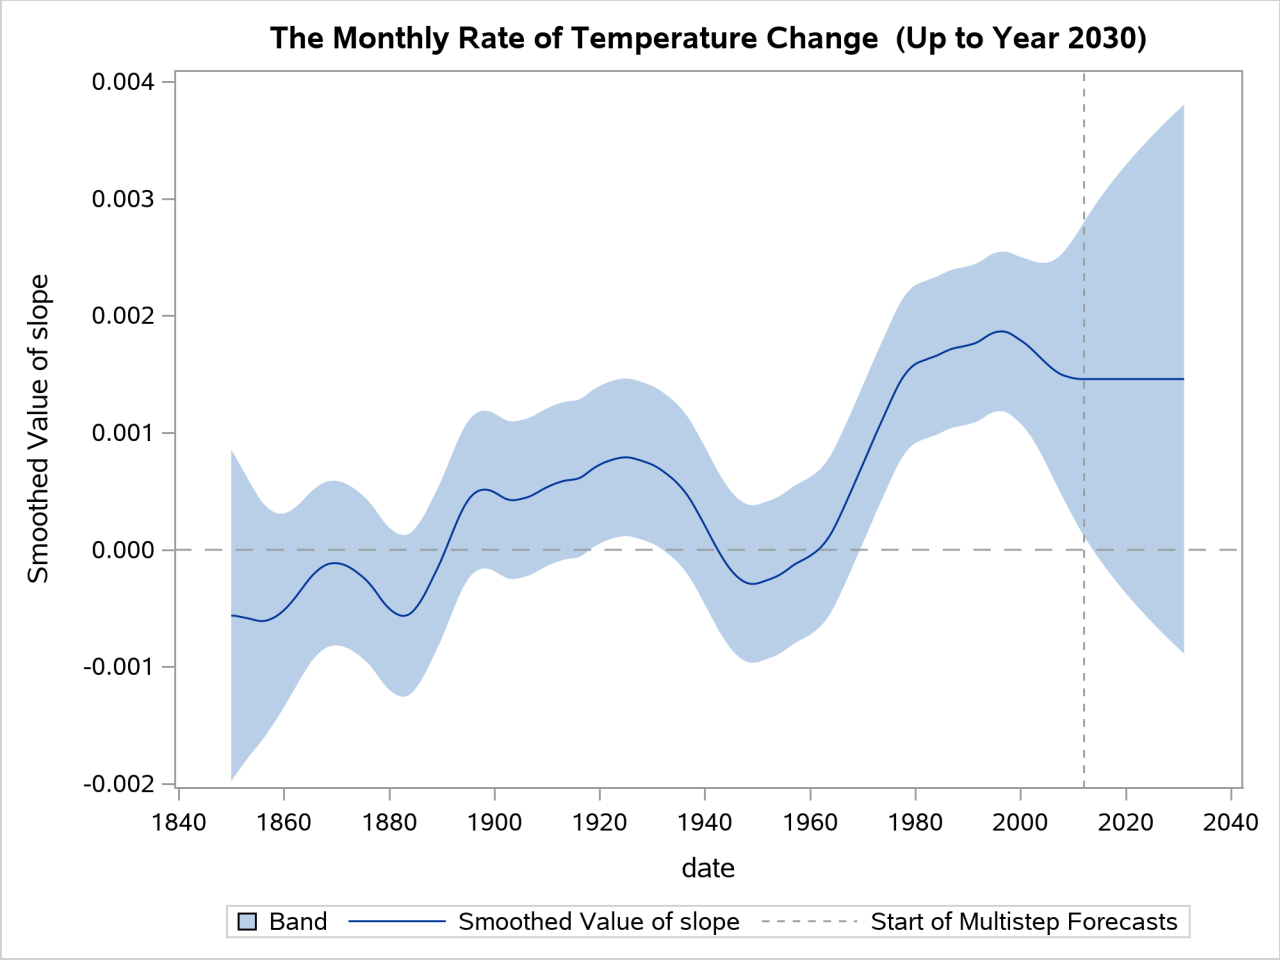
The following statements produce a similar graph for the estimated slope of μ_t:

```
proc sgplot data=For;
   where date <=  '01feb2031'd;
   title "The Monthly Rate of Temperature Change  (Up to Year 2030)";
   band x=date lower=smoothed_lower_slope upper=smoothed_upper_slope;
   series x=date y=smoothed_slope;
   refline '01feb2012'd / axis=x lineattrs=(pattern=shortdash)
      LEGENDLABEL= "Start of Multistep Forecasts"
```

```
      name="Forecast Reference Line";
   refline 0 / axis=y lineattrs=(pattern=dash);
run;
```

Output 33.12.6 shows the resulting plot of the estimated slope of μ_t.

Output 33.12.6 Forecasts of the Slope of μ_t



Based on the preceding analysis (see the plots of μ_t and its slope in Output 33.12.5 and Output 33.12.6), it appears that there has been statistically significant warming over the last 10 years, but the warming does not appear to be accelerating.

Example 33.13: Bivariate Model: Sales of Mink and Muskrat Furs

This example considers a bivariate time series of logarithms of the annual sales of mink and muskrat furs by the Hudson's Bay Company for the years 1850–1911. These data have been analyzed previously by many authors, including Chan and Wallis (1978); Harvey (1989); Reinsel (1997). There is known to be a predator-prey relationship between the mink and muskrat species: minks are principal predators of muskrats. Previous analyses for these data generally conclude the following:

- An increase in the muskrat population is followed by an increase in the mink population a year later, and an increase in the mink population is followed by a decrease in the muskrat population a year later.
- Because muskrats are not the only item in the mink diet and because both mink and muskrat populations are affected by many other factors, the model must include additional terms to explain the year-to-year variation.

The analysis in this example, which loosely follows the discussion in Harvey (1989, chap. 8, sec. 8), also leads to similar conclusions. It begins by taking Harvey's model 8.8.8 (a and b), with autoregressive order one, as the starting model—that is, it assumes that the bivariate (mink, muskrat) process $\mathbf{Y}_t$ satisfies the following relationship:

$$\boldsymbol{\mu}_t = \boldsymbol{\mu}_{t-1} + \boldsymbol{\beta} + \boldsymbol{\nu}_t$$
$$\mathbf{Y}_t = \boldsymbol{\mu}_t + \boldsymbol{\Phi}\mathbf{Y}_{t-1} + \boldsymbol{\xi}_t$$

This model postulates that $\mathbf{Y}_t$ can be expressed as a sum of three terms: $\boldsymbol{\mu}_t$, a bivariate trend that is modeled as a random walk with drift $\boldsymbol{\beta}$; $\boldsymbol{\Phi}\mathbf{Y}_{t-1}$, an AR(1) correction; and $\boldsymbol{\xi}_t$, a bivariate Gaussian white noise disturbance. It is assumed that the AR coefficient matrix $\boldsymbol{\Phi}$ is stable (that is, its eigenvalues are less than 1 in magnitude) and that the bivariate disturbances $\boldsymbol{\nu}_t$ (white noise associated with $\boldsymbol{\mu}_t$) and $\boldsymbol{\xi}_t$ are mutually independent.

The following statements show how you can specify this model in the SSM procedure:

```
proc ssm data=furs plots=residual;

   /* Specify the ID variable */
   id year interval=year;

   /* Define parameters */
   parms rho1 rho2/ lower=-0.9999 upper=0.9999;
   parms msd1 msd2 esd1 esd2 / lower=1.e-6;

   /* Specify the terms with lagged response variables */
   deplag LagsForMink(LogMink) LogMink(lags=1) LogMusk(lags=1);
   deplag LagsForMusk(LogMusk) LogMink(lags=1) LogMusk(lags=1);

   /* Specify the bivariate trend */
   array rwQ{2,2};
   rwQ[1,1] = msd1*msd1; rwQ[1,2] = msd1*msd2*rho1;
   rwQ[2,1] = rwQ[1,2]; rwQ[2,2]=msd2*msd2;
   state alpha(2) type=RW W(I) cov(g)=(rwQ);
   comp minkLevel = alpha[1];
```

```
    comp muskLevel = alpha[2];

    /* Specify the bivariate white noise */
    array wnQ{2,2};
    wnQ[1,1] = esd1*esd1; wnQ[1,2] = esd1*esd2*rho2;
    wnQ[2,1] = wnQ[1,2]; wnQ[2,2]=esd2*esd2;
    state error(2) type=WN cov(g)=(wnQ);
    comp minkWn = error[1];
    comp muskWn = error[2];

    /* Specify the observation equation */
    model LogMink = LagsForMink minkLevel minkWn;
    model LogMusk = LagsForMusk muskLevel muskWn;

    /* Specify an output data set to store component estimates */
    output out=salesFor press;
run;
```

The different parts of the program are explained as follows:

- The PARMS statements define parameters that are used to form the elements of Σ_1 (the covariance of $\boldsymbol{\nu}_t$, the disturbance term in the bivariate level equation) and Σ_2 (the covariance of $\boldsymbol{\xi}_t$, which is the bivariate white noise). Σ_1 is parameterized as (`msd1*msd1 msd1*msd2*rho1; msd1*msd2*rho1 msd2*msd2`). Σ_2 is similarly parameterized by using esd1, esd2, and rho2. In addition to ensuring that Σ_1 and Σ_2 are positive semidefinite, it turns out that this parameterization leads to an interpretable model at the end.
- The DEPLAG statements help define the terms that are associated with $\boldsymbol{\Phi}\mathbf{Y}_{t-1}$.
- The remaining statements are self-explanatory.

Output 33.13.1 shows the estimate of the drift vector $\boldsymbol{\beta}$ in the equation of $\boldsymbol{\mu}_t$ ($\boldsymbol{\mu}_t = \boldsymbol{\mu}_{t-1} + \boldsymbol{\beta} + \boldsymbol{\nu}_t$).

Output 33.13.1 Estimate of the Drift Vector $\boldsymbol{\beta}$

Clearly, both elements of $\boldsymbol{\beta}$ are statistically insignificant, and the $\boldsymbol{\mu}_t$ equation can be simplified as $\boldsymbol{\mu}_t = \boldsymbol{\mu}_{t-1} + \boldsymbol{\nu}_t$. Next, Output 33.13.2 shows the estimates of the elements of Σ_1, and Σ_2, and Output 33.13.3 shows the estimates of the lag coefficients.

Output 33.13.2 Estimates of Σ_1, and Σ_2

Estimates of Named Parameters

Parameter	Estimate	Standard Error	t Value
rho1	0.8310	0.1377	6.03
rho2	-0.9999	1.6555	-0.60
msd1	0.2500	0.0354	7.06
msd2	0.1991	0.0592	3.36
esd1	0.0662	0.0597	1.11
esd2	0.1344	0.0527	2.55

Output 33.13.3 Estimates of Lag Coefficients (Elements of $\mathbf{\Phi}$)

Model Parameter Estimates

Component	Type	Parameter	Estimate	Standard Error	t Value
LagsForMink	**Lag Coefficient Of LogMink**	**Lag[1]**	-0.0011	0.173	-0.01
LagsForMink	**Lag Coefficient Of LogMusk**	**Lag[1]**	0.3349	0.137	2.45
LagsForMusk	**Lag Coefficient Of LogMink**	**Lag[1]**	-0.9905	0.142	-6.98
LagsForMusk	**Lag Coefficient Of LogMusk**	**Lag[1]**	0.6570	0.121	5.44

The main points of the output can be summarized as follows:

- phi11, the first element of $\mathbf{\Phi}$, which relates the current value of LogMink with its lagged value, is statistically insignificant. That is, lagged LogMink term could be dropped from the model equation for LogMink.
- rho2, the correlation coefficient between the elements of $\boldsymbol{\xi}_t$—the bivariate noise vector in the equation $\mathbf{Y}_t = \boldsymbol{\mu}_t + \mathbf{\Phi}\mathbf{Y}_{t-1} + \boldsymbol{\xi}_t$—is very near its lower boundary of –1 (in such cases the standard error of the parameter estimate is not reliable). This implies that the two elements of $\boldsymbol{\xi}_t$ are perfectly negatively correlated.

Taken together, these observations suggest the reduced model

$$\boldsymbol{\mu}_t = \boldsymbol{\mu}_{t-1} + \boldsymbol{\nu}_t$$
$$\mathbf{Y}_t = \boldsymbol{\mu}_t + \mathbf{\Phi}\mathbf{Y}_{t-1} + \boldsymbol{\xi}_t$$

where $\mathbf{\Phi} = (0 \quad \phi_{12};\ \phi_{21} \quad \phi_{22})$ and $\mathrm{Cov}(\boldsymbol{\xi}_t) = \Sigma_2$ is parameterized as (`esd1*esd1 -esd1*esd2; -esd1*esd2 esd2*esd2`). The program that produces the reduced model is a simple modification of the preceding program and is not shown.

Output 33.13.4 Estimates of Σ_1, and Σ_2 (Reduced Model)

Estimates of Named Parameters

Parameter	Estimate	Standard Error	t Value
rho1	0.8526	0.0978	8.71
msd1	0.2472	0.0282	8.78
msd2	0.1955	0.0365	5.36
esd1	0.0679	0.0385	1.76
esd2	0.1372	0.0328	4.18

Output 33.13.5 Estimates of Lag Coefficients (elements of Φ) (Reduced Model)

Model Parameter Estimates

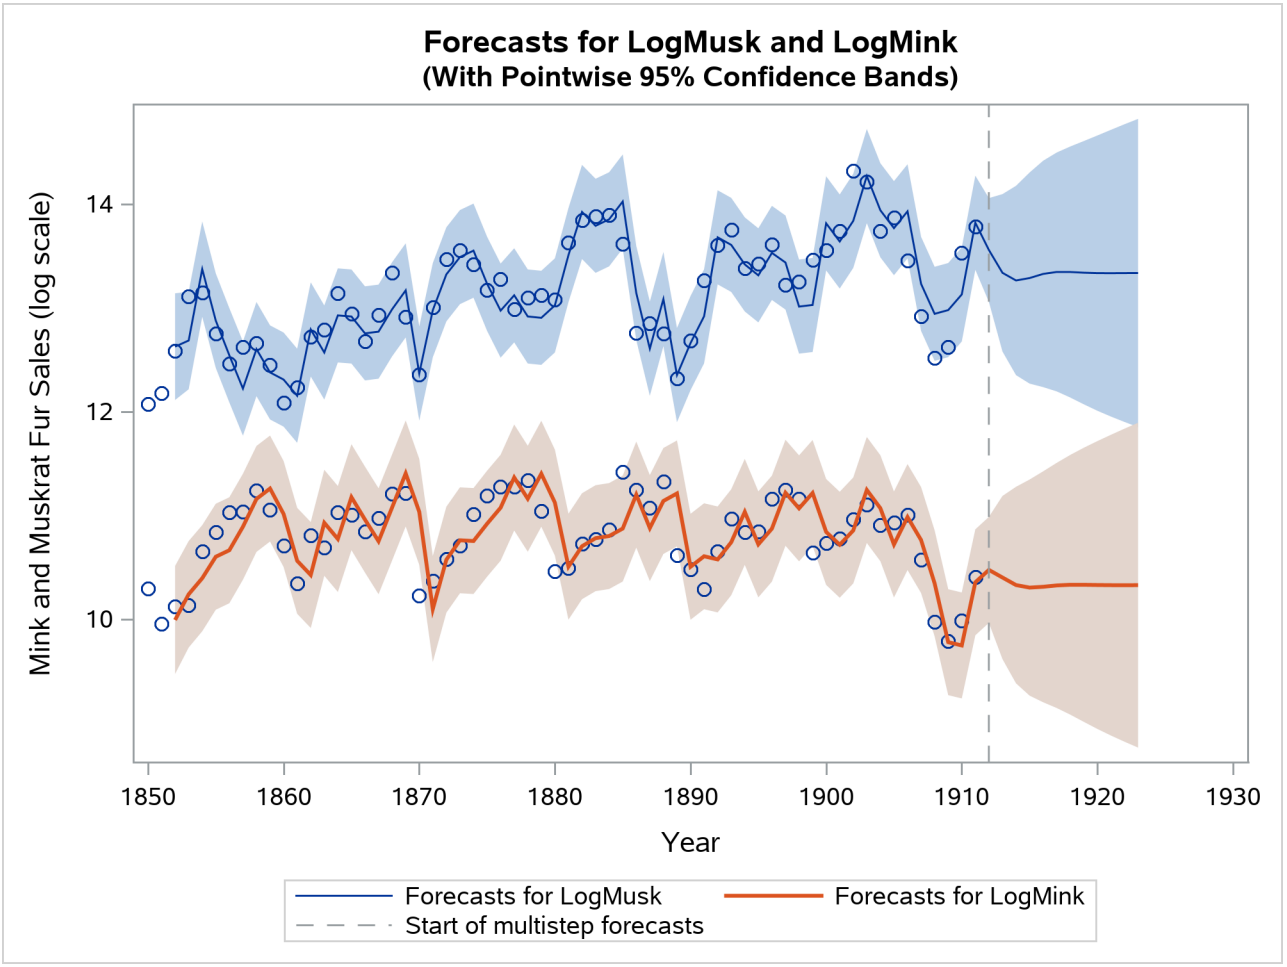
Component	Type	Parameter	Estimate	Standard Error	t Value
LagsForMink	**Lag Coefficient Of LogMusk**	**Lag[1]**	0.330	0.0986	3.35
LagsForMusk	**Lag Coefficient Of LogMink**	**Lag[1]**	-0.997	0.1168	-8.54
LagsForMusk	**Lag Coefficient Of LogMusk**	**Lag[1]**	0.668	0.1003	6.66

The tables in Output 33.13.4 and Output 33.13.5 show the new parameter estimates. By examining the parameter estimates, you can easily see that this model supports the general conclusions mentioned at the start of this example. In particular, note the following:

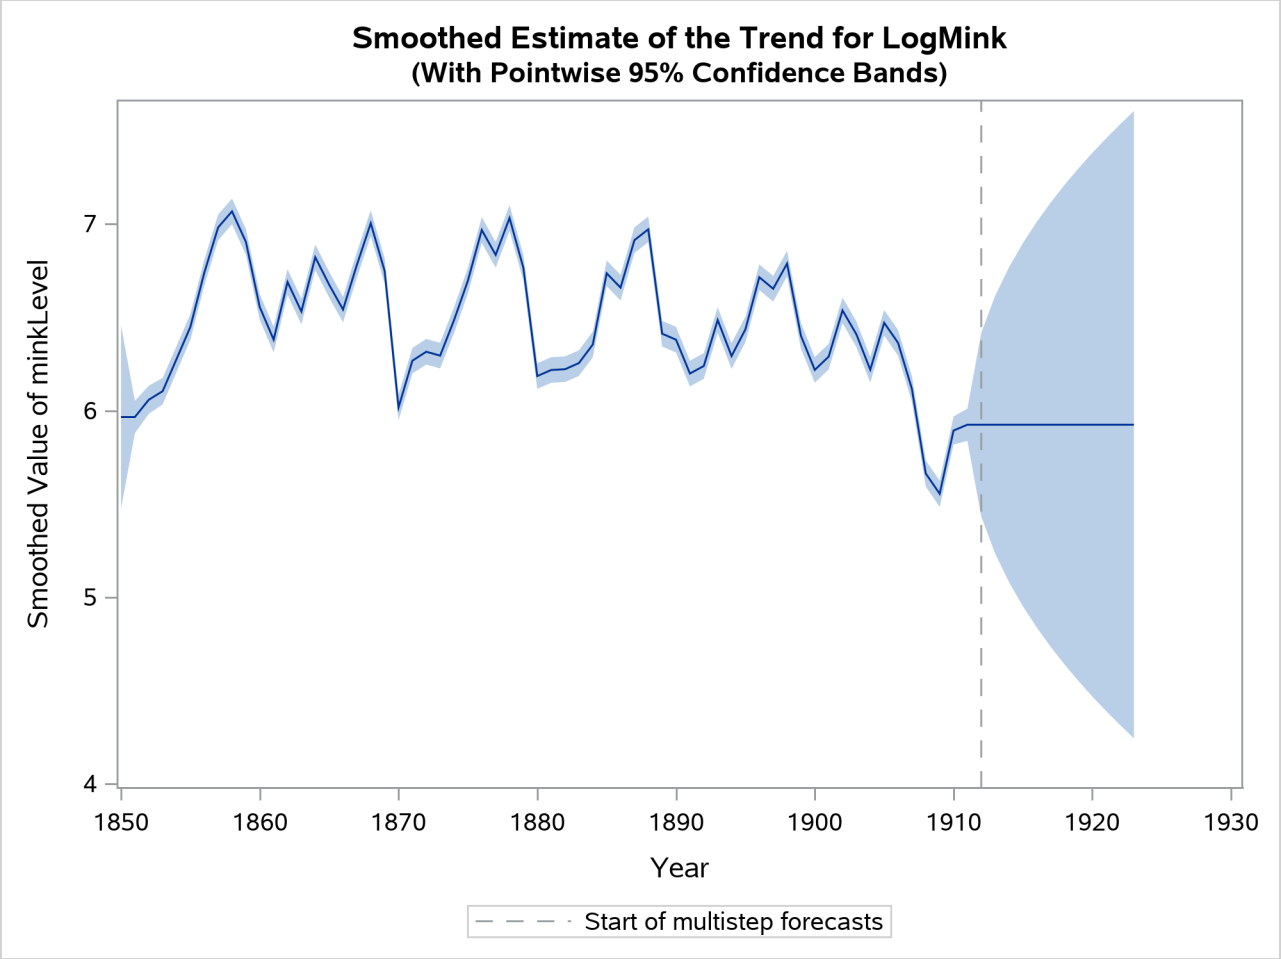
- $\hat{\phi}_{12} = 0.33$ implies that this year's mink abundance is positively correlated with last year's muskrat abundance.
- $\hat{\phi}_{21} = -0.99$ and $\hat{\phi}_{22} = 0.66$ imply that this year's muskrat abundance is negatively correlated with last year's mink abundance and positively correlated with last year's muskrat abundance.
- Even though the parameters were not restricted to ensure stability, the estimated Φ turns out to be stable with a pair of complex eigenvalues, $0.317 \pm i\ 0.473$, and a modulus of 0.570 (these calculations are done separately by using the IML procedure).
- The fact that elements of $\boldsymbol{\xi}_t$ are perfectly negatively correlated further supports the predator-prey relationship.

Finally, Output 33.13.6 shows the plots of one-step-ahead and post-sample forecasts for LogMink and LogMusk, and Output 33.13.7 shows the plot of the smoothed (full-sample) estimate of the first element of $\boldsymbol{\mu}_t$: LogMink Trend.

Output 33.13.6 Forecasts for Mink and Muskrat Fur Sales in Logarithms



Output 33.13.7 Smoothed Estimate of LogMink Trend



Example 33.14: Factor Model: Now-Casting the US Economy

A well-known business conditions index, the Aruoba-Diebold-Scotti (ADS) business conditions index, is designed to track real business conditions at high frequency (for more information about this index, see http://www.philadelphiafed.org/research-and-data/real-time-center/business-conditions-index/). Its underlying (seasonally adjusted) economic indicators (weekly initial jobless claims, monthly payroll employment, industrial production, personal income less transfer payments, manufacturing and trade sales, and quarterly real GDP) blend high- and low-frequency information with stock and flow data. The ADS index is based on a rather elaborate state space model that takes into account the stock and flow nature of the underlying economic indicators. To simplify the illustration, this example uses the same economic indicators to develop a similar index by using a simpler factor model. You can also use PROC SSM to carry out the more elaborate modeling that underlies the ADS index. All these economic indicators are freely available from the Federal Reserve Economic Data (FRED). You can access these data by using the SASEFRED interface engine; see Chapter 48, "The SASEFRED Interface Engine." The names of analysis variables and the relevant information that is needed for using the SASEFRED engine to obtain these data are shown in Table 33.11. All variables are transformed versions of the original series: all, except l_icsa, are both logged and differenced; l_icsa is only logged. The input data set for the analysis,

named econ, is formed by merging these six series of different frequencies. This merging is done by treating them as daily series that have missing values on the days when the series values are not available—for example, ld_pinc is nonmissing only for the first day of the month. The econ data set contains one more variable, recession, which is an indicator variable for the recessionary periods. This time series is an interpretation of the US Business Cycle Expansions and Contractions data that are provided by the National Bureau of Economic Research (NBER) at http://www.nber.org/cycles/cyclesmain.html (also see http://research.stlouisfed.org/fred2/series/USRECDM). The variable recession is not used in modeling. It is used later to demonstrate the adequacy of the activity index that is created in this example.

Table 33.11 Analysis Variables and Their FRED IDs

Name	FRED ID	Frequency	Description
ld_payemp	PAYEMS	Monthly	Payroll employment
ld_pinc	W875RX1	Monthly	Real personal income excluding current transfer receipts
ld_mnfctr	CMRMTSPL	Monthly	Real manufacturing and trade industries sales
ld_indpro	INDPRO	Monthly	Industrial production index
ld_gdp	GDPC1	Quarterly	Real GDP
l_icsa	ICSA	Weekly	Initial jobless claims

For easier model description, the variables ld_payemp to ld_gdp are also denoted as y_{1t} to y_{5t}, and the variable l_icsa is denoted as y_{6t}. Using this notation, the following model is postulated for the six daily time series:

$$\mathbf{y}_{it} = \text{intercept}_i + \beta_i * \text{irw}_t + \epsilon_{it} \qquad 1 \le i \le 5$$
$$\mathbf{y}_{6t} = \mu_t + \beta_6 * \text{irw}_t + \epsilon_{6t}$$

A justification for this model is based on the following observations:

- The five time series y_{1t} to y_{5t} are logged and differenced versions of the underlying economic variables. Their plots (not shown here) show them to be hovering around a constant level, with some periods of deviation from this level. The plot of the sixth series, y_{6t}, which is logged but not differenced, shows a pronounced nonstationary pattern.

- All these series can be considered as proxies, possibly noisy, for the national economic activity. It is therefore reasonable to assume that a model for each of them will contain a common component, appropriately weighted, that is associated with the economic activity. In the current model this common component, named irw_t, is modeled as an integrated random walk. For y_{1t} to y_{5t}, the only other terms in the model are the respective intercepts, intercept_i, and the random disturbances, ϵ_{it}. Because y_{6t} shows a pronounced nonstationary pattern, its model has a time-varying level, μ_t, which is also modeled as an integrated random walk. For identifiability purposes, the initial condition for irw_t is taken to be 0. For the same reason, β_1, the coefficient of irw_t in the model for y_{1t} is taken to be 1.

- The underlying economic variables of the five time series y_{1t} to y_{5t} are positively correlated with the economic activity—for example, payroll employment is expected to increase with increased economic activity. On the other hand, y_{6t}, which is associated with the initial jobless claims, is negatively correlated with the economic activity. This means that, with β_1 taken to be 1, the estimates of

$\beta_2, \ldots, \beta_5$ are expected to be positive and the estimate of β_6 is expected to be negative. In the factor modeling terminology, irw_t is called a factor and $\beta_1, \ldots, \beta_6$ are called the associated factor loadings.

The following statements show you how to specify this model in the SSM procedure:

```
ods output NamedParameterEstimates = named;
proc ssm data=econ opt(tech=activeset);
  id date interval=day;
  parms beta2-beta6;
  parms lv1-lv8;
  avar = exp(lv7);
  wnv1 = exp(lv1);  wnv2 = exp(lv2);
  wnv3 = exp(lv3);  wnv4 = exp(lv4);
  wnv5 = exp(lv5);  wnv6 = exp(lv6);
  tvar = exp(lv8);
  zero = 0;

   /* --- start of model spec ---*/
  state latent(2) t(g)=(1 1 0 1) cov(d)=(zero avar);
  comp c1 = latent[1];
  comp c2 = (beta2)*latent[1];
  comp c3 = (beta3)*latent[1];
  comp c4 = (beta4)*latent[1];
  comp c5 = (beta5)*latent[1];
  comp c6 = (beta6)*latent[1];

  irregular w1 variance=wnv1;
  int1 = 1;
  model ld_payemp = int1 c1 w1;

  irregular w2 variance=wnv2;
  int2 = 1;
  model ld_pinc = int2 c2 w2;

  irregular w3 variance=wnv3;
  int3 = 1;
  model ld_mnfctr = int3 c3 w3;

  irregular w4 variance=wnv4;
  int4 = 1;
  model ld_indpro = int4 c4 w4;

  irregular w5 variance=wnv5;
  int5 = 1;
  model ld_gdp = int5 c5 w5;

  irregular w6 variance=wnv6 ;
  trend t_icsa(ll) levelvar=0 slopevar=tvar;
  model l_icsa = c6 t_icsa w6;
  /* ---model spec done---*/

  eval icsaPattern = c6 + t_icsa;
  /*--index is a scaled version of the common factor--*/
  eval Index = 1000*c1;
```

```
 comp slope = latent[2];
 eval IndexSlope = 1000*slope;
 /*--just so recession is output to the output data set--*/
 rec = recession;
 output out=forecast1 press pdv;
run;
```

A few comments about the program:

- If the model and data are in reasonable accord, the default likelihood optimization settings work in most situations. However, in some cases the likelihood optimization process needs additional customization. Some experimentation with alternative optimization techniques and different parameterization of the model parameters can help. This example turns out to be one such case. The optimization technique ACTIVESET (`opt(tech=activeset)`) works better for WINDOWS and a few other platforms, whereas the default optimization technique works better for the AIX platform. In addition, the variances of all the disturbance terms in the model are parameterized in the exponential scale.

- The two-dimensional state that is associated with irw_t is named latent, and irw_t (the first element of latent) itself is named c1. Note that the second element of latent corresponds to the slope of irw_t. The components c2 to c6 correspond to $\beta_i * \text{irw}_t$ for $2 \leq i \leq 6$.

- The desired business index, named index, is a scaled version of irw_t (`eval Index = 1000*c1;`). This scaling is done purely for ease of display—the scaled values turn out to be in the range of –6.0 to 5.0. Another component, named IndexSlope, contains the slope of index, which is also a quantity of interest.

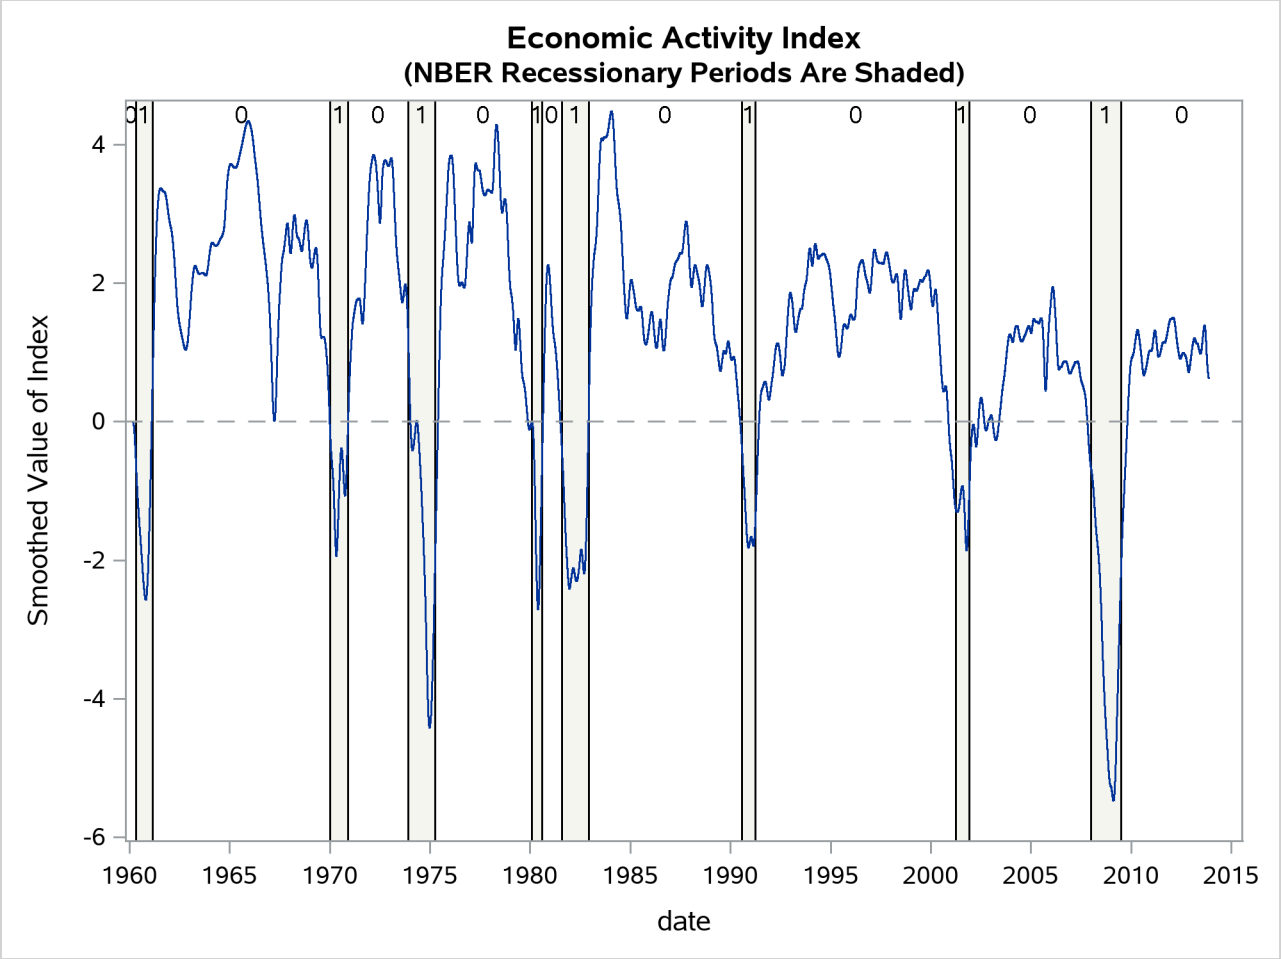
Output 33.14.1 Estimated Factor Loadings

The Estimated Loadings

Parameter	Estimate	StdErr	tValue
beta2	1.15	0.1276	8.98
beta3	1.96	0.2390	8.20
beta4	2.48	0.1646	15.08
beta5	3.27	0.2653	12.33
beta6	-96.44	9.6051	-10.04

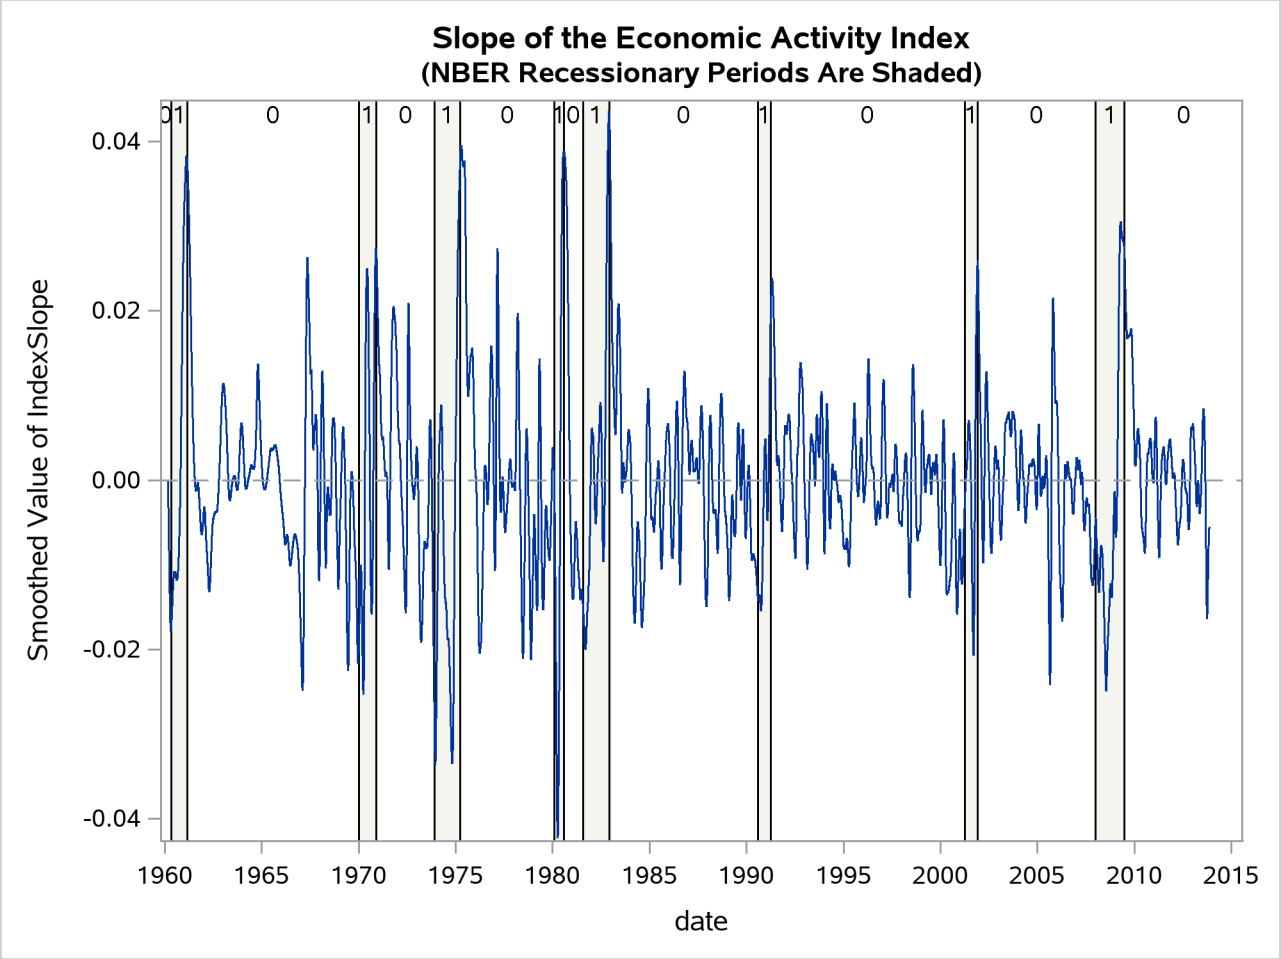
Output 33.14.1 shows the estimated factor loadings. They are statistically significant and their signs are consistent.

Output 33.14.2 The Estimate of Economic Activity Index



Output 33.14.2 shows the plot of the smoothed index. Note that it coheres quite well with the NBER recessionary periods. In Aruoba, Diebold, and Scotti (2009, sec. 4.4) the features of an earlier version of the ADS index are discussed in detail. Similar comments apply to this indicator also.

Output 33.14.3 Estimated Slope of the Economic Activity Index



Finally, Output 33.14.3 shows the plot of the slope of the index, which gives an idea of the direction of the economic activity.

Example 33.15: Longitudinal Data: Lung Function Analysis

The data for this example, which consist of 209 measurements of the lung function of an asthma patient, are analyzed in Wang (2013). The time series is measured mostly at two-hour time intervals but with irregular gaps. Wang (2013) fit a fourth-order continuous-time autoregressive model, CAR(4), to these data. The analysis results in a decomposition of the observed time series in three components:

- a slowly varying trend pattern, which appears to have a slight downward drift
- a diurnal component—a periodic pattern with a period of 24 hours
- a residual component

As shown in Wang (2013), the continuous-time autoregressive models can be formulated as state space models. However, in general, the form of such SSMs is quite complex. Consequently, specifying such a

model by using the current SSM procedure syntax is impractical. On the other hand, you can analyze these types of longitudinal data by using continuous-time structural models, which are easy to specify in the SSM procedure. In this example, the lung function measurements, `y`, are modeled as

$$y_t = \text{intercept} + \beta * t + \zeta_t + \epsilon_t$$

where (intercept $+ \beta * t$) is a simple linear time trend, ζ_t is a continuous-time stochastic cycle, and ϵ_t is a Gaussian white noise sequence. Replacing the linear time trend with a more general time trend, such as a spline smoother, does not seem to change the fit, because the estimated smoothing spline turns out to be almost perfectly linear.

The following statements show you how to specify this model in the SSM procedure:

```
proc ssm data=asth;
   id time;
   state s1(1) type=cycle(CT) cov(g);
   comp c1 = s1[1];
   intercept = 1;
   irregular wn;
   model y= intercept time c1 wn;
   output out=for1 press;
   eval pattern=intercept+time+c1;
run;
```

The continuous-time stochastic cycle, named `c1`, is defined by a pair of STATE and COMPONENT statements. The STATE statement defines `s1` as a state subsection that is associated with a univariate, continuous-time cycle (signified by the use of **`type=cycle(CT)`**). The COMPONENT statement defines `c1` as its first element.

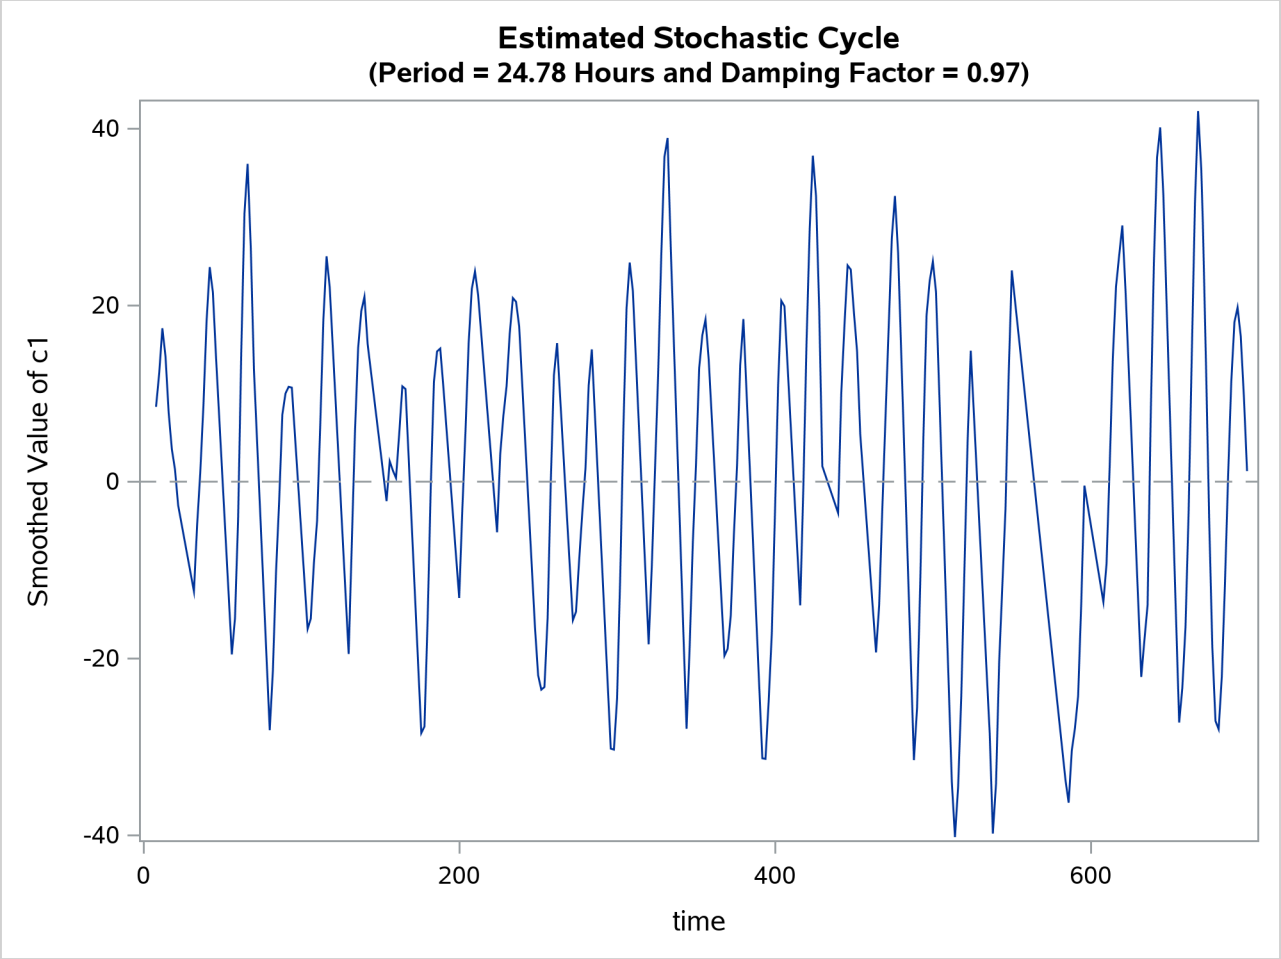
Output 33.15.1 Linear Time Trend: Estimates of Intercept and Slope

Regression Parameter Estimates

Response Variable	Regression Variable	Estimate	Standard Error	t Value	Pr > |t|
y	intercept	502.1637	3.50470	143.28	<.0001
y	time	-0.0201	0.00918	-2.19	0.0286

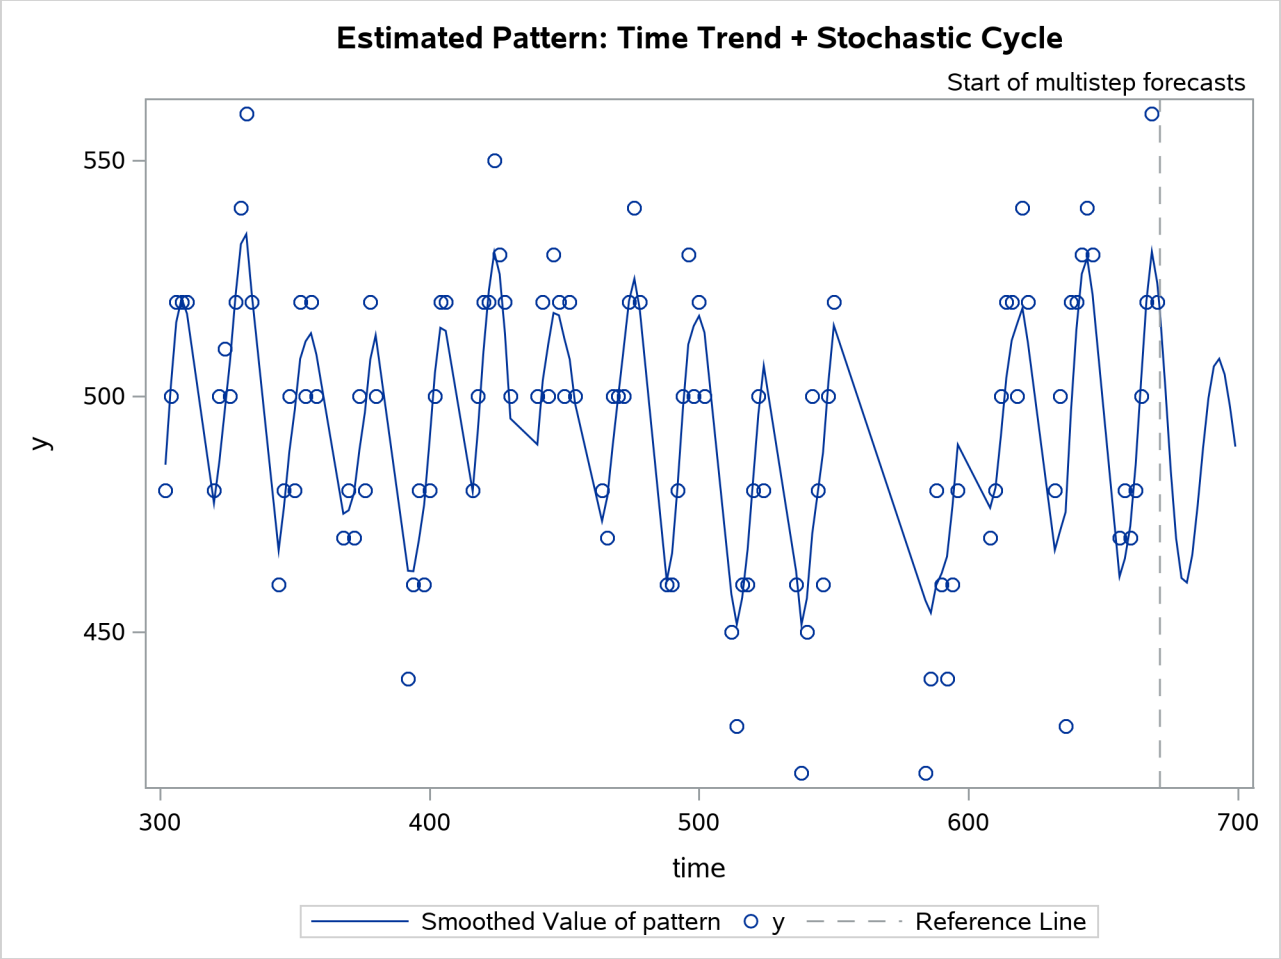
Output 33.15.1 shows the estimated intercept and slope of the time trend. The estimated slope (only marginally significant) is negative, which is consistent with the overall downward drift.

Output 33.15.2 Estimated Stochastic Cycle: ζ_t



Output 33.15.2 shows the plot of the estimated cycle component, which has a period of 24.78 hours and a damping factor of 0.97. That is, it is a nearly persistent diurnal cycle.

Output 33.15.3 Estimated Pattern: Intercept $+ \beta * t + \zeta_t$



Output 33.15.3 shows the fit of the de-noised y values (intercept $+ \beta * t + \zeta_t$). To reduce the clutter, only the second half of the data are plotted. The fit appears to be quite reasonable.

Example 33.16: Temporal Distribution: Estimating Monthly GDP

This example is based on a case study described in Pelagatti (2015, chap. 9, Example 9.2). The case study shows how you can estimate the monthly GDP (gross domestic product) for the United States by temporally distributing the quarterly GDP time series, which is readily available. The temporal distribution process is based on a bivariate model that relates two variables, the quarterly GDP and the monthly industrial production index (both for the United States). Assuming that t denotes the monthly time index, $indp_t$ denotes the monthly industrial production index series, and gdp_t denotes the quarterly GDP series that is organized as a monthly series (by setting the GDP numbers to missing for the months when they are not published), the case

study uses the following model,

$$\begin{aligned} indp_t &= \mu_{1,t} + \psi_{1,t} + \epsilon_{1,t} \\ gdp_t^{\dagger} &= \mu_{2,t} + \psi_{2,t} + \epsilon_{2,t} \\ gdp_t &= gdp_t^{\dagger} + gdp_{t-1}^{\dagger} + gdp_{t-2}^{\dagger} \end{aligned}$$

where

- $gdp_t^{\dagger}$ is the unobserved monthly GDP series (which is to be estimated)
- $\boldsymbol{\mu}_t = (\mu_{1,t}\ \mu_{2,t})$ is a bivariate trend component that follows an integrated random walk
- $\boldsymbol{\psi}_t = (\psi_{1,t}\ \psi_{2,t})$ is a bivariate cycle component
- $\boldsymbol{\epsilon}_t = (\epsilon_{1,t}\ \epsilon_{2,t})$ is a bivariate white noise component

As explained in the section "Temporal Distribution" on page 2458, it is easy to fit this model by using the SSM procedure. As a first step, a data set, Useco, is created that organizes the monthly industrial production index and the quarterly GDP as monthly series. Specifically, Useco contains four variables: date dates the observations, indpro contains the monthly industrial production index, gdp contains the quarterly GDP, and startQ is a dummy variable that indicates the start of the quarter. This data set is essentially the same as the one that is used in the case study, except that, to improve the computational stability, gdp is scaled by 100. This data set has one peculiarity that is not mentioned in the case study: the GDP reporting pattern appears to have changed a few times over the years (October 1969, May 1992, and December 2014). The dummy variable, startQ, which indicates the start of the aggregation interval, is appropriately modified to take these changes into account. Output 33.16.1 shows the first few rows of Useco.

Output 33.16.1 First Few Rows of Useco

date	startQ	gdp	indpro
01JAN47	1	.	13.6351
01FEB47	0	.	13.7156
01MAR47	0	19.3447	13.7962
01APR47	1	.	13.6888
01MAY47	0	.	13.7425
01JUN47	0	19.3228	13.7425
01JUL47	1	.	13.6619
01AUG47	0	.	13.7425

The following statements show you how to specify the bivariate model for indpro and gdp:

```
proc ssm data=useco opt(maxiter=100);
   id date interval=month;
  /* Bivariate integrated random walk */
  state irwState(2) type=ll(slopecov(g));
  comp irwInd = irwState[1];
  comp irwGdp = irwState[2];
  /* Bivariate cycle */
  state cycle(2) type=cycle cov(g);
```

```
  comp cycInd = cycle[1];
  comp cycGdp = cycle[2];
  /* Bivariate white noise */
  state noise(2) type=wn cov(g);
  comp noiseInd = noise[1];
  comp noiseGdp = noise[2];
  /* Observation equations */
  model indpro = irwInd cycInd noiseInd;
  model gdp = irwGdp cycGdp noiseGdp / distribute(start=startQ);
  /* Components for output */
  eval trendCycGdp = irwGdp + cycGdp;
  eval trendCycInd = irwInd + cycInd;
  eval monthlyGdp = irwGdp + cycGdp + noiseGdp;
  /* Output data set */
  output out=forGdp pdv press;
run;
```

Here are a few comments about this program:

- The first STATE statement specifies irwState as a bivariate trend that follows an integrated random walk (which is a local linear trend without the disturbance term in the level equation); irwState corresponds to $\boldsymbol{\mu}_t$. The trend components in the models for indpro and gdp are specified in the two COMP statements that follow: irwInd and irwGdp correspond to $\mu_{1,t}$ and $\mu_{2,t}$, respectively.

- Similarly, the second STATE statement and the two COMP statements that follow it define cycInd and cycGdp as the two cycle components ($\psi_{1,t}$ and $\psi_{2,t}$) in the model.

- The noise components, noiseInd and noiseGdp, which correspond to $\epsilon_{1,t}$ and $\epsilon_{2,t}$, respectively, are also defined in the same way.

- The MODEL statement for indpro corresponds to the equation $indp_t = \mu_{1,t} + \psi_{1,t} + \epsilon_{1,t}$. On the other hand, the DISTRIBUTE(START=*startQ*) option in the MODEL statement of gdp causes gdp to be modeled as an aggregated version of the unobserved monthly GDP series ($gdp_t^{\dagger}$):

$$\begin{aligned} gdp_t^{\dagger} &= \mu_{2,t} + \psi_{2,t} + \epsilon_{2,t} \\ gdp_t &= gdp_t^{\dagger} + gdp_{t-1}^{\dagger} + gdp_{t-2}^{\dagger} \end{aligned}$$

- After the model specification is complete, EVAL statements are used to define some useful linear combinations of the components that are part of the model specification—for example, monthlyGdp (which is defined as a sum of irwGdp, cycGdp, and noiseGdp) corresponds to the unobserved monthly GDP ($gdp_t^{\dagger}$). The SSM procedure outputs the estimates of these components to the data set that is specified in the OUT= option in the OUTPUT statement.

The parameter estimates in Output 33.16.2 are similar to (but not the same as) the parameter estimates reported in the case study. In particular, the estimates of the parameters of the cycle component—for example, the damping factor (Rho = 0.99228) and the period (293.32178)—are reasonably close.

Output 33.16.2 Estimated Model Parameters

Model Parameter Estimates

Component	Type	Parameter	Estimate	Standard Error	t Value
irwState	Slope Disturbance Covari	RootCov[1, 1]	0.10652	0.013572	7.85
irwState	Slope Disturbance Covari	RootCov[2, 1]	0.02060	0.002921	7.05
irwState	Slope Disturbance Covari	RootCov[2, 2]	0.00128	0.000507	2.52

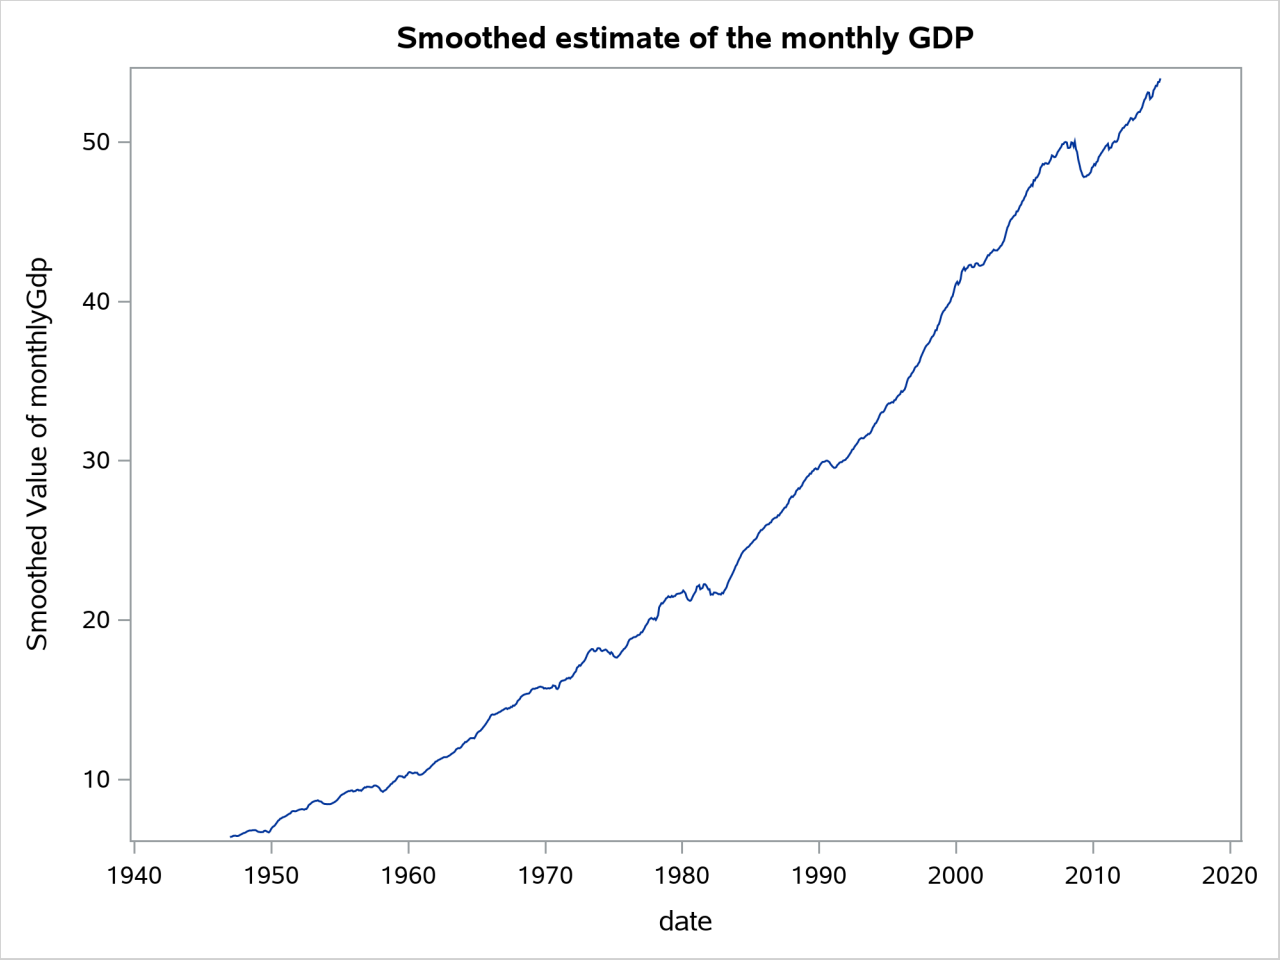
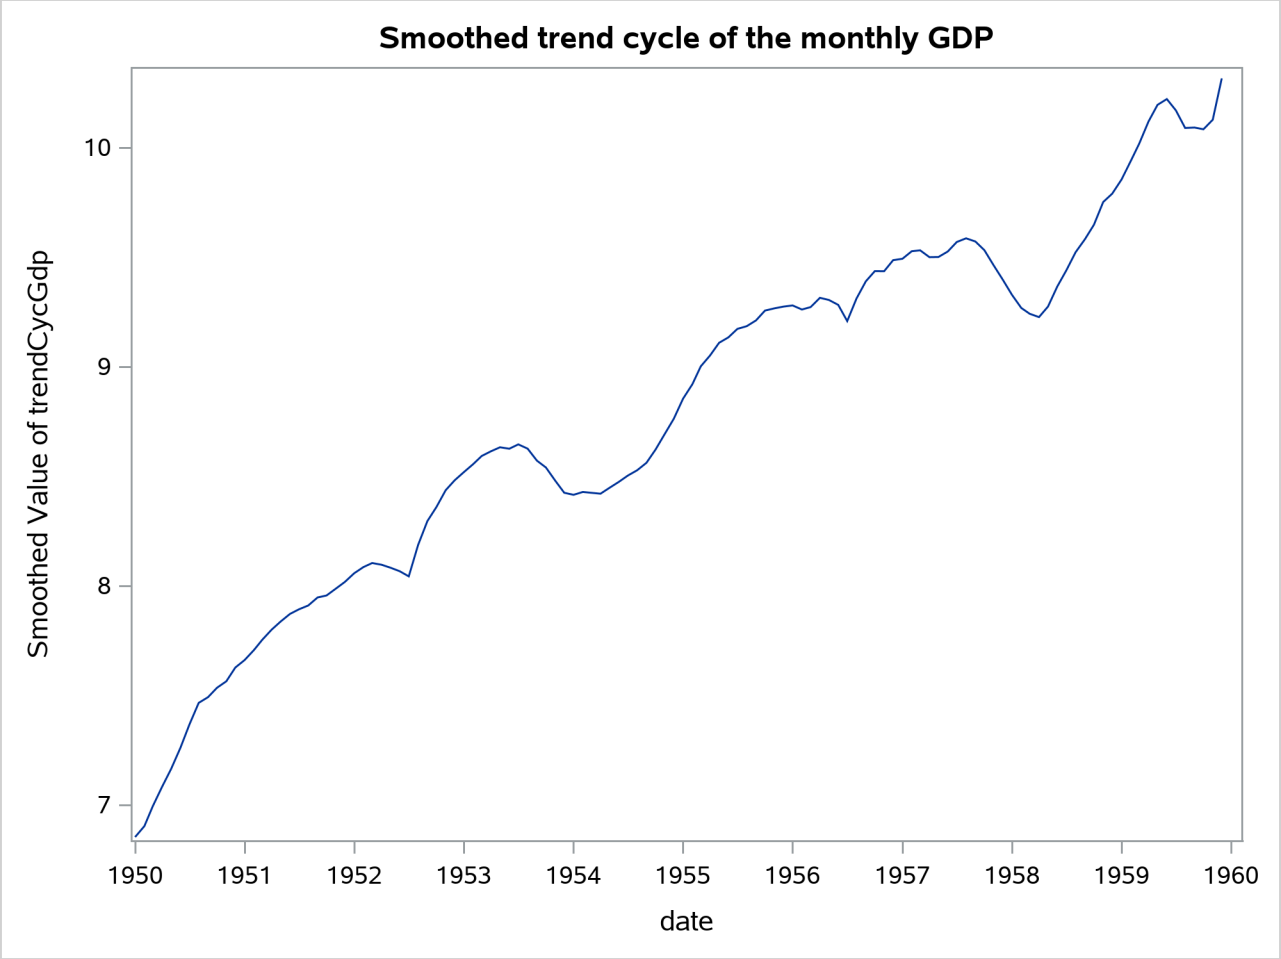
Output 33.16.3 shows the plot of the estimated monthly GDP, and Output 33.16.4 shows the plot of the estimate of monthly trend-cycle estimate ($\mu_{2,t} + \psi_{2,t}$) for GDP.

Output 33.16.3 Estimate of Monthly GDP



Output 33.16.4 Smoothed Trend-Cycle Component of Monthly GDP (1950 to 1960)



Example 33.17: Temporal Aggregation: Triannual Nile River Level

This example illustrates how you can do model-based temporal aggregation of a response variable. The following DATA step creates a data set, Nile, by using a well-known data set that contains annual recordings of the Nile water level measured between the years 1871 and 1970. The Nile water level is clearly a stock variable, and temporal aggregation of such variables is usually meaningless. However, for illustration purposes, assume that you are interested in forecasting triannual totals of the water level.

```
data Nile;
   input level @@;
   year = intnx( 'year', '1jan1871'd, _n_-1 );
   format year year4.;
   startAggr = (mod(_n_, 3) = 1);

```

The Nile date set contains three variables: year indicates the observation year, level contains the yearly water level, and startAggr is a dummy variable that indicates the start of the triannual aggregation intervals. It is known that for the time span of the observations, the yearly water levels can be reasonably modeled as a sum of a random walk trend, a level shift in the year 1899, and the observation error. The following statements show you how to obtain forecasts of the triannual water level that are consistent with the model postulated for the yearly water levels:

```
proc ssm data=Nile;
  id year interval=year;
  shift1899 = ( year >= '1jan1899'd );
  trend rw(rw);
  irregular wn;
  model level = shift1899 RW wn  / aggregate(start=startAggr);
  output out=nileOut;
quit;
```

As a result of running this program, you get the usual output that is associated with fitting the specified model to the yearly water level. In addition (as explained in the section "Temporal Aggregation" on page 2460), the AGGREGATE option in the MODEL statement causes the estimation and printing of triannual aggregates of the water level. Output 33.17.1 shows the last few rows of this output. When the summands—the response values—in the aggregation are known, the aggregation can be done without error; that is, the standard error of the estimation is zero. However, when at least one summand in the aggregate is missing, the standard error of estimation is nonzero.

Output 33.17.1 Triannual Aggregate Values of the Nile Water Levels (Partial Output)

Time	Response	Start_Flag	Aggregate	StdErr	Lower	Upper
1967	919	1	919	0	919	919
1968	718	0	1637	0	1637	1637
1969	714	0	2351	0	2351	2351
1970	740	1	740	0	740	740

Example 33.18: Invariance of the Marginal Likelihood under Linear Rescaling of the Diffuse Effects

Consider the following alternate but equivalent specifications of a trend-plus-seasonal model (monthly seasonality):

$$y_t = \mu_t + \psi_t + \epsilon_t \qquad \text{Spec1}$$
$$y_t = \mu_t + m_{1,t} + \cdots + m_{11,t} + \epsilon_t \qquad \text{Spec2}$$

Here the trend (μ_t, a random walk with drift) and the irregular component (ϵ_t, white noise) are the same in both the specifications. However, the seasonal component is specified differently: in Spec1 the seasonality is modeled as a deterministic trigonometric seasonal component (ψ_t) whereas in Spec2 it is modeled using the seasonal dummies ($m_1 \cdots m_{11}$). Spec1 and Spec2 are statistically equivalent models from the perspective of the data generation process. This example uses these two specifications to demonstrate a useful invariance property of the marginal and profile likelihoods, which is described in the section "Likelihood Computation and Model-Fitting Phase" on page 2439. The airline passenger series, given as Series G in Box and Jenkins (1976), is used to illustrate the computations. The following DATA step prepares the log-transformed passenger series and the seasonal dummies that are needed for this example:

```
data seriesG;
   set sashelp.air;
   logair = log(air);
   array m{11} m1-m11;
   do i=1 to 11;
      m[i] = (month(date)=i);
   end;
run;
```

The following statements fit the two models to the log-transformed passenger series. The first PROC SSM call fits Spec1, and the second call fits Spec2.

```
proc ssm data=seriesG plots=none like=marginal;
   id date interval=month;
   trend rwDrift(ll) slopevar=0;
   irregular wn;
   state trigState(1) type=season(length=12);
   comp season = trigState[1];
   model logair = rwDrift season wn;
run;

proc ssm data=seriesG plots=none like=marginal;
   id date interval=month;
   trend rwDrift(ll) slopevar=0;
   irregular wn;
   model logair = rwDrift m1-m11 wn;
run;
```

For these two models, the parameter estimates that are based on the diffuse likelihood (REML_D) and the marginal likelihood ((REML_M) coincide because the extra term in the marginal likelihood ($-\log(|\mathbf{S}^*_{n,p_n}|)$) turns out to be independent of these parameters. Nevertheless, it is useful to use the LIKE=MARGINAL option in the PROC SSM statement so that both the likelihood computation summary and the information criteria tables display the likelihood values and the information criteria for all three likelihoods—diffuse,

marginal, and profile—at the estimated parameters. The parameter estimates for Spec1 and Spec2 are displayed in Output 33.18.1 and Output 33.18.2, respectively. As expected, the parameter estimates for the two specifications are the same because they are statistically equivalent models. The other aspects of the fit (such as model-based forecasts), which are not shown, also agree.

Output 33.18.1 Parameter Estimates For Spec1

Model Parameter Estimates

Component	Type	Parameter	Estimate	Standard Error	t Value
rwDrift	LL Trend	Level Variance	0.000766	0.000219	3.49
wn	Irregular	Variance	0.000368	0.000141	2.60

Output 33.18.2 Parameter Estimates For Spec2

Model Parameter Estimates

Component	Type	Parameter	Estimate	Standard Error	t Value
rwDrift	LL Trend	Level Variance	0.000766	0.000219	3.49
wn	Irregular	Variance	0.000368	0.000141	2.60

The fit summary tables shown in Output 33.18.3 (for Spec1) and Output 33.18.4 (for Spec2) show that the marginal and profile likelihoods (the last two lines in each table) for the two specifications also agree. However, you can see that the diffuse likelihood value for the two specifications differ (diffuse likelihood = 215.45 for Spec1 and diffuse likelihood = 226.89 for Spec2). This difference occurs because the diffuse likelihood is not invariant to the different (but equivalent) formulations of the seasonal effects. This also means that the information criteria that are based on the marginal and profile likelihoods, which are shown in Output 33.18.5 (for Spec1) and Output 33.18.6 (for Spec2), correctly conclude that the two specifications cannot be distinguished on the basis of these criteria, whereas the information criteria that are based on the diffuse likelihood erroneously suggest that Spec1 is inferior to Spec2.

Output 33.18.3 Likelihood Computation Summary For Spec1

Likelihood Computation Summary

Statistic	Value
Nonmissing Response Values Used	144
Estimated Parameters	2
Initialized Diffuse State Elements	13
Normalized Residual Sum of Squares	131
Diffuse Log Likelihood	215.4522
Profile Log Likelihood	265.63882
Marginal Log Likelihood	248.01412

Output 33.18.4 Likelihood Computation Summary For Spec2

Likelihood Computation Summary	
Statistic	**Value**
Nonmissing Response Values Used	144
Estimated Parameters	2
Initialized Diffuse State Elements	13
Normalized Residual Sum of Squares	131
Diffuse Log Likelihood	226.8959
Profile Log Likelihood	265.63882
Marginal Log Likelihood	248.01412

Output 33.18.5 Information Criteria For Spec1

Information Criteria			
Statistic	**Diffuse Likelihood Based**	**Profile Likelihood Based**	**Marginal Likelihood Based**
AIC (lower is better)	-426.9044	-501.2776	-492.0282
BIC (lower is better)	-421.1540	-456.7304	-486.2779
AICC (lower is better)	-426.8106	-497.5276	-491.9345
HQIC (lower is better)	-424.5678	-483.1762	-489.6916
CAIC (lower is better)	-419.1540	-441.7304	-484.2779

Output 33.18.6 Information Criteria For Spec2

Information Criteria			
Statistic	**Diffuse Likelihood Based**	**Profile Likelihood Based**	**Marginal Likelihood Based**
AIC (lower is better)	-449.7918	-501.2776	-492.0282
BIC (lower is better)	-444.0414	-456.7304	-486.2779
AICC (lower is better)	-449.6981	-497.5276	-491.9345
HQIC (lower is better)	-447.4552	-483.1762	-489.6916
CAIC (lower is better)	-442.0414	-441.7304	-484.2779

This example highlights the care that must be taken while doing model selection based on information criteria. It suggests that information criteria that are based on the marginal and profile likelihoods are preferred over the information criteria that are based on diffuse likelihood.

Overview: STATESPACE Procedure

The STATESPACE procedure has largely been superseded by the newer SSM procedure. PROC SSM fits and forecasts very general linear state space models. It supports irregularly spaced time series and replicated longitudinal data, in addition to supporting regular fixed-period time series. The SSM procedure also provides a powerful expressive language for specifying state space models, and allows programming statements to define model elements through user-written functions of unlimited complexity. The SSM procedure also provides more modern estimation, filtering, and forecasting algorithms than the older STATESPACE procedure. For more information about PROC SSM, see Chapter 33, "The SSM Procedure."

Although the SSM procedure should be preferred to the STATESPACE procedure for most state space modeling applications, the STATESPACE procedure should be considered if you wish to perform automated multivariate forecasting using a state space model selected through the modeling strategy proposed by Akaike (1976). This strategy employs an initial sequence of unrestricted vector autoregressive (VAR) models, selection of an initial VAR model using Akaike's information criterion (AIC), followed by a canonical correlation analysis for the automatic identification of the state space model to use to forecast the vector of time series.

The operation of the STATESPACE procedure and the form of state space model it supports are described in the following.

The STATESPACE procedure uses the state space model to analyze and forecast multivariate time series. The STATESPACE procedure is appropriate for jointly forecasting several related time series that have dynamic interactions. By taking into account the autocorrelations among all the variables in a set, it is possible that the STATESPACE procedure may give better forecasts than methods that model each series separately.

By default, the STATESPACE procedure automatically selects a state space model appropriate for the time series, making the procedure a good tool for automatic forecasting of multivariate time series. Alternatively, you can specify the state space model by giving the form of the state vector and the state transition and innovation matrices.

The methods used by the STATESPACE procedure assume that the time series are jointly stationary. Nonstationary series must be made stationary by some preliminary transformation, usually by differencing. The STATESPACE procedure enables you to specify differencing of the input data. When differencing is specified, the STATESPACE procedure automatically integrates forecasts of the differenced series to produce forecasts of the original series.

The State Space Model

The *state space model* represents a multivariate time series through auxiliary variables, some of which might not be directly observable. These auxiliary variables are called the *state vector*. The state vector summarizes all the information from the present and past values of the time series that is relevant to the prediction of future values of the series. The observed time series are expressed as linear combinations of the state variables. The state space model is also called a Markovian representation, or a canonical representation, of a multivariate time series process. The state space approach to modeling a multivariate stationary time series is summarized in Akaike (1976).

The state space form encompasses a very rich class of models. Any Gaussian multivariate stationary time series can be written in a state space form, provided that the dimension of the predictor space is finite. In particular, any autoregressive moving average (ARMA) process has a state space representation and, conversely, any state space process can be expressed in an ARMA form (Akaike 1974). For more information about the relationship between the state space and ARMA forms, see the section "Relation of ARMA and State Space Forms" on page 2590.

Let $\mathbf{x}_t$ be the $r \times 1$ vector of observed variables, after differencing (if differencing is specified) and subtracting the sample mean. Let $\mathbf{z}_t$ be the state vector of dimension s, $s \geq r$, where the first r components of $\mathbf{z}_t$ consist of $\mathbf{x}_t$. Let the notation $\mathbf{x}_{t+k|t}$ represent the conditional expectation (or prediction) of $\mathbf{x}_{t+k}$ based on the information available at time t. Then the last $s - r$ elements of $\mathbf{z}_t$ consist of elements of $\mathbf{x}_{t+k|t}$, where $k > 0$ is specified or determined automatically by the procedure.

There are various forms of the state space model in use. The form of the state space model used by the STATESPACE procedure is based on Akaike (1976). The model is defined by the following *state transition equation*:

$$\mathbf{z}_{t+1} = \mathbf{F}\mathbf{z}_t + \mathbf{G}\mathbf{e}_{t+1}$$

In the state transition equation, the $s \times s$ coefficient matrix $\mathbf{F}$ is called the *transition matrix*; it determines the dynamic properties of the model.

The $s \times r$ coefficient matrix $\mathbf{G}$ is called the *input matrix*; it determines the variance structure of the transition equation. For model identification, the first r rows and columns of $\mathbf{G}$ are set to an $r \times r$ identity matrix.

The input vector $\mathbf{e}_t$ is a sequence of independent normally distributed random vectors of dimension r with mean $\mathbf{0}$ and covariance matrix $\Sigma_{\mathbf{ee}}$. The random error $\mathbf{e}_t$ is sometimes called the innovation vector or shock vector.

In addition to the state transition equation, state space models usually include a *measurement equation* or *observation equation* that gives the observed values $\mathbf{x}_t$ as a function of the state vector $\mathbf{z}_t$. However, since PROC STATESPACE always includes the observed values $\mathbf{x}_t$ in the state vector $\mathbf{z}_t$, the measurement equation in this case merely represents the extraction of the first r components of the state vector.

The measurement equation used by the STATESPACE procedure is

$$\mathbf{x}_t = [\mathbf{I}_r \mathbf{0}]\mathbf{z}_t$$

where $\mathbf{I}_r$ is an $r \times r$ identity matrix. In practice, PROC STATESPACE performs the extraction of $\mathbf{x}_t$ from $\mathbf{z}_t$ without reference to an explicit measurement equation.

In summary:

- $\mathbf{x}_t$ is an observation vector of dimension r.
- $\mathbf{z}_t$ is a state vector of dimension s, whose first r elements are $\mathbf{x}_t$ and whose last $s - r$ elements are conditional prediction of future $\mathbf{x}_t$.
- $\mathbf{F}$ is an $s \times s$ transition matrix.
- $\mathbf{G}$ is an $s \times r$ input matrix, with the identity matrix $\mathbf{I}_r$ forming the first r rows and columns.
- $\mathbf{e}_t$ is a sequence of independent normally distributed random vectors of dimension r with mean $\mathbf{0}$ and covariance matrix $\Sigma_{\mathbf{ee}}$.

How PROC STATESPACE Works

The design of the STATESPACE procedure closely follows the modeling strategy proposed by Akaike (1976). This strategy employs canonical correlation analysis for the automatic identification of the state space model.

Following Akaike (1976), the procedure first fits a sequence of unrestricted vector autoregressive (VAR) models and computes Akaike's information criterion (AIC) for each model. The vector autoregressive models are estimated using the sample autocovariance matrices and the Yule-Walker equations. The order of the VAR model that produces the smallest Akaike's information criterion is chosen as the order (number of lags into the past) to use in the canonical correlation analysis.

The elements of the state vector are then determined via a sequence of canonical correlation analyses of the sample autocovariance matrices through the selected order. This analysis computes the sample canonical correlations of the past with an increasing number of steps into the future. Variables that yield significant correlations are added to the state vector; those that yield insignificant correlations are excluded from further consideration. The importance of the correlation is judged on the basis of another information criterion proposed by Akaike. For more information, see the section "Canonical Correlation Analysis Options" on page 2575. If you specify the state vector explicitly, these model identification steps are omitted.

After the state vector is determined, the state space model is fit to the data. The free parameters in the $\mathbf{F}$, $\mathbf{G}$, and $\mathbf{\Sigma}_{\mathbf{ee}}$ matrices are estimated by approximate maximum likelihood. By default, the $\mathbf{F}$ and $\mathbf{G}$ matrices are unrestricted, except for identifiability requirements. Optionally, conditional least squares estimates can be computed. You can impose restrictions on elements of the $\mathbf{F}$ and $\mathbf{G}$ matrices.

After the parameters are estimated, the Kalman filtering technique is used to produce forecasts from the fitted state space model. If differencing was specified, the forecasts are integrated to produce forecasts of the original input variables.

Getting Started: STATESPACE Procedure

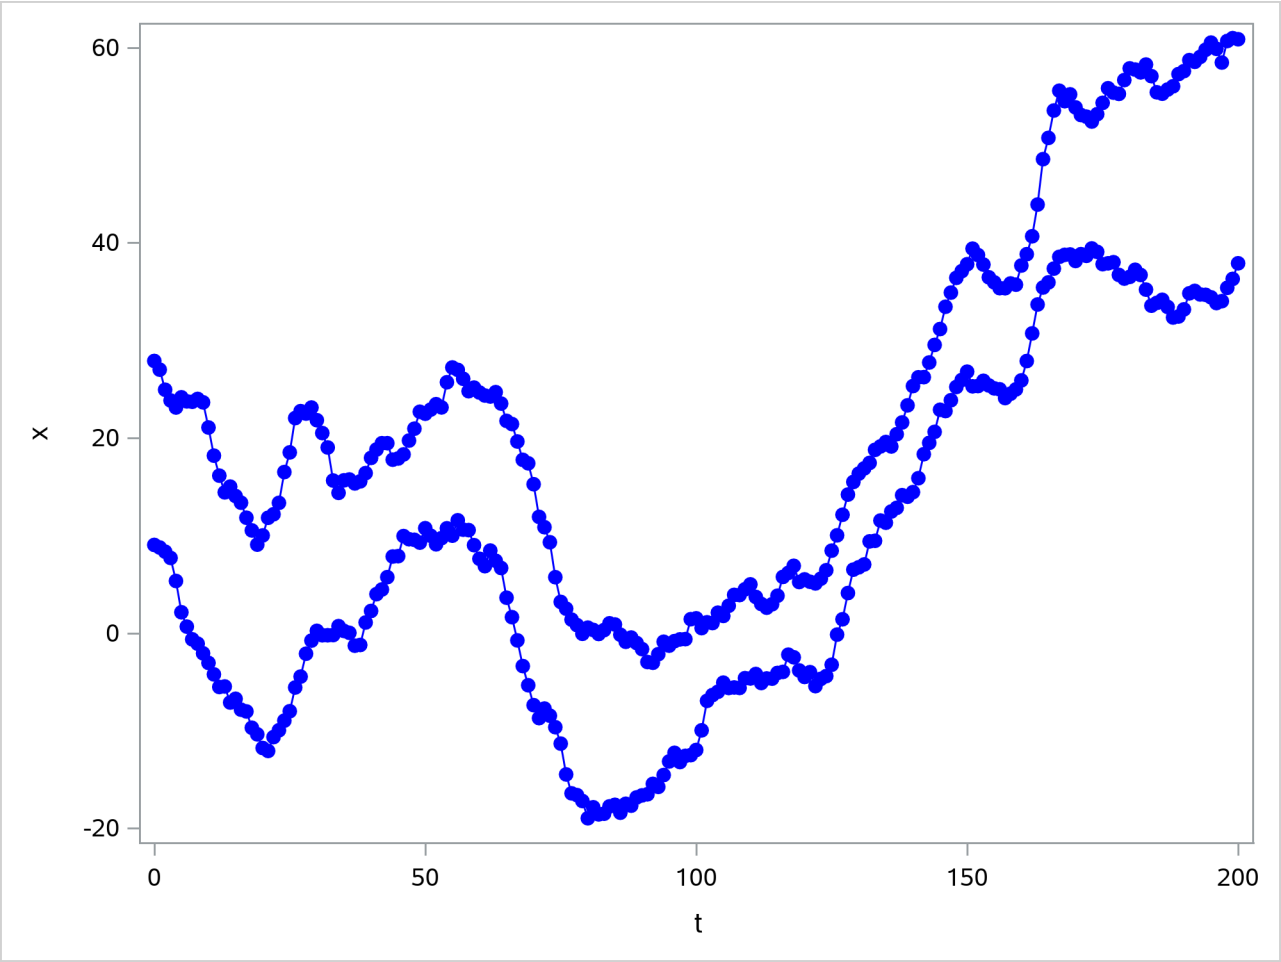
The following introductory example uses simulated data for two variables X and Y. The following statements generate the X and Y series:

```
data in;
   x=10;  y=40;
   x1=0; y1=0;
   a1=0; b1=0;
   iseed=123;
   do t=-100 to 200;
      a=rannor(iseed);
      b=rannor(iseed);
      dx = 0.5*x1 + 0.3*y1 + a - 0.2*a1 - 0.1*b1;
      dy = 0.3*x1 + 0.5*y1 + b;
      x = x + dx + .25;
      y = y + dy + .25;
      if t >= 0 then output;
      x1 = dx; y1 = dy;
      a1 = a; b1 = b;
   end;
```

```
    keep t x y;
run;
```

The simulated series X and Y are shown in Figure 34.1.

Figure 34.1 Example Series



Automatic State Space Model Selection

The STATESPACE procedure is designed to automatically select the best state space model for forecasting the series. You can specify your own model if you want, and you can use the output from PROC STATESPACE to help you identify a state space model. However, the easiest way to use PROC STATESPACE is to let it choose the model.

Stationarity and Differencing

Although PROC STATESPACE selects the state space model automatically, it does assume that the input series are stationary. If the series are nonstationary, then the process might fail. Therefore the first step is to examine your data and test to see if differencing is required. (For further discussion of this issue, see the section "Stationarity and Differencing" on page 2580.)

The series shown in Figure 34.1 are nonstationary. In order to forecast X and Y with a state space model, you must difference them (or use some other detrending method). If you fail to difference when needed and try to use PROC STATESPACE with nonstationary data, an inappropriate state space model might be selected, and the model estimation might fail to converge.

The following statements identify and fit a state space model for the first differences of X and Y, and forecast X and Y 10 periods ahead:

```
proc statespace data=in out=out lead=10;
   var x(1) y(1);
   id t;
run;
```

The DATA= option specifies the input data set and the OUT= option specifies the output data set for the forecasts. The LEAD= option specifies forecasting 10 observations past the end of the input data. The VAR statement specifies the variables to forecast and specifies differencing. The notation X(1) Y(1) specifies that the state space model analyzes the first differences of X and Y.

Descriptive Statistics and Preliminary Autoregressions

The first page of the printed output produced by the preceding statements is shown in Figure 34.2.

Figure 34.2 Descriptive Statistics and VAR Order Selection

Number of Observations	200

Variable	Mean	Standard Error	
x	0.144316	1.233457	Has been differenced. With period(s) = 1.
y	0.164871	1.304358	Has been differenced. With period(s) = 1.

The STATESPACE Procedure

Information Criterion for Autoregressive Models										
Lag=0	Lag=1	Lag=2	Lag=3	Lag=4	Lag=5	Lag=6	Lag=7	Lag=8	Lag=9	Lag=10
149.697	8.387786	5.517099	12.05986	15.36952	21.79538	24.00638	29.88874	33.55708	41.17606	47.70222

Schematic Representation of Correlations											
Name/Lag	0	1	2	3	4	5	6	7	8	9	10
x	++	++	++	++	++	++	+.	..	+.	+.	..
y	++	++	++	++	++	+.	+.	+.	+.	..	..

+ is > 2*std error, - is < -2*std error, . is between

Descriptive statistics are printed first, giving the number of nonmissing observations after differencing and

the sample means and standard deviations of the differenced series. The sample means are subtracted before the series are modeled (unless the NOCENTER option is specified), and the sample means are added back when the forecasts are produced.

Let X_t and Y_t be the observed values of X and Y, and let x_t and y_t be the values of X and Y after differencing and subtracting the mean difference. The series $\mathbf{x}_t$ modeled by the STATEPSPACE procedure is

$$\mathbf{x}_t = \begin{bmatrix} x_t \\ y_t \end{bmatrix} = \begin{bmatrix} (1-B)X_t - 0.144316 \\ (1-B)Y_t - 0.164871 \end{bmatrix}$$

where B represents the backshift operator.

After the descriptive statistics, PROC STATESPACE prints the Akaike's information criterion (AIC) values for the autoregressive models fit to the series. The smallest AIC value, in this case 5.517 at lag 2, determines the number of autocovariance matrices analyzed in the canonical correlation phase.

A schematic representation of the autocorrelations is printed next. This indicates which elements of the autocorrelation matrices at different lags are significantly greater than or less than 0.

The second page of the STATESPACE printed output is shown in Figure 34.3.

Figure 34.3 Partial Autocorrelations and VAR Model

Schematic Representation of Partial Autocorrelations

Name/Lag	1	2	3	4	5	6	7	8	9	10
x	++	+.	. .	. .	. .	. .	. .	. .	. .	. .
y	++	. .	. .	. .	. .	. .	. .	. .	. .	. .

+ is > 2*std error, - is < -2*std error, . is between

Yule-Walker Estimates for Minimum AIC

	Lag=1		Lag=2	
	x	y	x	y
x	0.257438	0.202237	0.170812	0.133554
y	0.292177	0.469297	-0.00537	-0.00048

Figure 34.3 shows a schematic representation of the partial autocorrelations, similar to the autocorrelations shown in Figure 34.2. The selection of a second order autoregressive model by the AIC statistic looks reasonable in this case because the partial autocorrelations for lags greater than 2 are not significant.

Next, the Yule-Walker estimates for the selected autoregressive model are printed. This output shows the coefficient matrices of the vector autoregressive model at each lag.

Selected State Space Model Form and Preliminary Estimates

After the autoregressive order selection process has determined the number of lags to consider, the canonical correlation analysis phase selects the state vector. By default, output for this process is not printed. You can use the CANCORR option to print details of the canonical correlation analysis. For an explanation of this process, see the section "Canonical Correlation Analysis Options" on page 2575.

After the state vector is selected, the state space model is estimated by approximate maximum likelihood. Information from the canonical correlation analysis and from the preliminary autoregression is used to form

preliminary estimates of the state space model parameters. These preliminary estimates are used as starting values for the iterative estimation process.

The form of the state vector and the preliminary estimates are printed next, as shown in Figure 34.4.

Figure 34.4 Preliminary Estimates of State Space Model

The STATESPACE Procedure
Selected Statespace Form and Preliminary Estimates

State Vector		
x(T;T)	y(T;T)	x(T+1;T)

Estimate of Transition Matrix		
0	0	1
0.291536	0.468762	-0.00411
0.24869	0.24484	0.204257

Input Matrix for Innovation	
1	0
0	1
0.257438	0.202237

Variance Matrix for Innovation	
0.945196	0.100786
0.100786	1.014703

Figure 34.4 first prints the state vector as X[T;T] Y[T;T] X[T+1;T]. This notation indicates that the state vector is

$$\mathbf{z}_t = \begin{bmatrix} x_{t|t} \\ y_{t|t} \\ x_{t+1|t} \end{bmatrix}$$

The notation $x_{t+1|t}$ indicates the conditional expectation or prediction of x_{t+1} based on the information available at time t, and $x_{t|t}$ and $y_{t|t}$ are x_t and y_t, respectively.

The remainder of Figure 34.4 shows the preliminary estimates of the transition matrix $\mathbf{F}$, the input matrix $\mathbf{G}$, and the covariance matrix $\mathbf{\Sigma}_{ee}$.

Estimated State Space Model

The next page of the STATESPACE output prints the final estimates of the fitted model, as shown in Figure 34.5. This output has the same form as in Figure 34.4, but it shows the maximum likelihood estimates instead of the preliminary estimates.

Figure 34.5 Fitted State Space Model

The STATESPACE Procedure
Selected Statespace Form and Fitted Model

State Vector		
x(T;T)	y(T;T)	x(T+1;T)

Estimate of Transition Matrix		
0	0	1
0.297273	0.47376	-0.01998
0.2301	0.228425	0.256031

Input Matrix for Innovation	
1	0
0	1
0.257284	0.202273

Variance Matrix for Innovation	
0.945188	0.100752
0.100752	1.014712

The estimated state space model shown in Figure 34.5 is

$$\begin{bmatrix} x_{t+1|t+1} \\ y_{t+1|t+1} \\ x_{t+2|t+1} \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 \\ 0.297 & 0.474 & -0.020 \\ 0.230 & 0.228 & 0.256 \end{bmatrix} \begin{bmatrix} x_t \\ y_t \\ x_{t+1|t} \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 0.257 & 0.202 \end{bmatrix} \begin{bmatrix} e_{t+1} \\ n_{t+1} \end{bmatrix}$$

$$\operatorname{var} \begin{bmatrix} e_{t+1} \\ n_{t+1} \end{bmatrix} = \begin{bmatrix} 0.945 & 0.101 \\ 0.101 & 1.015 \end{bmatrix}$$

The next page of the STATESPACE output lists the estimates of the free parameters in the **F** and **G** matrices with standard errors and t statistics, as shown in Figure 34.6.

Figure 34.6 Final Parameter Estimates

Parameter Estimates			
Parameter	Estimate	Standard Error	t Value
F(2,1)	0.297273	0.129995	2.29
F(2,2)	0.473760	0.115688	4.10
F(2,3)	-0.01998	0.313025	-0.06
F(3,1)	0.230100	0.126226	1.82
F(3,2)	0.228425	0.112978	2.02
F(3,3)	0.256031	0.305256	0.84
G(3,1)	0.257284	0.071060	3.62
G(3,2)	0.202273	0.068593	2.95

Convergence Failures

The maximum likelihood estimates are computed by an iterative nonlinear maximization algorithm, which might not converge. If the estimates fail to converge, warning messages are printed in the output.

If you encounter convergence problems, you should recheck the stationarity of the data and ensure that the specified differencing orders are correct. Attempting to fit state space models to nonstationary data is a common cause of convergence failure. You can also use the MAXIT= option to increase the number of iterations allowed, or experiment with the convergence tolerance options DETTOL= and PARMTOL=.

Forecast Data Set

The following statements print the output data set. The WHERE statement excludes the first 190 observations from the output, so that only the forecasts and the last 10 actual observations are printed.

```
proc print data=out;
   id t;
   where t > 190;
run;
```

The PROC PRINT output is shown in Figure 34.7.

Figure 34.7 OUT= Data Set Produced by PROC STATESPACE

210	.	41.3332	.	6.89383	.	64.0572	.	7.42114

The OUT= data set produced by PROC STATESPACE contains the VAR and ID statement variables. In addition, for each VAR statement variable, the OUT= data set contains the variables FOR*i*, RES*i*, and STD*i*. These variables contain the predicted values, residuals, and forecast standard errors for the *i*th variable in the VAR statement list. In this case, X is listed first in the VAR statement, so FOR1 contains the forecasts of X, while FOR2 contains the forecasts of Y.

The following statements plot the forecasts and actuals for the series:

```
proc sgplot data=out noautolegend;
   where t > 150;
   series x=t y=for1 / markers
    markerattrs=(symbol=circle color=blue)
    lineattrs=(pattern=solid color=blue);
  series x=t y=for2 / markers
   markerattrs=(symbol=circle color=blue)
   lineattrs=(pattern=solid color=blue);
  series x=t y=x / markers
   markerattrs=(symbol=circle color=red)
   lineattrs=(pattern=solid color=red);
  series x=t y=y / markers
   markerattrs=(symbol=circle color=red)
   lineattrs=(pattern=solid color=red);
  refline 200.5 / axis=x;
run;
```

The forecast plot is shown in Figure 34.8. The last 50 observations are also plotted to provide context, and a reference line is drawn between the historical and forecast periods.

Figure 34.8 Plot of Forecasts

Controlling Printed Output

By default, the STATESPACE procedure produces a large amount of printed output. The NOPRINT option suppresses all printed output. You can suppress the printed output for the autoregressive model selection process with the PRINTOUT=NONE option. The descriptive statistics and state space model estimation output are still printed when PRINTOUT=NONE is specified. You can produce more detailed output with the PRINTOUT=LONG option and by specifying the printing control options CANCORR, COVB, and PRINT.

Specifying the State Space Model

Instead of allowing the STATESPACE procedure to select the model automatically, you can use FORM and RESTRICT statements to specify a state space model.

Specifying the State Vector

Use the FORM statement to control the form of the state vector. You can use this feature to force PROC STATESPACE to estimate and forecast a model different from the model it would select automatically. You can also use this feature to reestimate the automatically selected model (possibly with restrictions) without repeating the canonical correlation analysis.

The FORM statement specifies the number of lags of each variable to include in the state vector. For example, the statement FORM X 3; forces the state vector to include $x_{t|t}$, $x_{t+1|t}$, and $x_{t+2|t}$. The following statement specifies the state vector $(x_{t|t}, y_{t|t}, x_{t+1|t})$, which is the same state vector selected in the preceding example:

```
form x 2 y 1;
```

You can specify the form for only some of the variables and allow PROC STATESPACE to select the form for the other variables. If only some of the variables are specified in the FORM statement, canonical correlation analysis is used to determine the number of lags included in the state vector for the remaining variables not specified by the FORM statement. If the FORM statement includes specifications for all the variables listed in the VAR statement, the state vector is completely defined and the canonical correlation analysis is not performed.

Restricting the F and G matrices

After you know the form of the state vector, you can use the RESTRICT statement to fix some parameters in the **F** and **G** matrices to specified values. One use of this feature is to remove insignificant parameters by restricting them to 0.

In the introductory example shown in the preceding section, the F[2,3] parameter is not significant. (The parameters estimation output shown in Figure 34.6 gives the t statistic for F[2,3] as –0.06. F[3,3] and F[3,1] also have low significance with $t < 2$.)

The following statements reestimate this model with F[2,3] restricted to 0. The FORM statement is used to specify the state vector and thus bypass the canonical correlation analysis.

```
proc statespace data=in out=out lead=10;
   var x(1) y(1);
   id t;
   form x 2 y 1;
   restrict f(2,3)=0;
```

```
run;
```

The final estimates produced by these statements are shown in Figure 34.10.

Figure 34.9 Results Using RESTRICT Statement

PROC STATESPACE Statement

PROC STATESPACE *options* **;**

The following options can be specified in the PROC STATESPACE statement.

Printing Options

NOPRINT
suppresses all printed output.

Input Data Options

DATA=*SAS-data-set*

specifies the name of the SAS data set to be used by the procedure. If the DATA= option is omitted, the most recently created SAS data set is used.

LAGMAX=*k*

specifies the number of lags for which the sample autocovariance matrix is computed. The LAGMAX= option controls the number of lags printed in the schematic representation of the autocorrelations.

The sample autocovariance matrix of lag i, denoted as $\mathbf{C}_i$, is computed as

$$\mathbf{C}_i = \frac{1}{N-1} \sum_{t=1+i}^{N} \mathbf{x}_t \mathbf{x}'_{t-i}$$

where $\mathbf{x}_t$ is the differenced and centered data and N is the number of observations. (If the NOCENTER option is specified, 1 is not subtracted from N.) LAGMAX= k specifies that $\mathbf{C_0}$ through $\mathbf{C}_k$ are computed. The default is LAGMAX=10.

NOCENTER

prevents subtraction of the sample mean from the input series (after any specified differencing) before the analysis.

Options for Preliminary Autoregressive Models

ARMAX=*n*

specifies the maximum order of the preliminary autoregressive models. The ARMAX= option controls the autoregressive orders for which information criteria are printed, and controls the number of lags printed in the schematic representation of partial autocorrelations. The default is ARMAX=10. For more information, see the section "Preliminary Autoregressive Models" on page 2581.

MINIC

writes to the OUTAR= data set only the preliminary Yule-Walker estimates for the VAR model that produces the minimum AIC. For more information, see the section "OUTAR= Data Set" on page 2592.

OUTAR=*SAS-data-set*

writes the Yule-Walker estimates of the preliminary autoregressive models to a SAS data set. For more information, see the section "OUTAR= Data Set" on page 2592.

PRINTOUT=SHORT | LONG | NONE

determines the amount of detail printed. PRINTOUT=LONG prints the lagged covariance matrices, the partial autoregressive matrices, and estimates of the residual covariance matrices from the sequence of autoregressive models. PRINTOUT=NONE suppresses the output for the preliminary autoregressive models. The descriptive statistics and state space model estimation output are still printed when PRINTOUT=NONE is specified. PRINTOUT=SHORT is the default.

Canonical Correlation Analysis Options

CANCORR
prints the canonical correlations and information criterion for each candidate state vector considered. For more information, see the section "Canonical Correlation Analysis Options" on page 2575.

DIMMAX=*n*
specifies the upper limit to the dimension of the state vector. The DIMMAX= option can be used to limit the size of the model selected. The default is DIMMAX=10.

PASTMIN=*n*
specifies the minimum number of lags to include in the canonical correlation analysis. The default is PASTMIN=0. For more information, see the section "Canonical Correlation Analysis Options" on page 2575.

SIGCORR=*value*
specifies the multiplier of the degrees of freedom for the penalty term in the information criterion used to select the state space form. The default is SIGCORR=2. The larger the value of the SIGCORR= option, the smaller the state vector tends to be. Hence, a large value causes a simpler model to be fit. For more information, see the section "Canonical Correlation Analysis Options" on page 2575.

State Space Model Estimation Options

COVB
prints the inverse of the observed information matrix for the parameter estimates. This matrix is an estimate of the covariance matrix for the parameter estimates.

DETTOL=*value*
specifies the convergence criterion. The DETTOL= and PARMTOL= option values are used together to test for convergence of the estimation process. If, during an iteration, the relative change of the parameter estimates is less than the PARMTOL= value and the relative change of the determinant of the innovation variance matrix is less than the DETTOL= value, then iteration ceases and the current estimates are accepted. The default is DETTOL=1E–5.

ITPRINT
prints the iterations during the estimation process.

KLAG=*n*
sets an upper limit for the number of lags of the sample autocovariance matrix used in computing the approximate likelihood function. If the data have a strong moving average character, a larger KLAG= value might be necessary to obtain good estimates. The default is KLAG=15. For more information, see the section "Parameter Estimation" on page 2586.

MAXIT=*n*
sets an upper limit to the number of iterations in the maximum likelihood or conditional least squares estimation. The default is MAXIT=50.

NOEST
suppresses the final maximum likelihood estimation of the selected model.

OUTMODEL=*SAS-data-set*
writes the parameter estimates and their standard errors to a SAS data set. For more information, see the section "OUTMODEL= Data Set" on page 2593.

PARMTOL=*value*
specifies the convergence criterion. The DETTOL= and PARMTOL= option values are used together to test for convergence of the estimation process. If, during an iteration, the relative change of the parameter estimates is less than the PARMTOL= value and the relative change of the determinant of the innovation variance matrix is less than the DETTOL= value, then iteration ceases and the current estimates are accepted. The default is PARMTOL=0.001.

RESIDEST
computes the final estimates by using conditional least squares on the raw data. This type of estimation might be more stable than the default maximum likelihood method but is usually more computationally expensive. For more information about the conditional least squares method, see the section "Parameter Estimation" on page 2586.

SINGULAR=*value*
specifies the criterion for testing for singularity of a matrix. A matrix is declared singular if a scaled pivot is less than the SINGULAR= value when sweeping the matrix. The default is SINGULAR=1E–7.

Forecasting Options

BACK=*n*
starts forecasting *n* periods before the end of the input data. The BACK= option value must not be greater than the number of observations. The default is BACK=0.

INTERVAL=*interval*
specifies the time interval between observations. The INTERVAL= value is used in conjunction with the ID variable to check that the input data are in order and have no missing periods. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data. For more information about the INTERVAL= values allowed, see Chapter 4, "Date Intervals, Formats, and Functions."

INTPER=*n*
specifies that each input observation corresponds to *n* time periods. For example, the options INTERVAL=MONTH and INTPER=2 specify bimonthly data and are equivalent to specifying INTERVAL=MONTH2. If the INTERVAL= option is not specified, the INTPER= option controls the increment used to generate ID values for the forecast observations. The default is INTPER=1.

LEAD=*n*
specifies how many forecast observations are produced. The forecasts start at the point set by the BACK= option. The default is LEAD=0, which produces no forecasts.

OUT=*SAS-data-set*
writes the residuals, actual values, forecasts, and forecast standard errors to a SAS data set. For more information, see the section "OUT= Data Set" on page 2591.

PRINT
prints the forecasts.

BY Statement

BY *variable ...* **;**

A BY statement can be used with the STATESPACE procedure to obtain separate analyses on observations in groups defined by the BY variables.

FORM Statement

FORM *variable value ...* **;**

The FORM statement specifies the number of times a variable is included in the state vector. Values can be specified for any variable listed in the VAR statement. If a value is specified for each variable in the VAR statement, the state vector for the state space model is entirely specified, and automatic selection of the state space model is not performed.

The FORM statement forces the state vector, $\mathbf{z}_t$, to contain a specific variable a given number of times. For example, if Y is one of the variables in $\mathbf{x}_t$, then the statement

```
form y 3;
```

forces the state vector to contain Y_t, $Y_{t+1|t}$, and $Y_{t+2|t}$, possibly along with other variables.

The following statements illustrate the use of the FORM statement:

```
proc statespace data=in;
   var x y;
   form x 3 y 2;
run;
```

These statements fit a state space model with the following state vector:

$$\mathbf{z_t} = \begin{bmatrix} x_{t|t} \\ y_{t|t} \\ x_{t+1|t} \\ y_{t+1|t} \\ x_{t+2|t} \end{bmatrix}$$

ID Statement

ID *variable* **;**

The ID statement specifies a variable that identifies observations in the input data set. The variable specified in the ID statement is included in the OUT= data set. The values of the ID variable are extrapolated for the forecast observations based on the values of the INTERVAL= and INTPER= options.

INITIAL Statement

INITIAL **F(***row,column***)=***value . . .* **G(***row, column***)=***value . . .* **;**

The INITIAL statement gives initial values to the specified elements of the **F** and **G** matrices. These initial values are used as starting values for the iterative estimation.

Parts of the **F** and **G** matrices represent fixed structural identities. If an element specified is a fixed structural element instead of a free parameter, the corresponding initialization is ignored.

The following is an example of an INITIAL statement:

```
initial f(3,2)=0 g(4,1)=0 g(5,1)=0;
```

RESTRICT Statement

RESTRICT **F(***row,column***)=***value . . .* **G(***row,column***)=***value . . .* **;**

The RESTRICT statement restricts the specified elements of the **F** and **G** matrices to the specified values.

To use the restrict statement, you need to know the form of the model. Either specify the form of the model with the FORM statement, or do a preliminary run (perhaps with the NOEST option) to find the form of the model that PROC STATESPACE selects for the data.

The following is an example of a RESTRICT statement:

```
restrict f(3,2)=0 g(4,1)=0 g(5,1)=0 ;
```

Parts of the **F** and **G** matrices represent fixed structural identities. If a restriction is specified for an element that is a fixed structural element instead of a free parameter, the restriction is ignored.

VAR Statement

VAR *variable (difference, difference, . . .) . . .* **;**

The VAR statement specifies the variables in the input data set to model and forecast. The VAR statement also specifies differencing of the input variables. The VAR statement is required.

Differencing is specified by following the variable name with a list of difference periods separated by commas. For more information about differencing of input variables, see the section "Stationarity and Differencing" on page 2580.

The order in which variables are listed in the VAR statement controls the order in which variables are included in the state vector. Usually, potential inputs should be listed before potential outputs.

For example, assuming the input data are monthly, the following VAR statement specifies modeling and forecasting of the one period and seasonal second difference of X and Y:

```
var x(1,12) y(1,12);
```

In this example, the vector time series analyzed is

$$\mathbf{x}_t = \begin{bmatrix} (1-B)(1-B^{12})X_t - \bar{x} \\ (1-B)(1-B^{12})Y_t - \bar{y} \end{bmatrix}$$

where B represents the back shift operator and $\bar{x}$ and $\bar{y}$ represent the means of the differenced series. If the NOCENTER option is specified, the mean differences are not subtracted.

Details: STATESPACE Procedure

Missing Values

The STATESPACE procedure does not support missing values. The procedure uses the first contiguous group of observations with no missing values for any of the VAR statement variables. Observations at the beginning of the data set with missing values for any VAR statement variable are not used or included in the output data set.

Stationarity and Differencing

The state space model used by the STATESPACE procedure assumes that the time series are stationary. Hence, the data should be checked for stationarity. One way to check for stationarity is to plot the series. A graph of series over time can show a time trend or variability changes.

You can also check stationarity by using the sample autocorrelation functions displayed by the ARIMA procedure. The autocorrelation functions of nonstationary series tend to decay slowly. For more information, see Chapter 7, "The ARIMA Procedure."

Another alternative is to use the STATIONARITY= option in the IDENTIFY statement in PROC ARIMA to apply Dickey-Fuller tests for unit roots in the time series. For more information about Dickey-Fuller unit root tests, see Chapter 7, "The ARIMA Procedure."

The most popular way to transform a nonstationary series to stationarity is by differencing. Differencing of the time series is specified in the VAR statement. For example, to take a simple first difference of the series X, use this statement:

```
var x(1);
```

In this example, the change in X from one period to the next is analyzed. When the series has a seasonal pattern, differencing at a period equal to the length of the seasonal cycle can be desirable. For example, suppose the variable X is measured quarterly and shows a seasonal cycle over the year. You can use the following statement to analyze the series of changes from the same quarter in the previous year:

```
var x(4);
```

To difference twice, add another differencing period to the list. For example, the following statement analyzes the series of second differences $(X_t - X_{t-1}) - (X_{t-1} - X_{t-2}) = X_t - 2X_{t-1} + X_{t-2}$:

```
var x(1,1);
```

The following statement analyzes the seasonal second difference series:

```
var x(1,4);
```

The series that is being modeled is the 1-period difference of the 4-period difference:
$(X_t - X_{t-4}) - (X_{t-1} - X_{t-5}) = X_t - X_{t-1} - X_{t-4} + X_{t-5}$.

Another way to obtain stationary series is to use a regression on time to detrend the data. If the time series has a deterministic linear trend, regressing the series on time produces residuals that should be stationary. The following statements write residuals of X and Y to the variable RX and RY in the output data set DETREND:

```
data a;
   set a;
   t=_n_;
run;

proc reg data=a;
   model x y = t;
   output out=detrend r=rx ry;
run;
```

You then use PROC STATESPACE to forecast the detrended series RX and RY. A disadvantage of this method is that you need to add the trend back to the forecast series in an additional step. A more serious

disadvantage of the detrending method is that it assumes a deterministic trend. In practice, most time series appear to have a stochastic rather than a deterministic trend. Differencing is a more flexible and often more appropriate method.

There are several other methods to handle nonstationary time series. For more information and examples, see Brockwell and Davis (1991).

Preliminary Autoregressive Models

After computing the sample autocovariance matrices, PROC STATESPACE fits a sequence of vector autoregressive models. These preliminary autoregressive models are used to estimate the autoregressive order of the process and limit the order of the autocovariances considered in the state vector selection process.

Yule-Walker Equations for Forward and Backward Models

Unlike a univariate autoregressive model, a multivariate autoregressive model has different forms, depending on whether the present observation is being predicted from the past observations or from the future observations.

Let $\mathbf{x}_t$ be the r-component stationary time series given by the VAR statement after differencing and subtracting the vector of sample means. (If the NOCENTER option is specified, the mean is not subtracted.) Let n be the number of observations of $\mathbf{x}_t$ from the input data set.

Let $\mathbf{e}_t$ be a vector white noise sequence with mean vector $\mathbf{0}$ and variance matrix $\mathbf{\Sigma}_p$, and let $\mathbf{n}_t$ be a vector white noise sequence with mean vector $\mathbf{0}$ and variance matrix $\mathbf{\Omega}_p$. Let p be the order of the vector autoregressive model for $\mathbf{x}_t$.

The forward autoregressive form based on the past observations is written as follows:

$$\mathbf{x}_t = \sum_{i=1}^{p} \mathbf{\Phi}_i^p \mathbf{x}_{t-i} + \mathbf{e}_t$$

The backward autoregressive form based on the future observations is written as follows:

$$\mathbf{x}_t = \sum_{i=1}^{p} \mathbf{\Psi}_i^p \mathbf{x}_{t+i} + \mathbf{n}_t$$

Letting E denote the expected value operator, the autocovariance sequence for the $\mathbf{x}_t$ series, $\mathbf{\Gamma}_i$, is

$$\mathbf{\Gamma}_i = E\mathbf{x}_t\mathbf{x}_{t-i}'$$

The Yule-Walker equations for the autoregressive model that matches the first p elements of the autocovariance sequence are

$$\begin{bmatrix} \mathbf{\Gamma}_0 & \mathbf{\Gamma}_1 & \cdots & \mathbf{\Gamma}_{p-1} \\ \mathbf{\Gamma}_1' & \mathbf{\Gamma}_0 & \cdots & \mathbf{\Gamma}_{p-2} \\ \vdots & \vdots & & \vdots \\ \mathbf{\Gamma}_{p-1}' & \mathbf{\Gamma}_{p-2}' & \cdots & \mathbf{\Gamma}_0 \end{bmatrix} \begin{bmatrix} \mathbf{\Phi}_1^p \\ \mathbf{\Phi}_2^p \\ \vdots \\ \mathbf{\Phi}_p^p \end{bmatrix} = \begin{bmatrix} \mathbf{\Gamma}_1 \\ \mathbf{\Gamma}_2 \\ \vdots \\ \mathbf{\Gamma}_p \end{bmatrix}$$

and

$$\begin{bmatrix} \mathbf{\Gamma}_0 & \mathbf{\Gamma}_1' & \cdots & \mathbf{\Gamma}_{p-1}' \\ \mathbf{\Gamma}_1 & \mathbf{\Gamma}_0 & \cdots & \mathbf{\Gamma}_{p-2}' \\ \vdots & \vdots & & \vdots \\ \mathbf{\Gamma}_{p-1} & \mathbf{\Gamma}_{p-2} & \cdots & \mathbf{\Gamma}_0 \end{bmatrix} \begin{bmatrix} \mathbf{\Psi}_1^p \\ \mathbf{\Psi}_2^p \\ \vdots \\ \mathbf{\Psi}_p^p \end{bmatrix} = \begin{bmatrix} \mathbf{\Gamma}_1' \\ \mathbf{\Gamma}_2' \\ \vdots \\ \mathbf{\Gamma}_p' \end{bmatrix}$$

Here $\mathbf{\Phi}_i^p$ are the coefficient matrices for the past observation form of the vector autoregressive model, and $\mathbf{\Psi}_i^p$ are the coefficient matrices for the future observation form. More information about the Yule-Walker equations in the multivariate setting can be found in Whittle (1963); Ansley and Newbold (1979).

The innovation variance matrices for the two forms can be written as follows:

$$\mathbf{\Sigma}_p = \mathbf{\Gamma}_0 - \sum_{i=1}^{p} \mathbf{\Phi}_i^p \mathbf{\Gamma}_i'$$

$$\mathbf{\Omega}_p = \mathbf{\Gamma}_0 - \sum_{i=1}^{p} \mathbf{\Psi}_i^p \mathbf{\Gamma}_i$$

The autoregressive models are fit to the data by using the preceding Yule-Walker equations with $\mathbf{\Gamma}_i$ replaced by the sample covariance sequence $\mathbf{C_i}$. The covariance matrices are calculated as

$$\mathbf{C}_i = \frac{1}{N-1} \sum_{t=i+1}^{N} \mathbf{x}_t \mathbf{x}_{t-i}'$$

Let $\widehat{\mathbf{\Phi}}_p$, $\widehat{\mathbf{\Psi}}_p$, $\widehat{\mathbf{\Sigma}}_p$, and $\widehat{\mathbf{\Omega}}_p$ represent the Yule-Walker estimates of $\mathbf{\Phi}_p$, $\mathbf{\Psi}_p$, $\mathbf{\Sigma}_p$, and $\mathbf{\Omega}_p$, respectively. These matrices are written to an output data set when the OUTAR= option is specified.

When the PRINTOUT=LONG option is specified, the sequence of matrices $\widehat{\mathbf{\Sigma}}_p$ and the corresponding correlation matrices are printed. The sequence of matrices $\widehat{\mathbf{\Sigma}}_p$ is used to compute Akaike's information criteria for selection of the autoregressive order of the process.

Akaike's Information Criterion

Akaike's information criterion (AIC) is defined as –2(*maximum of log likelihood*)+2(*number of parameters*). Since the vector autoregressive models are estimates from the Yule-Walker equations, not by maximum likelihood, the exact likelihood values are not available for computing the AIC. However, for the vector autoregressive model the maximum of the log likelihood can be approximated as

$$\ln(L) \approx -\frac{n}{2} \ln(|\widehat{\mathbf{\Sigma}}_p|)$$

Thus, the AIC for the order p model is computed as

$$\mathrm{AIC}_p = n \ln(|\widehat{\mathbf{\Sigma}}_p|) + 2pr^2$$

You can use the printed AIC array to compute a likelihood ratio test of the autoregressive order. The log-likelihood ratio test statistic for testing the order p model against the order $p-1$ model is

$$-n \ln(|\widehat{\mathbf{\Sigma}}_p|) + n \ln(|\widehat{\mathbf{\Sigma}}_{p-1}|)$$

This quantity is asymptotically distributed as a χ^2 with r^2 degrees of freedom if the series is autoregressive of order $p-1$. It can be computed from the AIC array as

$$\mathrm{AIC}_{p-1} - \mathrm{AIC}_p + 2r^2$$

You can evaluate the significance of these test statistics with the PROBCHI function in a SAS DATA step or with a χ^2 table.

Determining the Autoregressive Order

Although the autoregressive models can be used for prediction, their primary value is to aid in the selection of a suitable portion of the sample covariance matrix for use in computing canonical correlations. If the multivariate time series $\mathbf{x}_t$ is of autoregressive order p, then the vector of past values to lag p is considered to contain essentially all the information relevant for prediction of future values of the time series.

By default, PROC STATESPACE selects the order p that produces the autoregressive model with the smallest AIC_p. If the value p for the minimum AIC_p is less than the value of the PASTMIN= option, then p is set to the PASTMIN= value. Alternatively, you can use the ARMAX= and PASTMIN= options to force PROC STATESPACE to use an order you select.

Significance Limits for Partial Autocorrelations

The STATESPACE procedure prints a schematic representation of the partial autocorrelation matrices that indicates which partial autocorrelations are significantly greater than or significantly less than 0. Figure 34.11 shows an example of this table.

Figure 34.11 Significant Partial Autocorrelations

Schematic Representation of Partial Autocorrelations

Name/Lag	1	2	3	4	5	6	7	8	9	10
x	++	+.	..	..	..	..	..	..	..	..
y	++	..	..	..	..	..	..	..	..	..

+ is > 2*std error, - is < -2*std error, . is between

The partial autocorrelations are from the sample partial autoregressive matrices $\widehat{\mathbf{\Phi}}_p^p$. The standard errors used for the significance limits of the partial autocorrelations are computed from the sequence of matrices $\mathbf{\Sigma}_p$ and $\mathbf{\Omega}_p$.

Under the assumption that the observed series arises from an autoregressive process of order $p-1$, the pth sample partial autoregressive matrix $\widehat{\mathbf{\Phi}}_p^p$ has an asymptotic variance matrix $\frac{1}{n}\mathbf{\Omega}_p^{-1} \otimes \mathbf{\Sigma}_p$.

The significance limits for $\widehat{\mathbf{\Phi}}_p^p$ used in the schematic plot of the sample partial autoregressive sequence are derived by replacing $\mathbf{\Omega}_p$ and $\mathbf{\Sigma}_p$ with their sample estimators to produce the variance estimate, as follows:

$$\widehat{Var}\left(\widehat{\mathbf{\Phi}}_p^p\right) = \left(\frac{1}{n-rp}\right) \widehat{\mathbf{\Omega}}_p^{-1} \otimes \widehat{\mathbf{\Sigma}}_p$$

Canonical Correlation Analysis

Given the order p, let $\mathbf{p}_t$ be the vector of current and past values relevant to prediction of $\mathbf{x}_{t+1}$:

$$\mathbf{p}_t = (\mathbf{x}_t', \mathbf{x}_{t-1}', \ldots, \mathbf{x}_{t-p}')'$$

Let $\mathbf{f}_t$ be the vector of current and future values:

$$\mathbf{f}_t = (\mathbf{x}_t', \mathbf{x}_{t+1}', \ldots, \mathbf{x}_{t+p}')'$$

In the canonical correlation analysis, consider submatrices of the sample covariance matrix of $\mathbf{p}_t$ and $\mathbf{f}_t$. This covariance matrix, $\mathbf{V}$, has a block Hankel form:

$$\mathbf{V} = \begin{bmatrix} \mathbf{C}_0 & \mathbf{C}_1' & \mathbf{C}_2' & \cdots & \mathbf{C}_p' \\ \mathbf{C}_1' & \mathbf{C}_2' & \mathbf{C}_3' & \cdots & \mathbf{C}_{p+1}' \\ \vdots & \vdots & \vdots & & \vdots \\ \mathbf{C}_p' & \mathbf{C}_{p+1}' & \mathbf{C}_{p+2}' & \cdots & \mathbf{C}_{2p}' \end{bmatrix}$$

State Vector Selection Process

The canonical correlation analysis forms a sequence of potential state vectors $\mathbf{z}_t^j$. Examine a sequence $\mathbf{f}_t^j$ of subvectors of $\mathbf{f}_t$, form the submatrix $\mathbf{V}^j$ that consists of the rows and columns of $\mathbf{V}$ that correspond to the components of $\mathbf{f}_t^j$, and compute its canonical correlations.

The smallest canonical correlation of $\mathbf{V}^j$ is then used in the selection of the components of the state vector. The selection process is described in the following discussion. For more information about this process, see Akaike (1976).

In the following discussion, the notation $\mathbf{x}_{t+k|t}$ denotes the wide sense conditional expectation (best linear predictor) of $\mathbf{x}_{t+k}$, given all $\mathbf{x}_s$ with s less than or equal to t. In the notation $x_{i,t+1}$, the first subscript denotes the ith component of $\mathbf{x}_{t+1}$.

The initial state vector $\mathbf{z}_t^1$ is set to $\mathbf{x}_t$. The sequence $\mathbf{f}_t^j$ is initialized by setting

$$\mathbf{f}_t^1 = (\mathbf{z}_t^{1'}, x_{1,t+1|t})' = (\mathbf{x}_t', x_{1,t+1|t})'$$

That is, start by considering whether to add $x_{1,t+1|t}$ to the initial state vector $\mathbf{z}_t^1$.

The procedure forms the submatrix $\mathbf{V}^1$ that corresponds to $\mathbf{f}_t^1$ and computes its canonical correlations. Denote the smallest canonical correlation of $\mathbf{V}^1$ as $\rho_{\min}$. If $\rho_{\min}$ is significantly greater than 0, $x_{1,t+1|t}$ is added to the state vector.

If the smallest canonical correlation of $\mathbf{V}^1$ is not significantly greater than 0, then a linear combination of $\mathbf{f}_t^1$ is uncorrelated with the past, $\mathbf{p}_t$. Assuming that the determinant of $\mathbf{C}_0$ is not 0, (that is, no input series is a constant), you can take the coefficient of $x_{1,t+1|t}$ in this linear combination to be 1. Denote the coefficients of $\mathbf{z}_t^1$ in this linear combination as ℓ. This gives the relationship:

$$x_{1,t+1|t} = \ell' \mathbf{x}_t$$

Therefore, the current state vector already contains all the past information useful for predicting $x_{1,t+1}$ and any greater leads of $x_{1,t}$. The variable $x_{1,t+1|t}$ is not added to the state vector, nor are any terms $x_{1,t+k|t}$ considered as possible components of the state vector. The variable x_1 is no longer active for state vector selection.

The process described for $x_{1,t+1|t}$ is repeated for the remaining elements of $\mathbf{f}_t$. The next candidate for inclusion in the state vector is the next component of $\mathbf{f}_t$ that corresponds to an active variable. Components of $\mathbf{f}_t$ that correspond to inactive variables that produced a zero $\rho_{\min}$ in a previous step are skipped.

Denote the next candidate as $x_{l,t+k|t}$. The vector $\mathbf{f}_t^j$ is formed from the current state vector and $x_{l,t+k|t}$ as follows:

$$\mathbf{f}_t^j = (\mathbf{z}_t^{j'}, x_{l,t+k|t})'$$

The matrix $\mathbf{V}^j$ is formed from $\mathbf{f}_t^j$ and its canonical correlations are computed. The smallest canonical correlation of $\mathbf{V}^j$ is judged to be either greater than or equal to 0. If it is judged to be greater than 0, $x_{l,t+k|t}$ is added to the state vector. If it is judged to be 0, then a linear combination of $\mathbf{f}_t^j$ is uncorrelated with the $\mathbf{p}_t$, and the variable x_l is now inactive.

The state vector selection process continues until no active variables remain.

Testing Significance of Canonical Correlations

For each step in the canonical correlation sequence, the significance of the smallest canonical correlation $\rho_{\min}$ is judged by an information criterion from Akaike (1976). This information criterion is

$$-n\ln(1-\rho_{\min}^2) - \lambda(r(p+1)-q+1)$$

where q is the dimension of $\mathbf{f}_t^j$ at the current step, r is the order of the state vector, p is the order of the vector autoregressive process, and λ is the value of the SIGCORR= option. The default is SIGCORR=2. If this information criterion is less than or equal to 0, $\rho_{\min}$ is taken to be 0; otherwise, it is taken to be significantly greater than 0. (Do not confuse this information criterion with the AIC.)

Variables in $\mathbf{x}_{t+p|t}$ are not added in the model, even with positive information criterion, because of the singularity of $\mathbf{V}$. You can force the consideration of more candidate state variables by increasing the size of the $\mathbf{V}$ matrix by specifying a PASTMIN= option value larger than p.

Printing the Canonical Correlations

To print the details of the canonical correlation analysis process, specify the CANCORR option in the PROC STATESPACE statement. The CANCORR option prints the candidate state vectors, the canonical correlations, and the information criteria for testing the significance of the smallest canonical correlation.

Bartlett's χ^2 and its degrees of freedom are also printed when the CANCORR option is specified. The formula used for Bartlett's χ^2 is

$$\chi^2 = -(n - .5(r(p+1)-q+1))\ln(1-\rho_{\min}^2)$$

with $r(p+1)-q+1$ degrees of freedom.

Figure 34.12 shows the output of the CANCORR option for the introductory example shown in the "Getting Started: STATESPACE Procedure" on page 2562.

```
proc statespace data=in out=out lead=10 cancorr;
   var x(1) y(1);
   id t;
run;
```

Figure 34.12 Canonical Correlations Analysis

The STATESPACE Procedure
Canonical Correlations Analysis

x(T;T)	y(T;T)	x(T+1;T)	Information Criterion	Chi-Square	DF
1	1	0.237045	3.566167	11.4505	4

New variables are added to the state vector if the information criteria are positive. In this example, $\mathbf{y}_{t+1|t}$ and $\mathbf{x}_{t+2|t}$ are not added to the state space vector because the information criteria for these models are negative.

If the information criterion is nearly 0, then you might want to investigate models that arise if the opposite decision is made regarding $\rho_{\min}$. This investigation can be accomplished by using a FORM statement to specify part or all of the state vector.

Preliminary Estimates of F

When a candidate variable $x_{l,t+k|t}$ yields a zero $\rho_{\min}$ and is not added to the state vector, a linear combination of $\mathbf{f}_t^j$ is uncorrelated with the $\mathbf{p}_t$. Because of the method used to construct the $\mathbf{f}_t^j$ sequence, the coefficient of $x_{l,t+k|t}$ in $\mathbf{l}$ can be taken as 1. Denote the coefficients of $\mathbf{z}_t^j$ in this linear combination as $\mathbf{l}$.

This gives the relationship:

$$x_{l,t+k|t} = \mathbf{l}'\mathbf{z}_t^j$$

The vector $\mathbf{l}$ is used as a preliminary estimate of the first r columns of the row of the transition matrix $\mathbf{F}$ corresponding to $x_{l,t+k-1|t}$.

Parameter Estimation

The model is $\mathbf{z}_{t+1} = \mathbf{F}\mathbf{z}_t + \mathbf{G}\mathbf{e}_{t+1}$, where $\mathbf{e}_t$ is a sequence of independent multivariate normal innovations with mean vector $\mathbf{0}$ and variance $\Sigma_{\mathbf{ee}}$. The observed sequence $\mathbf{x}_t$ composes the first r components of $\mathbf{z}_t$, and thus $\mathbf{x}_t = \mathbf{H}\mathbf{z}_t$, where $\mathbf{H}$ is the $r \times s$ matrix $[\mathbf{I}_r \ \mathbf{0}]$.

Let $\mathbf{E}$ be the $r \times n$ matrix of innovations:

$$\mathbf{E} = \begin{bmatrix} \mathbf{e}_1 & \cdots & \mathbf{e}_n \end{bmatrix}$$

If the number of observations n is reasonably large, the log likelihood L can be approximated up to an additive constant as follows:

$$L = -\frac{n}{2}\ln(|\mathbf{\Sigma}_{\mathbf{ee}}|) - \frac{1}{2}\mathrm{trace}(\mathbf{\Sigma}_{\mathbf{ee}}^{-1}\mathbf{E}\mathbf{E}')$$

The elements of $\mathbf{\Sigma_{ee}}$ are taken as free parameters and are estimated as follows:

$$\mathbf{S_0} = \frac{1}{n}\mathbf{E}\mathbf{E}'$$

Replacing $\mathbf{\Sigma_{ee}}$ by $\mathbf{S_0}$ in the likelihood equation, the log likelihood, up to an additive constant, is

$$\mathbf{L} = -\frac{n}{2}\ln(|\mathbf{S_0}|)$$

Letting B be the backshift operator, the formal relation between $\mathbf{x}_t$ and $\mathbf{e}_t$ is

$$\mathbf{x}_t = \mathbf{H}(\mathbf{I} - B\mathbf{F})^{-1}\mathbf{G}\mathbf{e}_t$$

$$\mathbf{e}_t = (\mathbf{H}(\mathbf{I} - B\mathbf{F})^{-1}\mathbf{G})^{-1}\mathbf{x}_t = \sum_{i=0}^{\infty} \mathbf{\Xi}_i \mathbf{x}_{t-i}$$

Letting $\mathbf{C}_i$ be the ith lagged sample covariance of $\mathbf{x}_t$ and neglecting end effects, the matrix $\mathbf{S_0}$ is

$$\mathbf{S_0} = \sum_{i,j=0}^{\infty} \mathbf{\Xi}_i \mathbf{C}_{-i+j} \mathbf{\Xi}'_j$$

For the computation of $\mathbf{S_0}$, the infinite sum is truncated at the value of the KLAG= option. The value of the KLAG= option should be large enough that the sequence $\mathbf{\Xi}_i$ is approximately 0 beyond that point.

Let $\boldsymbol{\theta}$ be the vector of free parameters in the $\mathbf{F}$ and $\mathbf{G}$ matrices. The derivative of the log likelihood with respect to the parameter $\boldsymbol{\theta}$ is

$$\frac{\partial L}{\partial \boldsymbol{\theta}} = -\frac{n}{2}\,\mathrm{trace}\left(\mathbf{S_0}^{-1}\frac{\partial \mathbf{S_0}}{\partial \boldsymbol{\theta}}\right)$$

The second derivative is

$$\frac{\partial^2 \mathbf{L}}{\partial \boldsymbol{\theta}\,\partial \boldsymbol{\theta}'} = \frac{n}{2}\left(\mathrm{trace}\left(\mathbf{S_0}^{-1}\frac{\partial \mathbf{S_0}}{\partial \boldsymbol{\theta}'}\mathbf{S_0}^{-1}\frac{\partial \mathbf{S_0}}{\partial \boldsymbol{\theta}}\right) - \mathrm{trace}\left(\mathbf{S_0}^{-1}\frac{\partial^2 \mathbf{S_0}}{\partial \boldsymbol{\theta}\,\partial \boldsymbol{\theta}'}\right)\right)$$

Near the maximum, the first term is unimportant and the second term can be approximated to give the following second derivative approximation:

$$\frac{\partial^2 L}{\partial \boldsymbol{\theta}\,\partial \boldsymbol{\theta}'} \cong -n\,\mathrm{trace}\left(\mathbf{S_0}^{-1}\frac{\partial \mathbf{E}}{\partial \boldsymbol{\theta}}\frac{\partial \mathbf{E}'}{\partial \boldsymbol{\theta}'}\right)$$

The first derivative matrix and this second derivative matrix approximation are computed from the sample covariance matrix $\mathbf{C_0}$ and the truncated sequence $\mathbf{\Xi}_i$. The approximate likelihood function is maximized by a modified Newton-Raphson algorithm that employs these derivative matrices.

The matrix $\mathbf{S_0}$ is used as the estimate of the innovation covariance matrix, $\mathbf{\Sigma_{ee}}$. The negative of the inverse of the second derivative matrix at the maximum is used as an approximate covariance matrix for the parameter estimates. The standard errors of the parameter estimates printed in the parameter estimates tables are taken

from the diagonal of this covariance matrix. The parameter covariance matrix is printed when the COVB option is specified.

If the data are nearly nonstationary, a better estimate of $\mathbf{\Sigma_{ee}}$ and the other parameters can sometimes be obtained by specifying the RESIDEST option. The RESIDEST option estimates the parameters by using conditional least squares instead of maximum likelihood.

The residuals are computed using the state space equation and the sample mean values of the variables in the model as start-up values. The estimate of $\mathbf{S_0}$ is then computed using the residuals from the ith observation on, where i is the maximum number of times any variable occurs in the state vector. A multivariate Gauss-Marquardt algorithm is used to minimize $|\mathbf{S_0}|$. For a further description of this method, see Harvey (1981a).

Forecasting

Given estimates of $\mathbf{F}$, $\mathbf{G}$, and $\mathbf{\Sigma_{ee}}$, forecasts of $\mathbf{x}_t$ are computed from the conditional expectation of $\mathbf{z}_t$.

In forecasting, the parameters $\mathbf{F}$, $\mathbf{G}$, and $\mathbf{\Sigma_{ee}}$ are replaced with the estimates or by values specified in the RESTRICT statement. One-step-ahead forecasting is performed for the observation $\mathbf{x}_t$, where $t \leq n - b$. Here n is the number of observations and b is the value of the BACK= option. For the observation $\mathbf{x}_t$, where $t > n - b$, m-step-ahead forecasting is performed for $m = t - n + b$. The forecasts are generated recursively with the initial condition $\mathbf{z}_0 = 0$.

The m-step-ahead forecast of $\mathbf{z}_{t+m}$ is $\mathbf{z}_{t+m|t}$, where $\mathbf{z}_{t+m|t}$ denotes the conditional expectation of $\mathbf{z}_{t+m}$ given the information available at time t. The m-step-ahead forecast of $\mathbf{x}_{t+m}$ is $\mathbf{x}_{t+m|t} = \mathbf{H}\mathbf{z}_{t+m|t}$, where the matrix $\mathbf{H} = [\mathbf{I}_r \mathbf{0}]$.

Let $\Psi_i = \mathbf{F}^i\mathbf{G}$. Note that the last $s - r$ elements of $\mathbf{z}_t$ consist of the elements of $\mathbf{x}_{u|t}$ for $u > t$.

The state vector $\mathbf{z}_{t+m}$ can be represented as

$$\mathbf{z}_{t+m} = \mathbf{F}^m\mathbf{z}_t + \sum_{i=0}^{m-1} \mathbf{\Psi}_i \mathbf{e}_{t+m-i}$$

Since $\mathbf{e}_{t+i|t} = \mathbf{0}$ for $i > 0$, the m-step-ahead forecast $\mathbf{z}_{t+m|t}$ is

$$\mathbf{z}_{t+m|t} = \mathbf{F}^m\mathbf{z}_t = \mathbf{F}\mathbf{z}_{t+m-1|t}$$

Therefore, the m-step-ahead forecast of $\mathbf{x}_{t+m}$ is

$$\mathbf{x}_{t+m|t} = \mathbf{H}\mathbf{z}_{t+m|t}$$

The m-step-ahead forecast error is

$$\mathbf{z}_{t+m} - \mathbf{z}_{t+m|t} = \sum_{i=0}^{m-1} \mathbf{\Psi}_i \mathbf{e}_{t+m-i}$$

The variance of the m-step-ahead forecast error is

$$\mathbf{V}_{z,m} = \sum_{i=0}^{m-1} \mathbf{\Psi}_i \mathbf{\Sigma_{ee}} \Psi_i'$$

Letting $\mathbf{V}_{z,0} = \mathbf{0}$, the variance of the m-step-ahead forecast error of $\mathbf{z}_{t+m}$, $\mathbf{V}_{z,m}$, can be computed recursively as follows:

$$\mathbf{V}_{z,m} = \mathbf{V}_{z,m-1} + \mathbf{\Psi}_{m-1}\mathbf{\Sigma}_{\mathbf{ee}}\mathbf{\Psi}_{m-1}^{'}$$

The variance of the m-step-ahead forecast error of $\mathbf{x}_{t+m}$ is the $r \times r$ left upper submatrix of $\mathbf{V}_{z,m}$; that is,

$$\mathbf{V}_{x,m} = \mathbf{H}\mathbf{V}_{z,m}\mathbf{H}'$$

Unless the NOCENTER option is specified, the sample mean vector is added to the forecast. When differencing is specified, the forecasts $\mathbf{x}_{t+m|t}$ plus the sample mean vector are integrated back to produce forecasts for the original series.

Let $\mathbf{y}_t$ be the original series specified by the VAR statement, with some 0 values appended that correspond to the unobserved past observations. Let B be the backshift operator, and let $\mathbf{\Delta}(B)$ be the $s \times s$ matrix polynomial in the backshift operator that corresponds to the differencing specified by the VAR statement. The off-diagonal elements of $\mathbf{\Delta}_i$ are 0. Note that $\mathbf{\Delta}_0 = \mathbf{I}_s$, where $\mathbf{I}_s$ is the $s \times s$ identity matrix. Then $\mathbf{z}_t = \mathbf{\Delta}(B)\mathbf{y}_t$.

This gives the relationship

$$\mathbf{y}_t = \mathbf{\Delta}^{-1}(B)\mathbf{z}_t = \sum_{i=0}^{\infty} \mathbf{\Lambda}_i \mathbf{z}_{t-i}$$

where $\mathbf{\Delta}^{-1}(B) = \sum_{i=0}^{\infty} \mathbf{\Lambda}_i B^i$ and $\mathbf{\Lambda}_0 = \mathbf{I}_s$.

The m-step-ahead forecast of $\mathbf{y}_{t+m}$ is

$$\mathbf{y}_{t+m|t} = \sum_{i=0}^{m-1} \mathbf{\Lambda}_i \mathbf{z}_{t+m-i|t} + \sum_{i=m}^{\infty} \mathbf{\Lambda}_i \mathbf{z}_{t+m-i}$$

The m-step-ahead forecast error of $\mathbf{y}_{t+m}$ is

$$\sum_{i=0}^{m-1} \mathbf{\Lambda}_i \left(\mathbf{z}_{t+m-i} - \mathbf{z}_{t+m-i|t}\right) = \sum_{i=0}^{m-1} \left(\sum_{u=0}^{i} \mathbf{\Lambda}_u \mathbf{\Psi}_{i-u} \right) \mathbf{e}_{t+m-i}$$

Letting $\mathbf{V}_{y,0} = \mathbf{0}$, the variance of the m-step-ahead forecast error of $\mathbf{y}_{t+m}$, $\mathbf{V}_{y,m}$, is

$$\begin{aligned} \mathbf{V}_{y,m} &= \sum_{i=0}^{m-1} \left(\sum_{u=0}^{i} \mathbf{\Lambda}_u \mathbf{\Psi}_{i-u} \right) \mathbf{\Sigma}_{\mathbf{ee}} \left(\sum_{u=0}^{i} \mathbf{\Lambda}_u \mathbf{\Psi}_{i-u} \right)' \\ &= \mathbf{V}_{y,m-1} + \left(\sum_{u=0}^{m-1} \mathbf{\Lambda}_u \mathbf{\Psi}_{m-1-u} \right) \mathbf{\Sigma}_{\mathbf{ee}} \left(\sum_{u=0}^{m-1} \mathbf{\Lambda}_u \mathbf{\Psi}_{m-1-u} \right)' \end{aligned}$$

Relation of ARMA and State Space Forms

Every state space model has an ARMA representation, and conversely every ARMA model has a state space representation. This section discusses this equivalence. The following material is adapted from Akaike (1974), where there is a more complete discussion. Pham (1978) also contains a discussion of this material.

Suppose you are given the following ARMA model:

$$\mathbf{\Phi}(B)\mathbf{x}_t = \mathbf{\Theta}(B)\mathbf{e}_t$$

or, in more detail,

$$\mathbf{x}_t - \mathbf{\Phi}_1\mathbf{x}_{t-1} - \cdots - \mathbf{\Phi}_p\mathbf{x}_{t-p} = \mathbf{e}_t + \mathbf{\Theta}_1\mathbf{e}_{t-1} + \cdots + \mathbf{\Theta}_q\mathbf{e}_{t-q} \tag{1}$$

where $\mathbf{e}_t$ is a sequence of independent multivariate normal random vectors with mean $\mathbf{0}$ and variance matrix $\mathbf{\Sigma}_{\mathbf{ee}}$, B is the backshift operator ($B\mathbf{x}_t = \mathbf{x}_{t-1}$), $\mathbf{\Phi}(B)$ and $\mathbf{\Theta}(B)$ are matrix polynomials in B, and $\mathbf{x}_t$ is the observed process.

If the roots of the determinantial equation $|\mathbf{\Phi}(B)| = 0$ are outside the unit circle in the complex plane, the model can also be written as

$$\mathbf{x}_t = \mathbf{\Phi}^{-1}(B)\mathbf{\Theta}(B)\mathbf{e}_t = \sum_{i=0}^{\infty} \mathbf{\Psi}_i \mathbf{e}_{t-i}$$

The $\mathbf{\Psi}_i$ matrices are known as the impulse response matrices and can be computed as $\mathbf{\Phi}^{-1}(B)\mathbf{\Theta}(B)$.

You can assume $p > q$ since, if this is not initially true, you can add more terms $\mathbf{\Phi}_i$ that are identically 0 without changing the model.

To write this set of equations in a state space form, proceed as follows. Let $\mathbf{x}_{t+i|t}$ be the conditional expectation of $\mathbf{x}_{t+i}$ given $\mathbf{x}_w$ for $w \le t$. The following relations hold:

$$\mathbf{x}_{t+i|t} = \sum_{j=i}^{\infty} \mathbf{\Psi}_j \mathbf{e}_{t+i-j}$$

$$\mathbf{x}_{t+i|t+1} = \mathbf{x}_{t+i|t} + \mathbf{\Psi}_{i-1}\mathbf{e}_{t+1}$$

However, from equation (1) you can derive the following relationship:

$$\mathbf{x}_{t+p|t} = \mathbf{\Phi}_1\mathbf{x}_{t+p-1|t} + \cdots + \mathbf{\Phi}_p\mathbf{x}_t \tag{2}$$

Hence, when $i = p$, you can substitute for $\mathbf{x}_{t+p|t}$ in the right-hand side of equation (2) and close the system of equations.

This substitution results in the following model in the state space form $\mathbf{z}_{t+1} = \mathbf{F}\mathbf{z}_t + \mathbf{G}\mathbf{e}_{t+1}$:

$$\begin{bmatrix} \mathbf{x}_{t+1} \\ \mathbf{x}_{t+2|t+1} \\ \vdots \\ \mathbf{x}_{t+p|t+1} \end{bmatrix} = \begin{bmatrix} 0 & \mathbf{I} & 0 & \cdots & 0 \\ 0 & 0 & \mathbf{I} & \cdots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ \mathbf{\Phi}_p & \mathbf{\Phi}_{p-1} & & \cdots & \mathbf{\Phi}_1 \end{bmatrix} \begin{bmatrix} \mathbf{x}_t \\ \mathbf{x}_{t+1|t} \\ \vdots \\ \mathbf{x}_{t+p-1|t} \end{bmatrix} + \begin{bmatrix} \mathbf{I} \\ \mathbf{\Psi}_1 \\ \vdots \\ \mathbf{\Psi}_{p-1} \end{bmatrix} \mathbf{e}_{t+1}$$

Note that the state vector $\mathbf{z}_t$ is composed of conditional expectations of $\mathbf{x}_t$ and the first r components of $\mathbf{z}_t$ are equal to $\mathbf{x}_t$.

The state space form can be cast into an ARMA form by solving the system of difference equations for the first r components.

When converting from an ARMA form to a state space form, you can generate a state vector larger than needed; that is, the state space model might not be a minimal representation. When going from a state space form to an ARMA form, you can have nontrivial common factors in the autoregressive and moving average operators that yield an ARMA model larger than necessary.

If the state space form used is not a minimal representation, some but not all components of $\mathbf{x}_{t+i|t}$ might be linearly dependent. This situation corresponds to $[\mathbf{\Phi}_p \mathbf{\Theta}_{p-1}]$ being of less than full rank when $\mathbf{\Phi}(B)$ and $\mathbf{\Theta}(B)$ have no common nontrivial left factors. In this case, $\mathbf{z}_t$ consists of a subset of the possible components of $[\mathbf{x}_{t+i|t}] \quad i = 1, 2, \ldots, p-1$. However, once a component of $\mathbf{x}_{t+i|t}$ (for example, the jth one) is linearly dependent on the previous conditional expectations, then all subsequent jth components of $\mathbf{x}_{t+k|t}$ for $k > i$ must also be linearly dependent. Note that in this case, equivalent but seemingly different structures can arise if the order of the components within $\mathbf{x}_t$ is changed.

OUT= Data Set

The forecasts are contained in the output data set specified by the OUT= option in the PROC STATESPACE statement. The OUT= data set contains the following variables:

- the BY variables
- the ID variable
- the VAR statement variables. These variables contain the actual values from the input data set.
- FOR*i*, numeric variables that contain the forecasts. The variable FOR*i* contains the forecasts for the *i*th variable in the VAR statement list. Forecasts are one-step-ahead predictions until the end of the data or until the observation specified by the BACK= option.
- RES*i*, numeric variables that contain the residual for the forecast of the *i*th variable in the VAR statement list. For forecast observations, the actual values are missing and the RES*i* variables contain missing values.
- STD*i*, numeric variables that contain the standard deviation for the forecast of the *i*th variable in the VAR statement list. The values of the STD*i* variables can be used to construct univariate confidence limits for the corresponding forecasts. However, such confidence limits do not take into account the covariance of the forecasts.

OUTAR= Data Set

The OUTAR= data set contains the estimates of the preliminary autoregressive models. The OUTAR= data set contains the following variables:

- ORDER, a numeric variable that contains the order p of the autoregressive model that the observation represents
- AIC, a numeric variable that contains the value of the information criterion AIC_p
- SIGF*l*, numeric variables that contain the estimate of the innovation covariance matrices for the forward autoregressive models. The variable SIGF*l* contains the *l*th column of $\widehat{\mathbf{\Sigma}}_p$ in the observations with ORDER=*p*.
- SIGB*l*, numeric variables that contain the estimate of the innovation covariance matrices for the backward autoregressive models. The variable SIGB*l* contains the *l*th column of $\widehat{\mathbf{\Omega}}_p$ in the observations with ORDER=*p*.
- FOR*k_l*, numeric variables that contain the estimates of the autoregressive parameter matrices for the forward models. The variable FOR*k_l* contains the *l*th column of the lag *k* autoregressive parameter matrix $\widehat{\mathbf{\Phi}}_k^p$ in the observations with ORDER=*p*.
- BAC*k_l*, numeric variables that contain the estimates of the autoregressive parameter matrices for the backward models. The variable BAC*k_l* contains the *l*th column of the lag *k* autoregressive parameter matrix $\widehat{\mathbf{\Psi}}_k^p$ in the observations with ORDER=*p*.

The estimates for the order p autoregressive model can be selected as those observations with ORDER=*p*. Within these observations, the *k*,*l*th element of $\mathbf{\Phi}_i^p$ is given by the value of the FOR*i_l* variable in the *k*th observation. The *k*,*l*th element of $\mathbf{\Psi}_i^p$ is given by the value of BAC*i_l* variable in the *k*th observation. The *k*,*l*th element of $\mathbf{\Sigma}_p$ is given by SIGF*l* in the *k*th observation. The *k*,*l*th element of $\mathbf{\Omega}_p$ is given by SIGB*l* in the *k*th observation.

Table 34.2 shows an example of the OUTAR= data set, with ARMAX=3 and $\mathbf{x}_t$ of dimension 2. In Table 34.2, (i, j) indicate $(i, (n)$ element of the matrix.

The estimated autoregressive parameters can be used in the IML procedure to obtain autoregressive estimates of the spectral density function or forecasts based on the autoregressive models.

OUTMODEL= Data Set

The OUTMODEL= data set contains the estimates of the $\mathbf{F}$ and $\mathbf{G}$ matrices and their standard errors, the names of the components of the state vector, and the estimates of the innovation covariance matrix. The variables contained in the OUTMODEL= data set are as follows:

- the BY variables
- STATEVEC, a character variable that contains the name of the component of the state vector corresponding to the observation. The STATEVEC variable has the value STD for standard deviations observations, which contain the standard errors for the estimates given in the preceding observation.
- F_*j*, numeric variables that contain the columns of the $\mathbf{F}$ matrix. The variable F_*j* contains the *j*th column of $\mathbf{F}$. The number of F_*j* variables is equal to the value of the DIMMAX= option. If the model is of smaller dimension, the extraneous variables are set to missing.
- G_*j*, numeric variables that contain the columns of the $\mathbf{G}$ matrix. The variable G_*j* contains the *j*th column of $\mathbf{G}$. The number of G_*j* variables is equal to r, the dimension of $\mathbf{x}_t$ given by the number of variables in the VAR statement.
- SIG_*j*, numeric variables that contain the columns of the innovation covariance matrix. The variable SIG_*j* contains the *j*th column of $\mathbf{\Sigma}_{ee}$. There are r variables SIG_*j*.

Table 34.3 shows an example of the OUTMODEL= data set, with $\mathbf{x}_t = (x_t, y_t)'$, $\mathbf{z}_t = (x_t, y_t, x_{t+1|t})'$, and DIMMAX=4. In Table 34.3, $\mathbf{F}_{i,j}$ and $\mathbf{G}_{i,j}$ are the (i, j) elements of $\mathbf{F}$ and $\mathbf{G}$ respectively. Note that all elements for F_4 are missing because $\mathbf{F}$ is a 3×3 matrix.

Printed Output

The printed output produced by the STATESPACE procedure includes the following:

1. descriptive statistics, which include the number of observations used, the names of the variables, their means and standard deviations (Std), and the differencing operations used
2. Akaike's information criteria for the sequence of preliminary autoregressive models
3. if the PRINTOUT=LONG option is specified, the sample autocovariance matrices of the input series at various lags
4. if the PRINTOUT=LONG option is specified, the sample autocorrelation matrices of the input series
5. a schematic representation of the autocorrelation matrices, showing the significant autocorrelations
6. if the PRINTOUT=LONG option is specified, the partial autoregressive matrices. (These are $\mathbf{\Phi}_p^p$ as described in the section "Preliminary Autoregressive Models" on page 2581.)
7. a schematic representation of the partial autocorrelation matrices, showing the significant partial autocorrelations
8. the Yule-Walker estimates of the autoregressive parameters for the autoregressive model with the minimum AIC
9. if the PRINTOUT=LONG option is specified, the autocovariance matrices of the residuals of the minimum AIC model. This is the sequence of estimated innovation variance matrices for the solutions of the Yule-Walker equations.
10. if the PRINTOUT=LONG option is specified, the autocorrelation matrices of the residuals of the minimum AIC model
11. If the CANCORR option is specified, the canonical correlations analysis for each potential state vector considered in the state vector selection process. This includes the potential state vector, the canonical correlations, the information criterion for the smallest canonical correlation, Bartlett's χ^2 statistic ("Chi Square") for the smallest canonical correlation, and the degrees of freedom of Bartlett's χ^2.
12. the components of the chosen state vector
13. the preliminary estimate of the transition matrix, **F**, the input matrix, **G**, and the variance matrix for the innovations, $\mathbf{\Sigma_{ee}}$
14. if the ITPRINT option is specified, the iteration history of the likelihood maximization. For each iteration, this shows the iteration number, the number of step halvings, the determinant of the innovation variance matrix, the damping factor Lambda, and the values of the parameters.
15. the state vector, printed again to aid interpretation of the following listing of **F** and **G**
16. the final estimate of the transition matrix **F**
17. the final estimate of the input matrix **G**
18. the final estimate of the variance matrix for the innovations $\mathbf{\Sigma_{ee}}$

19. a table that lists the estimates of the free parameters in **F** and **G** and their standard errors and t statistics
20. if the COVB option is specified, the covariance matrix of the parameter estimates
21. if the COVB option is specified, the correlation matrix of the parameter estimates
22. if the PRINT option is specified, the forecasts and their standard errors

ODS Table Names

PROC STATESPACE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 34.4.

Table 34.4 ODS Tables Produced in PROC STATESPACE

ODS Table Name	Description	Option
NObs	Number of observations	Default
Summary	Simple summary statistics table	Default
InfoCriterion	Information criterion table	Default
CovLags	Covariance matrices of input series	PRINTOUT=LONG
CorrLags	Correlation matrices of input series	PRINTOUT=LONG
PartialAR	Partial autoregressive matrices	PRINTOUT=LONG
YWEstimates	Yule-Walker estimates for minimum AIC	Default
CovResiduals	Covariance of residuals	PRINTOUT=LONG
CorrResiduals	Residual correlations from AR models	PRINTOUT=LONG
StateVector	State vector table	Default
CorrGraph	Schematic representation of correlations	Default
TransitionMatrix	Transition matrix	Default
InputMatrix	Input matrix	Default
VarInnov	Variance matrix for the innovation	Default
CovB	Covariance of parameter estimates	COVB
CorrB	Correlation of parameter estimates	COVB
CanCorr	Canonical correlation analysis	CANCORR
IterHistory	Iterative fitting table	ITPRINT

Forecasts	Forecasts table	PRINT
ConvergenceStatus	Convergence status table	Default

Examples: STATESPACE Procedure

Example 34.1: Series J from Box and Jenkins

This example analyzes the gas furnace data (series J) from Box and Jenkins. (The data are not shown; see Box and Jenkins 1976 for the data.)

First, a model is selected and fit automatically using the following statements:

```
title1 'Gas Furnace Data';
title2 'Box & Jenkins Series J';
title3 'Automatically Selected Model';

proc statespace data=seriesj cancorr;
   var x y;
run;
```

The results for the automatically selected model are shown in Output 34.1.1.

The two series are believed to have a transfer function relation with the gas rate (variable X) as the input and the CO_2 concentration (variable Y) as the output. Since the parameter estimates shown in Output 34.1.1 support this kind of model, the model is reestimated with the feedback parameters restricted to 0. The following statements fit the transfer function (no feedback) model:

```
title3 'Transfer Function Model';
proc statespace data=seriesj printout=none;
   var x y;
   restrict f(3,2)=0 f(3,4)=0
            g(3,2)=0 g(4,1)=0 g(5,1)=0;
run;
```

The last two pages of the output are shown in Output 34.1.8.

Overview: SYSLIN Procedure

The SYSLIN procedure estimates parameters in an interdependent system of linear regression equations.

Ordinary least squares (OLS) estimates are biased and inconsistent when current period endogenous variables appear as regressors in other equations in the system. The errors of a set of related regression equations are often correlated, and the efficiency of the estimates can be improved by taking these correlations into account. The SYSLIN procedure provides several techniques that produce consistent and asymptotically efficient estimates for systems of regression equations.

The SYSLIN procedure provides the following estimation methods:

- ordinary least squares (OLS)
- two-stage least squares (2SLS)
- limited information maximum likelihood (LIML)
- K-class
- seemingly unrelated regressions (SUR)
- iterated seemingly unrelated regressions (ITSUR)
- three-stage least squares (3SLS)
- iterated three-stage least squares (IT3SLS)
- full information maximum likelihood (FIML)
- minimum expected loss (MELO)

Other features of the SYSLIN procedure enable you to:

- impose linear restrictions on the parameter estimates

- test linear hypotheses about the parameters
- write predicted and residual values to an output SAS data set
- write parameter estimates to an output SAS data set
- write the crossproducts matrix (SSCP) to an output SAS data set
- use raw data, correlations, covariances, or cross products as input

Getting Started: SYSLIN Procedure

This section introduces the use of the SYSLIN procedure. The problem of dependent regressors is introduced using a supply and demand example. This section explains the terminology used for variables in a system of regression equations and introduces the SYSLIN procedure statements for declaring the roles the variables play. The syntax used for the different estimation methods and the output produced is shown.

An Example Model

In simultaneous systems of equations, endogenous variables are determined jointly rather than sequentially. Consider the following supply and demand functions for some product:

$$Q_D = a_1 + b_1 P + c_1 Y + d_1 S + \epsilon_1 (\text{demand})$$

$$Q_S = a_2 + b_2 P + c_2 U + \epsilon_2 (\text{supply})$$

$$Q = Q_D = Q_S (\text{market equilibrium})$$

The variables in this system are as follows:

Q_D	quantity demanded
Q_S	quantity supplied
Q	the observed quantity sold, which equates quantity supplied and quantity demanded in equilibrium
P	price per unit
Y	income
S	price of substitutes
U	unit cost
ϵ_1	the random error term for the demand equation
ϵ_2	the random error term for the supply equation

In this system, quantity demanded depends on price, income, and the price of substitutes. Consumers normally purchase more of a product when prices are lower and when income and the price of substitute goods are higher. Quantity supplied depends on price and the unit cost of production. Producers supply more when price is high and when unit cost is low. The actual price and quantity sold are determined jointly by the values that equate demand and supply.

Since price and quantity are jointly endogenous variables, both structural equations are necessary to adequately describe the observed values. A critical assumption of OLS is that the regressors are uncorrelated with the residual. When current endogenous variables appear as regressors in other equations (endogenous variables depend on each other), this assumption is violated and the OLS parameter estimates are biased and inconsistent. The bias caused by the violated assumptions is called *simultaneous equation bias.* Neither the demand nor supply equation can be estimated consistently by OLS.

Variables in a System of Equations

Before explaining how to use the SYSLIN procedure, it is useful to define some terms. The variables in a system of equations can be classified as follows:

- *Endogenous variables,* which are also called *jointly dependent* or *response variables,* are the variables determined by the system. Endogenous variables can also appear on the right-hand side of equations.
- *Exogenous variables* are independent variables that do not depend on any of the endogenous variables in the system.
- *Predetermined variables* include both the exogenous variables and *lagged endogenous variables,* which are past values of endogenous variables determined at previous time periods. PROC SYSLIN does not compute lagged values; any lagged endogenous variables must be computed in a preceding DATA step.
- *Instrumental variables* are predetermined variables used in obtaining predicted values for the current period endogenous variables by a first-stage regression. The use of instrumental variables characterizes estimation methods such as two-stage least squares and three-stage least squares. Instrumental variables estimation methods substitute these first-stage predicted values for endogenous variables when they appear as regressors in model equations.

Using PROC SYSLIN

First specify the input data set and estimation method in the PROC SYSLIN statement. If any model uses dependent regressors, and you are using an instrumental variables regression method, declare the dependent regressors with an ENDOGENOUS statement and declare the instruments with an INSTRUMENTS statement. Next, use MODEL statements to specify the structural equations of the system.

The use of different estimation methods is shown by the following examples. These examples use the simulated data set WORK.IN, which follows:

```
data in;
   label q = "Quantity"
         p = "Price"
         s = "Price of Substitutes"
         y = "Income"
         u = "Unit Cost";
   drop i e1 e2;
   p = 0; q = 0;
   do i = 1 to 60;
      y = 1 + .05*i  + .15*rannor(123);
      u = 2          + .05*rannor(123) + .05*rannor(123);
      s = 4 - .001*(i-10)*(i-110) + .5*rannor(123);
      e1 = .15 * rannor(123);
      e2 = .15 * rannor(123);
      demandx = 1 + .3 * y + .35 * s + e1;
      supplyx = -1 - 1 * u + e2 - .4*e1;
      q = 1.4/2.15 * demandx + .75/2.15 * supplyx;
      p = ( - q + supplyx ) / -1.4;
      output;
   end;
run;
```

OLS Estimation

PROC SYSLIN performs OLS regression if you do not specify a method of estimation in the PROC SYSLIN statement. OLS does not use instruments, so the ENDOGENOUS and INSTRUMENTS statements can be omitted.

The following statements estimate the supply and demand model shown previously:

```
proc syslin data=in;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

The PROC SYSLIN output for the demand equation is shown in Figure 35.1, and the output for the supply equation is shown in Figure 35.2.

Intercept	1	-0.30389	0.471397	-0.64	0.5217	Intercept
p	1	1.218743	0.053914	22.61	<.0001	Price
u	1	-1.07757	0.234150	-4.60	<.0001	Unit Cost

For each MODEL statement, the output first shows the model label and dependent variable name and label. This is followed by an analysis-of-variance table for the model, which shows the model, error, and total mean squares, and an F test for the no-regression hypothesis. Next, the procedure prints the root mean squared

error, dependent variable mean and coefficient of variation, and the R^2 and adjusted R^2 statistics.

Finally, the table of parameter estimates shows the estimated regression coefficients, standard errors, and *t* tests. You would expect the price coefficient in a demand equation to be negative. However, note that the OLS estimate of the price coefficient P in the demand equation (0.1233) has a positive sign. This could be caused by simultaneous equation bias.

Two-Stage Least Squares Estimation

In the supply and demand model, P is an endogenous variable, and consequently the OLS estimates are biased. The following example estimates this model using two-stage least squares:

```
proc syslin data=in 2sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

The 2SLS option in the PROC SYSLIN statement specifies the two-stage least squares method. The ENDOGENOUS statement specifies that P is an endogenous regressor for which first-stage predicted values are substituted. You need to declare an endogenous variable in the ENDOGENOUS statement only if it is used as a regressor; thus although Q is endogenous in this model, it is not necessary to list it in the ENDOGENOUS statement.

Usually, all predetermined variables that appear in the system are used as instruments. The INSTRUMENTS statement specifies that the exogenous variables Y, U, and S are used as instruments for the first-stage regression to predict P.

The 2SLS results are shown in Figure 35.3 and Figure 35.4. The first-stage regressions are not shown. To see the first-stage regression results, use the FIRST option in the PROC SYSLIN statement.

Error	57	1.082503	0.018991		
Corrected Total	59	10.03724			

Root MSE	0.13781	**R-Square**	0.89910
Dependent Mean	1.30095	**Adj R-Sq**	0.89556
Coeff Var	10.59291		

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|	Variable Label
Intercept	1	-0.51878	0.490999	-1.06	0.2952	Intercept
p	1	1.333080	0.059271	22.49	<.0001	Price
u	1	-1.14623	0.243491	-4.71	<.0001	Unit Cost

The 2SLS output is similar in form to the OLS output. However, the 2SLS results are based on predicted values for the endogenous regressors from the first stage instrumental regressions. This makes the analysis-of-variance table and the R^2 statistics difficult to interpret. For more information, see the sections "ANOVA Table for Instrumental Variables Methods" on page 2638 and "The R-Square Statistics" on page 2639.

Note that, unlike the OLS results, the 2SLS estimate for the P coefficient in the demand equation (–1.115) is negative.

LIML, K-Class, and MELO Estimation

To obtain limited information maximum likelihood, general K-class, or minimum expected loss estimates, use the ENDOGENOUS, INSTRUMENTS, and MODEL statements as in the 2SLS case but specify the LIML, K=, or MELO option instead of 2SLS in the PROC SYSLIN statement. The following statements show this for K-class estimation:

```
proc syslin data=in k=.5;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

For more information about these estimation methods, see the section "Estimation Methods" on page 2636 and consult econometrics textbooks.

SUR, 3SLS, and FIML Estimation

In a multivariate regression model, the errors in different equations might be correlated. In this case, the efficiency of the estimation might be improved by taking these cross-equation correlations into account.

Seemingly Unrelated Regression

Seemingly unrelated regression (SUR), also called joint generalized least squares (JGLS) or Zellner estimation, is a generalization of OLS for multi-equation systems. Like OLS, the SUR method assumes that all the regressors are independent variables, but SUR uses the correlations among the errors in different equations to improve the regression estimates. The SUR method requires an initial OLS regression to compute residuals. The OLS residuals are used to estimate the cross-equation covariance matrix.

The SUR option in the PROC SYSLIN statement specifies seemingly unrelated regression, as shown in the following statements:

```
proc syslin data=in sur;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

INSTRUMENTS and ENDOGENOUS statements are not needed for SUR, because the SUR method assumes there are no endogenous regressors. For SUR to be effective, the models must use different regressors. SUR produces the same results as OLS unless the model contains at least one regressor not used in the other equations.

Three-Stage Least Squares

The three-stage least squares method generalizes the two-stage least squares method to take into account the correlations between equations in the same way that SUR generalizes OLS. Three-stage least squares requires three steps: first-stage regressions to get predicted values for the endogenous regressors; a two-stage least squares step to get residuals to estimate the cross-equation correlation matrix; and the final 3SLS estimation step.

The 3SLS option in the PROC SYSLIN statement specifies the three-stage least squares method, as shown in the following statements:

```
proc syslin data=in 3sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

The 3SLS output begins with a two-stage least squares regression to estimate the cross-model correlation matrix. This output is the same as the 2SLS results shown in Figure 35.3 and Figure 35.4, and is not repeated here. The next part of the 3SLS output prints the cross-model correlation matrix computed from the 2SLS residuals. This output is shown in Figure 35.5 and includes the cross-model covariances, correlations, the inverse of the correlation matrix, and the inverse covariance matrix.

y	1	0.404117	0.117179	3.45	0.0011	Income
s	1	0.359204	0.085077	4.22	<.0001	Price of Substitutes

Model	SUPPLY
Dependent Variable	q
Label	Quantity

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|	Variable Label
Intercept	1	-0.51878	0.490999	-1.06	0.2952	Intercept
p	1	1.333080	0.059271	22.49	<.0001	Price
u	1	-1.14623	0.243491	-4.71	<.0001	Unit Cost

This output first prints the system weighted mean squared error and system weighted R^2 statistics. The system weighted MSE and system weighted R^2 measure the fit of the joint model obtained by stacking all the models together and performing a single regression with the stacked observations weighted by the inverse of the model error variances. For more information, see the section "The R-Square Statistics" on page 2639.

Next, the table of 3SLS parameter estimates for each model is printed. This output has the same form as for the other estimation methods.

Note that, in some cases, the 3SLS and 2SLS results can be the same. Such a case could arise because of the same principle that causes OLS and SUR results to be identical, unless an equation includes a regressor not used in the other equations of the system. However, the application of this principle is more complex when instrumental variables are used. When all the exogenous variables are used as instruments, linear combinations of all the exogenous variables appear in the third-stage regressions through substitution of first-stage predicted values.

In this example, 3SLS produces different (and, it is hoped, more efficient) estimates for the demand equation. However, the 3SLS and 2SLS results for the supply equation are the same. This is because the supply equation has one endogenous regressor and one exogenous regressor not used in other equations. In contrast, the demand equation has fewer endogenous regressors than exogenous regressors not used in other equations in the system.

Full Information Maximum Likelihood

The FIML option in the PROC SYSLIN statement specifies the full information maximum likelihood method, as shown in the following statements:

```
proc syslin data=in fiml;
   endogenous  p q;
   instruments y u s;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

The FIML results are shown in Figure 35.7.

u	1	-1.14804	0.237793	-4.83	<.0001	Unit Cost

Computing Reduced Form Estimates

A system of structural equations with endogenous regressors can be represented as functions of only the predetermined variables. For this to be possible, there must be as many equations as endogenous variables. If there are more endogenous variables than regression models, you can use IDENTITY statements to complete the system. For more information, see the section "Reduced Form Estimates" on page 2641.

The REDUCED option in the PROC SYSLIN statement prints reduced form estimates. The following statements show this by using the 3SLS estimates of the structural parameters:

```
proc syslin data=in 3sls reduced;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   supply: model q = p u;
run;
```

The first four pages of this output were as shown previously and are not repeated here. (See Figure 35.3, Figure 35.4, Figure 35.5, and Figure 35.6.) The final page of the output from this example contains the reduced form coefficients from the 3SLS structural estimates, as shown in Figure 35.8.

Figure 35.8 Reduced Form 3SLS Results

Restricting Parameter Estimates

You can impose restrictions on the parameter estimates with RESTRICT and SRESTRICT statements. The RESTRICT statement imposes linear restrictions on parameters in the equation specified by the preceding MODEL statement. The SRESTRICT statement imposes linear restrictions that relate parameters in different models.

To impose restrictions involving parameters in different equations, use the SRESTRICT statement. Specify the parameters in the linear hypothesis as *model-label.regressor-name*. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.)

Tests for the significance of the restrictions are printed when RESTRICT or SRESTRICT statements are used. You can label RESTRICT and SRESTRICT statements to identify the restrictions in the output.

The RESTRICT statement in the following example restricts the price coefficient in the demand equation to equal 0.015. The SRESTRICT statement restricts the estimate of the income coefficient in the demand equation to be 0.01 times the estimate of the unit cost coefficient in the supply equation.

```
proc syslin data=in 3sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   peq015: restrict p = .015;
   supply: model q = p u;
   yeq01u: srestrict demand.y = .01 * supply.u;
run;
```

The restricted estimation results are shown in Figure 35.9.

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|	Variable Label
Intercept	1	-1.31894	0.477633	-2.76	0.0077	Intercept
p	1	1.291718	0.059101	21.86	<.0001	Price
u	1	-0.67887	0.235679	-2.88	0.0056	Unit Cost

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|	Variable Label
RESTRICT	-1	342.3605	38.12094	8.98	<.0001	YEQ01U

The standard error for P in the demand equation is 0, since the value of the P coefficient was specified by the RESTRICT statement and not estimated from the data. The "Parameter Estimates" table for the demand equation contains an additional row for the restriction specified by the RESTRICT statement. The parameter estimate for the restriction is the value of the Lagrange multiplier used to impose the restriction. The restriction is highly significant ($t = 6.777$), which means that the data are not consistent with the restriction, and the model does not fit as well with the restriction imposed. For more information, see the section "RESTRICT Statement" on page 2630.

Following the "Parameter Estimates" table for the supply equation, the results for the cross model restrictions are printed. This shows that the restriction specified by the SRESTRICT statement is not consistent with the data ($t = 8.98$). For more information, see the section "SRESTRICT Statement" on page 2631.

Testing Parameters

You can test linear hypotheses about the model parameters with TEST and STEST statements. The TEST statement tests hypotheses about parameters in the equation specified by the preceding MODEL statement. The STEST statement tests hypotheses that relate parameters in different models.

For example, the following statements test the hypothesis that the price coefficient in the demand equation is equal to 0.015:

```
proc syslin data=in 3sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   test_1: test p = .015;
   supply: model q = p u;
run;
```

The TEST statement results are shown in Figure 35.10. This reports an F test for the hypothesis specified by the TEST statement. In this case, the F statistic is 6.79 (3.879/.571) with 1 and 113 degrees of freedom. The p-value for this F statistic is 0.0104, which indicates that the hypothesis tested is almost but not quite rejected at the 0.01 level. For more information, see the section "TEST Statement" on page 2633.

Figure 35.10 TEST Statement Results

The SYSLIN Procedure

Label	Quantity

Parameter Estimates

Variable	DF	Parameter Estimate	Standard Error	t Value	Pr > |t|	Variable Label
Intercept	1	1.980269	1.169176	1.69	0.0959	Intercept
p	1	-1.17654	0.605015	-1.94	0.0568	Price
y	1	0.404117	0.117179	3.45	0.0011	Income
s	1	0.359204	0.085077	4.22	<.0001	Price of Substitutes

Test Results

Num DF	Den DF	F Value	Pr > F	Label
1	113	6.79	0.0104	TEST_1

To test hypotheses that involve parameters in different equations, use the STEST statement. Specify the parameters in the linear hypothesis as *model-label.regressor-name.* (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.)

For example, the following statements test the hypothesis that the income coefficient in the demand equation is 0.01 times the unit cost coefficient in the supply equation:

```
proc syslin data=in 3sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   supply: model q = p u;
   stest1: stest demand.y = .01 * supply.u;
run;
```

The STEST statement results are shown in Figure 35.11. The form and interpretation of the STEST statement results are like the TEST statement results. In this case, the F test produces a p-value less than 0.0001 and strongly rejects the hypothesis tested. For more information, see the section "STEST Statement" on page 2632.

p	1	1.333080	0.059271	22.49	<.0001	Price
u	1	-1.14623	0.243491	-4.71	<.0001	Unit Cost

Test Results

Num DF	Den DF	F Value	Pr > F	Label
1	113	22.46	0.0001	STEST1

You can combine TEST and STEST statements with RESTRICT and SRESTRICT statements to perform hypothesis tests for restricted models. Of course, the validity of the TEST and STEST statement results depends on the correctness of any restrictions you impose on the estimates.

Saving Residuals and Predicted Values

You can store predicted values and residuals from the estimated models in a SAS data set. Specify the OUT= option in the PROC SYSLIN statement and use the OUTPUT statement to specify names for new variables to contain the predicted and residual values.

For example, the following statements store the predicted quantity from the supply and demand equations in the data set PRED:

```
proc syslin data=in out=pred 3sls;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   output predicted=q_demand;
   supply: model q = p u;
   output predicted=q_supply;
run;
```

Plotting Residuals

You can plot the residuals against the regressors by using the PROC SGPLOT. For example, the following statements plot the 2SLS residuals for the demand model against price, income, and price of substitutes:

```
proc syslin data=in 2sls out=out;
   endogenous  p;
   instruments y u s;
   demand: model q = p y s;
   output residual=residual_q;
run;

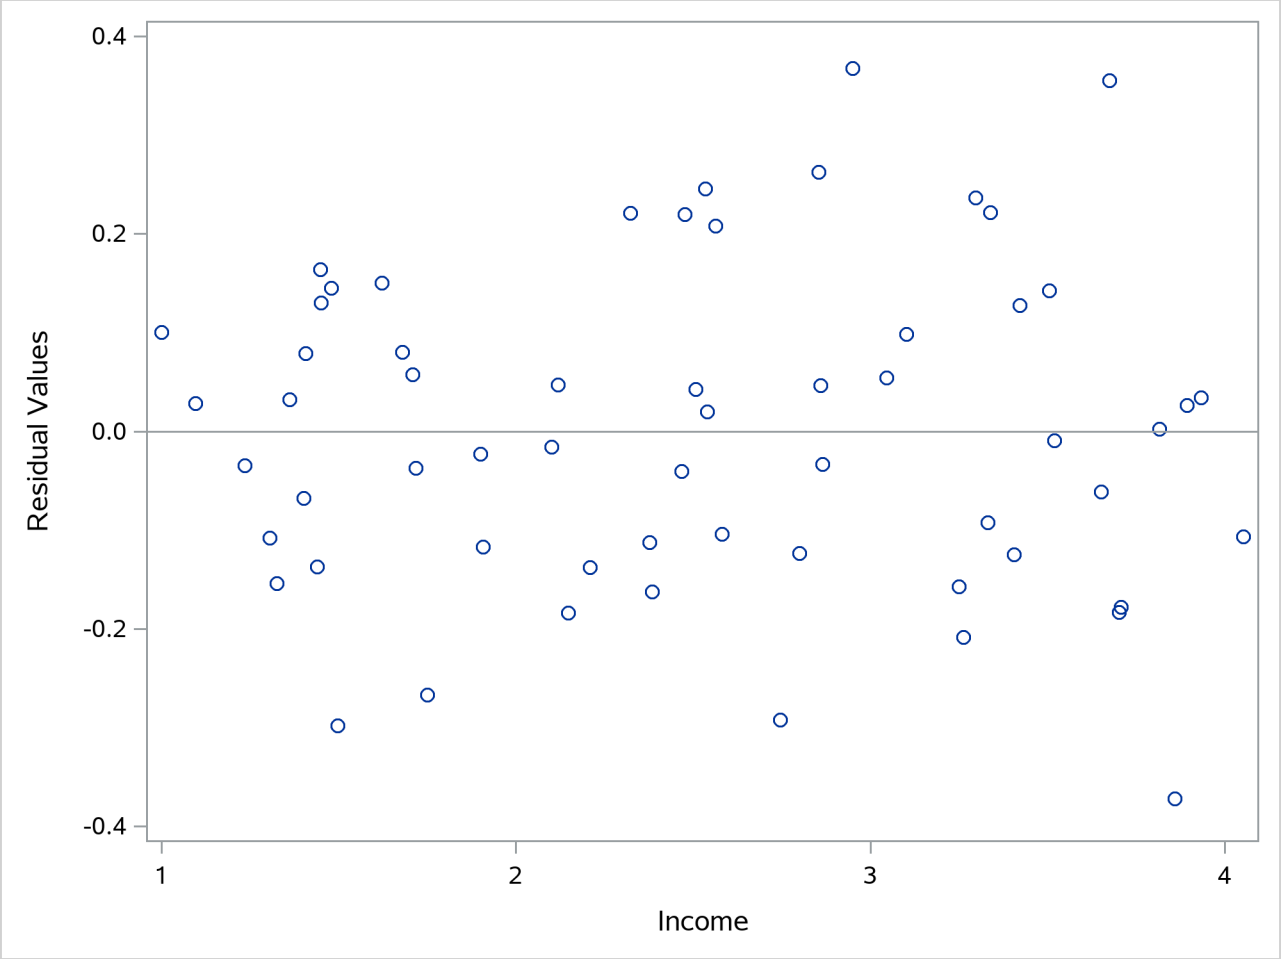
proc sgplot data=out;
   scatter x=p y=residual_q;
   refline 0 / axis=y;
run;

proc sgplot data=out;
   scatter x=y y=residual_q;
   refline 0 / axis=y;
run;

proc sgplot data=out;
   scatter x=s y=residual_q;
   refline 0 / axis=y;
run;
```

The plot for income is shown in Figure 35.12. The other plots are not shown.

Figure 35.12 Plot of Residuals against Income



Syntax: SYSLIN Procedure

The SYSLIN procedure uses the following statements:

PROC SYSLIN *options* ;
BY *variables* ;
ENDOGENOUS *variables* ;
IDENTITY *identities* ;
INSTRUMENTS *variables* ;
MODEL *response = regressors / options* ;
OUTPUT PREDICTED=*variable* **RESIDUAL=***variable* ;
RESTRICT *restrictions* ;
SRESTRICT *restrictions* ;
STEST *equations* ;
TEST *equations* ;
VAR *variables* ;
WEIGHT *variable* ;

Functional Summary

The SYSLIN procedure statements and options are summarized in Table 35.1.

Table 35.1 Functional Summary

Description	Statement	Option

PROC SYSLIN Statement

PROC SYSLIN *options* **;**

The following options can be used with the PROC SYSLIN statement.

Data Set Options

DATA=*SAS-data-set*
specifies the input data set. If the DATA= option is omitted, the most recently created SAS data set is used. In addition to ordinary SAS data sets, PROC SYSLIN can analyze data sets of TYPE=CORR, TYPE=COV, TYPE=UCORR, TYPE=UCOV, and TYPE=SSCP. For more information, see the section "Special TYPE= Input Data Sets" on page 2635.

OUT=*SAS-data-set*
specifies an output SAS data set for residuals and predicted values. The OUT= option is used in conjunction with the OUTPUT statement. For more information, see the section "OUT= Data Set" on page 2643.

OUTEST=*SAS-data-set*
writes the parameter estimates to an output data set. For more information, see the section "OUTEST= Data Set" on page 2643.

OUTCOV
COVOUT
writes the covariance matrix of the parameter estimates to the OUTEST= data set in addition to the parameter estimates.

OUTCOV3
COV3OUT
writes covariance matrices for each model in a system to the OUTEST= data set when the 3SLS, SUR, or FIML option is used.

OUTSSCP=*SAS-data-set*
writes the sum-of-squares-and-crossproducts matrix to an output data set. For more information, see the section "OUTSSCP= Data Set" on page 2644.

Estimation Method Options

2SLS
specifies the two-stage least squares estimation method.

3SLS
specifies the three-stage least squares estimation method.

ALPHA=*value*
specifies Fuller's modification to the LIML estimation method. For more information, see the section "Fuller's Modification to LIML" on page 2642.

CONVERGE=*value*
specifies the convergence criterion for the iterative estimation methods IT3SLS, ITSUR, and FIML. The default is CONVERGE=0.0001.

FIML
specifies the full information maximum likelihood estimation method.

ITSUR
specifies the iterative seemingly unrelated estimation method.

IT3SLS
specifies the iterative three-stage least squares estimation method.

K=*value*
specifies the K-class estimation method.

LIML
specifies the limited information maximum likelihood estimation method.

MAXITER=*n*
specifies the maximum number of iterations allowed for the IT3SLS, ITSUR, and FIML estimation methods. The MAXITER= option can be abbreviated as MAXIT=. The default is MAXITER=30.

MELO
specifies the minimum expected loss estimation method.

NOINCLUDE
excludes the RESTRICT statements from the final stage for the 3SLS, IT3SLS, SUR, and ITSUR estimation methods.

OLS
specifies the ordinary least squares estimation method. This is the default.

SDIAG
uses the diagonal of **S** instead of **S** to do the estimation, where **S** is the covariance matrix of equation errors. For more information, see the section "Uncorrelated Errors across Equations" on page 2642.

SINGULAR=*value*
specifies a criterion for testing singularity of the crossproducts matrix. This is a tuning parameter used to make PROC SYSLIN more or less sensitive to singularities. The value must be between 0 and 1. The default is SINGULAR=1E–8.

SUR
specifies the seemingly unrelated estimation method.

Printing Control Options

ALL
specifies the CORRB, COVB, DW, I, OVERID, PLOT, STB, and XPX options for every MODEL statement.

FIRST
prints first-stage regression statistics for the endogenous variables regressed on the instruments. This output includes sums of squares, estimates, variances, and standard deviations.

ITPRINT
prints parameter estimates, system-weighted residual sum of squares, and R^2 at each iteration for the IT3SLS and ITSUR estimation methods. For the FIML method, the ITPRINT option prints parameter estimates, negative of log-likelihood function, and norm of gradient vector at each iteration.

NOPRINT
suppresses all printed output. Specifying NOPRINT in the PROC SYSLIN statement is equivalent to specifying NOPRINT in every MODEL statement.

REDUCED
prints the reduced form estimates. If the REDUCED option is specified, you should specify any IDENTITY statements needed to make the system square. For more information, see the section "Reduced Form Estimates" on page 2641.

SIMPLE
prints descriptive statistics for the dependent variables. The statistics printed include the sum, mean, uncorrected sum of squares, variance, and standard deviation.

USSCP
prints the uncorrected sum-of-squares-and-crossproducts matrix.

USSCP2
prints the uncorrected sum-of-squares-and-crossproducts matrix for all variables used in the analysis, including predicted values of variables generated by the procedure.

VARDEF=DF | N | WEIGHT | WGT
specifies the denominator to use in calculating cross-equation error covariances and parameter standard errors and covariances. The default is VARDEF=DF, which corrects for model degrees of freedom. VARDEF=N specifies no degrees-of-freedom correction. VARDEF=WEIGHT specifies the sum of the observation weights. VARDEF=WGT specifies the sum of the observation weights minus the model degrees of freedom. For more information, see the section "Computation of Standard Errors" on page 2641.

BY Statement

BY *variables* **;**

A BY statement can be used with PROC SYSLIN to obtain separate analyses on observations in groups defined by the BY variables.

ENDOGENOUS Statement

ENDOGENOUS *variables* **;**

The ENDOGENOUS statement declares the jointly dependent variables that are projected in the first-stage regression through the instrument variables. The ENDOGENOUS statement is not needed for the SUR, ITSUR, or OLS estimation methods. The default ENDOGENOUS list consists of all the dependent variables in the MODEL and IDENTITY statements that do not appear in the INSTRUMENTS statement.

IDENTITY Statement

IDENTITY *equation* **;**

The IDENTITY statement specifies linear relationships among variables to write to the OUTEST= data set. It provides extra information in the OUTEST= data set but does not create or compute variables. The OUTEST= data set can be processed by the SIMLIN procedure in a later step.

The IDENTITY statement is also used to compute reduced form coefficients when the REDUCED option in the PROC SYSLIN statement is specified. For more information, see the section "Reduced Form Estimates" on page 2641.

The *equation* given by the IDENTITY statement has the same form as equations in the MODEL statement. A label can be specified for an IDENTITY statement as follows:

label **: IDENTITY . . . ;**

INSTRUMENTS Statement

INSTRUMENTS *variables* **;**

The INSTRUMENTS statement declares the variables used in obtaining first-stage predicted values. All the instruments specified are used in each first-stage regression. The INSTRUMENTS statement is required for the 2SLS, 3SLS, IT3SLS, LIML, MELO, and K-class estimation methods. The INSTRUMENTS statement is not needed for the SUR, ITSUR, OLS, or FIML estimation methods.

MODEL Statement

MODEL *response = regressors / options* **;**

The MODEL statement regresses the response variable on the left side of the equal sign against the regressors listed on the right side.

Models can be given labels. Model labels are used in the printed output to identify the results for different models. Model labels are also used in SRESTRICT and STEST statements to refer to parameters in different models. If no label is specified, the response variable name is used as the label for the model. The model label is specified as follows:

label : **MODEL . . . ;**

The following options can be used in the MODEL statement after a slash (/):

ALL
specifies the CORRB, COVB, DW, I, OVERID, PLOT, STB, and XPX options.

ALPHA=*value*
specifies the α parameter for Fuller's modification to the LIML estimation method. For more information, see the section "Fuller's Modification to LIML" on page 2642.

CORRB
prints the matrix of estimated correlations between the parameter estimates.

COVB
prints the matrix of estimated covariances between the parameter estimates.

DW
prints Durbin-Watson statistics and autocorrelation coefficients for the residuals. If there are missing values, d' is calculated according to Savin and White (1978). Use the DW option only if the data set to be analyzed is an ordinary SAS data set with time series observations sorted in time order. The Durbin-Watson test is not valid for models with lagged dependent regressors.

I
prints the inverse of the crossproducts matrix for the model, $(\mathbf{X}'\mathbf{X})^{-1}$. If restrictions are specified, the crossproducts matrix printed is adjusted for the restrictions. For more information, see the section "Computational Details" on page 2640.

K=*value*
specifies K-class estimation.

NOINT
suppresses the intercept parameter from the model.

NOPRINT
suppresses the normal printed output.

OVERID
prints Basmann's (1960) test for over identifying restrictions. For more information, see the section "Overidentification Restrictions" on page 2642.

PLOT
plots residual values against regressors. A plot of the residuals for each regressor is printed.

STB
prints standardized parameter estimates. Sometimes known as a standard partial regression coefficient, a standardized parameter estimate is a parameter estimate multiplied by the standard deviation of the associated regressor and divided by the standard deviation of the response variable.

UNREST
prints parameter estimates computed before restrictions are applied. The UNREST option is valid only if a RESTRICT statement is specified.

XPX
prints the model crossproducts matrix, $X'X$. For more information, see the section "Computational Details" on page 2640.

OUTPUT Statement

OUTPUT < **PREDICTED=***variable* > < **RESIDUAL=***variable* > **;**

The OUTPUT statement writes predicted values and residuals from the preceding model to the data set specified by the OUT= option in the PROC SYSLIN statement. An OUTPUT statement must come after the MODEL statement to which it applies. The OUT= option must be specified in the PROC SYSLIN statement.

The following options can be specified in the OUTPUT statement:

PREDICTED=*variable*
names a new variable to contain the predicted values for the response variable. The PREDICTED= option can be abbreviated as PREDICT=, PRED=, or P=.

RESIDUAL=*variable*
names a new variable to contain the residual values for the response variable. The RESIDUAL= option can be abbreviated as RESID= or R=.

For example, the following statements create an output data set named B. In addition to the variables in the input data set, the data set B contains the variable YHAT, with values that are predicted values of the response variable Y, and the YRESID, with values that are the residual values of Y.

```
proc syslin data=a out=b;
   model y = x1 x2;
   output p=yhat r=yresid;
run;
```

For example, the following statements create an output data set named PRED. In addition to the variables in the input data set, the data set PRED contains the variables Q_DEMAND and Q_SUPPLY, with values that are predicted values of the response variable Q for the demand and supply equations, respectively, and the variables R_DEMAND and R_SUPPLY, with values that are the residual values of the demand and supply equations, respectively.

```
proc syslin data=in out=pred;
   demand: model q = p y s;
   output p=q_demand r=r_demand;
   supply: model q = p u;
   output p=q_supply r=r_supply;
run;
```

For more information, see the section "OUT= Data Set" on page 2643.

RESTRICT Statement

RESTRICT *equation , . . . , equation* **;**

The RESTRICT statement places restrictions on the parameter estimates for the preceding MODEL statement. Any number of RESTRICT statements can follow a MODEL statement. Each restriction is written as a linear equation. If more than one restriction is specified in a single RESTRICT statement, the restrictions are separated by commas.

Parameters are referred to by the name of the corresponding regressor variable. Each name used in the equation must be a regressor in the preceding MODEL statement. The keyword INTERCEPT is used to refer to the intercept parameter in the model.

RESTRICT statements can be given labels. The labels are used in the printed output to distinguish results for different restrictions. Labels are specified as follows:

label **: RESTRICT . . . ;**

The following is an example of the use of the RESTRICT statement, in which the coefficients of the regressors X1 and X2 are required to sum to 1:

```
proc syslin data=a;
   model y = x1 x2;
   restrict x1 + x2 = 1;
run;
```

Variable names can be multiplied by constants. When no equal sign appears, the linear combination is set equal to 0. Note that the parameters associated with the variables are restricted, not the variables themselves. Here are some examples of valid RESTRICT statements:

```
restrict x1 + x2 = 1;
restrict x1 + x2 - 1;
restrict 2 * x1 = x2 + x3 , intercept + x4 = 0;
restrict x1 = x2 = x3 = 1;
restrict 2 * x1 - x2;
```

Restricted parameter estimates are computed by introducing a Lagrangian parameter λ for each restriction (Pringle and Rayner 1971). The estimates of these Lagrangian parameters are printed in the "Parameter Estimates" table. If a restriction cannot be applied, its parameter value and degrees of freedom are listed as 0.

The Lagrangian parameter λ measures the sensitivity of the sum of squared errors (SSE) to the restriction. If the restriction is changed by a small amount ϵ, the SSE is changed by $2\lambda\epsilon$.

The t ratio tests the significance of the restrictions. If λ is zero, the restricted estimates are the same as the unrestricted.

Any number of restrictions can be specified in a RESTRICT statement, and any number of RESTRICT statements can be used. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

NOTE: The RESTRICT statement is not supported for the FIML estimation method.

SRESTRICT Statement

SRESTRICT *equation , . . . , equation* **;**

The SRESTRICT statement imposes linear restrictions that involve parameters in two or more MODEL statements. The SRESTRICT statement is like the RESTRICT statement but is used to impose restrictions across equations, whereas the RESTRICT statement applies only to parameters in the immediately preceding MODEL statement.

Each restriction is written as a linear equation. Parameters are referred to as *label.variable,* where *label* is the model label and *variable* is the name of the regressor to which the parameter is attached. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.) Each variable name used must be a regressor in the indicated MODEL statement. The keyword INTERCEPT is used to refer to intercept parameters.

SRESTRICT statements can be given labels. The labels are used in the printed output to distinguish results for different restrictions. Labels are specified as follows:

label **: SRESTRICT . . . ;**

The following is an example of the use of the SRESTRICT statement, in which the coefficient for the regressor X2 is constrained to be the same in both models:

```
proc syslin data=a 3sls;
   endogenous y1 y2;
   instruments x1 x2;
   model y1 = y2 x1 x2;
   model y2 = y1 x2;
   srestrict y1.x2 = y2.x2;
run;
```

When no equal sign is used, the linear combination is set equal to 0. Thus, the restriction in the preceding example can also be specified as

```
   srestrict y1.x2 - y2.x2;
```

Any number of restrictions can be specified in an SRESTRICT statement, and any number of SRESTRICT statements can be used. The estimates are computed subject to all restrictions specified. However, restrictions should be consistent and not redundant.

When a system restriction is requested for a single equation estimation method (such as OLS or 2SLS), PROC SYSLIN produces the restricted estimates by actually using a corresponding system method. For example, when an SRESTRICT statement is specified along with OLS, PROC SYSLIN produces the restricted OLS estimates via a two-step process equivalent to using SUR estimation with the SDIAG option. First, the unrestricted OLS results are produced. Then, the GLS (SUR) estimation with the system restriction is performed, using the diagonal of the covariance matrix of the residuals. When an SRESTRICT statement is specified along with 2SLS, PROC SYSLIN produces the restricted 2SLS estimates via a multistep process equivalent to using 3SLS estimation with the SDIAG option. First, the unrestricted 2SLS results are produced. Then, the GLS (3SLS) estimation with the system restriction is performed, using the diagonal of the covariance matrix of the residuals.

The results of the SRESTRICT statements are printed after the parameter estimates for all the models in the system. The format of the SRESTRICT statement output is the same as the “Parameter Estimates” table. In

this output the parameter estimate is the Lagrangian parameter λ used to impose the restriction.

The Lagrangian parameter λ measures the sensitivity of the system sum of square errors to the restriction. The system SSE is the system MSE shown in the printed output multiplied by the degrees of freedom. If the restriction is changed by a small amount ϵ, the system SSE is changed by $2\lambda\epsilon$.

The *t* ratio tests the significance of the restriction. If λ is zero, the restricted estimates are the same as the unrestricted estimates.

The model degrees of freedom are not adjusted for the cross-model restrictions imposed by SRESTRICT statements.

NOTE: The SRESTRICT statement is only supported for 2SLS, 3SLS, IT3SLS, OLS, SUR and ITSUR estimation methods.

STEST Statement

STEST *equation , . . . , equation / options* **;**

The STEST statement performs an *F* test for the joint hypotheses specified in the statement.

The hypothesis is represented in matrix notation as

$$\mathbf{L}\beta = \mathbf{c}$$

and the *F* test is computed as

$$\frac{(\mathbf{L}b - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{L}')^{-1}(\mathbf{L}b - \mathbf{c})}{m\hat{\sigma}^2}$$

where b is the estimate of β, m is the number of restrictions, and $\hat{\sigma}^2$ is the system weighted mean squared error. For information about the matrix $\mathbf{X}'\mathbf{X}$, see the section "Computational Details" on page 2640.

Each hypothesis to be tested is written as a linear equation. Parameters are referred to as *label.variable,* where *label* is the model label and *variable* is the name of the regressor to which the parameter is attached. (If the MODEL statement does not have a label, you can use the dependent variable name as the label for the model, provided the dependent variable uniquely labels the model.) Each variable name used must be a regressor in the indicated MODEL statement. The keyword INTERCEPT is used to refer to intercept parameters.

STEST statements can be given labels. The label is used in the printed output to distinguish different tests. Any number of STEST statements can be specified. Labels are specified as follows:

label **: STEST . . . ;**

The following is an example of the STEST statement:

```
proc syslin data=a 3sls;
   endogenous y1 y2;
   instruments x1 x2;
   model y1 = y2 x1 x2;
   model y2 = y1 x2;
   stest y1.x2 = y2.x2;
run;
```

The test performed is exact only for ordinary least squares, given the OLS assumptions of the linear model. For other estimation methods, the *F* test is based on large sample theory and is only approximate in finite samples.

If RESTRICT or SRESTRICT statements are used, the tests computed by the STEST statement are conditional on the restrictions specified. The validity of the tests can be compromised if incorrect restrictions are imposed on the estimates.

The following are examples of STEST statements:

```
stest a.x1 + b.x2 = 1;
stest 2 * b.x2 = c.x3 + c.x4 ,
      a.intercept + b.x2 = 0;
stest a.x1 = c.x2 = b.x3 = 1;
stest 2 * a.x1 - b.x2 = 0;
```

The PRINT option can be specified in the STEST statement after a slash (/):

PRINT
prints intermediate calculations for the hypothesis tests.

NOTE: The STEST statement is only supported for 2SLS, 3SLS, IT3SLS, OLS, SUR and ITSUR estimation methods.

TEST Statement

TEST *equation , . . . , equation / options* **;**

The TEST statement performs *F* tests of linear hypotheses about the parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. If more than one equation is specified, the equations are separated by commas.

Variable names must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT is used to refer to the model intercept.

TEST statements can be given labels. The label is used in the printed output to distinguish different tests. Any number of TEST statements can be specified. Labels are specified as follows:

label **: TEST . . . ;**

The following is an example of the use of TEST statement, which tests the hypothesis that the coefficients of X1 and X2 are the same:

```
proc syslin data=a;
   model y = x1 x2;
   test x1 = x2;
run;
```

The following statements perform *F* tests for the hypothesis that the coefficients of X1 and X2 are equal, for the hypothesis that the sum of the X1 and X2 coefficients is twice the intercept, and for the joint hypothesis:

```
proc syslin data=a;
   model y = x1 x2;
   x1eqx2:  test x1 = x2;
   sumeq2i: test x1 + x2 = 2 * intercept;
   joint:   test x1 = x2, x1 + x2 = 2 * intercept;
run;
```

The following are additional examples of TEST statements:

```
test x1 + x2 = 1;
test x1 = x2 = x3 = 1;
test 2 * x1 = x2 + x3, intercept + x4 = 0;
test 2 * x1 - x2;
```

The TEST statement performs an F test for the joint hypotheses specified. The hypothesis is represented in matrix notation as follows:

$$\mathbf{L}\beta = \mathbf{c}$$

The F test is computed as

$$\frac{(\mathbf{L}b - \mathbf{c})'(\mathbf{L}(\mathbf{X}'\mathbf{X})^{-}\mathbf{L}')^{-1}(\mathbf{L}b - \mathbf{c})}{m\hat{\sigma}^2}$$

where b is the estimate of β, m is the number of restrictions, and $\hat{\sigma}^2$ is the model mean squared error. For information about the matrix $\mathbf{X}'\mathbf{X}$, see the section "Computational Details" on page 2640.

The test performed is exact only for ordinary least squares, given the OLS assumptions of the linear model. For other estimation methods, the F test is based on large sample theory and is only approximate in finite samples.

If RESTRICT or SRESTRICT statements are used, the tests computed by the TEST statement are conditional on the restrictions specified. The validity of the tests can be compromised if incorrect restrictions are imposed on the estimates.

The PRINT option can be specified in the TEST statement after a slash (/):

PRINT
prints intermediate calculations for the hypothesis tests.

NOTE: The TEST statement is not supported for the FIML estimation method.

VAR Statement

VAR *variables* **;**

The VAR statement is used to include variables in the crossproducts matrix that are not specified in any MODEL statement. This statement is rarely used with PROC SYSLIN and is used only with the OUTSSCP= option in the PROC SYSLIN statement.

WEIGHT Statement

WEIGHT *variable* **;**

The WEIGHT statement is used to perform weighted regression. The WEIGHT statement names a variable in the input data set whose values are relative weights for a weighted least squares fit. If the weight value is proportional to the reciprocal of the variance for each observation, the weighted estimates are the best linear unbiased estimates (BLUE).

Details: SYSLIN Procedure

Input Data Set

PROC SYSLIN does not compute new values for regressors. For example, if you need a lagged variable, you must create it with a DATA step. No values are computed by IDENTITY statements; all values must be in the input data set.

Special TYPE= Input Data Sets

The input data set for most applications of the SYSLIN procedure contains standard rectangular data. However, PROC SYSLIN can also process input data in the form of a crossproducts, covariance, or correlation matrix. Data sets that contain such matrices are identified by values of the TYPE= data set option.

These special kinds of input data sets can be used to save computer time. It takes nk^2 operations, where n is the number of observations and k is the number of variables, to calculate cross products; the regressions are of the order k^3. When n is in the thousands and k is much smaller, you can save most of the computer time in later runs of PROC SYSLIN by reusing the SSCP matrix rather than recomputing it.

The SYSLIN procedure can process TYPE=CORR, COV, UCORR, UCOV, or SSCP data sets. TYPE=CORR and TYPE=COV data sets, usually created by the CORR procedure, contain means and standard deviations, and correlations or covariances. TYPE=SSCP data sets, usually created in previous runs of PROC SYSLIN, contain sums of squares and cross products. For more information about special SAS data sets, see *SAS/STAT User's Guide*.

When special SAS data sets are read, you must specify the TYPE= data set option. PROC CORR and PROC SYSLIN automatically set the type for output data sets; however, if you create the data set by some other means, you must specify its type with the TYPE= data set option.

When the special data sets are used, the DW (Durbin-Watson test) and PLOT options in the MODEL statement cannot be performed, and the OUTPUT statements are not valid.

Estimation Methods

A brief description of the methods used by the SYSLIN procedure follows. For more information about these methods, see the references at the end of this chapter.

There are two fundamental methods of estimation for simultaneous equations: least squares and maximum likelihood. There are two approaches within each of these categories: single equation methods (also referred to as limited information methods) and system methods (also referred to as full information methods). System methods take into account cross-equation correlations of the disturbances in estimating parameters, while single equation methods do not.

OLS, 2SLS, MELO, K-class, SUR, ITSUR, 3SLS, and IT3SLS use the least squares method; LIML and FIML use the maximum likelihood method.

OLS, 2SLS, MELO, K-class, and LIML are single equation methods. The system methods are SUR, ITSUR, 3SLS, IT3SLS, and FIML.

Single Equation Estimation Methods

Single equation methods do not take into account correlations of errors across equations. As a result, these estimators are not asymptotically efficient compared to full information methods; however, there are instances in which they may be preferred. (For more information, see the section "Choosing a Method for Simultaneous Equations" on page 2638.)

Let y_i be the dependent endogenous variable in equation i, and X_i and Y_i be the matrices of exogenous and endogenous variables appearing as regressors in the same equation.

The 2SLS method owes its name to the fact that, in a first stage, the instrumental variables are used as regressors to obtain a projected value $\hat{Y}_i$ that is uncorrelated with the residual in equation i. In a second stage, $\hat{Y}_i$ replaces Y_i on the right-hand side to obtain consistent least squares estimators.

Normally, the predetermined variables of the system are used as the instruments. It is possible to use variables other than predetermined variables from your system as instruments; however, the estimation might not be as efficient. For consistent estimates, the instruments must be uncorrelated with the residual and correlated with the endogenous variables.

The LIML method results in consistent estimates that are equal to the 2SLS estimates when an equation is exactly identified. LIML can be viewed as a least-variance ratio estimation or as a maximum likelihood estimation. LIML involves minimizing the ratio $\lambda = (rvar\_eq)/(rvar\_sys)$, where $rvar\_eq$ is the residual variance associated with regressing the weighted endogenous variables on all predetermined variables that appear in that equation, and $rvar\_sys$ is the residual variance associated with regressing weighted endogenous variables on all predetermined variables in the system.

The MELO method computes the minimum expected loss estimator. MELO estimators "minimize the posterior expectation of generalized quadratic loss functions for structural coefficients of linear structural models" (Judge et al. 1985, p. 635).

K-class estimators are a class of estimators that depends on a user-specified parameter k. A k value less than 1 is recommended but not required. The parameter k can be deterministic or stochastic, but its probability

limit must equal 1 for consistent parameter estimates. When all the predetermined variables are listed as instruments, they include all the other single equation estimators supported by PROC SYSLIN. The instance when some of the predetermined variables are not listed among the instruments is not supported by PROC SYSLIN for the general K-class estimation. However, it is supported for the other methods.

For $k = 1$, the K-class estimator is the 2SLS estimator, while for $k = 0$, the K-class estimator is the OLS estimator. The K-class interpretation of LIML is that $k = \lambda$. Note that k is stochastic in the LIML method, unlike for OLS and 2SLS.

MELO is a Bayesian K-class estimator. It yields estimates that can be expressed as a matrix-weighted average of the OLS and 2SLS estimates. MELO estimators have finite second moments and hence finite risk. Other frequently used K-class estimators might not have finite moments under some commonly encountered circumstances, and hence there can be infinite risk relative to quadratic and other loss functions.

One way of comparing K-class estimators is to note that when k =1, the correlation between regressor and the residual is completely corrected for. In all other cases, it is only partially corrected for.

For more information about K-class estimators, see the section "Computational Details" on page 2640.

SUR and 3SLS Estimation Methods

SUR might improve the efficiency of parameter estimates when there is contemporaneous correlation of errors across equations. In practice, the contemporaneous correlation matrix is estimated using OLS residuals. Under two sets of circumstances, SUR parameter estimates are the same as those produced by OLS: when there is no contemporaneous correlation of errors across equations (the estimate of the contemporaneous correlation matrix is diagonal) and when the independent variables are the same across equations.

Theoretically, SUR parameter estimates are always at least as efficient as OLS in large samples, provided that your equations are correctly specified. However, in small samples the need to estimate the covariance matrix from the OLS residuals increases the sampling variability of the SUR estimates. This effect can cause SUR to be less efficient than OLS. If the sample size is small and the cross-equation correlations are small, then OLS is preferred to SUR. The consequences of specification error are also more serious with SUR than with OLS.

The 3SLS method combines the ideas of the 2SLS and SUR methods. Like 2SLS, the 3SLS method uses $\hat{Y}$ instead of Y for endogenous regressors, which results in consistent estimates. Like SUR, the 3SLS method takes the cross-equation error correlations into account to improve large sample efficiency. For 3SLS, the 2SLS residuals are used to estimate the cross-equation error covariance matrix.

The SUR and 3SLS methods can be iterated by recomputing the estimate of the cross-equation covariance matrix from the SUR or 3SLS residuals and then computing new SUR or 3SLS estimates based on this updated covariance matrix estimate. Continuing this iteration until convergence produces ITSUR or IT3SLS estimates.

FIML Estimation Method

The FIML estimator is a system generalization of the LIML estimator. The FIML method involves minimizing the determinant of the covariance matrix associated with residuals of the reduced form of the equation system. From a maximum likelihood standpoint, the LIML method involves assuming that the errors are normally distributed and then maximizing the likelihood function subject to restrictions on a particular equation. FIML is similar, except that the likelihood function is maximized subject to restrictions on all of the parameters in the model, not just those in the equation being estimated.

NOTE: The RESTRICT, SRESTRICT, TEST, and STEST statements are not supported when the FIML method is used.

Choosing a Method for Simultaneous Equations

A number of factors should be taken into account in choosing an estimation method. Although system methods are asymptotically most efficient in the absence of specification error, system methods are more sensitive to specification error than single equation methods.

In practice, models are never perfectly specified. It is a matter of judgment whether the misspecification is serious enough to warrant avoidance of system methods.

Another factor to consider is sample size. With small samples, 2SLS might be preferred to 3SLS. In general, it is difficult to say much about the small sample properties of K-class estimators because the results depend on the regressors used.

LIML and FIML are invariant to the normalization rule imposed but are computationally more expensive than 2SLS or 3SLS.

If the reason for contemporaneous correlation among errors across equations is a common, omitted variable, it is not necessarily best to apply SUR. SUR parameter estimates are more sensitive to specification error than OLS. OLS might produce better parameter estimates under these circumstances. SUR estimates are also affected by the sampling variation of the error covariance matrix. There is some evidence from Monte Carlo studies that SUR is less efficient than OLS in small samples.

ANOVA Table for Instrumental Variables Methods

In the instrumental variables methods (2SLS, LIML, K-class, MELO), first-stage predicted values are substituted for the endogenous regressors. As a result, the regression sum of squares (RSS) and the error sum of squares (ESS) do not sum to the total corrected sum of squares for the dependent variable (TSS). The analysis-of-variance table included in the second-stage results gives these sums of squares and the mean squares that are used for the F test, but this table is not a variance decomposition in the usual sense.

The F test shown in the instrumental variables case is a valid test of the no-regression hypothesis that the true coefficients of all regressors are 0. However, because of the first-stage projection of the regression mean square, this is a Wald-type test statistic, which is asymptotically F but not exactly F-distributed in finite samples. Thus, for small samples the F test is only approximate when instrumental variables are used.

The R-Square Statistics

As explained in the section "ANOVA Table for Instrumental Variables Methods" on page 2638, when instrumental variables are used, the regression sum of squares (RSS) and the error sum of squares (ESS) do not sum to the total corrected sum of squares. In this case, there are several ways that the R^2 statistic can be defined.

The definition of R^2 used by the SYSLIN procedure is

$$R^2 = \frac{\mathrm{RSS}}{\mathrm{RSS} + \mathrm{ESS}}$$

This definition is consistent with the F test of the null hypothesis that the true coefficients of all regressors are zero. However, this R^2 might not be a good measure of the goodness of fit of the model.

System Weighted R-Square and System Weighted Mean Squared Error

The system weighted R^2, printed for the 3SLS, IT3SLS, SUR, ITSUR, and FIML methods, is computed as follows.

$$R^2 = \mathbf{Y}'\mathbf{W}\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}'\mathbf{W}\mathbf{Y}/\mathbf{Y}'\mathbf{W}\mathbf{Y}$$

In this equation, the matrix $\mathbf{X}'\mathbf{X}$ is $\mathbf{R}'\mathbf{W}\mathbf{R}$ and $\mathbf{W}$ is the projection matrix of the instruments:

$$\mathbf{W} = \mathbf{S}^{-1} \otimes \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$$

The matrix $\mathbf{Z}$ is the instrument set, $\mathbf{R}$ is the regressor set, and $\mathbf{S}$ is the estimated cross-model covariance matrix.

The system weighted MSE, printed for the 3SLS, IT3SLS, SUR, ITSUR, and FIML methods, is computed as follows:

$$\mathrm{MSE} = \frac{1}{tdf}(\mathbf{Y}'\mathbf{W}\mathbf{Y} - \mathbf{Y}'\mathbf{W}\mathbf{R}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{R}'\mathbf{W}\mathbf{Y})$$

In this equation, *tdf* is the sum of the error degrees of freedom for the equations in the system.

Computational Details

This section discusses various computational details.

Computation of Least Squares–Based Estimators

Let the system be composed of G equations, and let the ith equation be expressed in the form

$$y_i = Y_i \boldsymbol{\beta}_i + X_i \boldsymbol{\gamma}_i + \mathbf{u}$$

where

y_i is the vector of observations on the dependent variable

Y_i is the matrix of observations on the endogenous variables included in the equation

$\boldsymbol{\beta}_i$ is the vector of parameters associated with Y_i

X_i is the matrix of observations on the predetermined variables included in the equation

$\boldsymbol{\gamma}_i$ is the vector of parameters associated with X_i

$\mathbf{u}$ is a vector of errors

Let $\hat{V}_i = Y_i - \hat{Y}_i$, where $\hat{Y}_i$ is the projection of Y_i onto the space spanned by the instruments matrix $\mathbf{Z}$.

Let

$$\boldsymbol{\delta}_i = \begin{bmatrix} \boldsymbol{\beta}_i \\ \boldsymbol{\gamma}_i \end{bmatrix}$$

be the vector of parameters associated with both the endogenous and exogenous variables.

The K-class of estimators (Theil 1971) is defined by

$$\hat{\boldsymbol{\delta}}_{i,k} = \begin{bmatrix} Y_i'Y_i - k\hat{V}_i'\hat{V}_i & Y_i'X_i \\ X_i'Y_i & X_i'X_i \end{bmatrix}^{-1} \begin{bmatrix} (Y_i - kV_i)'y_i \\ X_i'y_i \end{bmatrix}$$

where k is a user-defined value.

Let

$$\mathbf{R} = [Y_i\, X_i]$$

and

$$\hat{\mathbf{R}} = [\hat{Y}_i\ X_i]$$

The 2SLS estimator is defined as

$$\hat{\boldsymbol{\delta}}_{i,\mathrm{2SLS}} = [\hat{R}_i'\ \hat{R}_i]^{-1}\hat{R}_i'y_i$$

Let $\mathbf{y}$ and $\boldsymbol{\delta}$ be the vectors obtained by stacking the vectors of dependent variables and parameters for all G equations, and let $\mathbf{R}$ and $\hat{\mathbf{R}}$ be the block diagonal matrices formed by R_i and $\hat{R}_i$, respectively.

The SUR and ITSUR estimators are defined as

$$\hat{\boldsymbol{\delta}}_{(\mathrm{IT})\mathrm{SUR}} = \left[\mathbf{R}'\left(\hat{\Sigma}^{-1} \otimes \mathbf{I}\right)\mathbf{R}\right]^{-1} \mathbf{R}'\left(\hat{\Sigma}^{-1} \otimes \mathbf{I}\right)\mathbf{y}$$

while the 3SLS and IT3SLS estimators are defined as

$$\hat{\boldsymbol{\delta}}_{(\mathrm{IT})3\mathrm{SLS}} = \left[\hat{\mathbf{R}}'\left(\hat{\Sigma}^{-1} \otimes \mathbf{I}\right)\hat{\mathbf{R}}\right]^{-1} \hat{\mathbf{R}}'\left(\hat{\Sigma}^{-1} \otimes \mathbf{I}\right)\mathbf{y}$$

where $\mathbf{I}$ is the identity matrix and $\hat{\Sigma}$ is an estimator of the cross-equation correlation matrix. For 3SLS, $\hat{\Sigma}$ is obtained from the 2SLS estimation, while for SUR it is derived from the OLS estimation. For IT3SLS and ITSUR, it is obtained iteratively from the previous estimation step, until convergence.

Computation of Standard Errors

The VARDEF= option in the PROC SYSLIN statement controls the denominator used in calculating the cross-equation covariance estimates and the parameter standard errors and covariances. The values of the VARDEF= option and the resulting denominator are as follows:

N	uses the number of nonmissing observations.
DF	uses the number of nonmissing observations less the degrees of freedom in the model.
WEIGHT	uses the sum of the observation weights given by the WEIGHTS statement.
WDF	uses the sum of the observation weights given by the WEIGHTS statement less the degrees of freedom in the model.

The VARDEF= option does not affect the model mean squared error, root mean squared error, or R^2 statistics. These statistics are always based on the error degrees of freedom, regardless of the VARDEF= option. The VARDEF= option also does not affect the dependent variable coefficient of variation (CV).

Reduced Form Estimates

The REDUCED option in the PROC SYSLIN statement computes estimates of the reduced form coefficients. The REDUCED option requires that the equation system be square. If there are fewer models than endogenous variables, IDENTITY statements can be used to complete the equation system.

The reduced form coefficients are computed as follows. Represent the equation system, with all endogenous variables moved to the left-hand side of the equations and identities, as

$$\mathbf{B}\mathbf{Y} = \boldsymbol{\Gamma}\mathbf{X}$$

Here $\mathbf{B}$ is the estimated coefficient matrix for the endogenous variables $\mathbf{Y}$, and $\boldsymbol{\Gamma}$ is the estimated coefficient matrix for the exogenous (or predetermined) variables $\mathbf{X}$.

The system can be solved for $\mathbf{Y}$ as follows, provided $\mathbf{B}$ is square and nonsingular:

$$\mathbf{Y} = \mathrm{B}^{-1}\boldsymbol{\Gamma}\mathbf{X}$$

The reduced form coefficients are the matrix $\mathbf{B}^{-1}\boldsymbol{\Gamma}$.

Uncorrelated Errors across Equations

The SDIAG option in the PROC SYSLIN statement computes estimates by assuming uncorrelated errors across equations. As a result, when the SDIAG option is used, the 3SLS estimates are identical to 2SLS estimates, and the SUR estimates are the same as the OLS estimates.

Overidentification Restrictions

The OVERID option in the MODEL statement can be used to test for overidentifying restrictions on parameters of each equation. The null hypothesis is that the predetermined variables that do not appear in any equation have zero coefficients. The alternative hypothesis is that at least one of the assumed zero coefficients is nonzero. The test is approximate and rejects the null hypothesis too frequently for small sample sizes.

The formula for the test is given as follows. Let $y_i = \beta_i \mathbf{Y}_i + \gamma_i \mathbf{Z}_i + e_i$ be the ith equation. $\mathbf{Y}_i$ are the endogenous variables that appear as regressors in the ith equation, and $\mathbf{Z}_i$ are the instrumental variables that appear as regressors in the ith equation. Let N_i be the number of variables in $\mathbf{Y}_i$ and $\mathbf{Z}_i$.

Let $v_i = y_i - \mathbf{Y}_i \hat{\beta}_i$. Let $\mathbf{Z}$ represent all instrumental variables, T be the total number of observations, and K be the total number of instrumental variables. Define $\hat{l}$ as follows:

$$\hat{l} = \frac{v'_i(\mathbf{I} - \mathbf{Z}_i(\mathbf{Z}'_i\mathbf{Z}_i)^{-1}\mathbf{Z}'_i)v_i}{v'_i(\mathbf{I} - \mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}')v_i}$$

Then the test statistic

$$\frac{T-K}{K-N_i}(\hat{l} - 1)$$

is distributed approximately as an F with $K - N_i$ and $T - K$ degrees of freedom. For more information, see Basmann (1960).

Fuller's Modification to LIML

The ALPHA= option in the PROC SYSLIN and MODEL statements parameterizes Fuller's modification to LIML. This modification is $k = \gamma - (\alpha/(n-g))$, where α is the value of the ALPHA= option, γ is the LIML k value,n is the number of observations, and g is the number of predetermined variables. Fuller's modification is not used unless the ALPHA= option is specified. For more information, see Fuller (1977).

Missing Values

Observations that have a missing value for any variable in the analysis are excluded from the computations.

OUT= Data Set

The output SAS data set produced by the OUT= option in the PROC SYSLIN statement contains all the variables in the input data set and the variables that contain predicted values and residuals specified by OUTPUT statements.

The residuals are computed as actual values minus predicted values. Predicted values never use lags of other predicted values, as would be desirable for dynamic simulation. For these applications, PROC SIMLIN is available to predict or simulate values from the estimated equations.

OUTEST= Data Set

The OUTEST= option produces a TYPE=EST output SAS data set that contains estimates from the regressions. The variables in the OUTEST= data set are as follows:

BY variables	identifies the BY statement variables that are included in the OUTEST= data set.
TYPE	identifies the estimation type for the observations. The _TYPE_ value INST indicates first-stage regression estimates. Other values indicate the estimation method used: 2SLS indicates two-stage least squares results, 3SLS indicates three-stage least squares results, LIML indicates limited information maximum likelihood results, and so forth. Observations added by IDENTITY statements have the _TYPE_ value IDENTITY.
STATUS	identifies the convergence status of the estimation. The value of _STATUS_ is 0 when convergence criteria are met. Otherwise, the value of _STATUS_ is 1 when the estimation converges with a note, 2 when it converges with a warning, or 3 when it fails to converge.
MODEL	identifies the model label. The model label is the label specified in the MODEL statement or the dependent variable name if no label is specified. For first-stage regression estimates, _MODEL_ has the value FIRST.
DEPVAR	identifies the name of the dependent variable for the model.
NAME	identifies the names of the regressors for the rows of the covariance matrix, if the COVOUT option is specified. _NAME_ has a blank value for the parameter estimates observations. The _NAME_ variable is not included in the OUTEST= data set unless the COVOUT option is used to output the covariance of parameter estimates matrix.
SIGMA	contains the root mean squared error for the model, which is an estimate of the standard deviation of the error term. The _SIGMA_ variable contains the same values reported as Root MSE in the printed output.
INTERCEPT	identifies the intercept parameter estimates.
regressors	identifies the regressor variables from all the MODEL statements that are included in the OUTEST= data set. Variables used in IDENTIFY statements are also included in the OUTEST= data set.

The parameter estimates are stored under the names of the regressor variables. The intercept parameters are stored in the variable INTERCEPT. The dependent variable of the model is given a coefficient of –1. Variables that are not in a model have missing values for the OUTEST= observations for that model.

Some estimation methods require computation of preliminary estimates. All estimates computed are output to the OUTEST= data set. For each BY group and each estimation, the OUTEST= data set contains one observation for each MODEL or IDENTITY statement. Results for different estimations are identified by the _TYPE_ variable.

For example, consider the following statements:

```
proc syslin data=a outest=est 3sls;
   by b;
   endogenous y1 y2;
   instruments x1-x4;
   model y1 = y2 x1 x2;
   model y2 = y1 x3 x4;
   identity x1 = x3 + x4;
run;
```

The 3SLS method requires both a preliminary 2SLS stage and preliminary first-stage regressions for the endogenous variable. The OUTEST= data set thus contains three different kinds of estimates. The observations for the first-stage regression estimates have the _TYPE_ value INST. The observations for the 2SLS estimates have the _TYPE_ value 2SLS. The observations for the final 3SLS estimates have the _TYPE_ value 3SLS.

Since there are two endogenous variables in this example, there are two first-stage regressions and two _TYPE_=INST observations in the OUTEST= data set. Since there are two model statements, there are two OUTEST= observations with _TYPE_=2SLS and two observations with _TYPE_=3SLS. In addition, the OUTEST= data set contains an observation with the _TYPE_ value IDENTITY that contains the coefficients specified by the IDENTITY statement. All these observations are repeated for each BY group in the input data set defined by the values of the BY variable B.

When the COVOUT option is specified, the estimated covariance matrix for the parameter estimates is included in the OUTEST= data set. Each observation for parameter estimates is followed by observations that contain the rows of the parameter covariance matrix for that model. The row of the covariance matrix is identified by the variable _NAME_. For observations that contain parameter estimates, _NAME_ is blank. For covariance observations, _NAME_ contains the regressor name for the row of the covariance matrix and the regressor variables contain the covariances.

For an example of the OUTEST= data set, see Example 35.1.

OUTSSCP= Data Set

The OUTSSCP= option produces a TYPE=SSCP output SAS data set that contains sums of squares and cross products. The data set contains all variables used in the MODEL, IDENTITY, and VAR statements. Observations are identified by the variable _NAME_.

The OUTSSCP= data set can be useful when a large number of observations are to be explored in many different PROC SYSLIN runs. The sum-of-squares-and-crossproducts matrix can be saved with the OUTSSCP= option and used as the DATA= data set on subsequent PROC SYSLIN runs. This is much less expensive computationally because PROC SYSLIN never reads the original data again. In the step that creates the OUTSSCP= data set, include in the VAR statement all the variables you expect to use.

Printed Output

The printed output produced by the SYSLIN procedure is as follows:

1. If the SIMPLE option is used, a table of descriptive statistics is printed that shows the sum, mean, sum of squares, variance, and standard deviation for all the variables used in the models.
2. If the FIRST option is specified and an instrumental variables method is used, first-stage regression results are printed. The results show the regression of each endogenous variable on the variables in the INSTRUMENTS list.
3. The results of the second-stage regression are printed for each model. (For more information, see the section "Printed Output for Each Model" on page 2645.)
4. If a systems method like 3SLS, SUR, or FIML is used, the cross-equation error covariance matrix is printed. This matrix is shown four ways: the covariance matrix itself, the correlation matrix form, the inverse of the correlation matrix, and the inverse of the covariance matrix.
5. If a systems method like 3SLS, SUR, or FIML is used, the system weighted mean squared error and system weighted R^2 statistics are printed. The system weighted MSE and R^2 measure the fit of the joint model obtained by stacking all the models together and performing a single regression with the stacked observations weighted by the inverse of the model error variances.
6. If a systems method like 3SLS, SUR, or FIML is used, the final results are printed for each model.
7. If the REDUCED option is used, the reduced form coefficients are printed. These consist of the structural coefficient matrix for the endogenous variables, the structural coefficient matrix for the exogenous variables, the inverse of the endogenous coefficient matrix, and the reduced form coefficient matrix. The reduced form coefficient matrix is the product of the inverse of the endogenous coefficient matrix and the exogenous structural coefficient matrix.

Printed Output for Each Model

The results printed for each model include the analysis-of-variance table, the "Parameter Estimates" table, and optional items requested by TEST statements or by options in the MODEL statement.

The printed output produced for each model is described in the following.

The analysis-of-variance table includes the following:

- the model degrees of freedom, sum of squares, and mean square
- the error degrees of freedom, sum of squares, and mean square. The error mean square is computed by dividing the error sum of squares by the error degrees of freedom and is not affected by the VARDEF= option.
- the corrected total degrees of freedom and total sum of squares. Note that for instrumental variables methods, the model and error sums of squares do not add to the total sum of squares.

- the *F* ratio, labeled "F Value," and its significance, labeled "PROB>F," for the test of the hypothesis that all the nonintercept parameters are 0
- the root mean squared error. This is the square root of the error mean square.
- the dependent variable mean
- the coefficient of variation (CV) of the dependent variable
- the R^2 statistic. This R^2 is computed consistently with the calculation of the *F* statistic. It is valid for hypothesis tests but might not be a good measure of fit for models estimated by instrumental variables methods.
- the R^2 statistic adjusted for model degrees of freedom, labeled "Adj R-SQ"

The "Parameter Estimates" table includes the following:

- estimates of parameters for regressors in the model and the Lagrangian parameter for each restriction specified
- a degrees of freedom column labeled DF. Estimated model parameters have 1 degree of freedom. Restrictions have a DF of –1. Regressors or restrictions dropped from the model due to collinearity have a DF of 0.
- the standard errors of the parameter estimates
- the *t* statistics, which are the parameter estimates divided by the standard errors
- the significance of the *t* tests for the hypothesis that the true parameter is 0, labeled "Pr > |t|." As previously noted, the significance tests are strictly valid in finite samples only for OLS estimates but are asymptotically valid for the other methods.
- the standardized regression coefficients, if the STB option is specified. This is the parameter estimate multiplied by the ratio of the standard deviation of the regressor to the standard deviation of the dependent variable.
- the labels of the regressor variables or restriction labels

In addition to the analysis-of-variance table and the "Parameter Estimates" table, the results printed for each model can include the following:

- If TEST statements are specified, the test results are printed.
- If the DW option is specified, the Durbin-Watson statistic and first-order autocorrelation coefficient are printed.
- If the OVERID option is specified, the results of Basmann's test for overidentifying restrictions are printed.
- If the PLOT option is used, plots of residual against each regressor are printed.

- If the COVB or CORRB options are specified, the results for each model also include the covariance or correlation matrix of the parameter estimates. For systems methods like 3SLS and FIML, the COVB and CORB output is printed for the whole system after the output for the last model, instead of separately for each model.

The third-stage output for 3SLS, SUR, IT3SLS, ITSUR, and FIML does not include the analysis-of-variance table. When a systems method is used, the second-stage output does not include the optional output, except for the COVB and CORRB matrices.

ODS Table Names

PROC SYSLIN assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 35.2. If the estimation method used is 3SLS, IT3SLS, ITSUR or SUR, you can obtain tables by specifying ODS OUTPUT CorrResiduals, InvCorrResiduals, InvCovResiduals.

Table 35.2 ODS Tables Produced in PROC SYSLIN

ODS Table Name	Description	Option
ANOVA	Summary of the SSE, MSE for the equations	Default
AugXPXMat	Model crossproducts	XPX or USSCP
AutoCorrStat	Autocorrelation statistics	DW
ConvergenceStatus	Convergence status	Default
CorrB	Correlations of parameters	CORRB
CorrResiduals	Correlations of residuals	
CovB	Covariance of parameters	COVB
CovResiduals	Covariance of residuals	
EndoMat	Endogenous variables	REDUCED
ExogMat	Exogenous variables	REDUCED
FitStatistics	Statistics of fit	Default
InvCorrResiduals	Inverse correlations of residuals	
InvCovResiduals	Inverse covariance of residuals	
InvEndoMat	Inverse endogenous variables	REDUCED
InvXPX	$X'X$ inverse for system	I
IterHistory	Iteration printing	ITPRINT
MissingValues	Missing values generated by the program	Default
ModelVars	Name and label for the model	Default
ParameterEstimates	Parameter estimates	Default
RedMat	Reduced form	REDUCED
SimpleStatistics	Descriptive statistics	SIMPLE
SSCP	Model crossproducts	XPX or USSCP
TestResults	Test for overidentifying restrictions	
Weight	Weighted model statistics	

ODS Graphics

This section describes the use of ODS for creating graphics with the SYSLIN procedure.

ODS Graph Names

PROC SYSLIN assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when you use ODS. The names are listed in Table 35.3.

To request these graphs, you must specify the ODS GRAPHICS statement.

Table 35.3 ODS Graphics Produced by PROC SYSLIN

ODS Graph Name	Plot Description
DiagnosticsPanel	All applicable plots listed below
ActualByPredicted	Predicted versus actual plot
QQPlot	Q-Q plot of residuals
ResidualHistogram	Histogram of the residuals
ResidualPlot	Residual plot

Examples: SYSLIN Procedure

Example 35.1: Klein's Model I Estimated with LIML and 3SLS

This example uses PROC SYSLIN to estimate the classic Klein Model I. For a discussion of this model, see Theil (1971). The following statements read the data:

```
*---------------------------Klein's Model I----------------------------*
| By L.R. Klein, Economic Fluctuations in the United States, 1921-1941 |
| (1950), NY: John Wiley.   A macro-economic model of the U.S. with    |
| three behavioral equations, and several identities. See Theil, p.456.|
*--------------------------------------------------------------------*;
data klein;
input year c p w i x wp g t k wsum;
   date=mdy(1,1,year);
   format date monyy.;
   y   =c+i+g-t;
   yr  =year-1931;
   klag=lag(k);
   plag=lag(p);
   xlag=lag(x);
   label year='Year'
         date='Date'
         c   ='Consumption'
         p   ='Profits'
         w   ='Private Wage Bill'
```

```
          i   ='Investment'
          k   ='Capital Stock'
          y   ='National Income'
          x   ='Private Production'
          wsum='Total Wage Bill'
          wp  ='Govt Wage Bill'
          g   ='Govt Demand'
          i   ='Taxes'
          klag='Capital Stock Lagged'
          plag='Profits Lagged'
          xlag='Private Product Lagged'
          yr  ='YEAR-1931';

   ... more lines ...
```

The following statements estimate the Klein model using the limited information maximum likelihood method. In addition, the parameter estimates are written to a SAS data set with the OUTEST= option.

```
proc syslin data=klein outest=b liml;
   endogenous c p w i x wsum k y;
   instruments klag plag xlag wp g t yr;
   consume: model c = p plag  wsum;
   invest:  model i = p plag  klag;
   labor:   model w = x xlag  yr;
run;

proc print data=b;
run;
```

The PROC SYSLIN estimates are shown in Output 35.1.1 through Output 35.1.3.

Example 35.2: Grunfeld's Model Estimated with SUR

The following example was used by Zellner in his classic 1962 paper on seemingly unrelated regressions. Different stock prices often move in the same direction at a given point in time. The SUR technique might provide more efficient estimates than OLS in this situation.

The following statements read the data. (The prefix GE stands for General Electric and WH stands for Westinghouse.)

```

Example 35.3: Illustration of ODS Graphics

This example illustrates the use of ODS graphics. This is a continuation of the section "Example 35.1: Klein's Model I Estimated with LIML and 3SLS" on page 2648. These graphical displays are requested by specifying the ODS GRAPHICS statement before running PROC SYSLIN. For information about the graphics available in the SYSLIN procedure, see the section "ODS Graphics" on page 2648.

The following statements show how to generate ODS graphics plots with the SYSLIN procedure. The plots of residuals for each one of the equations in the model are displayed in Figure 35.3.1 through Figure 35.3.3.

Overview: TIMEDATA Procedure

The TIMEDATA procedure analyzes time-stamped transactional data with respect to time and accumulates the data into a time series format.

After the transactional data are accumulated to form a time series and any missing values are interpreted, the accumulated time series can be functionally transformed using log, square root, logistic, or Box-Cox transformations. The time series can be further transformed using simple differencing, seasonal differencing, or both. After functional and difference transformations have been applied, the accumulated and transformed time series can be stored in an output data set. This working time series can then be analyzed further using various time series analysis techniques provided by this procedure or other SAS/ETS procedures.

The TIMEDATA procedure is very similar to the TIMESERIES procedure. However, unlike the TIMESERIES procedure (which enables you to perform a variety of standard time series analysis techniques), the TIMEDATA procedure enables you to define your own analyses using SAS programming statements.

By default, the TIMEDATA procedure provides no further analyses.

The TIMEDATA procedure forms time series vectors and then provides these vectors as SAS data arrays for subsequent processing by your SAS programming statements. Your programming statements are processed independently for each BY group. The TIMEDATA procedure is like the SAS DATA step for time series data. The SAS DATA step processes data by each row; the TIMEDATA procedure processes time series vectors.

As part of your SAS programming statements, you can include user-defined functions and subroutines created by the FCMP procedure. Additionally, you can use the RUN_MACRO subroutine provided by the FCMP procedure to submit SAS statements that use any SAS procedures.

All results of the transactional or time series analysis can be stored in output data sets or printed using the Output Delivery System (ODS).

Getting Started: TIMEDATA Procedure

This section outlines the use of the TIMEDATA procedure and gives a cursory description of some of the analysis techniques that you can perform on time-stamped transactional data.

Given an input data set that contains numerous transaction variables recorded over time at no specific frequency, the TIMEDATA procedure can form time series as follows:

```
PROC TIMEDATA DATA=<input-data-set>
                 OUT=<output-data-set>;
   BY <list-of-BY-variables>;
   ID <time-ID-variable> INTERVAL=<frequency>
                         ACCUMULATE=<statistic>;
   VAR <time-series-variables>;
   /* programming statements */
RUN;
```

The TIMEDATA procedure forms time series from the input time-stamped transactional data. It can provide results in output data sets or in other output formats by using the Output Delivery System (ODS).

Time-stamped transactional data are recorded at no fixed interval. Analysts often want to use time series analysis techniques that require fixed-time intervals. Therefore, the transactional data must be accumulated to form a fixed-interval time series, such as daily, weekly, or monthly.

Suppose that a bank wants to analyze the transactions that are associated with each of its customers over time. Further, suppose that the data set Work.Transactions contains four variables that are related to these transactions: Customer, Date, Withdrawals, and Deposits. The following examples illustrate possible ways to analyze these transactions by using the TIMEDATA procedure.

The following TIMEDATA procedure statements accumulate the time-stamped transactional data to form a daily time series based on the accumulated daily totals of each type of transaction (Withdrawals and Deposits):

```
proc timedata data=transactions
              out=timeseries
              outarray=arrays;
   by customer;
   id date interval=day accumulate=total;
   var withdrawals deposits;
   outarrays balance;

   balance[1] = deposits[1] - withdrawals[1];
   do t = 2 to _LENGTH_;
      balance[t] = balance[t-1] + (deposits[t] - withdrawals[t]);
   end;

run;
```

The OUT=TIMESERIES option specifies that the resulting time series data for each customer are to be stored in the data set Work.Transactions. The OUTARRAY=ARRAYS option specifies that the resulting time series data along with a newly created variable, Balance, are to be stored in the data set Work.Arrays. The INTERVAL=DAY option specifies that the transactions are to be accumulated on a daily basis. The ACCUMULATE=TOTAL option specifies that the sum of the transactions is to be calculated. After the transactional data are accumulated into a time series format, many of the procedures provided with SAS/ETS software can be used to analyze the resulting time series data.

For example, the following statements use the ARIMA procedure to model and forecast each customer's balance data by using an ARIMA$(1,0,0)(0,1,0)_s$ model (where the number of seasons is s=7 days in a week):

```
proc arima data=arrays;
   by customer;
   identify var=balance(7) noprint;
   estimate p=(1) outest=estimates noprint;
   forecast id=date interval=day out=forecasts;
quit;
```

The OUTEST=ESTIMATES data set contains the parameter estimates of the model specified. The OUT=FORECASTS data set contains forecasts based on the model specified. For more information, see Chapter 7, "The ARIMA Procedure."

By default, the TIMEDATA procedure produces no printed output.

Syntax: TIMEDATA Procedure

The following statements are available in the TIMEDATA procedure:

PROC TIMEDATA *options* ;
  BY *variables* ;
  ID *variable* **INTERVAL**= *interval-option* ;
  FCMPOPT *options* ;
  OUTARRAYS *array-name-list* ;
  OUTSCALARS *scalar-name-list* ;
  VAR *variable-list / options* ;
  REGISTER *package* ;
  Programming Statements ;

Functional Summary

Table 36.1 summarizes the statements and options that control the TIMEDATA procedure.

PROC TIMEDATA Statement

PROC TIMEDATA *options* **;**

The following *options* can be used in the PROC TIMEDATA statement:

AUXDATA=*SAS-data-set*
names a SAS data set that contains auxiliary input data for the procedure to use for supplying time series variables. For more information, see the section "Auxiliary Data Sets" on page 2680.

CYCLETYPE=*option*
specifies the indexing of each time series with respect to life-cycle. By default, CYCLETYPE=BOL.

The following CYCLETYPE= *options* are available:

BOL indexes the time series by the beginning of life. The first time value is 1. The following values are incremented by 1.

MOL indexes the time series by the middle of life. The middle time value is zero. The preceding values are decremented by 1. The following values are incremented by 1.

EOL indexes the time series by the end of life. The last time value is 1. The preceding values are incremented by 1.

The CYCLETYPE= option specifies the indexing of the _CYCLE_ variable contained in the OUTARRAY= data set and the predefined array _CYCLE_.

DATA=*SAS-data-set*
names the SAS data set that contains the input data from which the procedure creates the time series. If the DATA= option is not specified, the most recently created SAS data set is used.

LEAD=*n*
specifies the number of periods ahead to forecast (forecast lead or horizon) used to extend the data set. The default is LEAD=0.

The LEAD= value is relative to the last observation in the input data set and not to the last nonmissing observation of a particular series.

MAXERROR=*number*
limits the number of warning and error messages that are produced during the execution of the procedure to the specified *number*. This option is particularly useful in BY-group processing, where it can be used to suppress recurring messages. By default, MAXERROR=50.

MAXDATAERROR=*number*
limits the number of warning and error messages that are produced during the loading of data to the specified *number*. This option is particularly useful in BY-group processing, where it can be used to suppress recurring messages. By default, MAXDATAERROR=50.

OUT=*SAS-data-set*
names the output data set to contain the time series variables specified in the subsequent VAR statements. If BY variables are specified, they are also included in the OUT= data set. If an ID variable is specified, it is also included in the OUT= data set. The values are accumulated based on the INTERVAL= option or the ACCUMULATE= option or both in the ID statement. The OUT= data set is particularly useful when you want to further analyze, model, or forecast the resulting time series with other SAS/ETS procedures.

OUTARRAY=*SAS-data-set*
names the output data set to contain the time series vectors listed in the VAR and OUTARRAYS statements.

The OUTARRAY= data set contains the variables specified in the BY, ID, and VAR statements in addition to the arrays that are specified in the OUTARRAYS statements.

OUTSCALAR=*SAS-data-set*
names the output data set to contain the scalar names listed in the OUTSCALARS statements.

The OUTSCALAR= data set contains the variables specified in the BY statement and the scalars that are specified in the OUTSCALARS statements.

OUTPROCINFO=*SAS-data-set*
names the output data set to summarize information in the SAS log, specifically the number of notes, errors, and warnings and the number of series processed, analyses requested, and analyses failed.

OUTSUM=*SAS-data-set*
names the output data set to contain the descriptive statistics. The descriptive statistics are based on the accumulated time series when the ACCUMULATE= option, the SETMISSING= option, or both are specified in the ID or VAR statements. The OUTSUM= data set is particularly useful when analyzing large numbers of series and a summary of the results is needed.

PLOTS=*option* | **(** *options* **)**
specifies the univariate graphical output desired. By default, the TIMEDATA procedure produces no graphical output. The PLOTS= option produces results that are similar to the data sets shown in parentheses next to the following *options*:

ARRAYS plots the time series (OUT= data set).

ALL same as PLOTS=(ARRAYS).

For example, PLOTS=ARRAYS plots the time series. The PLOTS= option produces graphical output for these results by using the Output Delivery System (ODS).

PRINT=*option* | **(** *options* **)**
specifies the printed output desired. By default, the TIMEDATA procedure produces no printed output. The PRINT= option produces results that are similar to the data sets shown in parentheses next to the following *options*:

ARRAYS prints the arrays table (OUTARRAY= data set).

SCALARS prints the scalars table (OUTSCALAR= data set).

SUMMARY prints the descriptive statistics table for all time series (OUTSUM= data set).

ALL same as PRINT=(ARRAYS SCALARS SUMMARY).

For example, PRINT=SCALARS prints the scalars specified in the OUTSCALARS statement. The PRINT= option produces printed output for these results by using the Output Delivery System (ODS).

SEASONALITY=*number*
specifies the length of the seasonal cycle. For example, SEASONALITY=3 means that every group of three time periods forms a seasonal cycle. By default, the length of the seasonal cycle is 1 (no seasonality) or the length implied by the INTERVAL= option specified in the ID statement. For example, INTERVAL=MONTH implies that the length of the seasonal cycle is 12.

BY Statement

You can include a BY statement with PROC TIMEDATA to obtain separate dummy variable definitions for groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the option NOTSORTED or DESCENDING in the BY statement for the TIMEDATA procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Programmers Guide: Essentials*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

FCMPOPT Statement

FCMPOPT *options* **;**

The FCMPOPT statement specifies the following *options* that are related to user-defined functions and subroutines:

QUIET=ON | OFF
specifies whether the nonfatal errors and warnings that are generated by the user-defined SAS language functions and subroutines are printed to the log. Nonfatal errors are usually associated with operations with missing values. The default is QUIET=ON.

TRACE=ON | OFF
specifies whether the user-defined SAS language functions and subroutines tracings are printed to the log. Tracings are the results of every operation executed. This option is generally used for debugging. The default is TRACE=OFF.

ID Statement

ID *variable* **INTERVAL=***interval* < *options* > **;**

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date or datetime values. In addition, the ID statement specifies the (desired) frequency associated with the time series. The ID statement *options* also specify how the observations are accumulated and how the time ID values are aligned to form the time series. The information specified affects all variables listed in subsequent VAR statements. If the ID statement is specified, the INTERVAL= must also be used. If an ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID.

You can specify the following *options* in the ID statement:

ACCUMULATE=*option*
specifies how the data set observations are to be accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option. The ID variable contains the time ID values. Each time ID variable value corresponds to a specific time period. The accumulated values form the time series, which is used in subsequent analysis.

The ACCUMULATE= option is useful when there are zero or more than one input observations that coincide with a particular time period (for example, time-stamped transactional data). The EXPAND procedure offers additional frequency conversions and transformations that can also be useful in creating a time series.

The following *options* determine how the observations are accumulated within each time period based on the ID variable and the frequency specified by the INTERVAL= option:

NONE	No accumulation occurs; the ID variable values must be equally spaced with respect to the frequency. This is the default. Observations are accumulated based on the following:
TOTAL	total sum of their values
AVERAGE | AVG	average of their values
MINIMUM | MIN	minimum of their values
MEDIAN | MED	median of their values
MAXIMUM | MAX	maximum of their values
N	number of nonmissing observations
NMISS	number of missing observations
NOBS	number of observations
FIRST	first of their values

LAST	last of their values
STDDEV | STD	standard deviation of their values
CSS	corrected sum of squares of their values
USS	uncorrected sum of squares of their values

If the ACCUMULATE= option is specified, the SETMISSING= option is useful for specifying how accumulated missing values are to be treated. If missing values should be interpreted as zero, then SETMISSING=0 should be used. For more information about accumulation, see the section "Details: TIMEDATA Procedure" on page 2676.

ALIGN=*option*

controls the alignment of SAS dates that are used to identify output observations. The ALIGN= option accepts the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. BEGINNING is the default.

END=*option*

specifies a SAS date or datetime value that represents the end of the data. If the last time ID variable value is less than the END= value, the series is extended with missing values. If the last time ID variable value is greater than the END= value, the series is truncated. For example, END="&sysdate"D uses the automatic macro variable SYSDATE to extend or truncate the series to the current date. You can specify the START= and END= options to ensure that the data that are associated within each BY group contain the same number of observations.

FORMAT=*format*

specifies the SAS format for the time ID values. If the FORMAT= option is not specified, the default format is inferred from the INTERVAL= option.

INTERVAL=*interval*

specifies the frequency of the accumulated time series. For example, if the input data set consists of quarterly observations, then INTERVAL=QTR should be used. If the SEASONALITY= option is not specified in the PROC TIMEDATA statement, the length of the seasonal cycle is implied from the INTERVAL= option. For example, INTERVAL=QTR implies a seasonal cycle of length 4. If the ACCUMULATE= option is also specified, the INTERVAL= option determines the time periods for the accumulation of observations. The INTERVAL= option is required and must be specified in the ID statement.

NOTSORTED

specifies that the time ID values not be in sorted order. The TIMEDATA procedure sorts the data with respect to the time ID prior to analysis.

SETMISSING=*option* | *number*

specifies how missing values (either actual or accumulated) are to be interpreted in the accumulated time series. If a *number* is specified, missing values are set to the *number*. If a missing value indicates an unknown value, specify SETMISSING=MISSING. If a missing value indicates a zero value, specify SETMISSING=0. You would typically use SETMISSING=0 for transactional data because no recorded data usually implies no activity. You can use the following *options* to determine how missing values are assigned. Missing values are set as follows:

MISSING	a missing value. This is the default.
AVERAGE | AVG	the accumulated average value
MINIMUM | MIN	the accumulated minimum value
MEDIAN | MED	the accumulated median value
MAXIMUM | MAX	the accumulated maximum value
FIRST	the accumulated first nonmissing value
LAST	the accumulated last nonmissing value
PREVIOUS | PREV	the previous period's accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.
NEXT	the next period's accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.

START=*option*

specifies a SAS date or datetime value that represents the beginning of the data. If the first time ID variable value is greater than the START= value, missing values are added at the beginning of the series. If the first time ID variable value is less than the START= value, the series is truncated. You can specify the START= and END= options to ensure that data associated with each BY group contain the same number of observations.

ZEROMISS=*option*

specifies how beginning and ending zero values (either actual or accumulated) are interpreted in the accumulated time series. The following *options* can also be used to determine how beginning and ending zero values are assigned:

NONE	Beginning and ending zeros are unchanged. This is the default.
LEFT	Beginning zeros are set to missing.
RIGHT	Ending zeros are set to missing.
BOTH	Both beginning and ending zeros are set to missing.

If the accumulated series is all missing or zero, the series is not changed.

OUTARRAYS Statements

OUTARRAYS *array-name-list* **;**

Each array name listed in an OUTARRAYS statement specifies a numeric output array variable to be stored in the OUTARRAY= data set. You can include any number of OUTARRAYS statements.

Your programming statements can create and use any number of arrays. Only arrays that are listed in the OUTARRAYS statement are predefined and included in your output. The arrays are initialized to missing values.

OUTSCALARS Statements

OUTSCALARS *scalar-name-list* **;**

Each scalar name listed in an OUTSCALARS statement specifies a numeric output scalar variable to be stored in the OUTSCALAR= data set. You can include any number of OUTSCALARS statements.

Your programming statements can create and use any number of scalars. Only scalars that are listed in the OUTSCALARS statement are predefined and included in your output. The scalars are initialized to missing values.

VAR Statements

VAR *variable-list* < */ options* > **;**

The VAR statements list the numeric variables in the DATA= data set whose values are to be accumulated to form the time series.

An input data set variable can be specified in only one VAR statement. You can specify any number of VAR statements. You can also specify the following *options* in the VAR statements:

ACCUMULATE=*option*
specifies how the data set observations are to be accumulated within each time period for the variables listed in the VAR statement. If the ACCUMULATE= option is not specified in the VAR statement, accumulation is determined by the ACCUMULATE= option in the ID statement. For more information, see the ACCUMULATE= option in the ID statement.

DIF=(*numlist***)**
specifies the differencing to be applied to the accumulated time series. The list of differencing orders must be separated by spaces or commas. For example, DIF=(1,3) specifies first then third order differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the DIF= option.

SDIF=(*numlist***)**
specifies the seasonal differencing to be applied to the accumulated time series. The list of seasonal differencing orders must be separated by spaces or commas. For example, SDIF=(1,3) specifies first then third order seasonal differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the SDIF= option.

SETMISS=*option* | *number*

SETMISSING= *option* | *number*
specifies how missing values (either actual or accumulated) are to be interpreted in the accumulated time series for variables listed in the VAR statement. If the SETMISSING= option is not specified in the VAR statement, missing values are set based on the SETMISSING= option in the ID statement. For more information, see the SETMISSING= option in the ID statement.

TRANSFORM=*option*

specifies the time series transformation to be applied to the accumulated time series. You can specify the following transformation *options*:

NONE	No transformation is applied. This option is the default.
LOG	Logarithmic transformation
SQRT	Square-root transformation
LOGISTIC	Logistic transformation
BOXCOX(*n*)	Box-Cox transformation with parameter number where *n* is between –5 and 5

When the TRANSFORM= option is specified, the time series must be strictly positive.

ZEROMISS=*option*

specifies how beginning and ending zero values (either actual or accumulated) are interpreted in the accumulated time series or ordered sequence for variables listed in the VAR statement. If the ZEROMISS= option is not specified in the VAR statement, beginning and ending zero values are set based on the ZEROMISS= option of the ID statement. If the ZEROMISS= option is not specified in the ID statement or the VAR statement, no zero value interpretation is performed. For more information, see the ZEROMISS= option in the ID statement.

REGISTER Statement

REGISTER *package* **;**

The REGISTER statement specifies which time series and time frequency analysis packages to make available for your user-defined program. These packages include functions that you can utilize from your program to perform sophisticated time series processing. These packages provide functionality that ranges from a simple function to count missing observations in an array to very sophisticated functions that perform time series statistical analysis.

The REGISTER statement enables you to specify package names that are available for use. You can only specify a single package in a REGISTER statement. However, you can specify multiple REGISTER statements.

All packages that are specified in REGISTER statements are loaded prior to parsing your program statements so that any references are defined at the time your code is parsed. If you specify an invalid package name, then an error is returned prior to parsing your program statements. For more information, see *SAS Forecast Server: Time Series Packages*.

Program Statements

Program Statements ;

You can use most of the programming statements that are allowed in the SAS DATA step.

Details: TIMEDATA Procedure

The TIMEDATA procedure forms time series data from transactional data. The accumulated time series can then be processed using SAS programming statements. The resulting time series can then be analyzed using time series techniques. The data are analyzed using the following steps (the relevant option is listed to the left):

1. accumulation — ACCUMULATE= option in the ID or VAR statement
2. missing value interpretation — SETMISSING= option in the ID or VAR statement
3. time series transformation — TRANSFORM= option in the VAR statement
4. time series differencing — DIF= and SDIF= options in the VAR statement
5. program execution — SAS programming statements
6. descriptive statistics — OUTSUM= option

Accumulation

If the ACCUMULATE= option in the ID or VAR statement is specified, data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= option in the ID statement. The ID variable contains the time ID values. Each time ID value corresponds to a specific time period. Accumulation is useful when the input data set contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series, which is used in subsequent analyses.

For example, suppose a data set contains the following observations:

```
19MAR1999    10
19MAR1999    30
11MAY1999    50
12MAY1999    20
23MAY1999    20
```

If the INTERVAL=MONTH is specified, all of the preceding observations fall within a three-month period of time between March 1999 and May 1999. The observations are accumulated within each time period as follows:

If the ACCUMULATE=NONE option is specified, an error is generated because the ID variable values are not equally spaced with respect to the specified frequency (MONTH).

If the ACCUMULATE=TOTAL option is specified, the resulting time series is

```
O1MAR1999    40
O1APR1999    .
O1MAY1999    90
```

If the ACCUMULATE=AVERAGE option is specified, the resulting time series is

```
O1MAR1999    20
O1APR1999    .
O1MAY1999    30
```

If the ACCUMULATE=MINIMUM option is specified, the resulting time series is

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=MEDIAN option is specified, the resulting time series is

```
O1MAR1999    20
01APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=MAXIMUM option is specified, the resulting time series is

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=FIRST option is specified, the resulting time series is

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=LAST option is specified, the resulting time series is

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=STDDEV option is specified, the resulting time series is

```
O1MAR1999    14.14
O1APR1999    .
O1MAY1999    17.32
```

As you can see from the preceding examples, the accumulated time series can have missing values even though the data set observations contain no missing values.

Missing Value Interpretation

Sometimes missing values should be interpreted as unknown values. But sometimes missing values are known, such as when missing values are created from accumulation and no observations should be interpreted as no value—that is, zero. In the former case, the SETMISSING= option can be used to interpret how missing values are treated. Specify SETMISSING=0 when missing observations are to be treated as no (zero) values. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is used in subsequent analyses.

Time Series Transformation

Four transformations are available for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log — is the logarithmic transformation.

$$w_t = \ln(y_t)$$

Logistic — is the logistic transformation.

$$w_t = \ln(c y_t / (1 - c y_t))$$

where the scaling factor c is

$$c = (1 - 10^{-6}) 10^{-\mathrm{ceil}(\log_{10}(\max(y_t)))}$$

and $\mathrm{ceil}(x)$ is the smallest integer greater than or equal to x.

Square root — is the square root transformation.

$$w_t = \sqrt{y_t}$$

Box Cox — is the Box-Cox transformation.

$$w_t = \begin{cases} \frac{y_t^{\lambda} - 1}{\lambda}, & \lambda \neq 0 \\ \ln(y_t), & \lambda = 0 \end{cases}$$

More complex time series transformations can be performed by using the EXPAND procedure in SAS/ETS.

Time Series Differencing

After you optionally transform the series, you can simply or seasonally difference the accumulated series by using the DIF= and SDIF= options in the VAR statement. For example, suppose y_t is a monthly time series. The following examples of the DIF= and SDIF= options demonstrate how to simply and seasonally difference the time series:

```
dif=(1) sdif=(1)
dif=(1,12)
```

Additionally, when y_t is strictly positive and the TRANSFORM=, DIF=, and SDIF= options are combined in the VAR statements, the transformation operation is performed before the differencing operations.

Summary Statistics

You can compute summary statistics from the working series by specifying the OUTSUM= option or PRINT=SUMMARY.

Programming Statements

You can typically use most of the SAS programming statements and SAS functions that you can use in a DATA step for defining the FCMP functions and subroutines. However, there are a few differences in the capabilities of the DATA step and the FCMP procedure. For more information, see the "FCMP Procedure" chapter in the *Base SAS Procedures Guide*.

All variables listed in the ID and VAR statements are assigned as predefined arrays for subsequent processing. Additionally, all of the array names listed in the OUTARRAYS statements and all of the scalars names listed in the OUTSCALARS statements are assigned as predefined symbols for subsequent processing.

Predefined Symbols

In addition to both the predefined arrays listed in the OUTARRAYS statements and also the predefined scalars listed in the OUTSCALARS statements, the TIMEDATA procedure creates the following predefined symbols for use in the program statements:

Predefined Scalar Values

FORMAT	time format either implied by the INTERVAL= option or specified by the FORMAT= option in the ID statement
INTERVAL	time interval specified by the INTERVAL= option in the ID statement
LEAD	forecast horizon or lead specified by the LEAD= option in the PROC TIMEDATA statement
LENGTH	length of the time series associated with the current BY group

SERIES	series index or BY-group counter
SEASONALITY	length of the seasonal cycle specified by the SEASONALITY= option PROC TIMEDATA statement or implied by the INTERVAL= option in the ID statement

Predefined Array Values

TIMEID	time ID values
SEASON	season index values
CYCLE	life-cycle index values

Auxiliary Data Sets

Auxiliary data set support enables the TIMEDATA procedure to use auxiliary data sets to contribute input variables to the run of the procedure step. This functionality creates a virtual data source that enables some of the input variables to physically reside in different data sets with some defined in the primary data set defined by the DATA= option and others defined in the data sets that are specified by one or more AUXDATA= options. For example, this functionality enables sharing of common time series data across multiple projects.

Furthermore, auxiliary data set support enables more than the simple separation of shared data. It also facilitates the elimination of redundancy in these auxiliary data sources by performing partial matching on BY-group qualification. Duplication of time series for the full BY-group hierarchy is no longer required for the auxiliary data sets.

Finally, this functionality permits more than one auxiliary data source to be used concurrently to materialize the virtual time series vectors across a given BY-group hierarchy. So variables that have naturally different levels of BY-group qualification can be isolated into separate data sets and supplied with separate AUXDATA= options to optimize data management and performance.

AUXDATA Functionality

When used, this option declares the presence of an auxiliary data set to optionally provide time series variables to satisfy various declaration statements in the respective procedure steps.

There are two classes of time series data set sources:

- a primary data set from the DATA=DataSet option
- auxiliary data sources from AUXDATA=DataSet options

You can specify zero or more AUXDATA= options in the PROC TIMEDATA statement. Each AUXDATA= option establishes an auxiliary data set source to supply variables declared in subsequent statements that comprise the procedure step.

Variables referenced in the PROC TIMEDATA invocation fall into three classes:

- those that must be physically present in the primary data set

- those that must be physically present in each auxiliary data set
- those that can reside in either the primary or an auxiliary data set

If you specify an ID variable for PROC TIMEDATA, it must be present in the primary data set and all of the auxiliary data sets that you specify. Variables that you specify in the BY statement must be present in the primary data set. A leftmost subset of those BY variables can be present in each of the auxiliary data sets that you specify, and it is not required that all auxiliary data sets contain the same subset. Partial BY-group matching is performed for each auxiliary data set independent of the others.

The time series variables that you specify in VAR statements can be resolved from either the primary data set or an auxiliary data set. Variable resolution proceeds in reverse order from the last AUXDATA= option in the PROC TIMEDATA statement to the first. If the variable in question is not found in any of those, the variable must be present in the primary data set for the procedure step to be successful.

AUXDATA Alignment across BY Groups

All BY statement variables must be physically present in the primary data set. However, it is not necessary to have the BY variables present in any of the auxiliary data sets. All, some, or none of the BY variables can be present in any auxiliary data set, as your requirements dictate. Partial BY-group matching is performed between the primary data set and the auxiliary data sets based on the number of BY statement variables that are present in the respective auxiliary data sets.

For example, suppose you have a hierarchy of (REGION, PRODUCT) in the primary data set, which holds the time series variables for monthly sales metrics. Suppose you have an auxiliary data set with time series qualified by REGION for pertinent explanatory variables and another with time series for other explanatory variables to be applied across all (REGION, PRODUCT) groupings of the primary data set. In this scenario, each (REGION, PRODUCT) group in the primary data set seeks a match with a corresponding REGION from the first auxiliary data set to materialize the time series for its variables, but no matching is performed on the second auxiliary data set to materialize the time series for its variables. So if (‘SOUTH’,‘EDSEL’) is a BY group from the primary data set, the ‘SOUTH’ BY-group series from the first auxiliary data set are used, and the series from the second auxiliary data set are supplied without qualification. If the next primary BY group is (‘SOUTH’, ‘HUDSON’), then the ‘SOUTH’ BY group is again used to supply the time series from the first auxiliary data set, and the unqualified series are supplied from the second auxiliary data set. So on it goes, each auxiliary data set performing a partial match on the BY variables it holds within the BY group from the primary data set.

AUXDATA Alignment over the Time Dimension

The series from each BY group of the primary data set defines a reference time span for the auxiliary data sets. Only the intersection of the time interval for each auxiliary series with the reference span is materialized. Head or tail missing values are inserted into the auxiliary series for start or stop times that lie inside the reference span. More generally, missing value semantics apply to the head and tail regions that require filling to materialize the full reference time span.

With time series materialized from a single primary data set, there is no latitude for different time ID ranges between the different variables because each observation read contains not only the time ID but also the associated values for all of the variables. With some series materialized from the primary data set and some materialized from auxiliary data sets, the possibility exists for the reference time span to have an arbitrary intersection with the time span of the corresponding series from the auxiliary sources. The intent is to

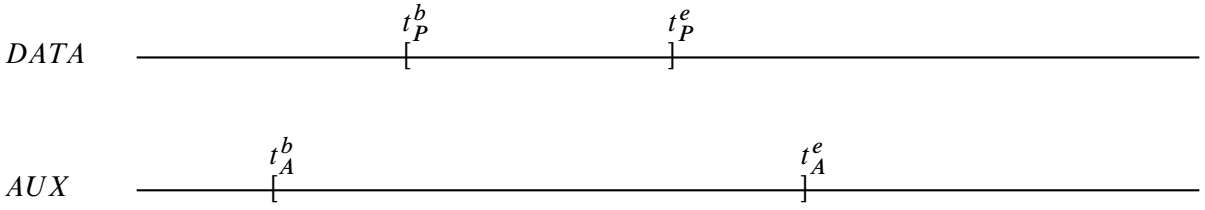
materialize the portion of the auxiliary series time span that intersects with the reference time span and to handle head and tail shortages via missing value semantics as needed.

For the previous usage scenario with a primary data set and two auxiliary data sets, when data are read over a sequence of primary BY groups it might be necessary to materialize various spans of the auxiliary series with appropriate missing value semantics applied as needed to resolve head and tail shortages even though the actual time series contributed from the auxiliary data sets does not physically change. The following discussion breaks this down into several cases depending on intersection possibilities between the reference time span and the auxiliary time span.

Legend:

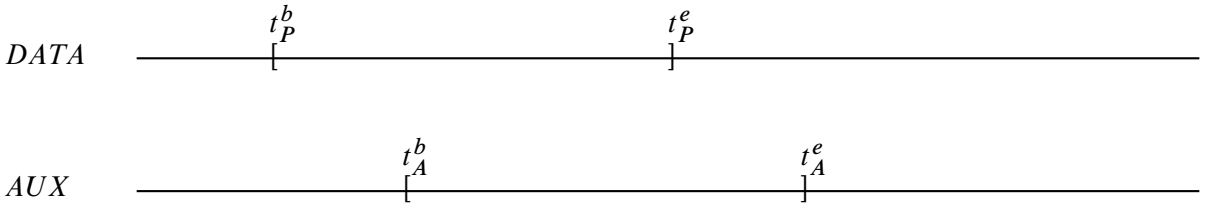
- t_P^b denotes the begin time ID of the primary (DATA=) series.
- t_P^e denotes the end time ID of the primary (DATA=) series.
- t_A^b denotes the begin time ID of the AUXDATA series.
- t_A^e denotes the end time ID of the AUXDATA series.
- $[t_P^b, t_P^e]$ denotes the time span for the primary (DATA=) series (also known as the reference time span).
- $[t_A^b, t_A^e]$ denotes the time span for the AUXDATA series.

Case 1:



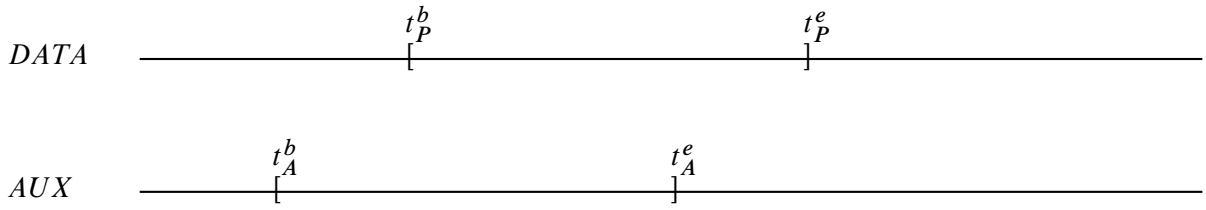
Here $[t_P^b, t_P^e] \subseteq [t_A^b, t_A^e]$. The auxiliary time span includes the reference span as a subset. Values in the AUXDATA series to the left of t_P^b and values to the right of t_P^e are truncated from the AUXDATA series that is materialized in connection with the primary series.

Case 2:



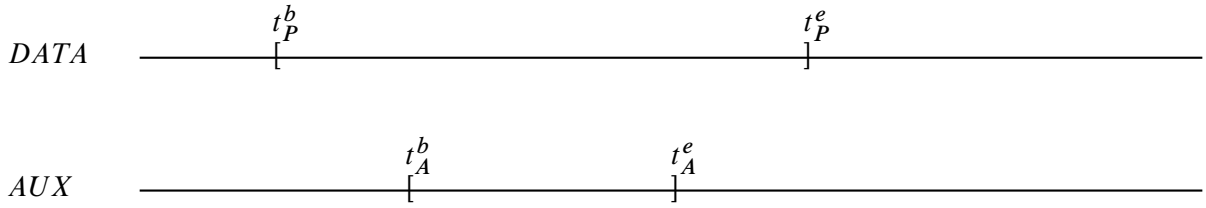
Here $[t_P^b, t_P^e] = [t_P^b, t_A^b) \cup [t_A^b, t_P^e]$. The reference time span leads the auxiliary time span with a non-empty intersection. AUXDATA series values in $[t_P^b, t_A^b)$ are materialized with missing value semantics. AUXDATA series values in $[t_A^b, t_P^e]$ are materialized as actual subject to missing value semantics.

Case 3:



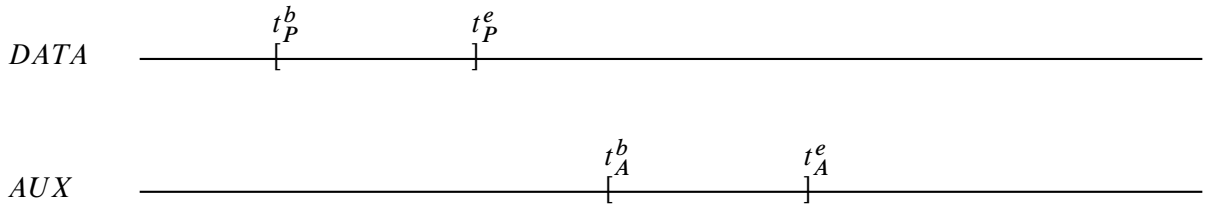
Here $[t_P^b, t_P^e] = [t_P^b, t_A^e] \cup (t_A^e, t_P^e]$. The reference time span lags the auxiliary time span with a non-empty intersection. AUXDATA series values in $[t_P^b, t_A^e]$ are materialized as actual subject to missing value semantics. AUXDATA series values in $(t_A^e, t_P^e]$ are materialized with missing value semantics.

Case 4:



Here $[t_A^b, t_A^e] \subset [t_P^b, t_P^e]$. The auxiliary time span is a subset of the reference time span. AUXDATA series values in $[t_P^b, t_A^b)$ and values in $(t_A^e, t_P^e]$ are materialized with missing value semantics. AUXDATA series values in $[t_A^b, t_A^e]$ are materialized as actual subject to missing value semantics.

Case 5:



Here $[t_P^b, t_P^e] \cap [t_A^b, t_A^e] = \oslash$. The auxiliary time span does not intersect the reference time span at all. In this case all AUXDATA series values are materialized with missing value semantics.

Data Set Output

The TIMEDATA procedure can create the OUT=, OUTARRAY=, OUTPROCINFO=, OUTSCALAR=, and OUTSUM= data sets. In general, these data sets contain the variables listed in the BY statement. If an analysis step that is related to an output step fails, the values of this step are not recorded or are set to missing in the related output data set but appropriate error or warning messages (or both) are recorded in the log.

OUT= Data Set

The OUT= data set contains the variables specified in the BY, ID, or VAR statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN= and INTERVAL= options. The values of the variables specified in the VAR statements are accumulated based on the ACCUMULATE= option, and missing values are interpreted based on the SETMISSING= option.

OUTARRAY= Data Set

The OUTARRAY= data set contains the variables specified in the BY, ID, or VAR statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN= and INTERVAL= options. The values of the variables specified in the VAR statements are accumulated based on the ACCUMULATE= option, and missing values are interpreted based on the SETMISSING= option. Additionally, the OUTARRAY= data set contains the variables that are specified in the OUTARRAYS statements and the following variables:

STATUS	status flag that indicates whether the requested analyses were successful
SERIES	series index or BY-group index
TIMEID	time ID values
SEASON	season index values
CYCLE	life-cycle index values
Array-Variable-Names	variables listed in the OUTARRAYS statement

The OUTARRAY= data set contains the arrays that are related to the (accumulated) time series.

OUTPROCINFO= Data Set

The OUTPROCINFO= data set contains information about the run of the TIMEDATA procedure. The following variables are present:

SOURCE	name of the procedure, in this case TIMEDATA
NAME	name of the item being reported
LABEL	descriptive label for the item in _NAME_
STAGE	current stage of the procedure (for TIMEDATA this is set to ALL)
VALUE	value of the item specified in _NAME_

OUTSCALAR= Data Set

The OUTSCALAR= data set contains the variables specified in the BY statement. Additionally, the OUTSCALAR= data set contains the variables that are specified in the OUTSCALARS statements and following variables:

STATUS	status flag that indicates whether the requested analyses were successful
SERIES	series index or BY-group counter
Scalar-Variable-Names	variables listed in the OUTSCALARS statement

The OUTSCALAR= data set contains the scalars that are related to the (accumulated) time series.

OUTSUM= Data Set

The OUTSUM= data set contains the variables that are specified in the BY statement as and the variables in the following list. The OUTSUM= data set records the descriptive statistics for each variable specified in a VAR statement. Variables related to descriptive statistics are based on the ACCUMULATE= and SETMISSING= options in the ID and VAR statements:

NAME	variable name
STATUS	status flag that indicates whether the requested analyses were successful
SERIES	count of the series processed in each BY group
START	the starting date of each series
END	the ending date of each series
STARTOBS	the beginning observation number of each series
ENDOBS	the ending observation number of each series
NOBS	number of observations
N	number of nonmissing observations

NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
AVG	average value
STDDEV	standard deviation

The OUTSUM= data set contains the descriptive statistics of the (accumulated) time series.

STATUS Variable Values

The _STATUS_ variable that appears in the OUTSUM= data set contains a value that specifies whether the analysis has been successful or not. The _STATUS_ variable can take the following values:

0	Analysis was successful.
3000	Accumulation failed.
4000	Missing value interpretation failed.
6000	Series is all missing.
7000	Transformation failed.
8000	Differencing failed.
9000	Descriptive statistics could not be computed.

Printed Output

The TIMEDATA procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. All output is controlled by the PRINT= option associated with the PROC TIMEDATA statement. In general, if an analysis step related to printed output fails, the values of this step are not printed and appropriate error or warning messages or both are recorded in the log. The printed output is similar to the output data set as follows:

PRINT=ARRAYS	prints the arrays similar to the OUTARRAY= data set.
PRINT=SCALARS	prints the scalars similar to the OUTSCALAR= data set.
PRINT=SUMMARY	prints the summary statistics similar to the OUTSUM= data set.

ODS Table Names

Table 36.2 relates the PRINT= options to ODS tables.

Table 36.2 ODS Tables Produced in PROC TIMEDATA

ODS Table Name	Description	Statement	Option
Arrays	Arrays table	PRINT	ARRAYS
Scalars	Scalars table	PRINT	SCALARS
StatisticsSummary	Statistics summary	PRINT	SUMMARY

The tables are related to all series within a BY group.

Arrays Table

The arrays table (Arrays) illustrate the arrays in tabular form with respect to the Time ID values.

Scalars Table

The scalars table (Scalars) illustrate the scalars in tabular form.

Statistics Summary Table

The summary statistics table (StatisticsSummary) illustrate the summary statistics for each array in tabular form.

ODS Graphics Names

This section describes the graphical output produced by the TIMEDATA procedure. PROC TIMEDATA assigns a name to each graph it creates. These names are listed in Table 36.3.

Table 36.3 ODS Graphics Produced by PROC TIMEDATA

ODS Graph Name	Plot Description	Statement	Option
ArrayPlot	Array plot	PLOTS	ARRAY

The graphs are related to a single series within a BY group.

Array Plots

The array plots (ArraryPlot) illustrate time series associated with each array. The horizontal axis represents the time ID values, and the vertical axis represents the time series values.

Examples: TIMEDATA Procedure

Example 36.1: Accumulating Transactional Data into Time Series Data

This example uses the TIMEDATA procedure to accumulate time-stamped transactional data that has been recorded at no particular frequency into time series data at a specific frequency. After the time series is created, the various SAS/ETS procedures related to time series analysis, seasonal adjustment and decomposition, modeling, and forecasting can be used to further analyze the time series data.

Suppose that the input data set Work.Retail contains variables Store and Timestamp and numerous other numeric transaction variables. The BY variable Store contains values that break up the transactions into groups (BY groups). The time ID variable Timestamp contains SAS date values recorded at no particular frequency. The other data set variables contain the numeric transaction values to be analyzed. It is further assumed that the input data set is sorted by the variables Store and Timestamp. The following statements form monthly time series from the transactional data based on the median value (ACCUMULATE=MEDIAN) of the transactions recorded with each time period. Also, the accumulated time series values for time periods with no transactions are set to zero instead of to missing (SETMISS=0) and only transactions recorded between the first day of 1998 (START='01JAN1998'D) and last day of 2000 (END='31DEC2000'D) are considered and, if needed, extended to include this range.

```
proc timedata data=retail out=mseries;
   by store;
   id timestamp interval=month
                accumulate=median
                setmiss=0
                start='01jan1998'd
                end  ='31dec2000'd;
   var item1-item8;
run;
```

The monthly time series data are stored in the data set Work.Mseries. Each BY group associated with the BY variable Store contains an observation for each of the 36 months associated with the years 1998, 1999, and 2000. Each observation contains the values Store, Timestamp, and each of the analysis variables in the input data set.

After each set of transactions has been accumulated to form a corresponding time series, accumulated time series can be analyzed using various time series analysis techniques. For example, exponentially weighted moving averages can be used to smooth each series. The following statements use the EXPAND procedure to smooth the analysis variable named Storeitem:

```
proc expand data=mseries out=smoothed from=month;
   by store;
   id date;
   convert storeitem=smooth / transform=(ewma 0.1);
run;
```

The smoothed series are stored in the data set Work.Smoothed. The variable Smooth contains the smoothed series.

If the time ID variable Timestamp contains SAS datetime values instead of SAS date values, the INTERVAL=, START=, and END= options must be changed accordingly and the following statements could be used:

```
proc timedata data=retail out=tseries;
   by store;
   id timestamp interval=dtmonth
                accumulate=median
                setmiss=0
                start='01jan1998:00:00:00'dt
                end  ='31dec2000:00:00:00'dt;
   var _numeric_;
run;
```

The monthly time series data are stored in the data Work.Tseries, and the time ID values use a SAS datetime representation.

Example 36.2: Using User-Defined Functions and Subroutines

This example uses the TIMEDATA procedure with a user-defined function and subroutine created by the FCMP procedure.

The following statements use the FCMP procedure to create a user-defined subroutine and a user-defined function. Mylog is a subroutine that log-transforms a time series. Mymean is a function that compute the mean of a time series. The subroutine and function definitions are stored in the data set Work.Timefnc. The OPTIONS statement loads the subroutine and function definitions.

```
proc fcmp outlib=work.timefnc.funcs;

   subroutine mylog(actual[*], transform[*]);
   outargs transform;
   actlen  = DIM(actual);
   do t = 1 to actlen;
      transform[t] = log(actual[t]);
   end;
   endsub;

   function mymean(actual[*]);
   actlen  = DIM(actual);
   sum = 0;
   do t = 1 to actlen;
      sum = sum + actual[t];
   end;
```

```
   return( sum / actlen );
   endsub;

run;
quit;

options cmplib = work.timefnc;
```

The input data set Sashelp.Air contains the variables Air and Date. The time series is recorded monthly.

The following statements form quarterly time series from the monthly series based on the median value (ACCUMULATE=TOTAL) of the transactions recorded with each time period and assign the SAS time format (FORMAT=YYMMDD.). The OUTARRAYS statement specifies the Logair and Myair arrays as output. The OUTSCALARS statement specifies the Mystats scalars as output. The other arrays and scalars are not part of the output. The subsequent programming statements create the output arrays and scalars. The PRINT=(ARRAYS SCALARS) prints the output arrays and scalars.

```
proc timedata data=sashelp.air out=work.air
              print=(scalars arrays);
              id date interval=qtr acc=t format=yymmdd.;
              vars air;
              outarrays logair myair;
              outscalars mystats;

       call mylog(air,logair);
       do t = 1 to dim(air);
       myair[t] = air[t] - logair[t];
       end;
       mystats= mymean(air);

run;
```

Example 36.3: Using Auxiliary Data Sets with PROC TIMEDATA

This example demonstrates the use of the AUXDATA= option in PROC TIMEDATA. The data set Sashelp.Gulfoil contains oil and gas production data from the Gulf of Mexico. The variables RegionName and ProtractionName can be used to define a time series hierarchy of interest. Suppose you want to generate two new series that contain the protraction's share of oil and gas production for its associated region at each time index.

You first use PROC TIMESERIES to perform temporal aggregation (accumulation) of the time series for the RegionName level.

```
proc timeseries data=sashelp.gulfoil
                out=byregion(rename=(oil=roil gas=rgas));
   by regionname;
   id date interval=month accumulate=total notsorted;
   var oil gas;
run;
```

You can then use PROC TIMEDATA with the AUXDATA= option to compute the share of oil and gas production contributed by each protraction within its associated region. PROC TIMEDATA reads a monthly time series for each (RegionName, ProtractionName) group for the variables Oil and Gas from Sashelp.Gulfoil. Two new series are produced in the variables Oilshare and Gasshare that respectively contain the protraction's share of the oil and gas production at the region level of the hierarchy (given by variables Roil and Rgas). Those share variables are specified in the OUTARRAY statement for inclusion in the OUTARRAY= data set (Work.Shares). This example relies on the capability of the AUXDATA= feature to perform partial BY-group matching. The time series that are acquired for the variables Roil and Rgas are the result of matching on the RegionName BY variable from the data set Work.Byregion with the RegionName variable from the BY groups that are acquired from the Sashelp.Gulfoil data set.

```
proc timedata data=sashelp.gulfoil
              auxdata=byregion
              out=_null_
              outarray=shares;
   by regionname protractionname;
   outarray oilshare gasshare;
   var oil gas roil rgas;
   id date interval=month accumulate=total;
   do i=1 to _length_;
      oilshare[i] = oil[i] / roil[i];
      gasshare[i] = gas[i] / rgas[i];
   end;
run;
```

The following code demonstrates that the computed shares sum to 1 for each time index in the resulting Oilshare and Gasshare series. PROC TIMESERIES is used to accumulate the shares for these respective variables from the data set Work.Shares and the accumulated share series at the RegionName level are stored to the data set Work.Rshares with variable names Oilsum and Gassum, respectively. The summary from PROC MEANS for the distinct values of RegionName shows that per-time totals for both share series sums to 1.

```
proc timeseries data=shares
                out=rshares(rename=(oilshare=oilsum gasshare=gassum));
   by regionname;
   id date interval=month accumulate=total notsorted;
   var oilshare gasshare;
run;
proc means data=rshares;
   by regionname;
   var oilsum gassum;
run;
```

Output 36.3.1 Validation of Oil and Gas Shares by Region

The MEANS Procedure

Region within Gulf of Mexico=Central

Variable	N	Mean	Std Dev	Minimum	Maximum
oilsum	123	1.0000000	0	1.0000000	1.0000000
gassum	123	1.0000000	0	1.0000000	1.0000000

Output 36.3.1 *continued*

Region within Gulf of Mexico=Western

Variable	N	Mean	Std Dev	Minimum	Maximum
oilsum	123	1.0000000	0	1.0000000	1.0000000
gassum	123	1.0000000	0	1.0000000	1.0000000

You might also want to plot the share series. The following code produces a graph that overlays the protraction level share series for oil production for the Western region:

```
proc sgplot data=shares(where=(RegionName='Western'));
   series x=Date y=OilShare/group=ProtractionName;
run;
```

Output 36.3.2 Protraction Share of Oil Production for Western Region

Overview: TIMEID Procedure

The TIMEID procedure evaluates a variable in an input data set for its suitability as a time ID variable in SAS procedures and solutions that are used for time series analysis. PROC TIMEID assesses how well a time interval specification fits SAS date or datetime values, or observation numbers used to index a time series. The time interval used in this analysis can be either specified explicitly as input to PROC TIMEID or inferred by the procedure based on values of the time ID variable. The TIMEID procedure produces diagnostic information in the form of data sets and ODS tabular and plotted output. These diagnostic results summarize characteristics of the time ID variable that can help determine its use as an index in other time series procedures and solutions.

PROC TIMEID is intended for use as a tool to either identify the time interval of a variable or prepare problematic data sets for use in subsequent time series analyses. In particular, this procedure can be used to investigate inconsistencies between time ID values and the ID statement options used in other SAS procedures and solutions.

Getting Started: TIMEID Procedure

When a data set contains a time ID variable with corrupted, missing, or duplicate values, PROC TIMEID can help isolate and identify these problematic observations. For a data set with a small number of ID variable anomalies and a known time interval, a graphical depiction of the problem areas can be created using the following statements:

```
proc timeid data=<input-dataset> plot=values;
   id <time-ID-variable>  interval=<frequency>;
run;
```

For larger data sets whose quality is unknown, it can be useful to get a general overview of the relative number of observations with problematic time ID values. The following statements graphically summarize the prevalence of anomalous time ID values:

```
proc timeid data=<input-dataset> plot=(intervalcounts offsets spans);
   id <time-ID-variable>  interval=<frequency>;
run;
```

When prior knowledge of the time interval that separates observations is incomplete, PROC TIMEID can be used to infer the interval by omitting the INTERVAL= option from the ID statement as in the following statements:

```
proc timeid data=<input-dataset> outinterval=<output-dataset>;
   id <time-ID-variable>;
run;
```

Syntax: TIMEID Procedure

The TIMEID procedure uses the following statements:

PROC TIMEID *options* ;
BY *variables* ;
ID *variable* < *options* > ;

Functional Summary

The statements and options that control the TIMEID procedure are summarized in Table 37.1.

Table 37.1 Functional Summary

Description	Statement	Option
Statements		
Specifies data sets and options	PROC TIMEID	
Specifies BY-group processing	BY	
Specifies the time ID variable	ID	

Table 37.1 *continued*

Description	Statement	Option
Data Set Options		
Specifies the input data set	PROC TIMEID	DATA=
Specifies the maximum number of ID values to analyze	PROC TIMEID	NBYOBS=
Specifies the output frequency count data set	PROC TIMEID	OUTFREQ=
Specifies the output interval data set	PROC TIMEID	OUTINTERVAL=
Specifies the detailed output interval data set	PROC TIMEID	OUTINTERVALDETAILS=
Time ID Options		
Specifies the interval alignment	ID	ALIGN=
Specifies that duplicate time ID values can be present in the DATA= data set	ID	DUPLICATES
Specifies the time interval between observations	ID	INTERVAL=
Specifies that time ID variable values are not sorted	ID	NOTSORTED
Printing and Plotting Options		
Specifies the time ID format	ID	FORMAT=
Specifies the types of graphical output	PROC TIMEID	PLOT=
Specifies the types of printed output	PROC TIMEID	PRINT=
Miscellaneous Options		
Limits the number of error and warning messages	PROC TIMEID	MAXERROR=

PROC TIMEID Statement

PROC TIMEID *options* **;**

The following options can be used in the PROC TIMEID statement:

DATA=*SAS-data-set*
names the SAS data set that contains the input data for the procedure. If the DATA= option is not specified, the most recently created SAS data set is used.

MAXERROR=*number*
limits the number of warning and error messages produced during the execution of the procedure to the specified value. The default is MAXERRORS=50. This option is particularly useful in BY-group processing, where it can be used to suppress recurring messages.

NBYOBS=*number*
limits the number of observations that are used to analyze the time ID variable. The NBYOBS= option should be used instead of the OBS= data set option when BY variables are specified. The NBYOBS= option excludes observations from incomplete BY groups in the analysis. This option guarantees that any truncation of the DATA= data set occurs at a BY-group boundary. Only BY groups that are completely contained within the first *number* of observations are processed. When the NBYOBS= option is omitted, all observations are processed.

OUTFREQ=*SAS-data-set*
names the output data set to contain the frequency counts of each unique value of the time ID variable. The frequency counts are performed on time ID values that are recorded in the DATA= data set. The time ID values are not aligned with respect to an interval prior to computation of the frequency counts. For more information, see the section "OUTFREQ= Data Set" on page 2704.

OUTINTERVAL=*SAS-data-set*
names the output data set to contain the time ID interval information that is summarized across all BY groups in the DATA= data set. For more information, see the section "OUTINTERVAL= Data Set" on page 2704.

OUTINTERVALDETAILS=*SAS-data-set*
names the output data set to contain the time ID interval information for each BY group. For more information, see the section "OUTINTERVALDETAILS= Data Set" on page 2705.

PLOT(*global-option***)=***request-option* **|** **(***request-options***)**
specifies the graphical output desired. By default, the TIMEID procedure produces no graphical output. The following *global-options* are available:

UNPACK | UNPACKPANELS suppresses paneling.

By default, multiple plots can appear in some output panels. Specify UNPACKPANELS to get each plot in a separate panel. The following plot *request-options* are available:

COUNTS | INTCNTS | INTERVALCOUNTS
plots a histogram of the time ID interval counts.

OFFSETS plots a histogram of the time offsets for the time ID values.

PERIODS | SPANS plots a histogram of the spans between adjacent time ID values.

VALUES plots a panel of the counts, offsets, and spans for each of the time ID values.

ALL is equivalent to specifying PLOT=(INTERVALCOUNTS SPANS OFFSETS VALUES).

For more information, see the section "Time ID Diagnostics" on page 2701.

PRINT=*option* | **(***options***)**

specifies the printed output desired. By default, the TIMEID procedure produces no printed output. The following printing options are available:

COUNTS | INTCNTS | INTERVALCOUNTS
: prints a table that contains the counts of time ID values per interval.

INTERVAL
: prints a summary of information about the time interval.

OFFSETS
: prints a table that contains the time offsets for the time ID values.

PERIODS | SPANS
: prints tables that contain statistics on the spans between adjacent time ID values.

VALUES
: prints tables that contain offset span and count information for the time ID values.

ALL
: is equivalent to specifying PRINT=(INTERVALCOUNTS SPANS INTERVAL OFFSETS VALUES).

For more information, see the section "Time ID Diagnostics" on page 2701.

BY Statement

BY *variables* **;**

A BY statement can be used with PROC TIMEID to obtain separate analyses for groups of observations defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the option NOTSORTED or DESCENDING in the BY statement for the TIMESERIES procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS Programmers Guide: Essentials*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

ID Statement

ID *variable* < *options* > **;**

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date or datetime values. The ID statement options specify how the time ID values are spaced and aligned relative to a SAS date or datetime interval. The INTERVAL= option specifies the fundamental spacing that is used as the basis for counting intervals, offsets, and spans in the data. Specification of the ID variable in an ID statement is required.

ALIGN=*alignment*

specifies the alignment of the identifying SAS date or datetime that is used to represent intervals. The value of the ALIGN= option is used in the analysis of the time ID variable. The ALIGN= option accepts the following values: BEGINNING | BEG | B, MIDDLE | MID | M, ENDING | END | E, and INFER. For example, ALIGN=BEGIN specifies that the identifying date for the interval is the beginning date in the interval. If the ALIGN= option is not specified, then the default alignment is BEGIN. ALIGN=INFER specifies that the alignment of values within time intervals be inferred from the time ID values.

DUPLICATES

specifies that multiple observations in the DATA= data set can fall within the same time interval as defined by the time ID variable. When this option is omitted and multiple time ID values are encountered in a single time interval, error messages are written to the SAS log.

FORMAT=*format*

specifies the SAS format used for time ID values in the data sets and in printed and plotted output that is generated by PROC TIMEID. If the FORMAT= option is not specified, the format applied to the input time ID variable is used. If neither of these formats is specified, the format is inferred from the INTERVAL= option.

INTERVAL=*interval*

specifies the proposed time interval and shift that describe the time ID values in the input data set. For more information about the intervals that can be specified, see Chapter 4, "Date Intervals, Formats, and Functions." For more information about how the INTERVAL= option determines the nature of diagnostic information reported by the TIMEID procedure, see the section "Time ID Diagnostics" on page 2701.

If no interval is specified, the procedure attempts to infer an interval from the input time ID values. For more information about how the time interval is inferred, see the section "Inferring Time Intervals and Alignments" on page 2703.

NOTSORTED

specifies that the observations in the DATA= data set are not sorted by the time ID variable. When this option is omitted, error messages are generated for time ID values that are not sorted in ascending order.

Details: TIMEID Procedure

Time ID Diagnostics

For a specified time interval, PROC TIMEID decomposes the raw time ID values in an input data set into the following three quantities, whose values are represented by nonnegative integers at each unique time ID value in the input series:

interval counts the number of observations that share each time interval in the data set.

offsets the numerical difference between a time ID value and the aligned value for that time interval. The unit of measure used to express this distance is days for date values and seconds for datetime values. The offset is computed for each time ID value, t_i, by using the following SAS expression:

$$\text{offset}_i = t_i - \text{INTNX}(\text{interval}, t_i, 0, \text{alignment})$$

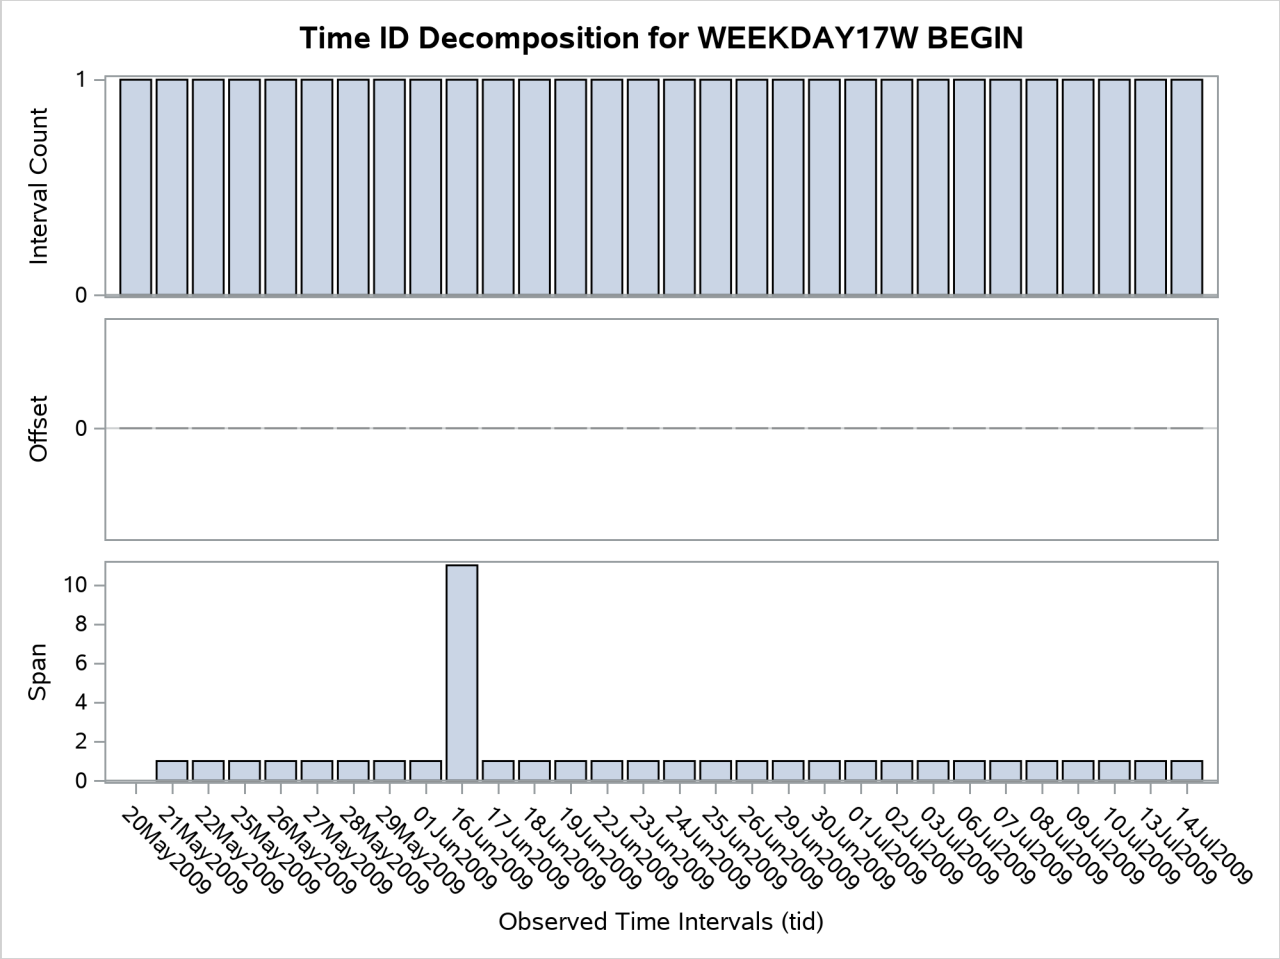
spans the number of intervals between each time ID value and the previous time ID value. The spans value is equivalent to the number returned by the following SAS expression:

$$\text{spans}_i = \text{INTCK}(\text{interval}, t_{i-1}, t_i)$$

Diagnostic Output Representation

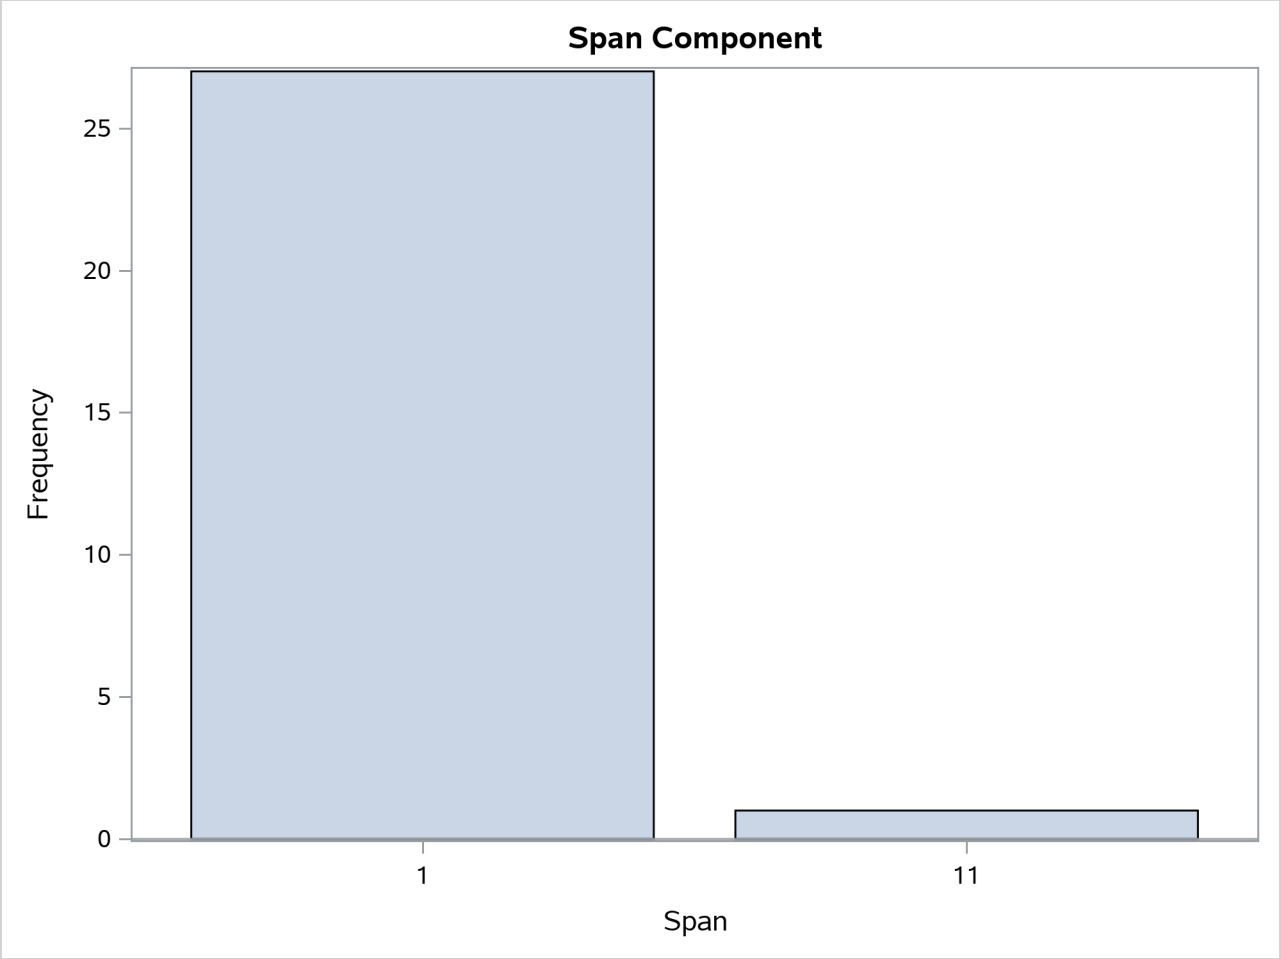
The TIMEID procedure produces time ID diagnostics as both time-ID-based and count-based frequency distributions to expose many of the possible problems that can occur in a time ID variable. The time-ID-based frequency distributions that are generated with the PLOT= option provide a detailed view of time ID values that can isolate problems with specific ID values. Figure 37.1 shows a time series that has a span of 10 observations in a weekday series based on the results of the PLOT=(VALUES SPANS) option. The single large bar in the spans plot shows where data are omitted.

Figure 37.1 Time ID Decomposition



The count-based frequency distributions summarize features of the time ID variable. Individual printed and plotted outputs are available to describe the distribution of the number of spans, offsets, and interval counts that occur in the time ID variable. Figure 37.2 illustrates a count-based frequency distribution of the spans within the weekday series.

Figure 37.2 Span Count Distribution



The large bar at the span of 1 shows that most of the observations are correctly separated by one interval. The bar at 11 indicates that one observation is separated by 11 intervals from the preceding value of the time ID variable. This further illustrates a span of 10 omitted observations.

Inferring Time Intervals and Alignments

When the INTERVAL= option is not specified in the ID statement, a time interval is inferred from the time ID values in the input data set. The technique used to infer a time interval involves searching for the interval that fits the greatest number of time ID values. First, time ID values are sampled from the input data set to generate a set of candidate intervals. Then the candidate interval that is consistent with greatest number of time ID values is chosen to represent the time series.

When the ALIGN=INFER option is specified, the convention that is used to specify time interval alignment is inferred from the time ID variable values by using a similar technique. When both the time interval and its alignment are to be inferred, each of the possible alignments, BEGIN, MIDDLE, and END, is considered in the search. Precedence in the search is given to intervals with the BEGIN alignment.

Data Set Output

The TIMEID procedure creates the OUTFREQ=, OUTINTERVAL=, and OUTINTERVALDETAILS= data sets. The OUTFREQ= and OUTINTERVALDETAILS= data sets contain the variables that are specified in the BY statement along with variables that characterize the time ID values. The OUTINTERVAL= option creates a data set without BY variables. The information in this data set summarizes time ID diagnostic information across all BY groups in the DATA= data set.

OUTFREQ= Data Set

The OUTFREQ= data set contains a single observation for each value of the time ID variable in the input data set for each BY group. Additionally, the following variables are written to the OUTFREQ= data set:

COUNT	number of the occurrences of the time ID value
PERCENT	percentage of all time ID values

OUTINTERVAL= Data Set

The OUTINTERVAL= data set contains information that is similar to the variables written to the OUTINTERVALDETAILS= data set; however, the OUTINTERVAL= data set summarizes the information across all BY groups into a single observation. The following variables are written to the OUTINTERVAL= data set:

TIMEID	time ID variable
START	smallest time ID interval
END	largest time ID interval
STARTSHARED	largest starting time ID interval
ENDSHARED	smallest ending time ID interval
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
NBY	number of BY groups
NINVALID	number of invalid observations
STATUS	status flag that indicates whether the requested analyses were successful:

0	The analysis completed successfully.
1	interval consistent but data contain gaps
2	interval not consistent with data
10	missing or invalid values found
20	ID values not sorted
21	duplicate ID values detected
30	fewer than three values found

4000	Inference of a time interval from the data set failed.
5000	Diagnosis of the DATA= data set for the specified time interval failed.

MSG	a message that provides further details when the STATUS variable is not zero
INTERVAL	time interval that is specified or recommended
INTNAME	time interval base name that is specified or recommended
MULTIPLIER	time interval multiplier that is specified or recommended
SHIFT_INDEX	time interval shift index that is specified or recommended
ALIGNMENT	time interval alignment that is specified or recommended
SEASONALITY	seasonality determined from specified or recommended time interval
TOTALSEASONCYCLES	total number of seasonal cycles spanned by all the observations
SEASONCYCLESSHARED	number of seasonal cycles that are shared among all BY groups
FORMAT	format of the time ID variable

The START, END, STARTSHARED, and ENDSHARED variables are reported using the interval and alignment specified in the ID statement or inferred from the time ID values.

OUTINTERVALDETAILS= Data Set

The OUTINTERVALDETAILS= data set contains statistics about the time interval that is specified in the ID statement or inferred from the time ID values for each BY group. The following variables represent these statistics:

TIMEID	time ID variable name
START	starting time ID interval
END	ending time ID interval
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
NINVALID	number of invalid observations
NINTCNTS	number of unique interval count values
PCTINTCNTS	percentage of interval counts greater than one
MININTCNT	minimum of interval counts
MAXINTCNT	maximum of interval counts
MEANINTCNT	mean of interval counts
STDINTCNT	standard deviation of interval counts
MEDINTCNT	median of interval counts
NOFFSETS	number of time ID offset
PCTOFFSETS	percentage of time ID offset

MINOFFSET minimum of time ID offsets

MAXOFFSET maximum of time ID offsets

MEANOFFSET mean of time ID offsets

STDOFFSET standard deviation of time ID offsets

MEDOFFSET median of time ID offsets

NSPANS number of spans between time ID values

PCTSPANS percentage of spans between time ID values

MINSPAN maximum of spans between time ID values

MAXSPAN minimum of spans between time ID values

MEANSPAN mean of spans between time ID values

STDSPAN standard deviation of spans between time ID values

MEDSPAN median of spans between time ID values

STATUS status flag that indicates whether the requested analyses were successful:

0	The analysis completed successfully.
1	interval consistent but data contain gaps
2	interval not consistent with data
10	missing or invalid values found
20	ID values not sorted
21	duplicate ID values detected
30	fewer than three values found
4000	Inference of a time interval from the data set failed.
5000	Diagnosis of the DATA= data set for specified time interval failed.

MSG a message that provides further details when the STATUS variable is not zero

INTERVAL time interval specified or recommended

INTNAME time interval base name specified or recommended

MULTIPLIER time interval multiplier specified or recommended

SHIFT_INDEX time interval shift index specified or recommended

ALIGNMENT time interval alignment specified or recommended

SEASONALITY seasonality determined from specified or recommended time interval

NSEASONCYCLES number of seasonal cycles spanned by the time ID values

FORMAT format of the time ID variable

The START and END variables are reported using the interval and alignment specified in the ID statement or inferred from the time ID values.

Printed Tabular Output

The TIMEID procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. The appearance of the printed tabular output is controlled by the PRINT= option in the PROC TIMEID statement.

Table 37.2 relates the PRINT= options to the names of the ODS tables.

Table 37.2 ODS Tables Produced in PROC TIMEID

ODS Name	Description	PRINT= Option
DataSet	Information about the input data set	ALL
Decomposition	Time ID counts, offsets, and spans	VALUES
Interval	Information about the time interval	INTERVAL
IntervalCountsComponent	Frequency distribution of interval counts	INTERVALCOUNTS
IntervalCountsStatistics	Statistics on interval count frequency distribution	INTERVALCOUNTS
OffsetsComponent	Frequency distribution of offsets	OFFSETS
OffsetStatistics	Statistics on offset frequency distribution	OFFSETS
SpansComponent	Frequency distribution of spans	SPANS
SpanStatistics	Statistics on the span frequency distribution	SPANS
Values	Time ID value counts	VALUES
ValueSummary	Summary of the number of valid observations	VALUES

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

The TIMEID procedure uses ODS Graphics to produce plotted output as specified by the PLOT= option. Table 37.3 relates the PLOT= options to the names of the ODS Graphics objects.

Table 37.3 ODS Graphics Produced by the PLOT= Option in PROC TIMEID

ODS Graph Name	Plot Description	PLOT= Option
DecompositionPlot	Panel of spans, offsets, and counts for each time interval	VALUES
IntervalCountsComponentPlot	Histogram of interval counts	INTERVALCOUNTS
IntervalCountsPlot	Plot of counts for each time interval value	VALUES
OffsetComponentPlot	Histogram of time ID offsets	OFFSETS
OffsetsPlot	Plot of offsets for each time interval value	VALUES
SpanComponentPlot	Histogram of span sizes between time ID values	SPANS
SpansPlot	Plot of spans for each time interval value	VALUES
ValuesPlot	Plot of counts of each time ID value	VALUES

Examples: TIMEID Procedure

Example 37.1: Examining a Weekly Time ID Variable

This example illustrates how problems in a weekly time series can be visualized and quantified using the TIMEID procedure's diagnostic capabilities.

The following DATA step creates a data set that contains time values spaced in three-week intervals where some weeks have been skipped or duplicated and some have been recorded on different weekdays:

```
data triweek;
   format date date.;
   input date : date. @@;
datalines;
28DEC48 18JAN49 08FEB49 01MAR49 22MAR49 12APR49 03MAY49 24MAY49
17JUN49 05JUL49 26JUL49 16AUG49 06SEP49 27SEP49 18OCT49 08NOV49
29NOV49 20DEC49 10JAN50 04FEB50 21FEB50 14MAR50 04APR50 25APR50

   ... more lines ...
```

The following TIMEID procedure statements generate an ODS display of the time series that characterizes interval counts, offsets, and spans in the time ID variable:

```
proc timeid data=triweek print=all plot=all;
  id date interval=week3;
run;
```

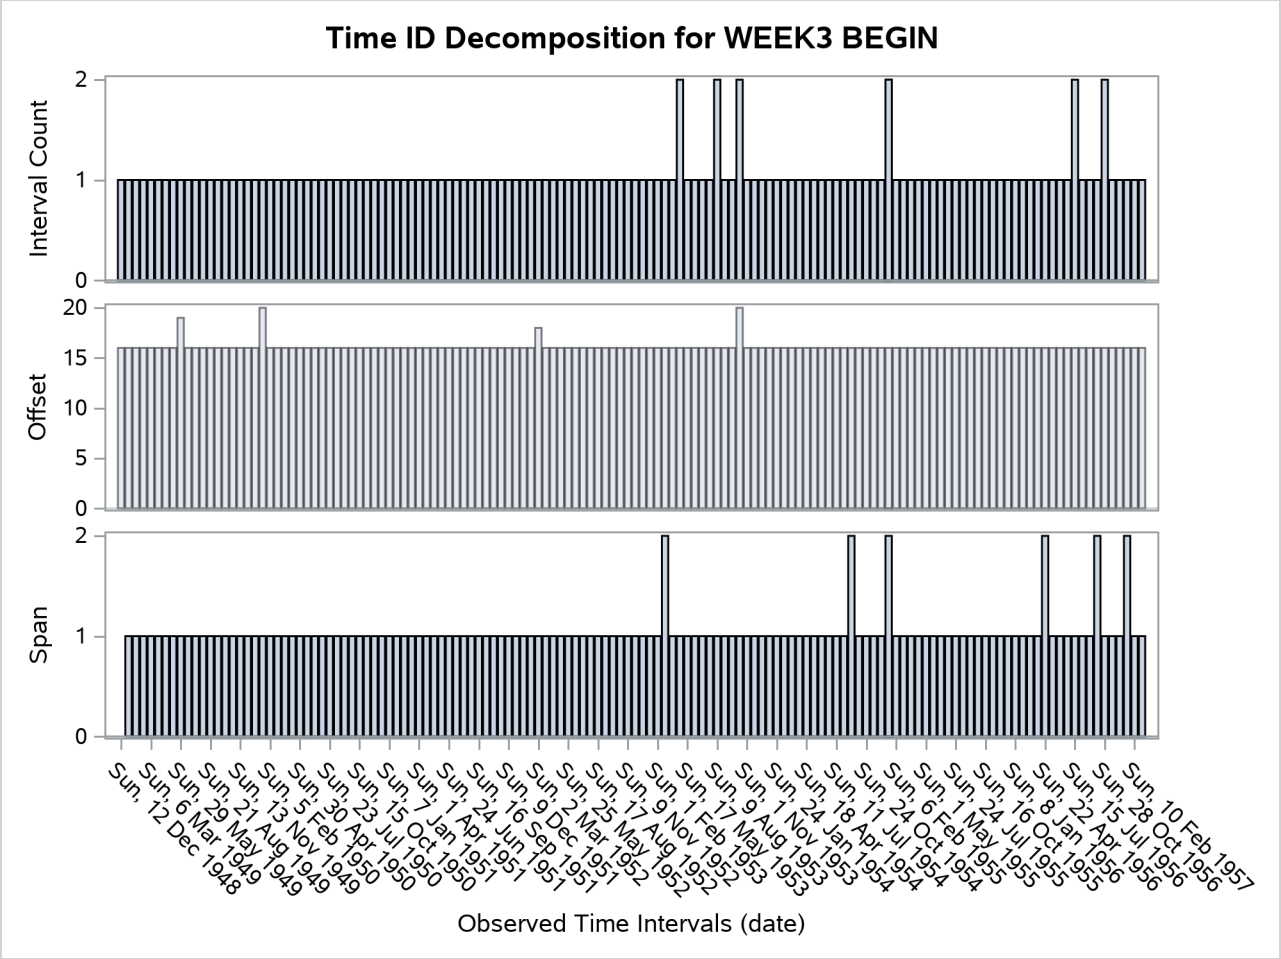
The Time ID decomposition listing and plot shown in Output 37.1.1 and Output 37.1.2 summarize how well the WEEK3 interval fits the time ID values by showing the number of counts, offsets, and spans for each time

interval that is represented by the DATE variable. The listing in Output 37.1.1 has been truncated to include only the first 10 observations. The Time ID plots in Output 37.1.2 indicate that there are duplicated time ID values for a three-week time interval in the Counts plot. The duplicated time intervals have a Count value of 2. The Offsets plot shows which days in the 21 day cycle have been used to record each time interval in the series. The Spans plot records values of 2 for six time intervals where no observations were recorded in the previous interval. The three component plots are histogram summaries of the diagnostic quantities plotted against individual intervals in the decomposition plots. The component plots can be useful in diagnosing time series that contain many time intervals.

Output 37.1.1 Time ID Decomposition Listing

	Time Component			
Value Index	date	Offset	Span	Interval Count
1	Sun, 12 Dec 1948	16	.	1
2	Sun, 2 Jan 1949	16	1	1
3	Sun, 23 Jan 1949	16	1	1
4	Sun, 13 Feb 1949	16	1	1
5	Sun, 6 Mar 1949	16	1	1
6	Sun, 27 Mar 1949	16	1	1
7	Sun, 17 Apr 1949	16	1	1
8	Sun, 8 May 1949	16	1	1
9	Sun, 29 May 1949	19	1	1
10	Sun, 19 Jun 1949	16	1	1

Output 37.1.2 Time ID Decomposition Plot



Output 37.1.3 and Output 37.1.4 describe the distribution of counts of duplicated WEEK3 intervals in the TriWeek data set. For this data set there are 134 intervals that contain one DATE value, and 10 intervals that contain two DATE values.

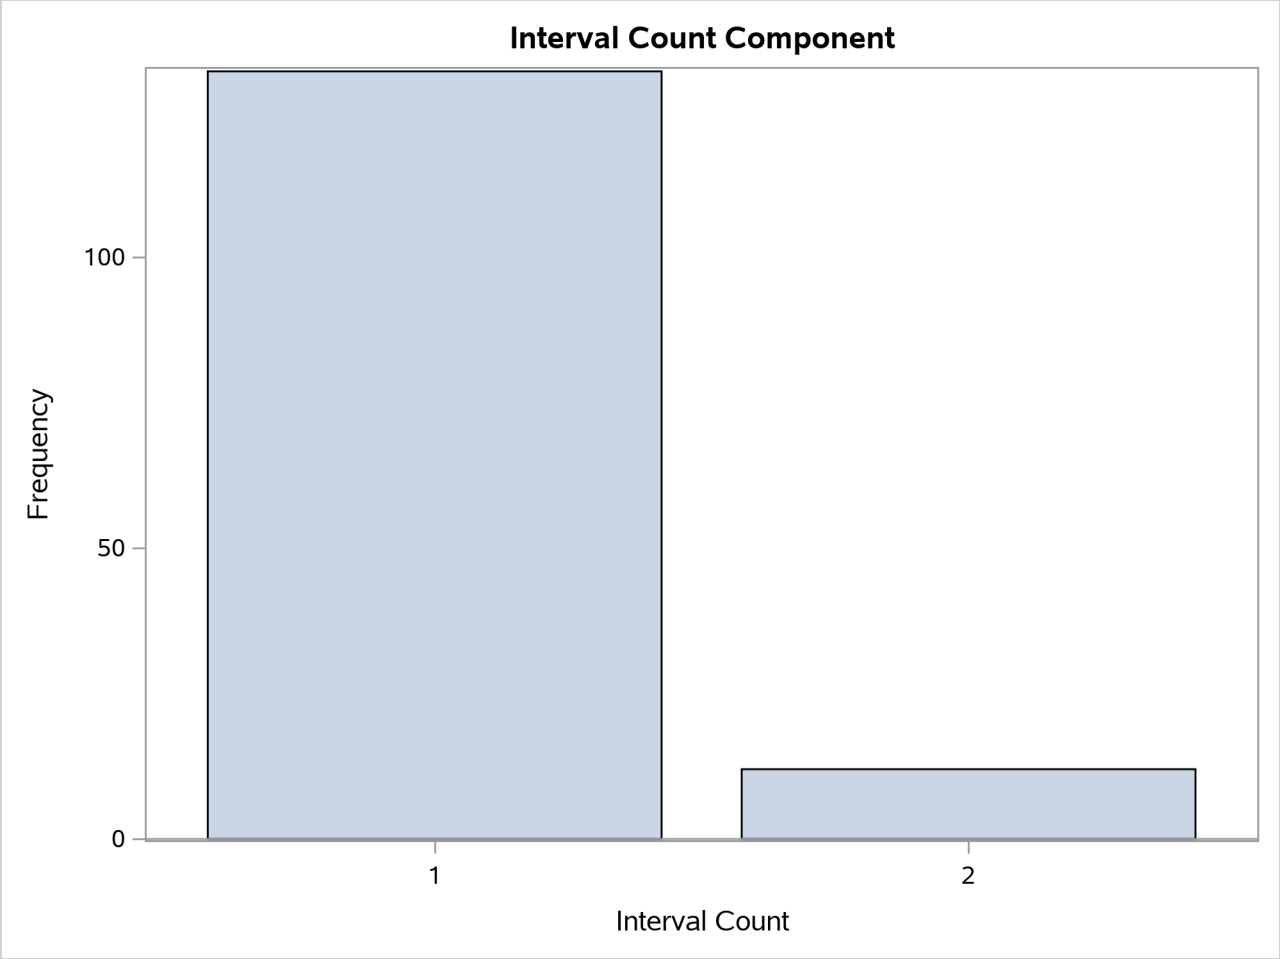
Output 37.1.3 Time ID Interval Counts Listings

The TIMEID Procedure

Component			
Value Index	Interval Count	Frequency	Percentage
1	1	132	91.666667
2	2	12	8.333333

Statistics Summary			
Minimum	Maximum	Mean	Standard Deviation
1	2	1.0833333	1.3008873

Output 37.1.4 Time ID Interval Counts Histogram



The offsets diagnostics Output 37.1.5 and Output 37.1.6 show the distribution of days in the 21-day WEEK3 interval used to record the time intervals in the series. The observations in the TriWeek data set represent intervals with five different offsets from the beginning of the WEEK3 interval: 0, 16, 18, 19, and 20. The high prevalence of intervals with offset 16 indicates that the TriWeek data set would be represented better using the WEEK3.17 interval.

Output 37.1.5 Time ID Offsets Listings

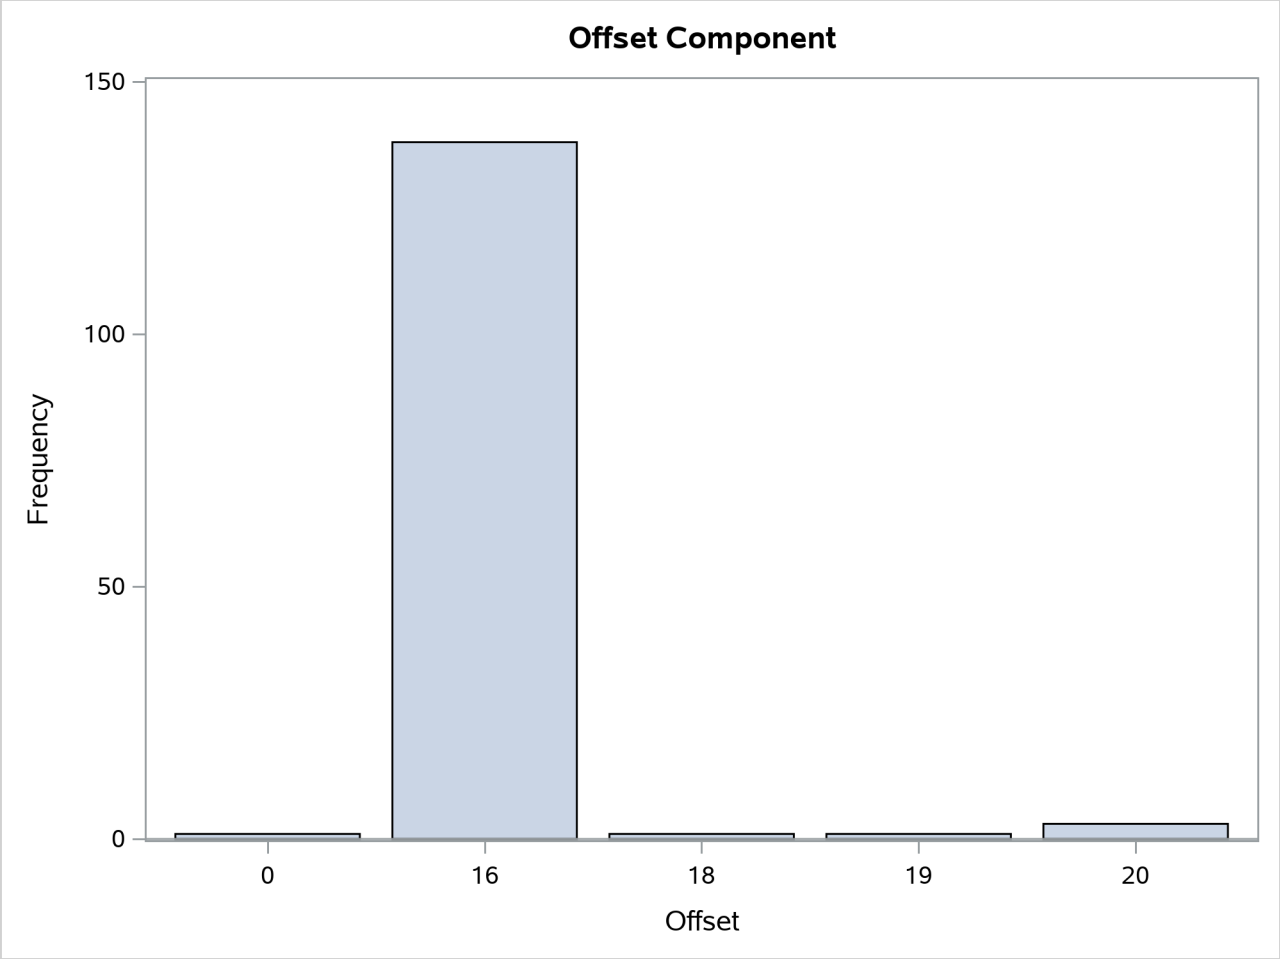
The TIMEID Procedure

	Component		
Value Index	Offset	Frequency	Percentage
1	0	1	0.694444
2	16	138	95.833333
3	18	1	0.694444
4	19	1	0.694444
5	20	3	2.083333

Output 37.1.5 *continued*

Statistics Summary			
Minimum	Maximum	Mean	Standard Deviation
0	20	16.006944	1.7006205

Output 37.1.6 Time ID Offsets Histogram



The span diagnostics Output 37.1.7 and Output 37.1.8 show the distribution of the span sizes between successive DATE values. The TriWeek data set has three different span sizes of widths 0, 1, and 2. Here one span corresponds to the width of a WEEK3 interval.

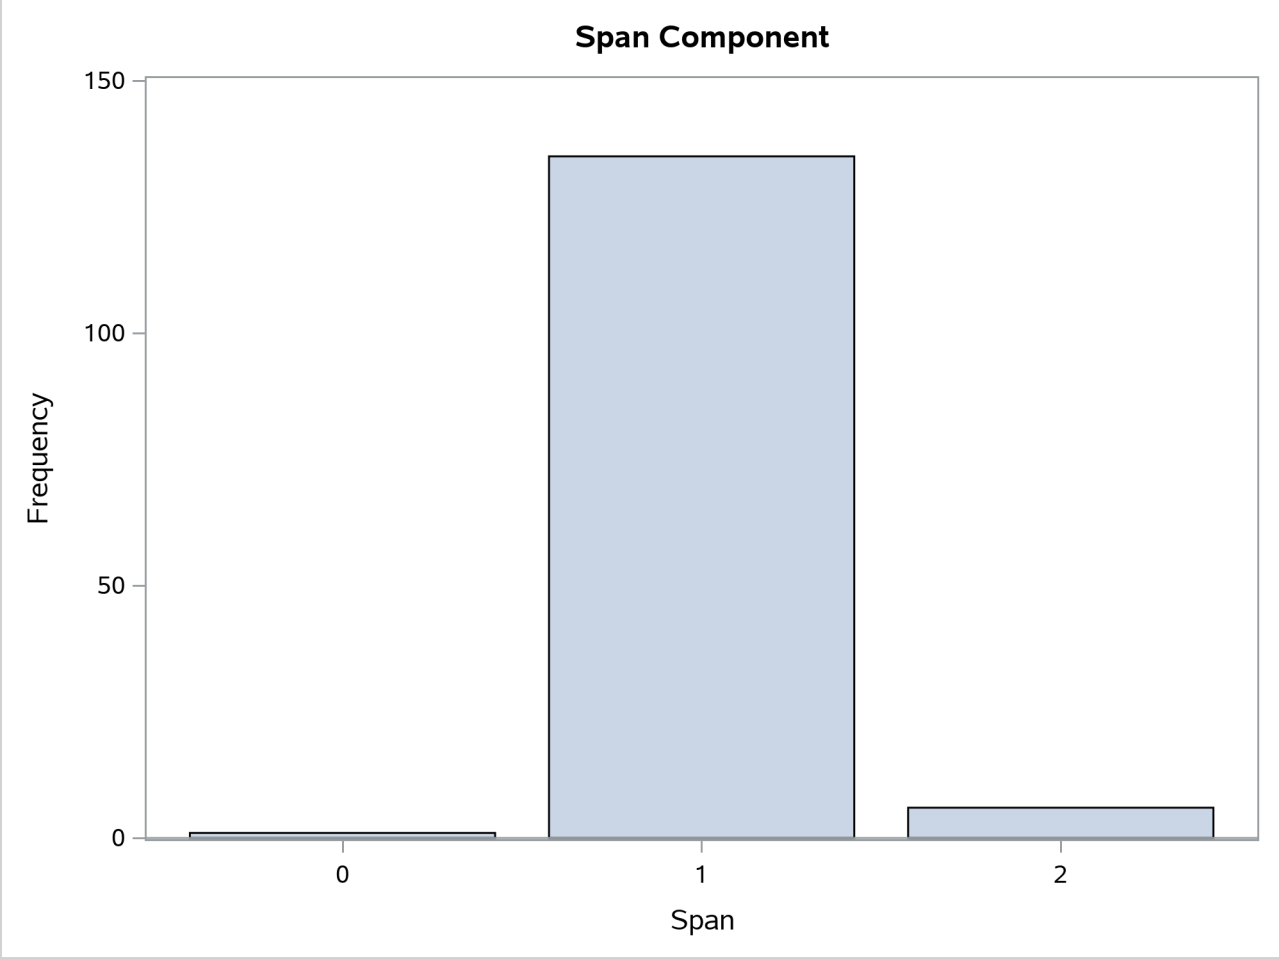
Output 37.1.7 Time ID Span Listings

The TIMEID Procedure

Component			
Value Index	Span	Frequency	Percentage
1	0	1	0.704225
2	1	135	95.070423
3	2	6	4.225352

Statistics Summary			
Minimum	Maximum	Mean	Standard Deviation
0	2	1.0352113	0.6367974

Output 37.1.8 Time ID Span Histogram

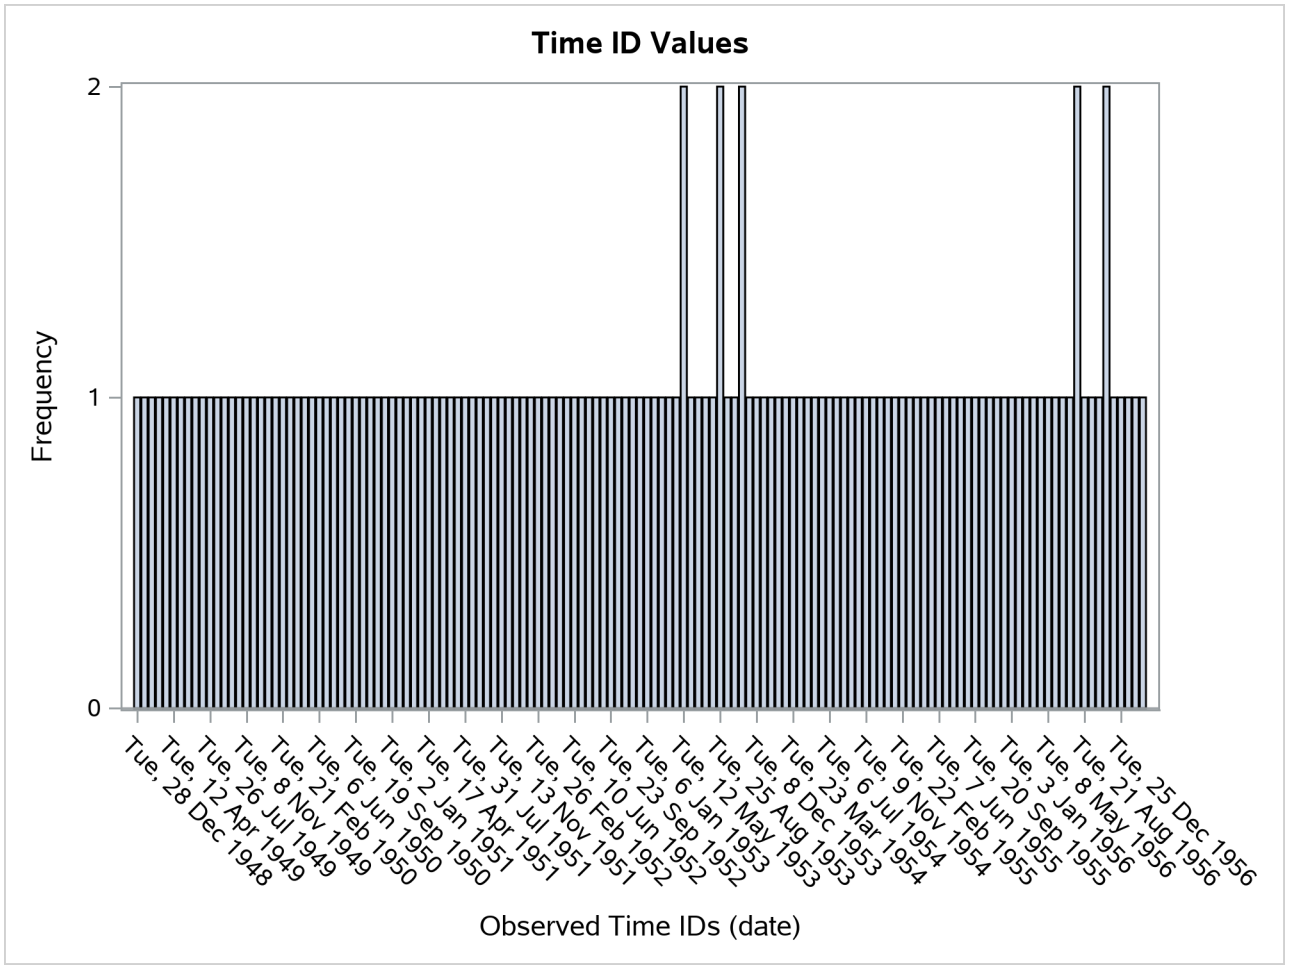


Output 37.1.9 and Output 37.1.10 show the distribution of time ID values before alignment to the WEEK3 interval. The listing in Output 37.1.9 has been truncated to include only the first 10 observations.

Output 37.1.9 Unaligned Time ID Listings

Time ID Values for DATE			
Value Index	date	Frequency	Percentage
1	Tue, 28 Dec 1948	1	0.694444
2	Tue, 18 Jan 1949	1	0.694444
3	Tue, 8 Feb 1949	1	0.694444
4	Tue, 1 Mar 1949	1	0.694444
5	Tue, 22 Mar 1949	1	0.694444
6	Tue, 12 Apr 1949	1	0.694444
7	Tue, 3 May 1949	1	0.694444
8	Tue, 24 May 1949	1	0.694444
9	Fri, 17 Jun 1949	1	0.694444
10	Tue, 5 Jul 1949	1	0.694444

Output 37.1.10 Unaligned Time ID Histogram



Example 37.2: Inferring a Date Interval

This example illustrates how a time ID variable can be inferred from a data set when a sufficient number of observations are present.

```
data workdays;
   format day weekdate.;
   input day : date. @@;
   datalines;
01AUG09 06AUG09 11AUG09 14AUG09 19AUG09 22AUG09
27AUG09 01SEP09 04SEP09 09SEP09 12SEP09 17SEP09
;

proc timeid data=workdays print=interval;
   id day;
run;
```

The 12 observations in the WorkDays data set are enough to determine that the DAY time ID variable is represented by the WEEKDAY12W3 interval. The WEEKDAY12W3 interval corresponds to every third day of the week excluding Sundays and Mondays. Characteristics of this interval are shown in Output 37.2.1.

Output 37.2.1 Inferred Time Interval Information

The TIMEID Procedure

Time Interval Analysis Summary	
Time ID Variable	day
Time Interval	WEEKDAY12W3
Base Name	WEEKDAY
Multiplier	3
Shift	0
Length of Seasonal Cycle	5
Time ID Format	DATE9.
Start	01AUG2009
End	17SEP2009

Example 37.3: Examining Multiple BY Groups

This example illustrates how a time ID variable can be examined independently over each BY group and summarized over all observations in the DATA= data set.

```
data bygroups;
   format tid date.;
   input tid : date. by @@;
datalines;
24NOV09 1 25NOV09 1 26NOV09 1 27NOV09 1 30NOV09 1 01DEC09 1 02DEC09 1 03DEC09 1

   ... more lines ...
```

The following TIMEID procedure statements generate two data sets that summarize a data set with four BY groups:

```
proc timeid data=bygroups outintervaldetails=int outinterval=intsum;
   id tid;
   by by;
run;
```

The summarized information in Output 37.3.1 shows that BY groups 2, 3, and 4 in the ByGroups data set contain some duplicate values and spans, and group 1 conforms exactly to the WEEKDAY17W interval. This listing also shows that the date ranges in these two BY groups start and end on different days and that they overlap between December 7, 2009, and December 28, 2009.

Output 37.3.1 Selected Variables in the Combined OUTINTERVALDETAILS= OUTINTERVAL= Data Sets

Overview: TIMESERIES Procedure

The TIMESERIES procedure analyzes time-stamped transactional data with respect to time and accumulates the data into a time series format. The procedure can perform trend and seasonal analysis on the transactions. After the transactional data are accumulated, time domain and frequency domain analysis can be performed on the accumulated time series.

For seasonal analysis of the transaction data, various statistics can be computed for each season. For trend analysis of the transaction data, various statistics can be computed for each time period. The analysis is similar to applying the MEANS procedure of Base SAS software to each season or time period of concern.

After the transactional data are accumulated to form a time series and any missing values are interpreted, the accumulated time series can be functionally transformed using log, square root, logistic, or Box-Cox transformations. The time series can be further transformed using simple and/or seasonal differencing. After functional and difference transformations have been applied, the accumulated and transformed time series can be stored in an output data set. This working time series can then be analyzed further using various time series analysis techniques provided by this procedure or other SAS/ETS procedures.

Time series analyses performed by the TIMESERIES procedure include the following:

- descriptive (global) statistics
- seasonal decomposition/adjustment analysis
- correlation analysis
- cross-correlation analysis
- spectral analysis

All results of the transactional or time series analysis can be stored in output data sets or printed using the Output Delivery System (ODS).

The TIMESERIES procedure can process large amounts of time-stamped transactional data. Therefore, the analysis results are useful for large-scale time series analysis or (temporal) data mining. All of the results can be stored in output data sets in either a time series format (default) or a coordinate format (transposed). The time series format is useful for preparing the data for subsequent analysis with other SAS/ETS procedures. For example, the working time series can be further analyzed, modeled, and forecast with other SAS/ETS procedures. The coordinate format is useful when using this procedure with SAS/STAT procedures or SAS Enterprise Miner. For example, clustering time-stamped transactional data can be achieved by using the results of this procedure with the clustering procedures of SAS/STAT and the nodes of SAS Enterprise Miner.

The EXPAND procedure can be used for the frequency conversion and transformations of time series output from this procedure.

Getting Started: TIMESERIES Procedure

This section outlines the use of the TIMESERIES procedure and gives a cursory description of some of the analysis techniques that can be performed on time-stamped transactional data.

Given an input data set that contains numerous transaction variables recorded over time at no specific frequency, the TIMESERIES procedure can form time series as follows:

```
PROC TIMESERIES DATA=<input-data-set>
                OUT=<output-data-set>;
   ID <time-ID-variable> INTERVAL=<frequency>
                         ACCUMULATE=<statistic>;
   VAR <time-series-variables>;
RUN;
```

The TIMESERIES procedure forms time series from the input time-stamped transactional data. It can provide results in output data sets or in other output formats by using the Output Delivery System (ODS).

Time-stamped transactional data are often recorded at no fixed interval. Analysts often want to use time series analysis techniques that require fixed-time intervals. Therefore, the transactional data must be accumulated to form a fixed-interval time series.

Suppose that a bank wants to analyze the transactions associated with each of its customers over time. Further, suppose that the data set WORK.TRANSACTIONS contains four variables that are related to these transactions: CUSTOMER, DATE, WITHDRAWAL, and DEPOSITS. The following examples illustrate possible ways to analyze these transactions by using the TIMESERIES procedure.

To accumulate the time-stamped transactional data to form a daily time series based on the accumulated daily totals of each type of transaction (WITHDRAWALS and DEPOSITS), the following TIMESERIES procedure statements can be used:

```
proc timeseries data=transactions
                out=timeseries;
   by customer;
   id date interval=day accumulate=total;
   var withdrawals deposits;
run;
```

The OUT=TIMESERIES option specifies that the resulting time series data for each customer is to be stored in the data set WORK.TIMESERIES. The INTERVAL=DAY option specifies that the transactions are to be accumulated on a daily basis. The ACCUMULATE=TOTAL option specifies that the sum of the transactions is to be calculated. After the transactional data are accumulated into a time series format, many of the procedures provided with SAS/ETS software can be used to analyze the resulting time series data.

For example, the ARIMA procedure can be used to model and forecast each customer's withdrawal data by using an ARIMA$(0,1,1)(0,1,1)_s$ model (where the number of seasons is s=7 days in a week) using the following statements:

```
proc arima data=timeseries;
   identify var=withdrawals(1,7) noprint;
   estimate q=(1)(7) outest=estimates noprint;
   forecast id=date interval=day out=forecasts;
quit;
```

The OUTEST=ESTIMATES data set contains the parameter estimates of the model specified. The OUT=FORECASTS data set contains forecasts based on the model specified. For more information, see Chapter 7, "The ARIMA Procedure."

A single set of transactions can be very large and must be summarized in order to analyze them effectively. Analysts often want to examine transactional data for trends and seasonal variation. To analyze transactional data for trends and seasonality, statistics must be computed for each time period and season of concern. For each observation, the time period and season must be determined and the data must be analyzed based on this determination.

The following statements illustrate how to use the TIMESERIES procedure to perform trend and seasonal analysis of time-stamped transactional data:

```
proc timeseries data=transactions out=out
                outseason=season outtrend=trend;
   by customer;
   id date interval=day accumulate=total;
   var withdrawals deposits;
run;
```

Since the INTERVAL=DAY option is specified, the length of the seasonal cycle is seven (7), where the first season is Sunday and the last season is Saturday. The output data set specified by the OUTSEASON=SEASON option contains the seasonal statistics for each day of the week by each customer. The output data set specified by the OUTTREND=TREND option contains the trend statistics for each day of the calendar by each customer.

Often it is desired to seasonally decompose into seasonal, trend, cycle, and irregular components or to seasonally adjust a time series. The following techniques describe how the changing seasons influence the time series.

The following statements illustrate how to use the TIMESERIES procedure to perform seasonal adjustment/decomposition analysis of time-stamped transactional data:

```
proc timeseries data=transactions
                out=out
                outdecomp=decompose;
   by customer;
   id date interval=day accumulate=total;
   var withdrawals deposits;
run;
```

The output data set specified by the OUTDECOMP=DECOMPOSE option contains the decomposed/adjusted time series for each customer.

A single time series can be very large. Often, a time series must be summarized with respect to time lags in order to be efficiently analyzed using time domain techniques. These techniques help describe how a current observation is related to the past observations with respect to the time (season) lag.

The following statements illustrate how to use the TIMESERIES procedure to perform time domain analysis of time-stamped transactional data:

```
proc timeseries data=transactions
                out=out
                outcorr=timedomain;
   by customer;
   id date interval=day accumulate=total;
   var withdrawals deposits;
run;
```

The output data set specified by the OUTCORR=TIMEDOMAIN option contains the time domain statistics, such as sample autocorrelations and partial autocorrelations, by each customer.

Sometimes time series data contain underlying patterns that can be identified using spectral analysis techniques. Two kinds of spectral analyses on univariate data can be performed using the TIMESERIES procedure. They are singular spectrum analysis and Fourier spectral analysis.

Singular spectrum analysis (SSA) is a technique for decomposing a time series into additive components and categorizing these components based on the magnitudes of their contributions. SSA uses a single parameter, the window length, to quantify patterns in a time series without relying on prior information about the series' structure. The window length represents the maximum lag that is considered in the analysis, and it corresponds to the dimensionality of the principle components analysis (PCA) on which SSA is based. The components are combined into groups to categorize their roles in the SSA decomposition.

Fourier spectral analysis decomposes a time series into a sum of harmonics. In the discrete Fourier transform, the contribution of components at evenly spaced frequencies are quantified in a periodogram and summarized in spectral density estimates.

The following statements illustrate how to use the TIMESERIES procedure to analyze time-stamped transactional data without prior information about the series' structure:

```
proc timeseries data=transactions
                outssa=ssa
                outspectra=spectra;
   by customer;
   id date interval=day accumulate=total;
```

```
   var withdrawals deposits;
run;
```

The output data set specified by the OUTSSA=SSA option contains a singular spectrum analysis of the withdrawals and deposits data. The data set specified by the OUTSPECTRA=SPECTRA option contains a Fourier spectral decomposition of the same data.

By default, the TIMESERIES procedure produces no printed output.

Syntax: TIMESERIES Procedure

The TIMESERIES procedure uses the following statements:

PROC TIMESERIES *options* ;
BY *variables* ;
CORR *statistics-list* / *options* ;
CROSSCORR *statistics-list* / *options* ;
CROSSVAR *variable-list* / *options* ;
COUNT / *options* ;
DECOMP *component-list* / *options* ;
ID *variable* **INTERVAL**= *interval-option* ;
SEASON *statistics-list* / *options* ;
SPECTRA *statistics-list* / *options* ;
SSA / *options* ;
TREND *statistics-list* / *options* ;
VAR *variable-list* / *options* ;

PROC TIMESERIES Statement

PROC TIMESERIES *options* **;**

You can specify the following *options*:

DATA=*SAS-data-set*
names the SAS data set that contains the input data for the procedure to create the time series. If the DATA= option is not specified, the most recently created SAS data set is used.

COUNTPLOTS=*option* **|** **(** *options* **)**
specifies the count series graphical output to be produced. You can specify the following plotting *options*:

COUNTS plots the counts of the discrete values of the time series (OUTFREQ= data set).

CHISQPROB | CHISQ plots the chi-square probabilities.

DISTRIBUTION | DIST plots the discrete probability distribution.

VALUES plots the distinct values of the time series (OUTFREQ= data set).

ALL is equivalent to PLOTS=(COUNTS CHISQPROB DISTRIBUTION VALUES).

The COUNTPLOTS= option produces graphical results similar to the information contained in the data sets that are listed in parentheses next to the options.

By default, the TIMESERIES procedure produces no graphical output.

CROSSPLOTS=*option* | **(** *options* **)**
specifies the cross-variable graphical output to be produced. You can specify the following plotting *options*:

SERIES	plots the two time series (OUT= data set).
CCF	plots the cross-correlation functions (OUTCROSSCORR= data set).
ALL	is equivalent to PLOTS=(SERIES CCF).

The CROSSPLOTS= option produces results similar to the information contained in the data sets that are listed in parentheses next to the options.

By default, the TIMESERIES procedure produces no graphical output.

MAXERROR=*number*
limits the number of warning and error messages that are produced during the execution of the procedure to the specified *number*. This option is particularly useful in BY-group processing, where it can be used to suppress recurring messages. By default, MAXERROR=50.

MAXDATAERROR=*number*
limits the number of warning and error messages that are produced during the loading of data to the specified *number*. This option is particularly useful in BY-group processing, where it can be used to suppress recurring messages. By default, MAXDATAERROR=50.

MAXVARLENGTH
specifies that processed variables be set to eight bytes in length. This option exists principally for use when data storage might be a concern.

OUT=*SAS-data-set*
names the output data set to contain the time series variables that are specified in the subsequent VAR and CROSSVAR statements. If BY variables are specified, they are also included in the OUT= data set. If an ID variable is specified, it is also included in the OUT= data set. The values are accumulated based on the INTERVAL= option or the ACCUMULATE= option (or both) in the ID statement. The OUT= data set is particularly useful when you want to further analyze, model, or forecast the resulting time series with other SAS/ETS procedures.

OUTCORR=*SAS-data-set*
names the output data set to contain the univariate time domain statistics.

OUTCROSSCORR=*SAS-data-set*
names the output data set to contain the cross-correlation statistics.

OUTDECOMP=*SAS-data-set*
names the output data set to contain the decomposed or seasonally adjusted time series (or both).

OUTFREQ=*SAS-data-set*
names the output data set to contain the frequency (count) analysis.

OUTPROCINFO=*SAS-data-set*
names the output data set to contain information in the SAS log, specifically the number of notes, errors, and warnings and the number of series processed, number of analyses requested, and number of analyses failed.

OUTSEASON=*SAS-data-set*
names the output data set to contain the seasonal statistics. The statistics are computed for each season as specified by the INTERVAL= option in the ID statement or the SEASONALITY= option in the PROC TIMESERIES statement. The OUTSEASON= data set is particularly useful when analyzing transactional data for seasonal variations.

OUTSPECTRA=*SAS-data-set*
names the output data set to contain the univariate frequency domain analysis results.

OUTSSA=*SAS-data-set*
names the output data set to contain the singular spectrum analysis result series.

OUTSUM=*SAS-data-set*
names the output data set to contain the descriptive statistics. The descriptive statistics are based on the accumulated time series when the ACCUMULATE= or SETMISSING= options are specified in the ID or VAR statements. The OUTSUM= data set is particularly useful when you analyze large numbers of series and you need a summary of the results.

OUTTREND=*SAS-data-set*
names the output data set to contain the trend statistics. The statistics are computed for each time period as specified by the INTERVAL= option in the ID statement . The OUTTREND= data set is particularly useful when you analyze transactional data for trends.

PLOTS=*option* | **(** *options* **)**
specifies the univariate graphical output desired. By default, the TIMESERIES procedure produces no graphical output. You can specify the following plotting *options*:

SERIES	plots the time series (OUT= data set).
RESIDUAL	plots the residual time series (OUT= data set).
HISTOGRAM	plots a histogram of the time series values
CYCLES	plots the seasonal cycles (OUT= data set).
CORR	plots the correlation panel (OUTCORR= data set).
ACF	plots the autocorrelation function (OUTCORR= data set).
PACF	plots the partial autocorrelation function (OUTCORR= data set).
IACF	plots the inverse autocorrelation function (OUTCORR= data set).
WN	plots the white noise probabilities (OUTCORR= data set).

DECOMP plots the seasonal adjustment panel (OUTDECOMP= data set).

TCS plots the trend-cycle-seasonal component (OUTDECOMP= data set).

TCC plots the trend-cycle component (OUTDECOMP= data set).

SIC plots the seasonal-irregular component (OUTDECOMP= data set).

SC plots the seasonal component (OUTDECOMP= data set).

SA plots the seasonal adjusted component (OUTDECOMP= data set).

PCSA plots the percent change in the seasonal adjusted component (OUTDECOMP= data set).

IC plots the irregular component (OUTDECOMP= data set).

TC plots the trend component (OUTDECOMP= data set).

CC plots the cycle component (OUTDECOMP= data set).

PERIODOGRAM<(*suboption***)>** plots the periodogram (OUTSPECTRA= data set). You can specify the following *suboptions*:

MAXFREQ=*number* specifies the maximum frequency in radians to include in the plot.

MINPERIOD=*number* specifies the minimum period to include in the plot.

SPECTRUM<(*suboption***)>** plots the spectral density estimate (OUTSPECTRA= data set). You can specify the following *suboptions*:

MAXFREQ=*number* specifies the maximum frequency in radians to include in the plot.

MINPERIOD=*number* specifies the minimum period to include in the plot.

SSA<(*suboption***)>** plots the singular spectrum analysis results (OUTSSA= data set). You can specify the following *suboptions*:

MAXWINDOW=*number* specifies the maximum window number to display in the SSASingularValuesPlot and SSAWCorrHeatmap.

ALL is equivalent to PLOTS=(SERIES HISTOGRAM ACF PACF IACF WN SSA PERIODOGRAM SPECTRUM).

BASIC is equivalent to PLOTS=(SERIES HISTOGRAM CYCLES CORR DECOMP)

The PLOTS= option produces graphical output for these results by using the Output Delivery System (ODS). The PLOTS= option produces results similar to the data sets listed in parentheses next to the preceding options.

PRINT=*option* | **(** *options* **)**
specifies the printed output desired. By default, the TIMESERIES procedure produces no printed output. You can specify the following printing *options*:

COUNTS	prints the discrete distribution analysis (OUTFREQ= data set).
DECOMP	prints the seasonal decomposition/adjustment table (OUTDECOMP= data set).
SEASONS	prints the seasonal statistics table (OUTSEASON= data set).
DESCSTATS	prints the descriptive statistics for the accumulated time series (OUTSUM= data set).
SUMMARY	prints the descriptive statistics table for all time series (OUTSUM= data set).
TRENDS	prints the trend statistics table (OUTTREND= data set).
SSA	prints the singular spectrum analysis results (OUTSSA= data set).
ALL	is equivalent to PRINT=(DESCSTATS SUMMARY).

The PRINT= option produces printed output for these results by using the Output Delivery System (ODS). The PRINT= option produces results similar to the data sets listed in parentheses next to the preceding options.

PRINTDETAILS
requests that output specified in the PRINT= option be printed in greater detail.

SEASONALITY=*number*
specifies the length of the seasonal cycle. For example, SEASONALITY=3 means that every group of three time periods forms a seasonal cycle. By default, the length of the seasonal cycle is one (no seasonality) or the length implied by the INTERVAL= option specified in the ID statement. For example, INTERVAL=MONTH implies that the length of the seasonal cycle is 12.

SORTNAMES
requests that the variables specified in the VAR and CROSSVAR statements be processed in sorted order by the variable names. This option enables the output data sets to be presorted by the variable names.

VECTORPLOTS=*option* | **(** *options* **)**
specifies the vector time series graphical output to be produced. You can specify the following plotting *options*:

SCALED	plots each time series scaled between 0 and 1.
SERIES	plots each time series on a common axis without scaling.
STACKED	plots each time series on stacked thumbnail plots.
ALL	is equivalent to PLOTS=(SCALED SERIES STACKED).

By default, the TIMESERIES procedure produces no graphical output.

BY Statement

You can use a BY statement to obtain separate dummy variable definitions for groups of observations that are defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the option NOTSORTED or DESCENDING in the BY statement for the TIMESERIES procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure.

For more information about the BY statement, see *SAS DATA Step Statements: Reference*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide*.

CORR Statement

CORR *statistics* < / *options* > **;**

You can use a CORR statement to specify options that are related to time domain analysis of the accumulated time series. Only one CORR statement is allowed.

You can specify the following time domain *statistics*:

LAG	time lag
N	number of variance products
ACOV	autocovariances
ACF	autocorrelations
ACFSTD	autocorrelation standard errors
ACF2STD	an indicator of whether autocorrelations are less than (–1), greater than (1), or within (0) two standard errors of zero
ACFNORM	normalized autocorrelations
ACFPROB	autocorrelation probabilities
ACFLPROB	autocorrelation log probabilities
PACF	partial autocorrelations
PACFSTD	partial autocorrelation standard errors

PACF2STD	an indicator of whether partial autocorrelation are less than (–1), greater than (1), or within (0) two standard errors of zero
PACFNORM	partial normalized autocorrelations
PACFPROB	partial autocorrelation probabilities
PACFLPROB	partial autocorrelation log probabilities
IACF	inverse autocorrelations
IACFSTD	inverse autocorrelation standard errors
IACF2STD	an indicator of whether the inverse autocorrelation is less than (–1), greater than (1) or within (0) two standard errors of zero
IACFNORM	normalized inverse autocorrelations
IACFPROB	inverse autocorrelation probabilities
IACFLPROB	inverse autocorrelation log probabilities
WN	white noise test statistics
WNPROB	white noise test probabilities
WNLPROB	white noise test log probabilities

If you do not specify any *statistics*, then the default is as follows:

```
corr lag n acov acf acfstd pacf pacfstd iacf iacfstd wn wnprob;
```

You can specify the following *options* after a slash (/):

LAGS=(*numlist***)**
specifies the list of lags to be stored in OUTCORR= data set or to be plotted. The list of lags must be separated by spaces or commas. For example, LAGS=(1,3) specifies the first then third lag.

NLAG=*number*
specifies the number of lags to be stored in the OUTCORR= data set or to be plotted. The default is 24 or three times the length of the seasonal cycle, whichever is smaller. The LAGS= option takes precedence over the NLAG= option.

NPARMS=*number*
specifies the number of parameters that are used in the model that created the residual time series. The number of parameters determines the degrees of freedom associated with the Ljung-Box statistics. This option is useful when you analyze the residuals of a time series model whose number of parameters is specified by *number*. By default, NPARMS=0.

TRANSPOSE=NO | YES
specifies which values are recorded as column names in the OUTCORR= data set. You can specify the following values:

NO	specifies that correlation statistics be recorded as the column names. This option is useful for graphing the correlation results with SAS/GRAPH procedures.

YES specifies that lags be recorded as the column names instead of correlation statistics as the column names. This option is useful for analyzing the correlation results with other SAS procedures such as the CLUSTER procedure in SAS/STAT or with SAS Enterprise Miner software.

By default, TRANSPOSE=NO.

COUNT Statement

COUNT < / *options* > **;**

You can use a COUNT statement to specify options that are related to the discrete distribution analysis of the accumulated time series. Only one COUNT statement is allowed.

You can specify the following *options* after a slash (/):

ALPHA=*number*
specifies the confidence limit size. The *number* must be between 0 and 1; the default is 0.05.

CRITERION=LOGLIK | AIC | BIC
specifies the discrete distribution selection criterion. The default is CRITERION=LOGLIK.

You can specify the following selection criteria:

AIC specifies Akaike's information criterion.

BIC specifies the Bayesian information criterion.

LOGLIK specifies the log likelihood as the criterion.

By default, CRITERION=LOGLIK.

DISTRIBUTION= *option* | **(** *options* **)**
specifies one or more discrete distributions for automatic selection. You can specify one or more of the following *options*:

BINOMIAL specifies the binomial distribution.

ZMBINOMIAL specifies the zero-modified binomial distribution.

GEOMETRIC specifies the geometric distribution.

ZMGEOMETRIC specifies the zero-modified geometric distribution.

POISSON specifies the Poisson distribution.

ZMPOISSON specifies the zero-modified Poisson distribution.

NEGBINOMIAL | NEGBIN specifies the negative binomial distribution.

CROSSCORR Statement

CROSSCORR *statistics* < */ options* > **;**

You can use a CROSSCORR statement to produce statistics that are related to cross-correlation analysis of the accumulated time series. Only one CROSSCORR statement is allowed.

You can specify the following time domain *statistics*:

LAG	time lag
N	number of variance products
CCOV	cross covariances
CCF	cross-correlations
CCFSTD	cross-correlation standard errors
CCF2STD	an indicator of whether cross-correlations are less than (–1), greater than (1), or within (0) two standard errors of zero
CCFNORM	normalized cross-correlations
CCFPROB	cross-correlation probabilities
CCFLPROB	cross-correlation log probabilities

If do not specify any *statistics*, the default is as follows:

```
crosscorr lag n ccov ccf ccfstd;
```

You can also specify the following *options* after a slash (*/*):

ADJSCALE=*option*
specifies the normalization of the cross-covariance and cross-correlation. Different ways of normalization means using different divisors (for more information, see the section "Cross-Correlation Statistics" on page 2756). You can specify the following values:

BIASED | B	specifies the biased normalization.
DEFAULT | D	specifies the default normalization.
UNBIASED | U	specifies the unbiased normalization.

LAGS=(*numlist***)**
specifies a list of lags to be stored in OUTCROSSCORR= data set or to be plotted. The list of lags must be separated by spaces or commas. For example, LAGS=(1,3) specifies the first then third lag.

NLAG=*number*
specifies the number of lags to be stored in the OUTCROSSCORR= data set or to be plotted. The default is 24 or three times the length of the seasonal cycle, whichever is smaller. The LAGS= option takes precedence over the NLAG= option.

TRANSPOSE=NO | YES

specifies which values are recorded as column names in the OUTCROSSCORR= data set. You can specify the following values:

NO specifies that cross-correlation statistics be recorded as the column names. This option is useful for graphing the cross-correlation results with SAS/GRAPH procedures.

YES specifies that lags instead of cross-correlation statistics be recorded as the column names. This option is useful for analyzing the cross-correlation results with other procedures such as the CLUSTER procedure in SAS/STAT or with SAS Enterprise Miner software.

By default, TRANSPOSE=NO.

DECOMP Statement

DECOMP *components* < / *options* > **;**

You can use a DECOMP statement to specify *options* that are related to classical seasonal decomposition of the time series data. Only one DECOMP statement is allowed. The *options* affect all variables that are listed in the VAR statements. Decomposition can be performed only when the length of the seasonal cycle specified by the SEASONALITY= option in the PROC TIMESERIES statement or implied by the INTERVAL= option in the ID statement is greater than 1.

You can specify the following seasonal decomposition *components*:

CC | CYCLE	cycle component
IC | IRREGULAR	irregular component
ORIG | ORIGINAL	original series
PCSA	percentage change seasonally adjusted series
SA | ADJUSTED	seasonally adjusted series
SC | SEASONAL	seasonal component
SCSTD	seasonal component standard errors
SIC | SEASONIRREGULAR	seasonal-irregular component
TC	trend component
TCC | TRENDCYCLE	trend-cycle component
TCS | TRENDCYCLESEASON	trend-cycle-seasonal component

If you do not specify any components, then the default is as follows:

```
decomp orig tcc sc ic sa;
```

You can also specify the following *options* after a slash (/):

MODE=*option*

specifies the type of decomposition to be used to decompose the time series. You can specify the following *options*:

ADD | ADDITIVE	uses additive decomposition.
MULT | MULTIPLICATIVE	uses multiplicative decomposition.
LOGADD | LOGADDITIVE	uses log-additive decomposition.
PSEUDOADD | PSEUDOADDITIVE	uses pseudo-additive decomposition.
MULTORADD	uses multiplicative decomposition when the accumulated time series contains only positive values, uses pseudo-additive decomposition when the accumulated time series contains only nonnegative values, and uses additive decomposition otherwise.

Multiplicative and log additive decomposition require strictly positive time series. If the accumulated time series contains nonpositive values and MODE=MULT or MODE=LOGADD, an error results. Pseudo-additive decomposition requires a nonnegative-valued time series. If the accumulated time series contains negative values and the MODE=PSEUDOADD option is specified, an error results.

By default, MODE=MULTORADD.

LAMBDA=*number*

specifies the Hodrick-Prescott filter parameter for trend-cycle decomposition. Filtering applies when the trend component or the cycle component is requested. If filtering is not specified, this option is ignored. By default, LAMBDA=1600.

NPERIODS=*number*

specifies the *number* of time periods to be stored in the OUTDECOMP= data set when the TRANSPOSE=YES option is specified. If TRANSPOSE=NO, the NPERIODS= option is ignored. If *number* is positive, the first or beginning time periods are recorded. If *number* is negative, the last or ending time periods are recorded. The NPERIODS= option specifies the number of OUTDECOMP= data set variables to contain the seasonal decomposition and is therefore limited to the maximum allowed number of SAS variables. If the number of time periods exceeds this limit, a warning is printed in the log and the number of periods stored is reduced to the limit.

If the NPERIODS= option is not specified, all of the periods specified between the ID statement START= and END= options are stored. If at least one of the START= or END= options is not specified, the default magnitude is the seasonality specified in the SEASONALITY= option in the PROC TIMESERIES statement or implied by the INTERVAL= option in the ID statement. If only the START= option or both the START= and END= options are specified and the seasonality is zero, the default is NPERIODS=5. If only the END= option or neither the START= nor END= option is specified and the seasonality is zero, the default is NPERIODS=–5.

TRANSPOSE=NO | YES

specifies which values are recorded as column names in the OUTDECOMP= data set.

NO	specifies that decomposition components be recorded as the column names. This option is useful for analyzing or displaying the decomposition results with SAS/GRAPH procedures.

YES specifies that the time periods be recorded as the column names instead of decomposition components. The first and last time periods stored in the OUTDECOMP= data set correspond to the period specified in the START= option and END= option, respectively, in the ID statement. If only the END= option is specified, the last time ID value of each accumulated time series corresponds to the last time period column. If only the START= option is specified, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option nor the END= option is specified in the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. This option is useful for analyzing the decomposition results with other SAS procedures or with SAS Enterprise Miner software.

By default, TRANSPOSE=NO.

ID Statement

ID *variable* **INTERVAL=***interval* < *options* > **;**

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date or datetime values. In addition, the ID statement specifies the frequency to be associated with the time series. The ID statement *option* also specify how the observations are accumulated and how the time ID values are aligned to form the time series. The specified information affects all variables that are listed in subsequent VAR statements. If you do not specify an ID statement, the observation number, with respect to the BY group, is used as the time ID.

You must specify the following argument:

INTERVAL=*interval*

specifies the frequency of the accumulated time series. For example, if the input data set consists of quarterly observations, then specify INTERVAL=QTR. If the PROC TIMESERIES statement SEASONALITY= option is not specified, the length of the seasonal cycle is implied from the INTERVAL= option. For example, INTERVAL=QTR implies a seasonal cycle of length 4. If the ACCUMULATE= option is also specified, the INTERVAL= option determines the time periods for the accumulation of observations. The INTERVAL= option is required and must be the first option specified in the ID statement.

You can also specify the following *options*:

ACCUMULATE=*option*

specifies how the data set observations are to be accumulated within each time period. The frequency (width of each time interval) is specified by the INTERVAL= *interval*. The ID variable contains the time ID values. Each time ID variable value corresponds to a specific time period. The accumulated values form the time series, which is used in subsequent analysis.

This option is useful when there are zero or more than one input observations that coincide with a particular time period (for example, time-stamped transactional data). The EXPAND procedure offers additional frequency conversions and transformations that can also be useful in creating a time series.

You can specify the following *options*, which determine how the observations are accumulated within each time period based on the ID variable and on the frequency specified in INTERVAL= *interval*:

NONE	does not accumulate observations; the ID variable values must be equally spaced with respect to the frequency.
TOTAL	accumulates observations based on the total sum of their values.
AVERAGE | AVG	accumulates observations based on the average of their values.
MINIMUM | MIN	accumulates observations based on the minimum of their values.
MEDIAN | MED	accumulates observations based on the median of their values.
MAXIMUM | MAX	accumulates observations based on the maximum of their values.
N	accumulates observations based on the number of nonmissing observations.
NMISS	accumulates observations based on the number of missing observations.
NOBS	accumulates observations based on the number of observations.
FIRST	accumulates observations based on the first of their values.
LAST	accumulates observations based on the last of their values.
STDDEV | STD	accumulates observations based on the standard deviation of their values.
CSS	accumulates observations based on the corrected sum of squares of their values.
USS	accumulates observations based on the uncorrected sum of squares of their values.

If you specify the ACCUMULATE= option, the SETMISSING= option is useful for specifying how accumulated missing values are to be treated. If missing values are to be interpreted as 0, then specify SETMISSING=0. For more information about accumulation, see the section "Details: TIMESERIES Procedure" on page 2747.

By default, ACCUMULATE=NONE.

ALIGN=*option*

controls the alignment of SAS dates that are used to identify output observations. The ALIGN= option accepts the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. BEGINNING is the default.

BOUNDARYALIGN=*option*

controls how the ACCUMULATE= option is processed for the two boundary time intervals, which include the START= and END= time ID values. Some time ID values might fall inside the first and last accumulation intervals but fall outside the START= and END= boundaries. In these cases the BOUNDARYALIGN= option determines which values to include in the accumulation operation. You can specify the following *options*:

NONE	does not accumulate any values outside the START= and END= boundaries.
START	accumulates all observations in the first time interval.
END	accumulates all observations in the last time interval.
BOTH	accumulates all observations in the first and last.

For more information, see the section "Details: TIMESERIES Procedure" on page 2747. By default, BOUNDARYALIGN=NONE.

END=*value*
specifies a SAS date or datetime value that represents the end of the data. If the last time ID variable value is less than *value*, the series is extended with missing values. If the last time ID variable value is greater than *value*, the series is truncated. For example, END="&sysdate"D uses the automatic macro variable SYSDATE to extend or truncate the series to the current date. You can use the START= and END= options to ensure that data associated within each BY group contains the same number of observations.

FORMAT=*format*
specifies the SAS format for the time ID values. The default format is implied from the INTERVAL= option.

NOTSORTED
specifies that the time ID values might not be in sorted order. Prior to analysis, the TIMESERIES procedure sorts the data with respect to the time ID.

SETMISSING=*option* | *number*
specifies how missing values (either actual or accumulated) are to be interpreted in the accumulated time series. If you specify a *number*, missing values are set to the *number*. If a missing value indicates an unknown value, this option should not be used. If a missing value indicates no value, specify SETMISSING=0. You would typically use SETMISSING=0 for transactional data because no recorded data usually implies no activity. Instead of specifying a *number*, you can specify one of the following *options* to determine how missing values are assigned:

MISSING	sets missing values to missing.
AVERAGE | AVG	sets missing values to the accumulated average value.
MINIMUM | MIN	sets missing values to the accumulated minimum value.
MEDIAN | MED	sets missing values to the accumulated median value.
MAXIMUM | MAX	sets missing values to the accumulated maximum value.
FIRST	sets missing values to the accumulated first nonmissing value.
LAST	sets missing values to the accumulated last nonmissing value.
PREVIOUS | PREV	sets missing values to the previous period's accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.
NEXT	sets missing values to the next period's accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.

By default, SETMISSING=MISSING.

START=*value*
specifies a SAS date or datetime value that represents the beginning of the data. If the first time ID variable value is greater than *value*, missing values are added to the beginning of the series. If the first time ID variable value is less than *value*, the series is truncated. You can specify the START= and END= options to ensure that data associated with each BY group contains the same number of observations.

SEASON Statement

SEASON *statistics* < / *options* > **;**

You can use a SEASON statement to specify seasonal *statistics* and *options* that are related to seasonal analysis of the time-stamped transactional data. Only one SEASON statement is allowed. The *options* affect all variables specified in the VAR statements. Seasonal analysis can be performed only when the length of the seasonal cycle specified by the SEASONALITY= option in the PROC TIMESERIES statement or implied by the INTERVAL= option in the ID statement is greater than 1.

You can specify the following seasonal *statistics*:

NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	range value
SUM	summation value
MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

If you do not specify any of the seasonal *statistics*, then the default is as follows:

```
season n min max mean std;
```

You can also specify the following *options* after a slash (/):

TRANSPOSE=NO | YES
specifies which values are recorded as column names in the OUTSEASON= data set. You can specify the following values:

NO	specifies that the seasonal statistics be recorded as the column names. This option is useful for graphing the seasonal analysis results with SAS/GRAPH procedures.
YES	specifies that the seasonal indices instead of the seasonal statistics be recorded as the column names. This option is useful for analyzing the seasonal analysis results with SAS procedures or with SAS Enterprise Miner software.

By default, TRANSPOSE=NO.

SPECTRA Statement

SPECTRA *statistics* < / *options* > **;**

You can use a SPECTRA statement to specify which *statistics* appear in the OUTSPECTRA= data set. The SPECTRA statement *options* are used in performing a spectral analysis on the variables listed in the VAR statement. These *options* affect values that are produced in the PROC TIMESERIES statement's OUTSPECTRA= data set, and in the periodogram and spectral density estimate. Only one SPECTRA statement is allowed.

You can request the following univariate frequency domain *statistics*:

FREQ	frequency in radians from 0 to π
PERIOD	period or wavelength
COS	cosine transform
SIN	sine transform
P	periodogram
S	spectral density estimates

If you do not specify any frequency domain *statistics*, then the default is as follows:

```
spectra period p;
```

You can also specify the following *options* after a slash (/):

C=*coefficient*
specifies the scale coefficient for the kernel function. For more information, see the section "Kernel Option Details" on page 2742.

E=*exponent*

EXP=*exponent*

EXPON=*exponent*
specifies the exponent for the kernel function. For more information, see the section "Kernel Option Details" on page 2742.

ADJUSTMEAN=NO | YES

CENTER=NO | YES
specifies whether the series is to be adjusted by its mean prior to performing the Fourier decomposition. This adjustment sets the first periodogram ordinate to 0 rather than to $2n$ times the squared mean. This option is commonly used when the periodograms are to be plotted to prevent a large first periodogram ordinate from distorting the scale of the plot.

NO	specifies that no adjustment of the series be performed.
YES	specifies that the series be transformed by subtracting its mean.

By default, ADJUSTMEAN=NO.

ALPHA=*num*
specifies the width of a window that is drawn around the spectral density estimate in a spectral density versus frequency plot. Based on approximations proposed by Brockwell and Davis (1991), periodogram ordinates fall within this window with a confidence level of $1 - num$. The value *num* must be between 0 and 1; the default is 0.5.

DOMAIN=*domain*
specifies how the smoothing function is interpreted. You can specify the following *domain* values:

FREQUENCY	smooths the periodogram ordinates.
TIME	applies the kernel as a filter to the time series autocovariance function.

By default DOMAIN=FREQUENCY, and smoothing is applied in the same manner as weights are applied when you specify the WEIGHTS= option.

kernel
specifies the smoothing function to use to calculate a spectral density estimate as the moving average of periodogram ordinates. The kernel function is an alternative smoothing method to using the WEIGHTS= option. You can specify the following *kernel* values:

PARZEN	Parzen kernel
BARTLETT	Bartlett kernel
TUKEY	Tukey-Hanning kernel
TRUNC | TRUNCAT	truncated kernel
QS | QUADR	quadratic spectral kernel

If neither a WEIGHTS= option nor a *kernel* function is specified, the spectral density estimate is identical to the unmodified periodogram.

WEIGHTS=*numlist*
specifies the relative weights to use to compute a spectral density estimate as the moving average smoothing of periodogram ordinates. If neither a WEIGHTS= option nor a kernel function is specified, the spectral density estimate is identical to the unmodified periodogram. The following SPECTRA statement uses the WEIGHTS= option to specify equal weighting for each of the three adjacent periodogram ordinates that are centered on each spectral density estimate:

```
spectra / weights 1 1 1;
```

For information about how the weights are applied, see the section "Using Specification of Weight Constants" on page 2760.

Kernel Option Details

You can further parameterize each of the kernel functions with a kernel scale factor by using the C= and E= options. The default values of the kernel scale parameters, c and e, that are associated with each of the kernel functions together with their kernel scale factor values, M, for a series with 100 periodogram ordinates are listed in Table 38.2. The formula that is used to generate the table entries is $M = cK^e$, where K is the number of Fourier component frequencies.

Table 38.2 Default Kernel Scale Factor Parameters

Kernel	c	e	M
Bartlett	1/2	1/3	2.32
Parzen	1	1/5	2.51
Quadratic	1/2	1/5	1.26
Tukey-Hanning	2/3	1/5	1.67
Truncated	1/4	1/5	0.63

For example, to apply the truncated kernel by using default scale factor parameters in the frequency domain, you could use the following SPECTRA statement:

```
spectra / truncat;
```

For more information about the kernel function parameterization and the DOMAIN= option, see the section "Using Kernel Specifications" on page 2758.

SSA Statement

SSA < / *options* > **;**

The SSA statement requests singular spectrum analysis (SSA) of the accumulated time series. Only one SSA statement is allowed.

You can also specify the following *options* after a slash (/):

ADJUSTMEAN=NO | YES

CENTER=NO | YES

specifies whether the series should be adjusted by its mean prior to performing the singular spectrum analysis. You can specify the following values:

NO specifies that no adjustment of the series be performed.

YES specifies that the series be transformed by subtracting its mean.

By default, ADJUSTMEAN=NO.

GROUPS=(*numlist***)...(***numlist***)** | **AUTO(***number***)**

(*numlist***)...(***numlist***)** specifies the lists that categorize window lags into groups. The window lags must be separated by spaces or commas. For example, GROUPS=(1,3) (2,4) specifies that the first and third window lags form the first group and the second and fourth window lags form the second group. If you do not specify this option, the window lags are divided into two groups based on the value of the THRESHOLDPCT= option.

For example, the following SSA statement specifies three groups:

```
ssa / groups=(1 3)(2 4 5)(6);
```

The first group contains the first and third principal components; the second group contains the second, fourth, and fifth principal components; and the third group contains the sixth principal component.

By default, the first group contains the principal components whose contributions to the series sum to greater than the THRESHOLDPCT= option value of 90%, and the second group contains the remaining components.

AUTO(*number***)** specifies the maximum number of groups to be retained when the automatic grouping is used. When you specify this option , the automatic grouping is based on the weighted correlations (w-correlations). For more information, see the section "Automatic Grouping" on page 2762.

LENGTH=*number*

specifies the window length to be used in the analysis. The window length represents the maximum lag to be used in the SSA autocovariance calculations, where *number* must be greater than 1. When the SEASONALITY= option is provided or implied by the INTERVAL= option in the ID statement, the default window length is the smaller of two times the length of the seasonal cycle and one-half the length of the time series. When no seasonality value is available, the default window length is the smaller of 12 and one-half the length of the time series.

For example, the following SSA statement specifies a window length of 10:

```
ssa / length=10;
```

If the specified *number* is greater than one-half the length of the accumulated time series, the window length is reduced and a warning message is displayed in the log. If you do not specify the window length option and the INTERVAL=MONTH or SEASONALITY=12 option is specified, a window length of 24 is used.

NPERIODS=*number*

specifies the *number* of time periods to be stored in the OUTSSA= data set when you specify the TRANSPOSE=YES option. If the TRANSPOSE option is not specified, the NPERIODS= option is ignored. The NPERIODS= option specifies the number of OUTSSA= data set variables to contain the groups.

If you do not specify this option, all the periods that are specified between the START= and END= options are stored in the ID statement. If at least one of the START= or END= options is not specified, the default magnitude is the seasonality specified by the SEASONALITY= option in the PROC

TIMESERIES statement or implied by the INTERVAL= option in the ID statement. If only the START= option or both the START= and END= options are specified and the seasonality is zero, the default is NPERIODS=5. If only the END= option or neither the START= nor END= option is specified and the seasonality is zero, the default is NPERIODS=–5.

THRESHOLDPCT=*percentage*

specifies a *percentage* to be used to divide the SSA components into two groups based on the cumulative percentage of their singular values. The *percentage* must be between 0 and 100, inclusive. By default, THRESHOLDPCT=90.

For example, the following SSA statement specifies 80%:

```
ssa / THRESHOLDPCT=80;
```

The size of the second group must be at least 1, and it must be less than the window length. The *percentage* is adjusted to achieve this requirement.

For example, the following SSA statement specifies THRESHOLDPCT=0, which effectively sets the size of the second group to one less than the window length:

```
ssa / THRESHOLDPCT = 0;
```

The following SSA statement specifies 100%, which implies that the size of the last group is one:

```
ssa / THRESHOLDPCT= 100;
```

TRANSPOSE=NO | YES

specifies which values are recorded as column names in the OUTSSA= data set.

NO specifies that the specified groups be recorded as the column names. This option is useful for displaying the SSA results.

YES specifies that the time periods instead of the specified groups be recorded as the column names. The first and last time periods stored in the OUTSSA= data set correspond to the periods that are specified in the START= and END= options, respectively, in the ID statement. If only the END= option is specified in the ID statement, the last time ID value of each accumulated time series corresponds to the last time period column. If only the START= option is specified in the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option nor the END= option is specified in the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. This option is useful for analyzing the SSA results using SAS Enterprise Miner software.

By default, TRANSPOSE=NO.

TREND Statement

TREND *statistics* < / *options* > **;**

You can use a TREND statement to specify *statistics* and related *options* for trend analysis of the time-stamped transactional data. Only one TREND statement is allowed. The specified *options* affect all variables that are listed in the VAR statements.

You can specify the following trend *statistics*:

NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	range value
SUM	summation value
MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

If you do not specify any trend *statistics*, the default is as follows:

```
trend n min max mean std;
```

You can also specify the following *options* after a slash (/):

NPERIODS=*number*

specifies the number of time periods to be stored in the OUTTREND= data set when the TRANSPOSE=YES option is specified. If the TRANSPOSE option is not specified, the NPERIODS= option is ignored. The NPERIODS= option specifies the number of OUTTREND= data set variables to contain the trend statistics and is therefore limited to the maximum allowed number of SAS variables.

If you do not specify this option, all the periods that are specified between the START= and END= options in the ID statement are stored. If at least one of the START= or END= options is not specified, the default magnitude is the seasonality that is specified in the SEASONALITY= option in the PROC TIMESERIES statement or implied by the INTERVAL= option in the ID statement. If only the START= option or both the START= and END= options are specified and the seasonality is zero, the default is NPERIODS=5. If only the END= option or neither the START= nor END= option is specified and the seasonality is zero, the default is NPERIODS=–5.

TRANSPOSE=NO | YES

specifies which values are recorded as column names in the OUTTREND= data set.

NO specifies that the specified groups be recorded as the column names. This option is useful for displaying the SSA results.

YES specifies that the time periods instead of the specified groups be recorded as the column names. The first and last time periods stored in the OUTSSA= data set correspond to the periods that are specified in the START= and END= options, respectively, in the ID statement. If only the END= option is specified in the ID statement, the last time ID value of each accumulated time series corresponds to the last time period column. If only the START= option is specified in the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. If neither the START= option nor the END= option is specified in the ID statement, the first time ID value of each accumulated time series corresponds to the first time period column. This option is useful for analyzing the SSA results using SAS Enterprise Miner software.

By default, TRANSPOSE=NO.

VAR and CROSSVAR Statements

VAR *variable-list* < / *options* > **;**

CROSSVAR *variable-list* < / *options* > **;**

The VAR and CROSSVAR statements list the numeric variables in the DATA= data set whose values are to be accumulated to form the time series.

An input data set variable can be specified in only one VAR or CROSSVAR statement. You can specify any number of VAR and CROSSVAR statements. You can specify the following *options* for either the VAR or CROSSVAR statement:

ACCUMULATE=*option*

specifies how the data set observations are to be accumulated within each time period for the variables in the *variable-list*. If you do not specify the ACCUMULATE= option in the VAR or CROSSVAR statement, accumulation is determined by the ACCUMULATE= option in the ID statement. For more information, see the ACCUMULATE= option in the ID statement.

DIF=(*numlist***)**

specifies the differencing to be applied to the accumulated time series. The list of differencing orders must be separated by spaces or commas. For example, DIF=(1,3) specifies first then third order differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the DIF= option.

SDIF=(*numlist***)**
specifies the seasonal differencing to be applied to the accumulated time series. The list of seasonal differencing orders must be separated by spaces or commas. For example, SDIF=(1,3) specifies first then third order seasonal differencing. Differencing is applied after time series transformation. The TRANSFORM= option is applied before the SDIF= option.

SETMISS=*option* | *number*

SETMISSING=*option* | *number*
specifies how missing values (either actual or accumulated) are to be interpreted in the accumulated time series for variables in the *variable-list*. If the SETMISSING= option is not specified in the VAR or CROSSVAR statement, missing values are set based on the SETMISSING= option of the ID statement. For more information, see the SETMISSING= option in the ID statement.

TRANSFORM=*transformation*
specifies the time series transformation to be applied to the accumulated time series. When you specify the TRANSFORM= option, the time series must be strictly positive. You can specify the following *transformations*:

NONE	does not apply any transformation.
LOG	logarithmic transformation
SQRT	square-root transformation
LOGISTIC	logistic transformation
BOXCOX(*n*)	Box-Cox transformation with parameter *n*, where *n* is between –5 and 5

By default, TRANSFORM=NONE.

Details: TIMESERIES Procedure

The TIMESERIES procedure can be used to perform trend and seasonal analysis on transactional data. For trend analysis, various sample statistics are computed for each time period defined by the time ID variable and INTERVAL= option. For seasonal analysis, various sample statistics are computed for each season defined by the INTERVAL= or the SEASONALITY= option. For example, if the transactional data ranges from June 1990 to January 2000 and the data are to be accumulated on a monthly basis, then the trend statistics are computed for every month: June 1990, July 1990, . . . , January 2000. The seasonal statistics are computed for each season: January, February, . . . , December.

The TIMESERIES procedure can be used to form time series data from transactional data. The accumulated time series can then be analyzed using time series techniques. The data are analyzed in the following order:

1. accumulation — ACCUMULATE= option in the ID, VAR, or CROSSVAR statement
2. missing value interpretation — SETMISSING= option in the ID, VAR, or CROSSVAR statement

3. time series transformation	TRANSFORM= option in the VAR or CROSSVAR statement
4. time series differencing	DIF= and SDIF= options in the VAR or CROSSVAR statement
5. descriptive statistics	OUTSUM= option and the PRINT=DESCSTATS option
6. seasonal decomposition	DECOMP statement or the OUTDECOMP= option in the PROC TIMESERIES statement
7. correlation analysis	CORR statement or the OUTCORR= option in the PROC TIMESERIES statement
8. singular spectrum analysis	SSA statement or the OUTSSA= option in the PROC TIMESERIES statement
9. Fourier spectral analysis	SPECTRA statement or the OUTSPECTRA= option in the PROC TIMESERIES statement
10. cross-correlation analysis	CROSSCORR statement or the OUTCROSSCORR= option in the PROC TIMESERIES statement

Accumulation

If the ACCUMULATE= option in the ID, VAR, or CROSSVAR statement is specified, data set observations are accumulated within each time period. The frequency (width of each time interval) is specified by the ID statement INTERVAL= option. The ID variable contains the time ID values. Each time ID value corresponds to a specific time period. Accumulation is useful when the input data set contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series, which is used in subsequent analyses.

For example, suppose a data set contains the following observations:

```
19MAR1999    10
19MAR1999    30
11MAY1999    50
12MAY1999    20
23MAY1999    20
```

If the INTERVAL=MONTH is specified, all of the above observations fall within a three-month period of time between March 1999 and May 1999. The observations are accumulated within each time period as follows:

If the ACCUMULATE=NONE option is specified, an error is generated because the ID variable values are not equally spaced with respect to the specified frequency (MONTH).

If the ACCUMULATE=TOTAL option is specified, the resulting time series is

```
01MAR1999    40
01APR1999    .
01MAY1999    90
```

If the ACCUMULATE=AVERAGE option is specified, the resulting time series is

```
O1MAR1999    20
O1APR1999    .
O1MAY1999    30
```

If the ACCUMULATE=MINIMUM option is specified, the resulting time series is

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=MEDIAN option is specified, the resulting time series is

```
O1MAR1999    20
01APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=MAXIMUM option is specified, the resulting time series is

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=FIRST option is specified, the resulting time series is

```
O1MAR1999    10
O1APR1999    .
O1MAY1999    50
```

If the ACCUMULATE=LAST option is specified, the resulting time series is

```
O1MAR1999    30
O1APR1999    .
O1MAY1999    20
```

If the ACCUMULATE=STDDEV option is specified, the resulting time series is

```
O1MAR1999    14.14
O1APR1999    .
O1MAY1999    17.32
```

As can be seen from the preceding examples, even though the data set observations contain no missing values, the accumulated time series can have missing values.

Boundary Alignment

When the BOUNDARYALIGN= option is used to qualify the START= or END= options, additional time series values can be incorporated into the accumulation operation. For instance, if a data set contains the observations

```
01JAN1999  10
01FEB1999  10
01MAR1999  10
01APR1999  10
01MAY1999  10
01JUN1999  10
```

and the options START='01FEB1999'd, END='01APR1999'd, INTERVAL=QUARTER, and ACCUMULATE=TOTAL are specified, using the BOUNDARYALIGN= option results in the following accumulated time series:

If BOUNDARYALIGN=START is specified, the accumulated time series is

```
01JAN1999  30
01APR1999  10
```

If BOUNDARYALIGN=END is specified, the accumulated time series is

```
01JAN1999  20
01APR1999  30
```

If BOUNDARYALIGN=BOTH is specified, the accumulated time series is

```
01JAN1999  30
01APR1999  30
```

If BOUNDARYALIGN=NONE is specified, the accumulated time series is

```
01JAN1999  20
01APR1999  10
```

Missing Value Interpretation

Sometimes missing values should be interpreted as unknown values. But sometimes missing values are known, such as when missing values are created from accumulation and no observations should be interpreted as no value—that is, zero. In the former case, the SETMISSING= option can be used to interpret how missing values are treated. The SETMISSING=0 option should be used when missing observations are to be treated as no (zero) values. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is used in subsequent analyses.

Time Series Transformation

There are four transformations available for strictly positive series only. Let $y_t > 0$ be the original time series, and let w_t be the transformed series. The transformations are defined as follows:

Log is the logarithmic transformation.

$$w_t = \ln(y_t)$$

Logistic is the logistic transformation.

$$w_t = \ln(c y_t / (1 - c y_t))$$

where the scaling factor c is

$$c = (1 - 10^{-6}) 10^{-\mathrm{ceil}(\log_{10}(\max(y_t)))}$$

and $\mathrm{ceil}(x)$ is the smallest integer greater than or equal to x.

Square root is the square root transformation.

$$w_t = \sqrt{y_t}$$

Box Cox is the Box-Cox transformation.

$$w_t = \begin{cases} \frac{y_t^{\lambda} - 1}{\lambda}, & \lambda \neq 0 \\ \ln(y_t), & \lambda = 0 \end{cases}$$

More complex time series transformations can be performed by using the EXPAND procedure of SAS/ETS.

Time Series Differencing

After optionally transforming the series, the accumulated series can be simply or seasonally differenced by using the VAR and CROSSVAR statement DIF= and SDIF= options. For example, suppose y_t is a monthly time series. The following examples of the DIF= and SDIF= options demonstrate how to simply and seasonally difference the time series.

```
dif=(1) sdif=(1)
dif=(1,12)
```

Additionally, when y_t is strictly positive and the TRANSFORM=, DIF=, and SDIF= options are combined in the VAR and CROSSVAR statements, the transformation operation is performed before the differencing operations.

Descriptive Statistics

Descriptive statistics can be computed from the working series by specifying the OUTSUM= option or PRINT=DESCSTATS.

Seasonal Decomposition

Seasonal decomposition/analysis can be performed on the working series by specifying the OUTDECOMP= option, the PRINT=DECOMP option, or one of the PLOTS= options associated with decomposition in the PROC TIMESERIES statement. The DECOMP statement enables you to specify options related to decomposition. The TIMESERIES procedure uses classical decomposition. More complex seasonal decomposition/adjustment analysis can be performed by using the X11 or the X12 procedure of SAS/ETS.

The DECOMP statement MODE= option determines the mode of the seasonal adjustment decomposition to be performed. There are four modes: multiplicative (MODE=MULT), additive (MODE=ADD), pseudo-additive (MODE=PSEUDOADD), and log-additive (MODE=LOGADD) decomposition. The default is MODE=MULTORADD which specifies MODE=MULT for series that are strictly positive, MODE=PSEUDOADD for series that are nonnegative, and MODE=ADD for series that are not nonnegative.

When MODE=LOGADD is specified, the components are exponentiated to the original metric.

The DECOMP statement LAMBDA= option specifies the Hodrick-Prescott filter parameter (Hodrick and Prescott 1980). The default is LAMBDA=1600. The Hodrick-Prescott filter is used to decompose the trend-cycle component into the trend component and cycle component in an additive fashion. A smaller parameter assigns less significance to the cycle; that is, LAMBDA=0 implies no cycle component.

The notation and keywords associated with seasonal decomposition/adjustment analysis are defined in Table 38.3.

Table 38.3 Seasonal Adjustment Formulas

Component	Keyword	MODE= Option	Formula
Original series	ORIGINAL	MULT	$O_t = TC_t S_t I_t$

Table 38.3 *continued*

Component	Keyword	MODE= Option	Formula
		ADD	$O_t = TC_t + S_t + I_t$
		LOGADD	$\log(O_t) = TC_t + S_t + I_t$
		PSEUDOADD	$O_t = TC_t(S_t + I_t - 1)$
Trend-cycle component	TCC	MULT	Centered moving average of O_t
		ADD	Centered moving average of O_t
		LOGADD	Centered moving average of $\log(O_t)$
		PSEUDOADD	Centered moving average of O_t
Seasonal-irregular component	SIC	MULT	$SI_t = S_t I_t = O_t / TC_t$
		ADD	$SI_t = S_t + I_t = O_t - TC_t$
		LOGADD	$SI_t = S_t + I_t = \log(O_t) - TC_t$
		PSEUDOADD	$SI_t = S_t + I_t - 1 = O_t / TC_t$
Seasonal component	SC	MULT	Seasonal averages of SI_t
		ADD	Seasonal averages of SI_t
		LOGADD	Seasonal averages of SI_t
		PSEUDOADD	Seasonal averages of SI_t
Irregular component	IC	MULT	$I_t = SI_t / S_t$
		ADD	$I_t = SI_t - S_t$
		LOGADD	$I_t = SI_t - S_t$
		PSEUDOADD	$I_t = SI_t - S_t + 1$
Trend-cycle-seasonal component	TCS	MULT	$TCS_t = TC_t S_t = O_t / I_t$
		ADD	$TCS_t = TC_t + S_t = O_t - I_t$
		LOGADD	$TCS_t = TC_t + S_t = O_t - I_t$
		PSEUDOADD	$TCS_t = TC_t S_t$
Trend component	TC	MULT	$T_t = TC_t - C_t$
		ADD	$T_t = TC_t - C_t$
		LOGADD	$T_t = TC_t - C_t$
		PSEUDOADD	$T_t = TC_t - C_t$
Cycle component	CC	MULT	$C_t = TC_t - T_t$
		ADD	$C_t = TC_t - T_t$
		LOGADD	$C_t = TC_t - T_t$
		PSEUDOADD	$C_t = TC_t - T_t$
Seasonally adjusted series	SA	MULT	$SA_t = O_t / S_t = TC_t I_t$
		ADD	$SA_t = O_t - S_t = TC_t + I_t$
		LOGADD	$SA_t = O_t / \exp(S_t) = \exp(TC_t + I_t)$
		PSEUDOADD	$SA_t = TC_t I_t$

When s is odd the trend-cycle component is computed from the s-period centered moving average as follows:

$$TC_t = \sum_{k=-\lfloor s/2 \rfloor}^{\lfloor s/2 \rfloor} y_{t+k}/s$$

When s is even the trend-cycle component is computed from the s-period centered moving average as follows:

$$TC_t = \sum_{k=-s/2}^{s/2-1} (y_{t+k} + y_{t+1+k})/2s$$

The seasonal component is obtained by averaging the seasonal-irregular component for each season.

$$S_{k+js} = \sum_{t=k \bmod s} \frac{SI_t}{T/s}$$

where $0 \le j \le T/s$ and $1 \le k \le s$. The seasonal components are normalized to sum to one (multiplicative) or zero (additive).

Correlation Analysis

Correlation analysis can be performed on the working series by specifying the OUTCORR= option or one of the PLOTS= options that are associated with correlation. The CORR statement enables you to specify options that are related to correlation analysis.

Autocovariance Statistics

LAGS	$h \in \{0, \ldots, H\}$
N	N_h is the number of observed products at lag h, ignoring missing values
ACOV	$\hat{\gamma}(h) = \frac{1}{T} \sum_{t=h+1}^{T} (y_t - \overline{y})(y_{t-h} - \overline{y})$
ACOV	$\hat{\gamma}(h) = \frac{1}{N_h} \sum_{t=h+1}^{T} (y_t - \overline{y})(y_{t-h} - \overline{y})$ when embedded missing values are present

Autocorrelation Statistics

ACF	$\hat{\rho}(h) = \hat{\gamma}(h)/\hat{\gamma}(0)$
ACFSTD	$\mathrm{Std}(\hat{\rho}(h)) = \sqrt{\frac{1}{T}\left(1 + 2\sum_{j=1}^{h-1} \hat{\rho}(j)^2\right)}$
ACFNORM	$\mathrm{Norm}(\hat{\rho}(h)) = \hat{\rho}(h)/\mathrm{Std}(\hat{\rho}(h))$
ACFPROB	$\mathrm{Prob}(\hat{\rho}(h)) = 2\,(1 - \Phi\,(\lvert\mathrm{Norm}(\hat{\rho}(h))\rvert))$
ACFLPROB	$\mathrm{LogProb}(\hat{\rho}(h)) = -\log_{10}(\mathrm{Prob}(\hat{\rho}(h))$
ACF2STD	$\mathrm{Flag}(\hat{\rho}(h)) = \begin{cases} 1 & \hat{\rho}(h) > 2\mathrm{Std}(\hat{\rho}(h)) \\ 0 & -2\mathrm{Std}(\hat{\rho}(h)) < \hat{\rho}(h) < 2\mathrm{Std}(\hat{\rho}(h)) \\ -1 & \hat{\rho}(h) < -2\mathrm{Std}(\hat{\rho}(h)) \end{cases}$

Partial Autocorrelation Statistics

PACF	$\hat{\varphi}(h) = \Gamma_{(0,h-1)}\{\gamma_j\}_{j=1}^{h}$
PACFSTD	$\mathrm{Std}(\hat{\varphi}(h)) = 1/\sqrt{N_0}$
PCFNORM	$\mathrm{Norm}(\hat{\varphi}(h)) = \hat{\varphi}(h)/\mathrm{Std}(\hat{\varphi}(h))$
PACFPROB	$\mathrm{Prob}(\hat{\varphi}(h)) = 2\left(1 - \Phi\left(\lvert\mathrm{Norm}(\hat{\varphi}(h))\rvert\right)\right)$
PACFLPROB	$\mathrm{LogProb}(\hat{\varphi}(h)) = -\log_{10}(\mathrm{Prob}(\hat{\varphi}(h))$
PACF2STD	$\mathrm{Flag}(\hat{\varphi}(h)) = \begin{cases} 1 & \hat{\varphi}(h) > 2\mathrm{Std}(\hat{\varphi}(h)) \\ 0 & -2\mathrm{Std}(\hat{\varphi}(h)) < \hat{\varphi}(h) < 2\mathrm{Std}(\hat{\varphi}(h)) \\ -1 & \hat{\varphi}(h) < -2\mathrm{Std}(\hat{\varphi}(h)) \end{cases}$

Inverse Autocorrelation Statistics

IACF	$\hat{\theta}(h)$
IACFSTD	$\mathrm{Std}(\hat{\theta}(h)) = 1/\sqrt{N_0}$
IACFNORM	$\mathrm{Norm}(\hat{\theta}(h)) = \hat{\theta}(h)/\mathrm{Std}(\hat{\theta}(h))$
IACFPROB	$\mathrm{Prob}(\hat{\theta}(h)) = 2\left(1 - \Phi\left(\lvert\mathrm{Norm}(\hat{\theta}(h))\rvert\right)\right)$
IACFLPROB	$\mathrm{LogProb}(\hat{\theta}(h)) = -\log_{10}(\mathrm{Prob}(\hat{\theta}(h))$
IACF2STD	$\mathrm{Flag}(\hat{\theta}(h)) = \begin{cases} 1 & \hat{\theta}(h) > 2\mathrm{Std}(\hat{\theta}(h)) \\ 0 & -2\mathrm{Std}(\hat{\theta}(h)) < \hat{\theta}(h) < 2\mathrm{Std}(\hat{\theta}(h)) \\ -1 & \hat{\theta}(h) < -2\mathrm{Std}(\hat{\theta}(h)) \end{cases}$

White Noise Statistics

WN	$Q(h) = T(T+2)\sum_{j=1}^{h} \rho(j)^2/(T-j)$
WN	$Q(h) = \sum_{j=1}^{h} N_j \rho(j)^2$ when embedded missing values are present
WNPROB	$\mathrm{Prob}(Q(h)) = \chi_{\max(1,h-p)}(Q(h))$
WNLPROB	$\mathrm{LogProb}(Q(h)) = -\log_{10}(\mathrm{Prob}(Q(h))$

Cross-Correlation Analysis

Cross-correlation analysis can be performed on the working series by specifying the OUTCROSSCORR= option or one of the CROSSPLOTS= options that are associated with cross-correlation. The CROSSCORR statement enables you to specify options that are related to cross-correlation analysis.

Cross-Correlation Statistics

The cross-correlation statistics for the variable x supplied in a VAR statement and the variable y supplied in a CROSSVAR statement are as follows:

LAGS $h \in \{-H, \ldots, 0, \ldots, H\}$

N N_h is the number of observed products at lag h, ignoring missing values

CCOV $\hat{\gamma}_{x,y}(h) = \begin{cases} \frac{1}{M}\sum_{t=h+1}^{T}(x_t - \overline{x})(y_{t-h} - \overline{y}) & 0 \le h < T \\ \frac{1}{M}\sum_{t=|h|+1}^{T}(x_{t-|h|} - \overline{x})(y_t - \overline{y}) & -T < h < 0 \end{cases}$
where $M = N_0$ if ADJSCALE=DEFAULT, $M = N_h$ if ADJSCALE=UNBIASED, and $M = N_0$ if ADJSCALE=BIASED

CCOV $\hat{\gamma}_{x,y}(h) = \begin{cases} \frac{1}{M}\sum_{t=h+1}^{T}(x_t - \overline{x})(y_{t-h} - \overline{y}) & 0 \le h < T \\ \frac{1}{M}\sum_{t=|h|+1}^{T}(x_{t-|h|} - \overline{x})(y_t - \overline{y}) & -T < h < 0 \end{cases}$
when embedded missing values are present, where $M = N_h$ if ADJSCALE=DEFAULT, $M = N_h$ if ADJSCALE=UNBIASED, and $M = N_0$ if ADJSCALE=BIASED

CCF $\hat{\rho}_{x,y}(h) = \hat{\gamma}_{x,y}(h)/\sqrt{\hat{\gamma}_x(0)\hat{\gamma}_y(0)}$

CCFSTD $\mathrm{Std}(\hat{\rho}_{x,y}(h)) = 1/\sqrt{N_0}$

CCFNORM $\mathrm{Norm}(\hat{\rho}_{x,y}(h)) = \hat{\rho}_{x,y}(h)/\mathrm{Std}(\hat{\rho}_{x,y}(h))$

CCFPROB $\mathrm{Prob}(\hat{\rho}_{x,y}(h)) = 2\left(1 - \Phi\left(|\mathrm{Norm}(\hat{\rho}_{x,y}(h))|\right)\right)$

CCFLPROB $\mathrm{LogProb}(\hat{\rho}_{x,y}(h)) = -\log_{10}(\mathrm{Prob}(\hat{\rho}_{x,y}(h))$

CCF2STD $\mathrm{Flag}(\hat{\rho}_{x,y}(h)) = \begin{cases} 1 & \hat{\rho}_{x,y}(h) > 2\mathrm{Std}(\hat{\rho}_{x,y}(h)) \\ 0 & -2\mathrm{Std}(\hat{\rho}_{x,y}(h)) < \hat{\rho}_{x,y}(h) < 2\mathrm{Std}(\hat{\rho}_{x,y}(h)) \\ -1 & \hat{\rho}_{x,y}(h) < -2\mathrm{Std}(\hat{\rho}_{x,y}(h)) \end{cases}$

Spectral Density Analysis

Spectral analysis can be performed on the working series by specifying the OUTSPECTRA= option or by specifying the PLOTS=PERIODOGRAM or PLOTS=SPECTRUM option in the PROC TIMESERIES statement. PROC TIMESERIES uses the finite Fourier transform to decompose data series into a sum of sine and cosine terms of different amplitudes and wavelengths. The finite Fourier transform decomposition of the series x_t is

$$x_t = \frac{a_0}{2} + \sum_{k=1}^{K-1} f_k(a_k \cos \omega_k t + b_k \sin \omega_k t)$$

$$f_k = \begin{cases} 1/2 & \text{if } T \text{ is even and } k = K-1 \\ 1 & \text{otherwise} \end{cases}$$

where

t is the time subscript, $t = 0, 1, 2, \ldots, T-1$

x_t are the equally spaced time series data

T is the number of observations in the time series

K	is the number of frequencies in the Fourier decomposition: $K = \frac{T+2}{2}$ if T is even, $K = \frac{T+1}{2}$ if T is odd
k	is the frequency subscript, $k = 0, 1, 2, \ldots, K-1$
a_0	is the mean term: $a_0 = 2\overline{x}$
a_k	are the cosine coefficients
b_k	are the sine coefficients
ω_k	are the Fourier frequencies: $\omega_k = \frac{2\pi k}{T}$

The Fourier decomposition is performed after the ACCUMULATE=, DIF=, SDIF=, and TRANSFORM= options in the ID and VAR statements have been applied.

Functions of the Fourier coefficients a_k and b_k can be plotted against frequency or against wavelength to form *periodograms*. The amplitude periodogram I_k is defined as follows:

$$I_k = \frac{T}{2}(a_k^2 + b_k^2)$$

Since the Fourier transform is an even, periodic function of frequency that repeats every T ordinates, the periodogram is also. Values of I_k for all k therefore can be mapped to the unique values $I_k : k = 0, \ldots, K-1$ using the equations

$$\begin{aligned} I_k &= I_{-k} && \text{for all } k \\ I_k &= I_{k+nT} && \text{for } n = \pm 1, \pm 2, \pm 3, \ldots \\ I_k &= I_{T-k} && \text{for } 0 \le k \le K-1 \end{aligned}$$

The periodogram, I_k, is an estimate at the discrete frequencies ω_k of the spectral density function which characterizes the series x_t. By smoothing the periodogram an improved spectral density estimate with reduced variance and bias can be achieved at these points. Smoothing can be accomplished either through use of a spectral window smoothing function or by applying a lag window filter to the series autocovariance function.

When the SPECTRA statement's DOMAIN=FREQUENCY option is in effect spectral density estimates are computed by smoothing the periodogram ordinates using the equation

$$S_k(M) = \sum_{\tau=K-T}^{K-1} \mathrm{w}\left(\frac{\tau}{M}\right) I_{k+\tau}$$

where $\mathrm{w}(\theta)$ is the spectral window function whose form is specified by either the KERNEL= option or the WEIGHTS option. M is the kernel scale parameter which acts as a frequency scaling factor in the spectral window smoothing function. Values of $I_{k+\tau}$ that fall outside of $0 \le k + \tau \le K - 1$ are mapped to values inside this range by the equations presented previously.

When the DOMAIN=TIME option is specified, spectral density values are estimated by applying a lag window filter, $\lambda(h, M)$, to the series autocovariance function. The spectral density estimate then can be computed from the filtered autocovariance function using the equation

$$S_k(M) = \sum_{h=-(T-1)}^{T-1} \lambda(h, M)\hat{\gamma}(h) \cos h\omega_k$$

In this case the kernel scale parameter, M, serves as a scale factor for the lag length, h, in the time domain. In the lag window formulation the spectral density estimate is a consistent estimator as $T, M \rightarrow \infty$ under the conditions $\lambda(h, M) = 0$ for $|h| > M$, and $\lim_{T\rightarrow\infty} M/T = 0$. These conditions lead to the following parameterization of M provided by the SPECTRA statement,

$$M = cK^e$$

where the values $c > 0$ and $0 < e < 1$ satisfy the consistency conditions. To specify the kernel scale parameter explicitly, set $c =$ to the desired scale factor and $e = 0$.

For uniformity and computational efficiency, all spectral density estimates are calculated using a spectral window weighting function, $\mathrm{w}(\theta)$, applied to the periodogram ordinates. In the case where the DOMAIN=TIME option is specified, the effective spectral window weighting function is computed by the equation

$$\mathrm{w}_{\mathrm{TIME}}(\theta) = \sum_{h=-(T-1)}^{T-1} \lambda(h, M) \cos h\theta$$

Because the kernel scale parameter, M, serves as a lag scale factor in the time domain and bandwidth scale factor in the frequency domain, the impact of M on spectral density estimates depends on the value of the DOMAIN= option. When DOMAIN=FREQUENCY, increasing values of M decrease variance and increase bias in the spectral density estimates; when DOMAIN=TIME, increasing values of M increase variance and decrease bias.

Using Kernel Specifications

You can specify one of ten different kernel smoothing functions in the SPECTRA statement. Five smoothing functions are available as KERNEL= options, and five complementary smoothing functions, which correspond to lag window filters, are available when the KERNEL= option is used in conjunction with the DOMAIN=TIME option.

For example, a Parzen kernel with a support of 11 periodogram ordinates in the frequency domain can be specified using the kernel option:

```
spectra / parzen c=5 expon=0;
```

The TIMESERIES procedure supports the following spectral window kernel functions in the frequency domain where $x = \tau/M$:

BARTLETT: Bartlett kernel

$$\mathrm{w}(x) = \begin{cases} 1 - |x| & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

PARZEN: Parzen kernel

$$\mathrm{w}(x) = \begin{cases} 1 - 6|x|^2 + 6|x|^3 & 0 \leq |x| \leq \frac{1}{2} \\ 2(1 - |x|)^3 & \frac{1}{2} \leq |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

QS: quadratic spectral kernel

$$\mathrm{w}(x) = \frac{3}{(2\pi x)^2}\left(\frac{\sin 2\pi x}{2\pi x} - \cos 2\pi x\right)$$

TUKEY: Tukey-Hanning kernel

$$\mathrm{w}(x) = \begin{cases} (1+\cos(\pi x))/2 & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

TRUNCAT: truncated kernel

$$\mathrm{w}(x) = \begin{cases} 1 & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

When the DOMAIN=TIME option is specified the five kernel functions above are interpreted as lag window filters on the autocovariance function. The lag window kernel functions correspond to the following spectral window smoothing functions where $\theta = 2\pi\tau/T$:

BARTLETT: Bartlett equivalent lag window filter

$$\mathrm{w}(\theta) = \frac{1}{2\pi M}\left(\frac{\sin(M\theta/2)}{\sin(\theta/2)}\right)^2$$

PARZEN: Parzen equivalent lag window filter

$$\mathrm{w}(\theta) = \frac{6}{\pi M^3}\left(\frac{\sin(M\theta/4)}{\sin(\theta/2)}\right)^4\left(1 - \frac{2}{3}\sin^2(\theta/2)\right)$$

QS: quadratic spectral equivalent lag window filter

$$\mathrm{w}(\theta) = \begin{cases} \frac{3M}{4\pi}(1-(M\theta/\pi)^2) & |\theta| \leq \pi/M \\ 0 & |\theta| > \pi/M \end{cases}$$

TUKEY: Tukey-Hanning equivalent lag window filter

$$\begin{aligned} \mathrm{w}(\theta) &= \frac{1}{4}D_M(\theta-\pi/M) + \frac{1}{2}D_M(\theta) + \frac{1}{4}D_M(\theta+\pi/M) \\ D_M(\theta) &= \frac{1}{2\pi}\frac{\sin[(M+1/2)\theta]}{\sin(\theta/2)} \end{aligned}$$

TRUNC: truncated equivalent lag window filter

$$\mathrm{w}(\theta) = D_M(\theta)$$

Using Specification of Weight Constants

Any number of weighting constants can be specified. The constants are interpreted symmetrically about the middle weight. The middle constant (or the constant to the right of the middle if an even number of weight constants is specified) is the relative weight of the current periodogram ordinate. The constant immediately following the middle one is the relative weight of the next periodogram ordinate, and so on. The actual weights used in the smoothing process are the weights specified in the WEIGHTS option scaled so that they sum to 1.

The moving average calculation reflects at each end of the periodogram to accommodate the periodicity of the periodogram function.

For example, a simple triangular weighting can be specified using the following WEIGHTS option:

```
spectra / weights 1 2 3 2 1;
```

Computational Method

If the number of observations, T, factors into prime integers that are less than or equal to 23, and the product of the square-free factors of T is less than 210, then the procedure uses the fast Fourier transform developed by Cooley and Tukey (1965) and implemented by Singleton (1969). If T cannot be factored in this way, then the procedure uses a Chirp-Z algorithm similar to that proposed by Monro and Branch (1977).

Missing Values

Missing values are replaced with an estimate of the mean to perform spectral analyses. This treatment of a series with missing values is consistent with the approach used by Priestley (1981).

Singular Spectrum Analysis

Given a time series, y_t, for $t = 1, \ldots, T$, and a window length, $2 \leq L < T/2$, singular spectrum analysis Golyandina, Nekrutkin, and Zhigljavsky (2001) decompose the time series into spectral groupings using the following steps:

Embedding Step

Using the time series, form a $K \times L$ trajectory matrix, $\mathbf{X}$, with elements

$$\mathbf{X} = \{x_{k,l}\}_{k=1,l=1}^{K,L}$$

such that $x_{k,l} = y_{k-l+1}$ for $k = 1, \ldots, K$ and $l = 1, \ldots, L$ and where $K = T - L + 1$. By definition $L \leq K < T$, because $2 \leq L < T/2$.

Decomposition Step

Using the trajectory matrix, $\mathbf{X}$, apply singular value decomposition to the trajectory matrix

$$\mathbf{X} = \mathbf{UQV}$$

where $\mathbf{U}$ represents the $K \times K$ matrix that contains the left-hand-side (LHS) eigenvectors, where $\mathbf{Q}$ represents the diagonal $K \times L$ matrix that contains the singular values, and where $\mathbf{V}$ represents the $L \times L$ matrix that contains the right-hand-side (RHS) eigenvectors.

Therefore,

$$\mathbf{X} = \sum_{l=1}^{L} \mathbf{X}^{(l)} = \sum_{l=1}^{L} \mathbf{u}_l q_l \mathbf{v}_l^T$$

where $\mathbf{X}^{(l)}$ represents the $K \times L$ principal component matrix, $\mathbf{u}_l$ represents the $K \times 1$ left-hand-side (LHS) eigenvector, q_l represents the singular value, and $\mathbf{v}_l$ represents the $L \times 1$ right-hand-side (RHS) eigenvector associated with the lth window index.

Grouping Step

For each group index, $m = 1, \ldots, M$, define a group of window indices $I_m \subset \{1, \ldots, L\}$. Let

$$\mathbf{X}_{I_m} = \sum_{l \in I_m} \mathbf{X}^{(l)} = \sum_{l \in I_m} \mathbf{u}_l q_l \mathbf{v}_l^T$$

represent the grouped trajectory matrix for group I_m. If groupings represent a spectral partition,

$$\bigcup_{m=1}^{M} I_m = \{1, \ldots, L\} \qquad \text{and} \qquad I_m \cap I_n = \emptyset \quad \text{for} \quad m \neq n$$

then according to the singular value decomposition theory,

$$\mathbf{X} = \sum_{m=1}^{M} \mathbf{X}_{I_m}$$

Averaging Step

For each group index, $m = 1, \ldots, M$, compute the diagonal average of $\mathbf{X}_{I_m}$,

$$\tilde{x}_t^{(m)} = \frac{1}{n_t} \sum_{l=s_t}^{e_t} x_{t-l+1,l}^{(m)}$$

where

$$\begin{array}{llll} s_t = 1, & e_t = t, & n_t = t & \text{for} \quad 1 \leq t < L \\ s_t = 1, & e_t = L, & n_t = L & \text{for} \quad L \leq t \leq T - L + 1 \\ s_t = t - T + L, & e_t = L, & n_t = T - t + 1 & \text{for} \quad T - L + 1 < t \leq T \end{array}$$

If the groupings represent a spectral partition, then by definition

$$y_t = \sum_{m=1}^{M} \tilde{x}_t^{(m)}$$

Hence, singular spectrum analysis additively decomposes the original time series, y_t, into m component series $\tilde{x}_t^{(m)}$ for $m = 1, \ldots, M$.

Computing W-Correlations

An important step in SSA is specifying the groups, $I_m \subset \{1, \ldots, L\}$ for $m = 1, \ldots, M$. In order to automate the SSA grouping step, the weighted correlations (w-correlations) are computed. $\rho_{i,j}^{(w)} = \frac{\left(\tilde{x}_t^{(i)}, \tilde{x}_t^{(j)}\right)_w}{||\tilde{x}_t^{(i)}, \tilde{x}_t^{(i)}||_w ||\tilde{x}_t^{(j)}, \tilde{x}_t^{(j)}||_w}$, where $\left(\tilde{x}_t^{(i)}, \tilde{x}_t^{(j)}\right)_w = \sum_{t-1}^{T} w_t \tilde{x}_t^{(i)} \tilde{x}_t^{(j)}$ and $w_t = \min(t, L, T-t)$.

Specifying the Window Length

You can explicitly specify the maximum window length, $2 \leq L \leq 1000$, by using the LENGTH= option, or you can implicitly specify the window length by using the INTERVAL= option in the ID statement or the SEASONALITY= option in the PROC TIMESERIES statement. Either way, the window length is reduced based on the accumulated time series length, T, to enforce the requirement that $2 \leq L \leq T/2$.

Specifying the Groups

The GROUPS=(*numlist*)...(*numlist*) option explicitly specifies the composition and number of groups, $I_m \subset \{1, \ldots, L\}$, or you can use the THRESHOLDPCT= option in the SSA statement to implicitly specify the grouping. The THRESHOLDPCT= option is useful for removing noise or less dominant patterns from the accumulated time series.

Let $0 < \alpha < 1$ be the cumulative percentage singular value that is specified in the THRESHOLDPCT= option. Then the last group, $I_M = \{l_\alpha, \ldots, L\}$, is determined by the smallest value such that

$$\left(\sum_{l=1}^{l_\alpha - 1} q_l \Big/ \sum_{l=1}^{L} q_l \right) \geq \alpha \qquad 1 < l_\alpha \leq L$$

Using this rule, the last group, I_M, describes the least dominant patterns in the time series, and the size of the last group is at least one and is less than the window length, $L \geq 2$.

The magnitudes of the principal components that are plotted using the PLOT=SSA option and selected by the THRESHOLDPCT= option are based on the singular values that appear on the diagonal of $\mathbf{Q}$. Alternatively, each principal component's contribution to variation in the series can be quantified by using the squares of the singular values. The relative contributions of the principal components to variation in the series are included in the printed tabular output that is produced by the PRINT=SSA option.

Automatic Grouping

Besides specifying the groups explicitly, you can also use the GROUPS=AUTO(*number*) option to perform the automatic grouping. In this SSA automatic grouping, the following steps are performed:

1. Initially assume the maximal number of groups: $M = L$.
2. Diagonally average the groups as described previously: $\tilde{x}_t^{(m)}$ for $m = 1, \ldots, L$.
3. Compute the weighted correlations (w-correlations) between groups: $\rho_{i,j}^{(m)}$.
4. Choose the groups based on the w-correlations for which the absolute values are close to one. Or more formally, $I_m \subset \{1, \ldots, L\}$ such that $|\rho_{i,j}^{(m)}| \approx 1$ whenever $i, j \in I_m$.

Data Set Output

The TIMESERIES procedure can create the OUT=, OUTCORR=, OUTCROSSCORR=, OUTDECOMP=, OUTFREQ=, OUTSEASON=, OUTSPECTRA=, OUTSSA=, OUTSUM=, and OUTTREND= data sets. In general, these data sets contain the variables listed in the BY statement. If an analysis step that is related to an output data step fails, the values of this step are not recorded or are set to missing in the related output data set and appropriate error and/or warning messages are recorded in the log.

OUT= Data Set

The OUT= data set contains the variables specified in the BY, ID, VAR, and CROSSVAR statements. If the ID statement is specified, the ID variable values are aligned and extended based on the ALIGN= and INTERVAL= options. The values of the variables specified in the VAR and CROSSVAR statements are accumulated based on the ACCUMULATE= option, and missing values are interpreted based on the SETMISSING= option.

OUTCORR= Data Set

The OUTCORR= data set contains the variables specified in the BY statement as well as the variables in the following list. The OUTCORR= data set records the correlations for each variable specified in a VAR statement (not the CROSSVAR statement).

When the CORR statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to correlation statistics specified in the CORR statement options and the variable *values* are related to the NLAG= or LAGS= option.

NAME	variable name
LAG	time lag
N	number of variance products
ACOV	autocovariances
ACF	autocorrelations
ACFSTD	autocorrelation standard errors
ACF2STD	an indicator of whether autocorrelations are less than (–1), greater than (1), or within (0) two standard errors of zero
ACFNORM	normalized autocorrelations
ACFPROB	autocorrelation probabilities
ACFLPROB	autocorrelation log probabilities
PACF	partial autocorrelations
PACFSTD	partial autocorrelation standard errors
PACF2STD	an indicator of whether partial autocorrelations are less than (–1), greater than (1), or within (0) two standard errors of zero

PACFNORM	partial normalized autocorrelations
PACFPROB	partial autocorrelation probabilities
PACFLPROB	partial autocorrelation log probabilities
IACF	inverse autocorrelations
IACFSTD	an indicator of whether inverse autocorrelations are less than (–1), greater than (1), or within (0) two standard errors of zero
IACF2STD	two standard errors beyond inverse autocorrelation
IACFNORM	normalized inverse autocorrelations
IACFPROB	inverse autocorrelation probabilities
IACFLPROB	inverse autocorrelation log probabilities
WN	white noise test statistics
WNPROB	white noise test probabilities
WNLPROB	white noise test log probabilities

The preceding correlation statistics are computed for each specified time lag.

When the CORR statement TRANSPOSE=YES option is specified, the variable *values* are related to correlation statistics specified in the CORR statement and the variable *names* are related to the NLAG= or LAGS= option.

NAME	variable name
STAT	correlation statistic name
LABEL	correlation statistic label
LAG*h*	correlation statistics for lag *h*

OUTCROSSCORR= Data Set

The OUTCROSSCORR= data set contains the variables specified in the BY statement as well as the variables in the following list. The OUTCROSSCORR= data set records the cross-correlations for each variable specified in a VAR and the CROSSVAR statements.

When the CROSSCORR statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to cross-correlation statistics specified in the CROSSCORR statement options and the variable *values* are related to the NLAG= or LAGS= option.

NAME	variable name
CROSS	cross variable name
LAG	time lag
N	number of variance products
CCOV	cross-covariances
CCF	cross-correlations

CCFSTD	cross-correlation standard errors
CCF2STD	an indicator of whether cross-correlations are less than (–1), greater than (1), or within (0) two standard errors of zero
CCFNORM	normalized cross-correlations
CCFPROB	cross-correlation probabilities
CCFLPROB	cross-correlation log probabilities

The preceding cross-correlation statistics are computed for each specified time lag.

When the CROSSCORR statement TRANSPOSE=YES option is specified, the variable *values* are related to cross-correlation statistics specified in the CROSSCORR statement and the variable *names* are related to the NLAG= or LAGS= option.

NAME	variable name
CROSS	cross variable name
STAT	cross-correlation statistic name
LABEL	cross-correlation statistic label
LAG*h*	cross-correlation statistics for lag *h*

OUTDECOMP= Data Set

The OUTDECOMP= data set contains the variables specified in the BY statement as well as the variables in the following list. The OUTDECOMP= data set records the seasonal decomposition/adjustments for each variable specified in a VAR statement (not the CROSSVAR statement).

When the DECOMP statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to decomposition/adjustments specified in the DECOMP statement and the variable *values* are related to the ID statement INTERVAL= option and the PROC TIMESERIES statement SEASONALITY= option.

NAME	variable name
MODE	mode of decomposition
TIMEID	time ID values
SEASON	seasonal index
ORIGINAL	original series values
TCC	trend-cycle component
SIC	seasonal-irregular component
SC	seasonal component
SCSTD	seasonal component standard errors
TCS	trend-cycle-seasonal component
IC	irregular component

SA	seasonally adjusted series
PCSA	percent change seasonally adjusted series
TC	trend component
CC	cycle component

The preceding decomposition components are computed for each time period.

When the DECOMP statement TRANSPOSE=YES option is specified, the variable *values* are related to decomposition/adjustments specified in the DECOMP statement and the variable *names* are related to the ID statement INTERVAL= option, the PROC TIMESERIES statement SEASONALITY= option, and the DECOMP statement NPERIODS= option.

NAME	variable name
MODE	mode of decomposition name
COMP	decomposition component name
LABEL	decomposition component label
PERIOD*t*	decomposition component value for time period *t*

OUTFREQ= Data Set

The OUTFREQ= data set contains the variables specified in the BY statement as well as the variables in the following list. The OUTFREQ= data set records the counts of the discrete values of the time series for each variable specified in a VAR statement (not the CROSSVAR statement).

NAME	variable name
VALUES	distinct series values
COUNTS	counts of the discrete values
PERCENT	percentage of the total counts

OUTPROCINFO= Data Set

The OUTPROCINFO= data set contains information about the run of the TIMESERIES procedure. The following variables are present:

SOURCE	set to the name of the procedure, in this case TIMESERIES
NAME	name of the item being reported
LABEL	descriptive label for the item in _NAME_
STAGE	set to the current stage of the procedure; for TIMESERIES this is set to ALL
VALUE	value of the item specified in _NAME_

OUTSEASON= Data Set

The OUTSEASON= data set contains the variables specified in the BY statement as well as the variables in the following list. The OUTSEASON= data set records the seasonal statistics for each variable specified in a VAR statement (not the CROSSVAR statement).

When the SEASON statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to seasonal statistics specified in the SEASON statement and the variable *values* are related to the ID statement INTERVAL= option or the PROC TIMESERIES statement SEASONALITY= option.

NAME	variable name
TIMEID	time ID values
SEASON	seasonal index
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	range value
SUM	summation value
MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

The preceding statistics are computed for each season.

When the SEASON statement TRANSPOSE=YES option is specified, the variable *values* are related to seasonal statistics specified in the SEASON statement and the variable *names* are related to the ID statement INTERVAL= option or the PROC TIMESERIES statement SEASONALITY= option.

NAME	variable name
STAT	season statistic name
LABEL	season statistic name
SEASON*s*	season statistic value for season *s*

OUTSPECTRA= Data Set

The OUTSPECTRA= data set contains the variables that are specified in the BY statement in addition to the variables in the following list. The OUTSPECTRA= data set records the frequency domain analysis for each variable specified in a VAR statement (not the CROSSVAR statement).

The following variable names are related to correlation statistics specified in the SPECTRA statement options:

NAME	variable name
FREQ	frequency in radians from 0 to π
PERIOD	period or wavelength
COS	cosine transform
SIN	sine transform
P	periodogram
S	spectral density estimates

OUTSSA= Data Set

The OUTSSA= data set contains the variables that are specified in the BY statement in addition to the variables in the following list. The OUTSSA= data set records the singular spectrum analysis (SSA) for each variable specified in a VAR statement (not the CROSSVAR statement).

When the SSA statement TRANSPOSE=NO option is omitted or specified explicitly, the variable *names* are related to singular spectrum analysis specified in the SSA statement, and the variable *values* are related to the INTERVAL= option in the ID statement and the SEASONALITY= option in the PROC TIMESERIES statement.

NAME	variable name
TIMEID	time ID values
CYCLE	cycle index
SEASON	seasonal index
ORIGINAL	original series values
GROUP*i*	SSA result groups

The _GROUP*i*_ decomposition components are computed for each time period.

When the SSA statement TRANSPOSE=YES option is specified, the variable *values* are related to singular spectrum analysis specified in the SSA statement, and the variable *names* are related to the INTERVAL= option in the ID statement, the SEASONALITY= option in the PROC TIMESERIES statement, or the NPERIODS= option in the SSA statement. The following variables are written to a transposed OUTSSA= data set:

NAME	variable name
GROUP	group number
PERIOD*t*	SSA group value for time period *t*

OUTSUM= Data Set

The OUTSUM= data set contains the variables specified in the BY statement as well as the variables in the following list. The OUTSUM= data set records the descriptive statistics for each variable specified in a VAR statement (not the CROSSVAR statement).

Variables related to descriptive statistics are based on the ACCUMULATE= and SETMISSING= options in the ID and VAR statements:

NAME	variable name
STATUS	status flag that indicates whether the requested analyses were successful
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
START	the starting date of the time series
END	the ending date of the time series
STARTOBS	the beginning observation of the time series
ENDOBS	the ending observation of the time series
MINIMUM	minimum value
MAXIMUM	maximum value
AVG	average value
STDDEV	standard deviation
MEDIAN	median value

The OUTSUM= data set contains the descriptive statistics of the (accumulated) time series.

OUTTREND= Data Set

The OUTTREND= data set contains the variables specified in the BY statement as well as the variables in the following list. The OUTTREND= data set records the trend statistics for each variable specified in a VAR statement (not the CROSSVAR statement).

When the TREND statement TRANSPOSE=NO option is omitted or explicitly specified, the variable *names* are related to trend statistics specified in the TREND statement and the variable *values* are related to the INTERVAL= option in the ID statement or the SEASONALITY= option in the PROC TIMESERIES statement.

NAME	variable name
TIMEID	time ID values
SEASON	seasonal index
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
RANGE	range value
SUM	summation value
MEAN	mean value
STDDEV	standard deviation
CSS	corrected sum of squares
USS	uncorrected sum of squares
MEDIAN	median value

The preceding statistics are computed for each time period.

When the TREND statement TRANSPOSE=YES option is specified, the variable *values* related to trend statistics specified in the TREND statement and the variable *names* are related to the INTERVAL= option in the ID statement, the SEASONALITY= option in the PROC TIMESERIES statement, or the NPERIODS= option in the TREND statement. The following variables are written to the OUTTREND= data set:

NAME	variable name
STAT	trend statistic name
LABEL	trend statistic name
PERIOD*t*	trend statistic value for time period *t*

STATUS Variable Values

The _STATUS_ variable that appears in the OUTSUM= data set contains a code that specifies whether the analysis has been successful or not. The _STATUS_ variable can take the following values:

0	success
1000	transactional trend statistics failure
2000	transactional seasonal statistics failure
3000	accumulation failure
4000	missing value interpretation failure
6000	series is all missing
7000	transformation failure
8000	differencing failure
9000	unable to compute descriptive statistics
10000	seasonal decomposition failure
11000	correlation analysis failure
15000	singular spectrum analysis failure
16000	spectral analysis failure

Printed Output

The TIMESERIES procedure optionally produces printed output by using the Output Delivery System (ODS). By default, the procedure produces no printed output. All output is controlled by the PRINT= and PRINTDETAILS options associated with the PROC TIMESERIES statement. In general, if an analysis step related to printed output fails, the values of this step are not printed and appropriate error or warning messages or both are recorded in the log. The printed output is similar to the output data set, and these similarities are described as follows.

PRINT=COUNTS	prints the discrete distribution analysis.
PRINT=DECOMP	prints the seasonal decomposition similar to the OUTDECOMP= data set.
PRINT=DESCSTATS	prints a table of descriptive statistics for each variable.
PRINT=SEASONS	prints the seasonal statistics similar to the OUTSEASON= data set.
PRINT=SSA	prints the singular spectrum analysis similar to the OUTSSA= data set.
PRINT=SUMMARY	prints the summary statistics similar to the OUTSUM= data set.
PRINT=TRENDS	prints the trend statistics similar to the OUTTREND= data set.
PRINTDETAILS	prints each table with greater detail.

If the PRINT=SEASONS and PRINTDETAILS options are both specified, all seasonal statistics are printed.

ODS Table Names

Table 38.4 relates the PRINT= options to ODS tables.

Table 38.4 ODS Tables Produced in PROC TIMESERIES

ODS Table Name	Description	Statement	Option
CountStatistics	Sample count statistics	PRINT	COUNTS
DistSelection	Discrete distribution selection	PRINT	COUNTS
DistParmEst	Discrete distribution parameter estimates	PRINT	COUNTS
DistEst	Discrete distribution estimates	PRINT	COUNTS
SeasonalDecomposition	Seasonal decomposition	PRINT	DECOMP
DescStats	Descriptive statistics	PRINT	DESCSTATS
GlobalStatistics	Global statistics	PRINT	SEASONS
SeasonStatistics	Season statistics	PRINT	SEASONS
StatisticsSummary	Statistics summary	PRINT	SUMMARY
TrendStatistics	Trend statistics	PRINT	TRENDS
GlobalStatistics	Global statistics	PRINT	TRENDS
SSASingularValues	SSA singular values	PRINT	SSA
SSAResults	SSA results	PRINT	SSA
SSAGroups	SSA groups	PRINT	SSA

The tables are related to a single series within a BY group.

ODS Graphics Names

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

This section describes the graphical output produced by the TIMESERIES procedure. PROC TIMESERIES assigns a name to each graph it creates. These names are listed in Table 38.5.

Table 38.5 ODS Graphics Produced by PROC TIMESERIES

ODS Graph Name	Plot Description	Statement	Option
ACFPlot	Autocorrelation function	PLOTS	ACF
ACFNORMPlot	Normalized autocorrelation function	PLOTS	ACF

Table 38.5 *continued*

ODS Graph Name	Plot Description	Statement	Option
CCFNORMPlot	Normalized cross-correlation function	CROSSPLOTS	CCF
CCFPlot	Cross-correlation function	CROSSPLOTS	CCF
ChiSqProbPlot	Discrete distribution evaluation	COUNTPLOTS	CHISQPROB
ChiSqLogProbPlot	Discrete distribution evaluation	COUNTPLOTS	CHISQPROB
CorrelationPlots	Correlation graphics panel	PLOTS	CORR
CrossSeriesPlot	Cross series plot	CROSSPLOTS	SERIES
CycleComponentPlot	Cycle component	PLOTS	CC
CyclePlot	Seasonal cycles plot	PLOTS	CYCLES
DecompositionPlots	Decomposition graphics panel	PLOTS	DECOMP
DiscreteDistPlot	Discrete distribution	COUNTPLOTS	DISTRIBUTION
ZeroModDiscreteDistPlot	Zero-modified discrete distribution	COUNTPLOTS	DISTRIBUTION
FreqDistPlot	Frequency distribution	COUNTPLOTS	COUNTS
FreqIndexDistPlot	Frequency index distribution	COUNTPLOTS	COUNTS
FreqValueByIndexPlot	Frequency values by index	COUNTPLOTS	COUNTS
IACFPlot	Inverse autocorrelation function	PLOTS	IACF
IACFNORMPlot	Normalized inverse autocorrelation function	PLOTS	IACF
IrregularComponentPlot	Irregular component	PLOTS	IC
PACFPlot	Partial autocorrelation function	PLOTS	PACF
PACFNORMPlot	Standardized partial autocorrelation function	PLOTS	PACF
PercentChangeAdjustedPlot	Percent-change seasonally adjusted	PLOTS	PCSA
Periodogram	Periodogram versus period	PLOTS	PERIODOGRAM
ResidualPlot	Residual time series plot	PLOTS	RESIDUAL
SeasonallyAdjustedPlot	Seasonally adjusted	PLOTS	SA
SeasonalComponentPlot	Seasonal component	PLOTS	SC
SeasonalIrregularComponentPlot	Seasonal-irregular component	PLOTS	SIC
SeriesHistogram	Histogram of series values	PLOTS	HISTOGRAM
SeriesPlot	Time series plot	PLOTS	SERIES
SpectralDensityPlot	Spectral density versus period	PLOTS	SPECTRUM

WhiteNoiseProbabilityPlot	White noise probability	PLOTS	WN

Examples: TIMESERIES Procedure

Example 38.1: Accumulating Transactional Data into Time Series Data

This example illustrates using the TIMESERIES procedure to accumulate time-stamped transactional data that has been recorded at no particular frequency into time series data at a specific frequency. After the time series is created, the various SAS/ETS procedures related to time series analysis, seasonal adjustment/decomposition, modeling, and forecasting can be used to further analyze the time series data.

Suppose that the input data set WORK.RETAIL contains the variables STORE and TIMESTAMP and numerous other numeric transaction variables. The BY variable STORE contains values that break up the transactions into groups (BY groups). The time ID variable TIMESTAMP contains SAS date values recorded at no particular frequency. The other data set variables contain the numeric transaction values to be analyzed. It is further assumed that the input data set is sorted by the variables STORE and TIMESTAMP. The following statements form monthly time series from the transactional data based on the median value (ACCUMULATE=MEDIAN) of the transactions recorded with each time period. Also, the accumulated time series values for time periods with no transactions are set to zero instead of to missing (SETMISS=0) and only transactions recorded between the first day of 1998 (START='01JAN1998'D) and last day of 2000 (END='31JAN2000'D) are considered and, if needed, extended to include this range.

```
proc timeseries data=retail out=mseries;
   by store;
   id timestamp interval=month
                accumulate=median
                setmiss=0
                start='01jan1998'd
                end  ='31dec2000'd;
   var item1-item8;
run;
```

The monthly time series data are stored in the data set WORK.MSERIES. Each BY group associated with the BY variable STORE contains an observation for each of the 36 months associated with the years 1998,

1999, and 2000. Each observation contains the variables STORE and TIMESTAMP and each of the analysis variables in the input data set.

After each set of transactions has been accumulated to form corresponding time series, accumulated time series can be analyzed using various time series analysis techniques. For example, exponentially weighted moving averages can be used to smooth each series. The following statements use the EXPAND procedure to smooth the analysis variable named STOREITEM:

```
proc expand data=mseries out=smoothed from=month;
   by store;
   id date;
   convert storeitem=smooth / transform=(ewma 0.1);
run;
```

The smoothed series are stored in the data set WORK.SMOOTHED. The variable SMOOTH contains the smoothed series.

If the time ID variable TIMESTAMP contains SAS datetime values instead of SAS date values, the INTERVAL=, START=, and END= options must be changed accordingly and the following statements could be used:

```
proc timeseries data=retail out=tseries;
   by store;
   id timestamp interval=dtmonth
                accumulate=median
                setmiss=0
                start='01jan1998:00:00:00'dt
                end  ='31dec2000:00:00:00'dt;
   var _numeric_;
run;
```

The monthly time series data are stored in the data WORK.TSERIES, and the time ID values use a SAS datetime representation.

Example 38.2: Trend and Seasonal Analysis

This example illustrates using the TIMESERIES procedure for trend and seasonal analysis of time-stamped transactional data.

Suppose that the data set Sashelp.Air contains two variables: DATE and AIR. The variable DATE contains sorted SAS date values recorded at no particular frequency. The variable AIR contains the transaction values to be analyzed.

The following statements accumulate the transactional data on an average basis to form a quarterly time series and perform trend and seasonal analysis on the transactions:

```
proc timeseries data=sashelp.air
                out=series
                outtrend=trend
                outseason=season print=seasons;
   id date interval=qtr accumulate=avg;
   var air;
run;
```

The time series is stored in the data set WORK.SERIES, the trend statistics are stored in the data set WORK.TREND, and the seasonal statistics are stored in the data set WORK.SEASON. Additionally, the seasonal statistics are printed (PRINT=SEASONS) and the results of the seasonal analysis are shown in Output 38.2.1.

Output 38.2.1 Seasonal Statistics Table

The TIMESERIES Procedure

Season Statistics for Variable AIR

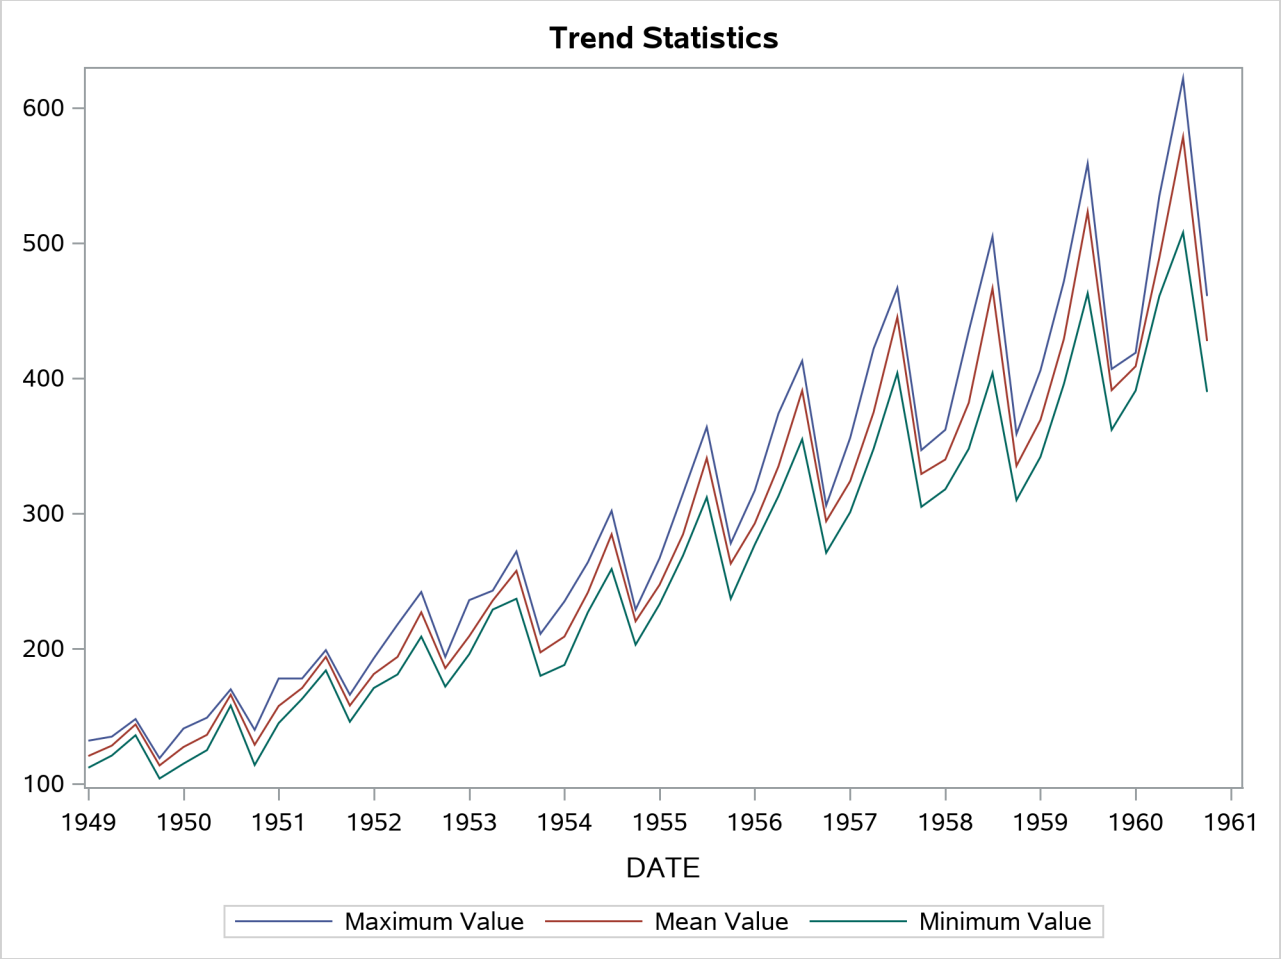
Season Index	N	Minimum	Maximum	Sum	Mean	Standard Deviation
1	36	112.0000	419.0000	8963.00	248.9722	95.65189
2	36	121.0000	535.0000	10207.00	283.5278	117.61839
3	36	136.0000	622.0000	12058.00	334.9444	143.97935
4	36	104.0000	461.0000	9135.00	253.7500	101.34732

Using the trend statistics stored in the WORK.TREND data set, the following statements plot various trend statistics associated with each time period over time:

```
title1 "Trend Statistics";
proc sgplot data=trend;
   series x=date y=max  / lineattrs=(pattern=solid);
   series x=date y=mean / lineattrs=(pattern=solid);
   series x=date y=min  / lineattrs=(pattern=solid);
   yaxis display=(nolabel);
   format date year4.;
run;
```

The results of this trend analysis are shown in Output 38.2.2.

Output 38.2.2 Trend Statistics Plot

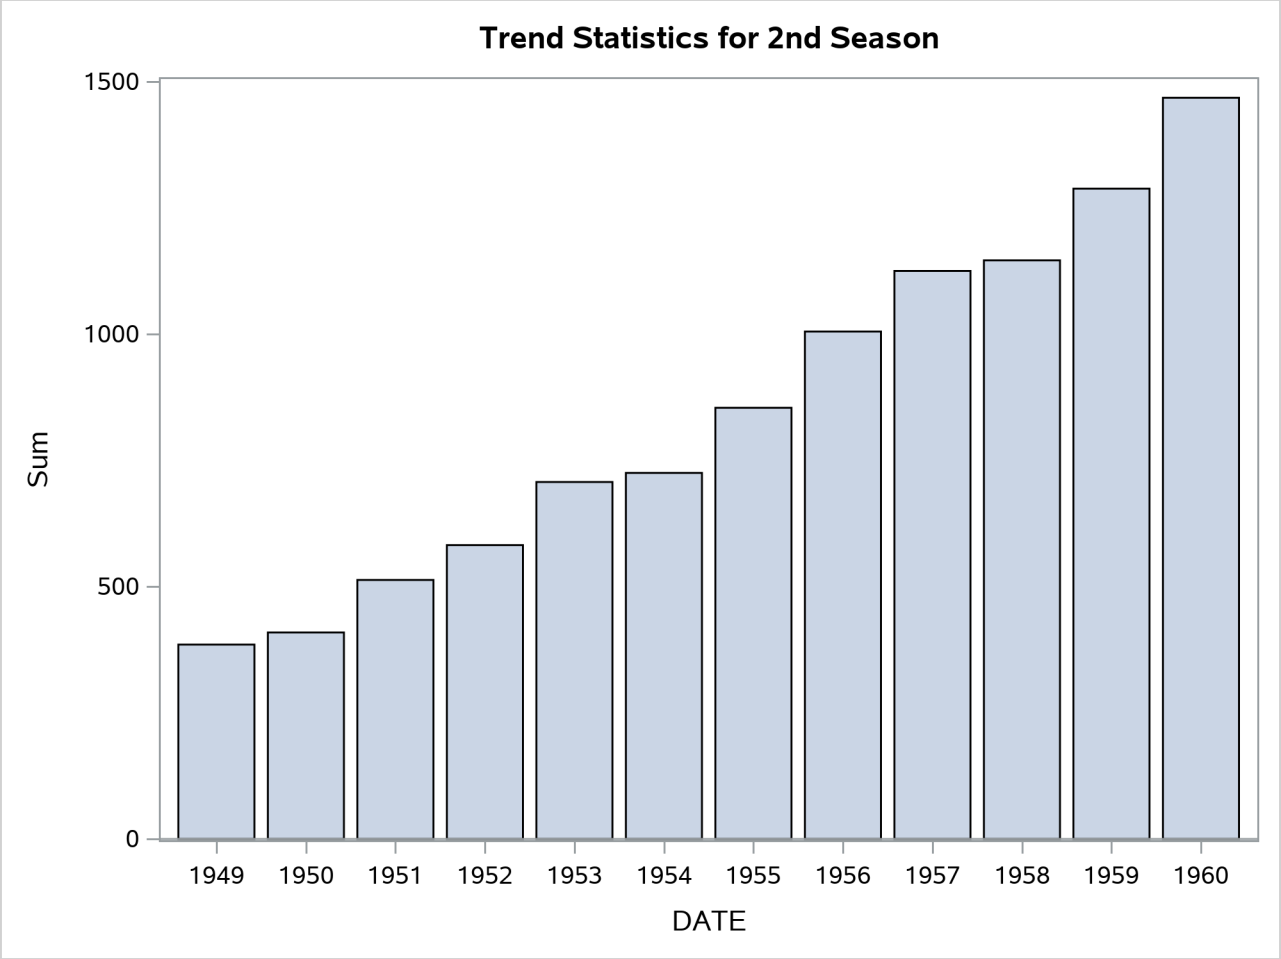


Using the trend statistics stored in the WORK.TREND data set, the following statements chart the sum of the transactions associated with each time period for the second season over time:

```
title1 "Trend Statistics for 2nd Season";
proc sgplot data=trend;
   where _season_ = 2;
   vbar date / freq=sum;
   format date year4.;
   yaxis label='Sum';
run;
```

The results of this trend analysis are shown in Output 38.2.3.

Output 38.2.3 Trend Statistics Bar Chart



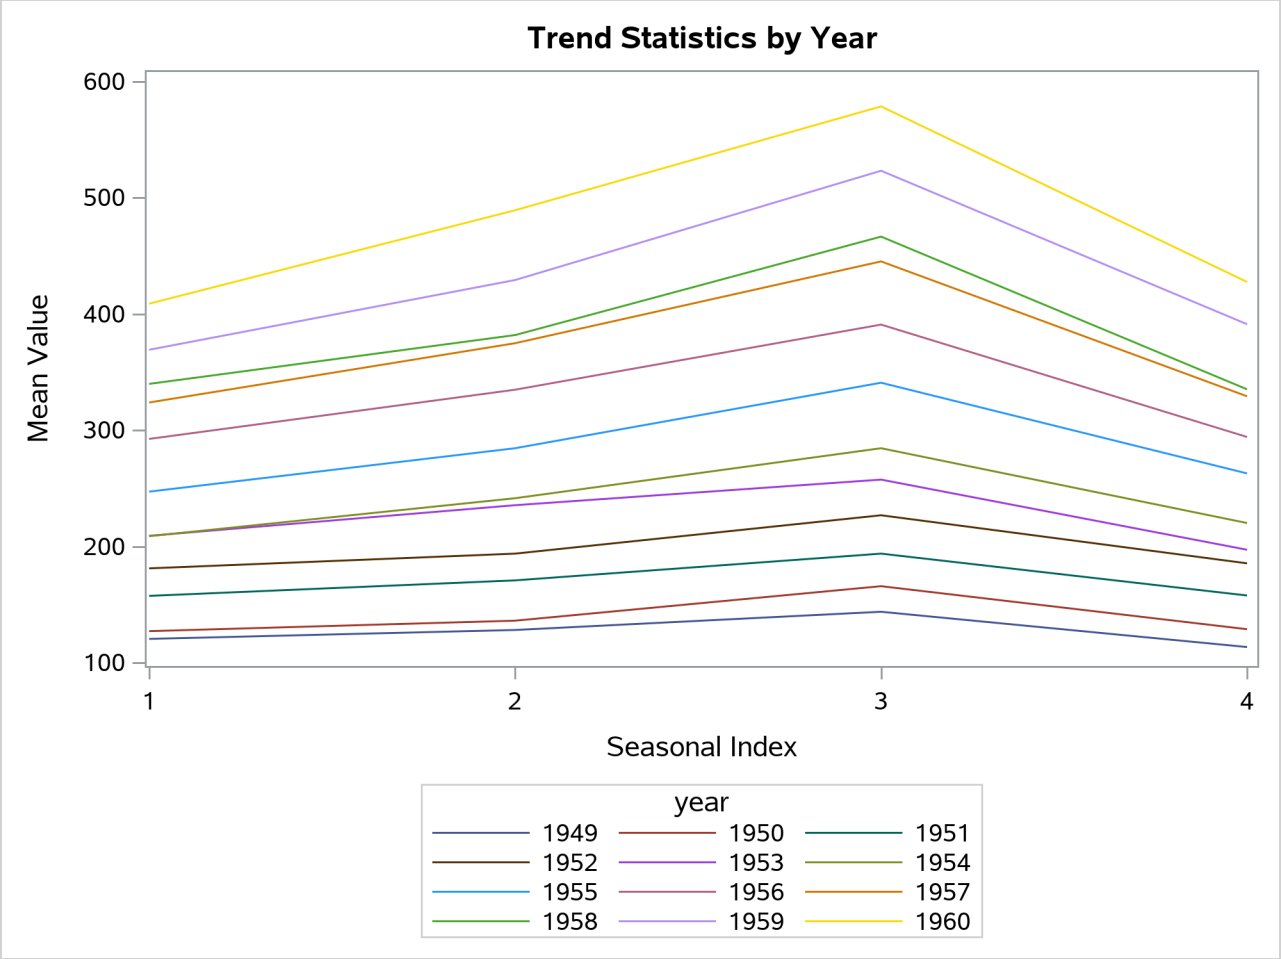
Using the trend statistics stored in the WORK.TREND data set, the following statements plot the mean of the transactions associated with each time period by each year over time:

```
data trend;
   set trend;
   year = year(date);
run;

title1 "Trend Statistics by Year";
proc sgplot data=trend;
   series x=_season_ y=mean / group=year lineattrs=(pattern=solid);
   xaxis values=(1 to 4 by 1);
run;
```

The results of this trend analysis are shown in Output 38.2.4.

Output 38.2.4 Trend Statistics

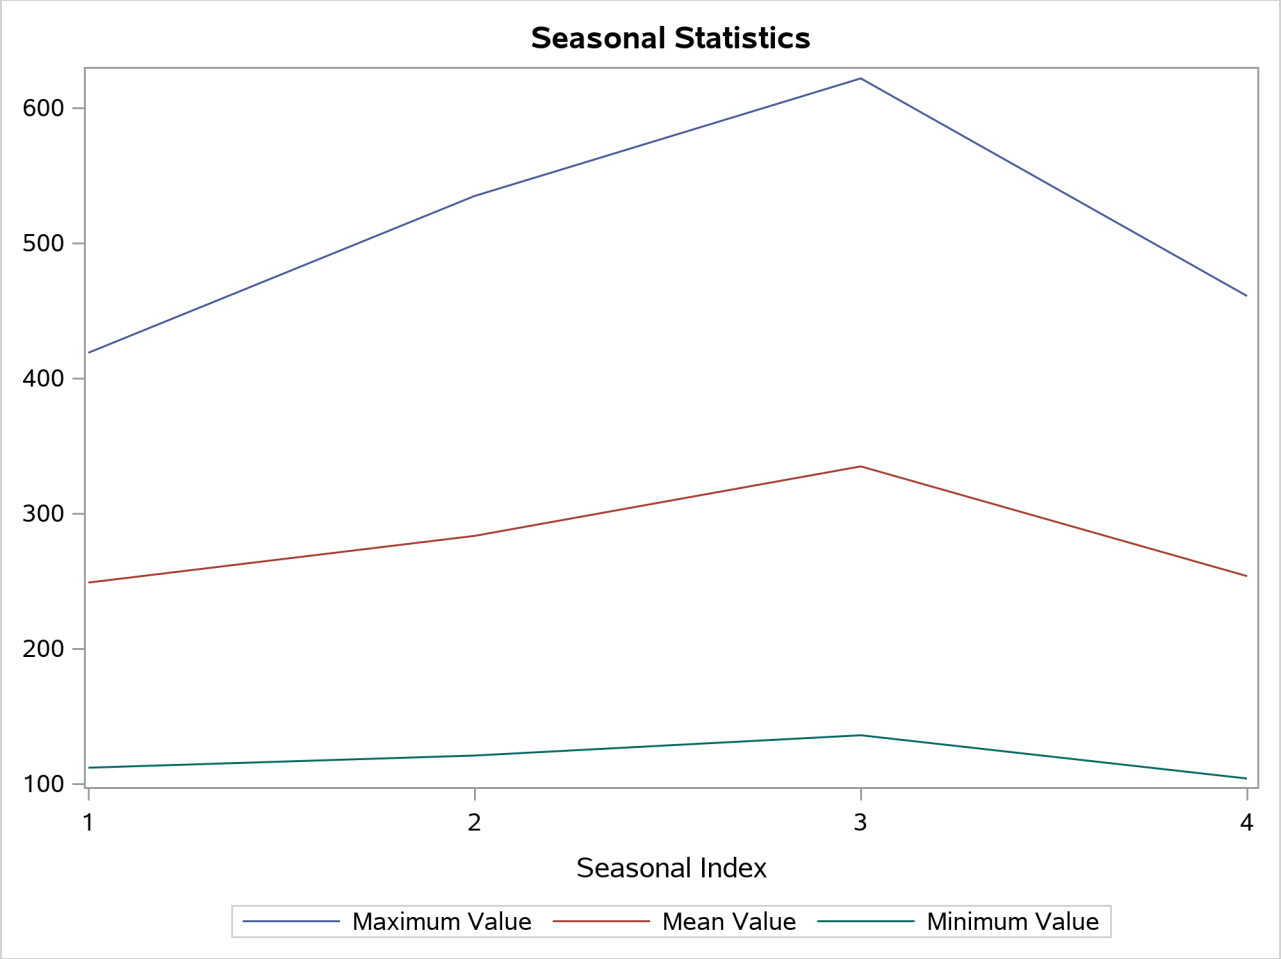


Using the season statistics stored in the WORK.SEASON data set, the following statements plot various season statistics for each season:

```
title1 "Seasonal Statistics";
proc sgplot data=season;
   series x=_season_ y=max  / lineattrs=(pattern=solid);
   series x=_season_ y=mean / lineattrs=(pattern=solid);
   series x=_season_ y=min  / lineattrs=(pattern=solid);
   yaxis display=(nolabel);
   xaxis values=(1 to 4 by 1);
run;
```

The results of this seasonal analysis are shown in Output 38.2.5.

Output 38.2.5 Seasonal Statistics Plot



Example 38.3: Illustration of ODS Graphics

This example illustrates the use of ODS graphics.

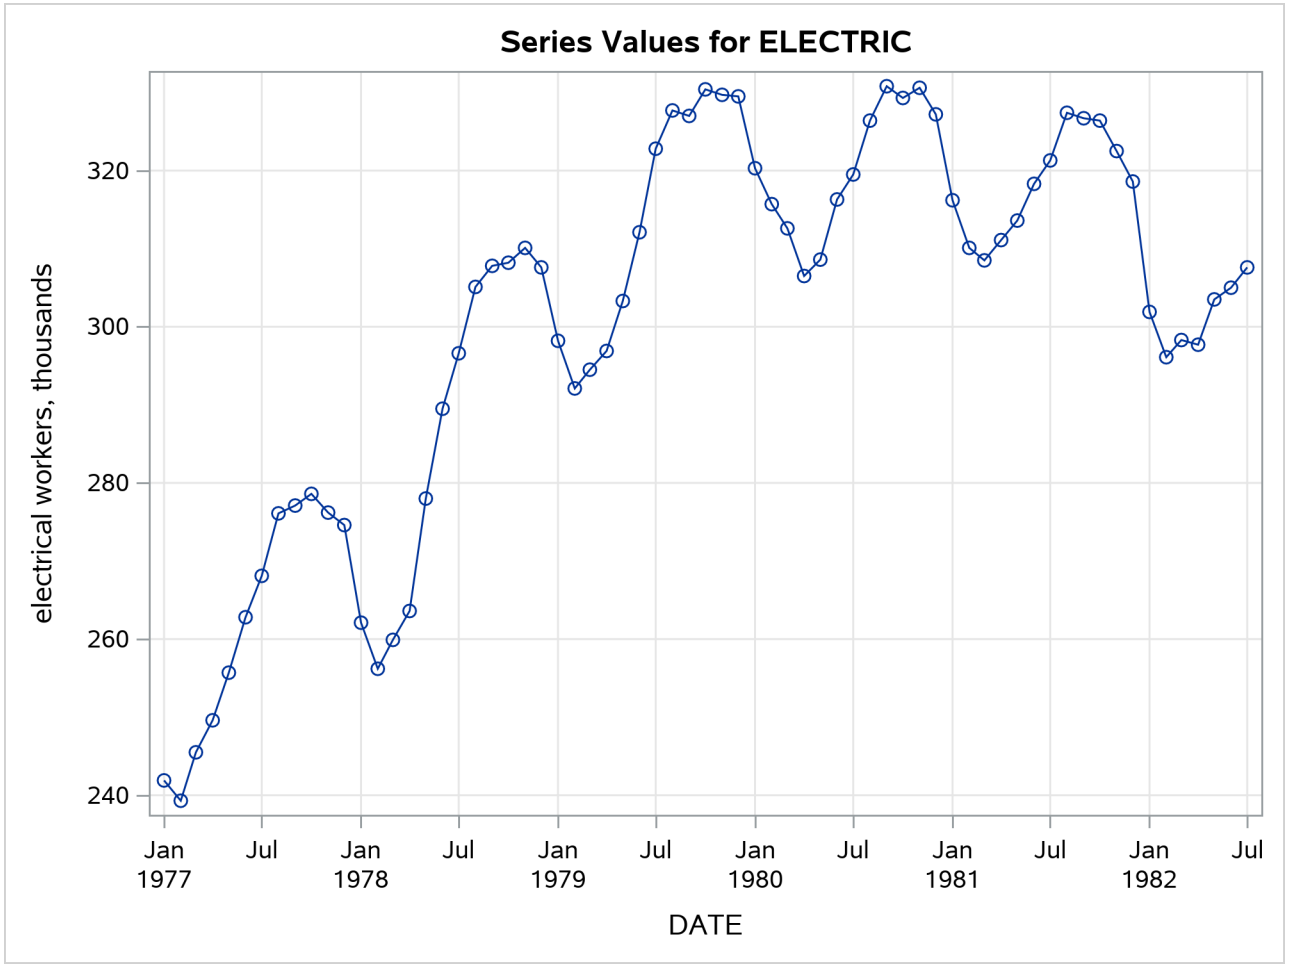
The following statements use the Sashelp.Workers data set to study the time series of electrical workers and its interaction with the simply differenced series of masonry workers. The series plot, the correlation panel, the seasonal adjustment panel, and all cross-series plots are requested. Output 38.3.1 through Output 38.3.4 show a selection of the plots created.

The graphical displays are requested by specifying the PLOTS= or CROSSPLOTS= option in the PROC TIMESERIES statement. For information about the graphics available in the TIMESERIES procedure, see the section "ODS Graphics Names" on page 2772.

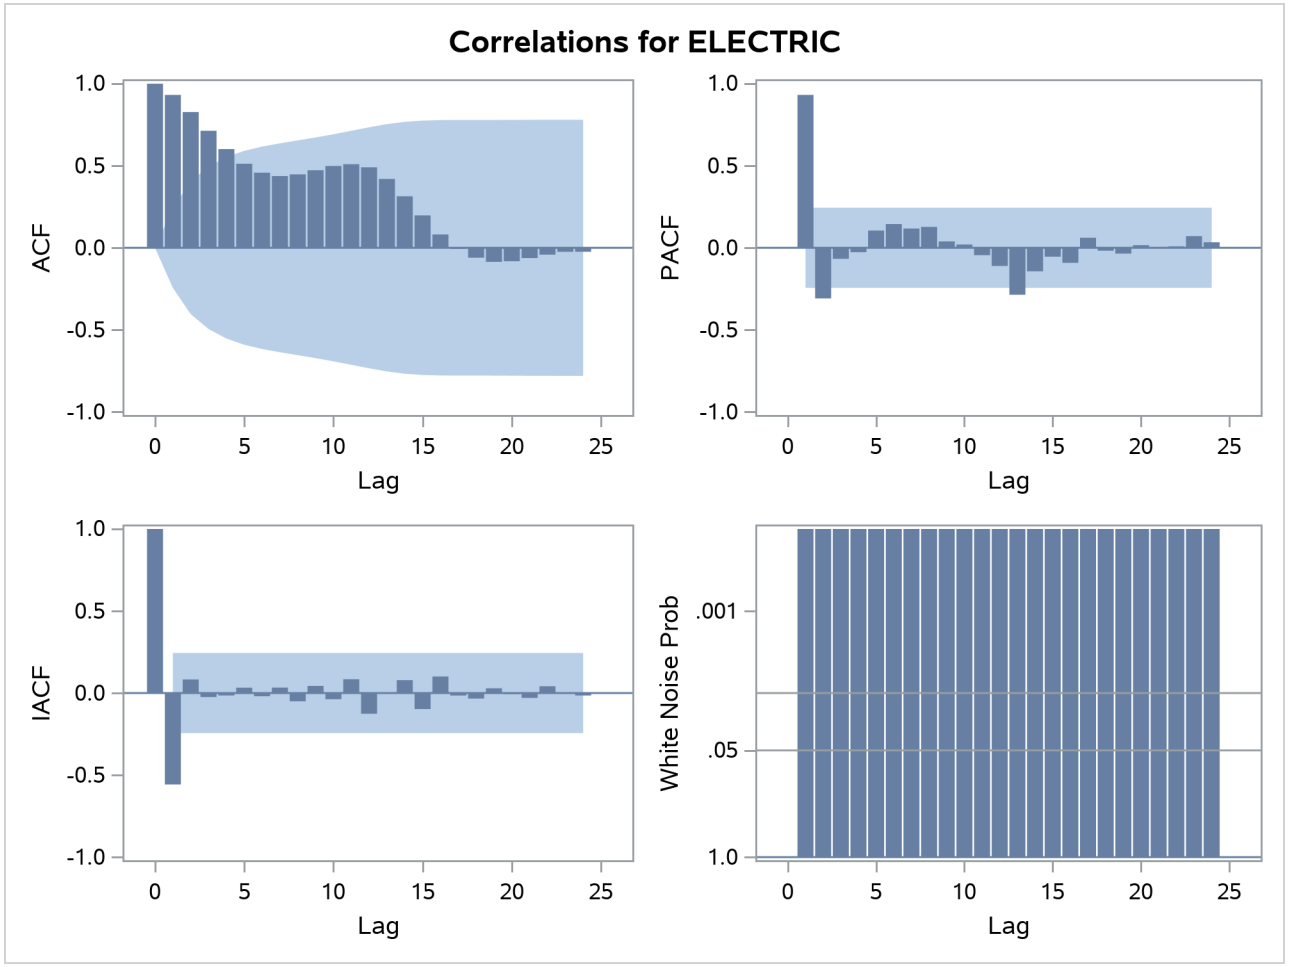
```
title "Illustration of ODS Graphics";
proc timeseries data=sashelp.workers out=_null_
                plots=(series corr decomp)
                crossplots=all;
   id date interval=month;
   var electric;
```

```
   crossvar masonry / dif=(1);
run;
```

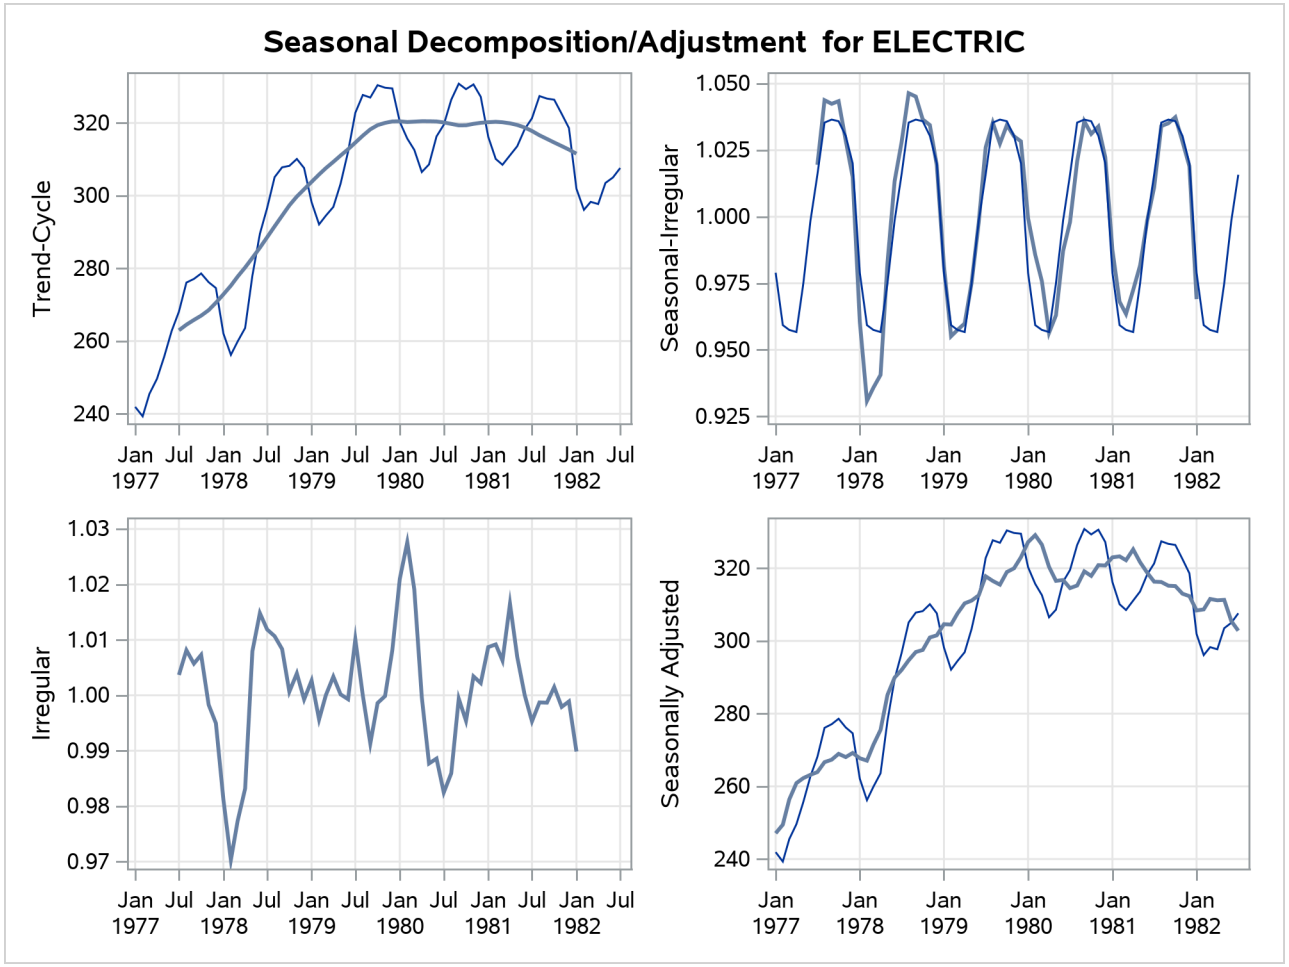
Output 38.3.1 Series Plot



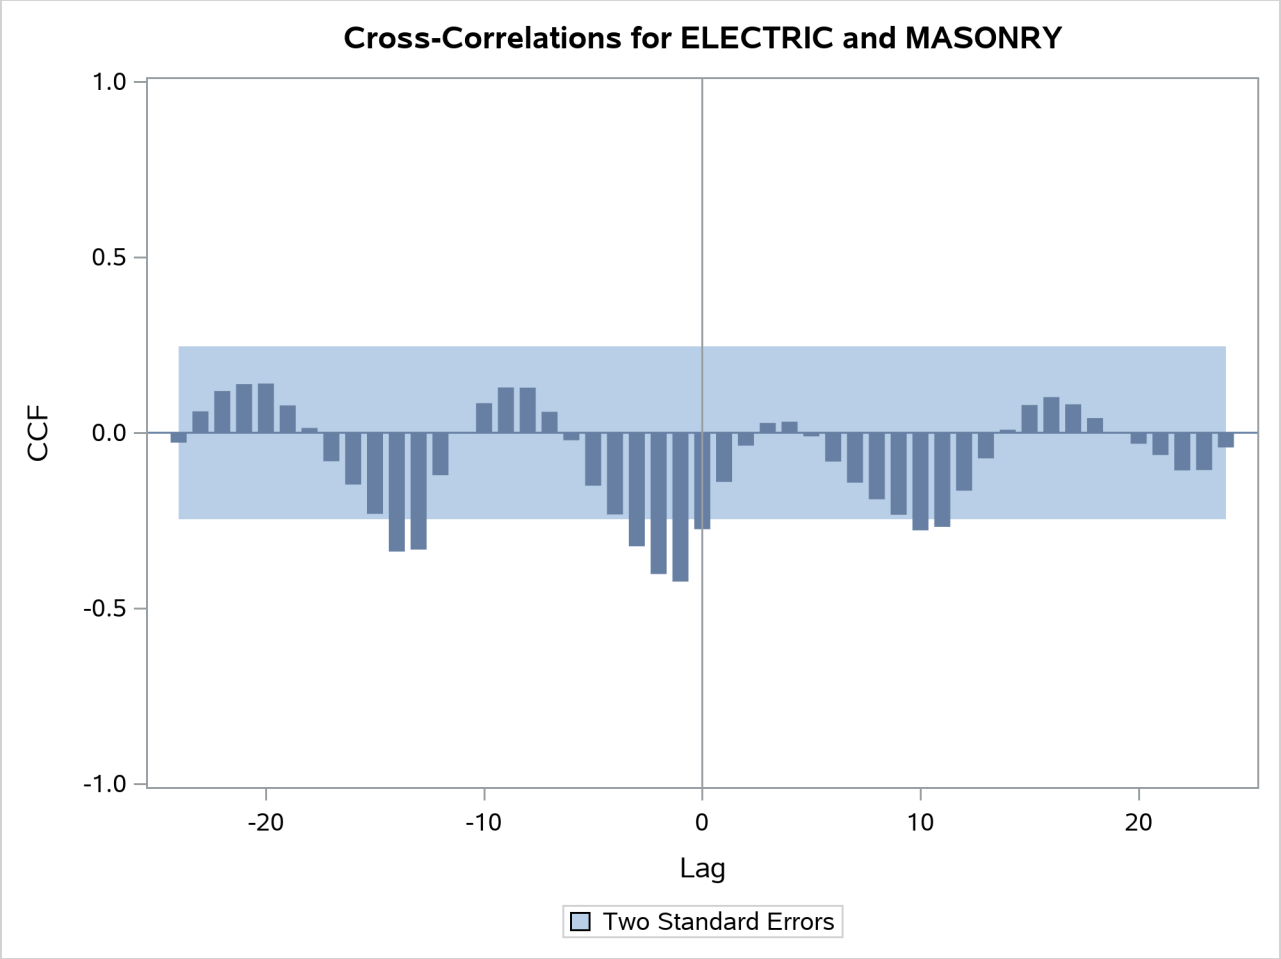
Output 38.3.2 Correlation Panel



Output 38.3.3 Seasonal Decomposition Panel



Output 38.3.4 Cross-Correlation Plot



Example 38.4: Illustration of Spectral Analysis

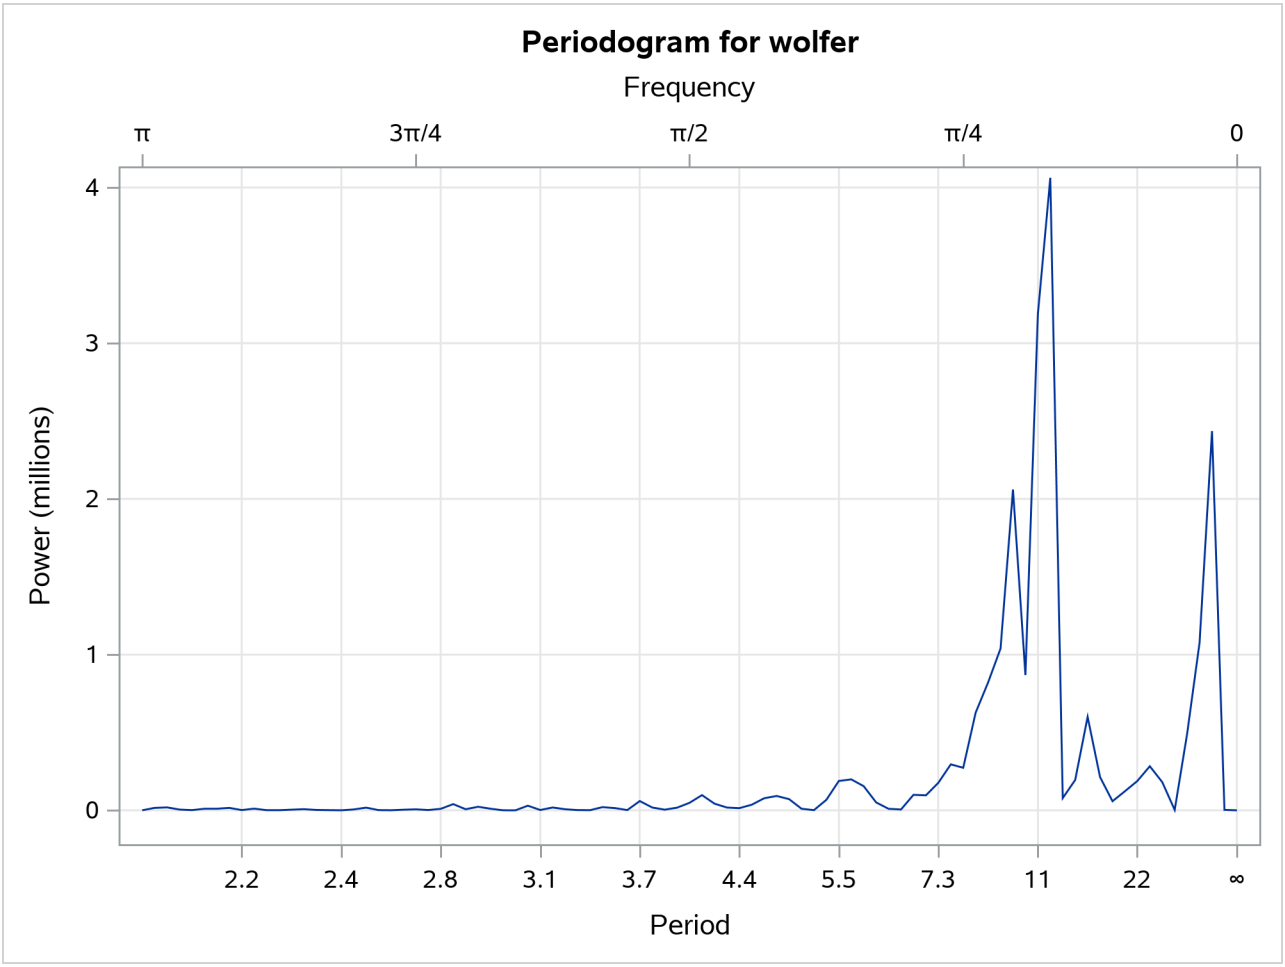
This example illustrates the use of spectral analysis.

The following statements perform a spectral analysis on the SUNSPOT data set. The periodogram is displayed as a function of the period and frequency in Output 38.4.1. The estimated spectral density together with its 50% confidence limits is displayed in Output 38.4.2.

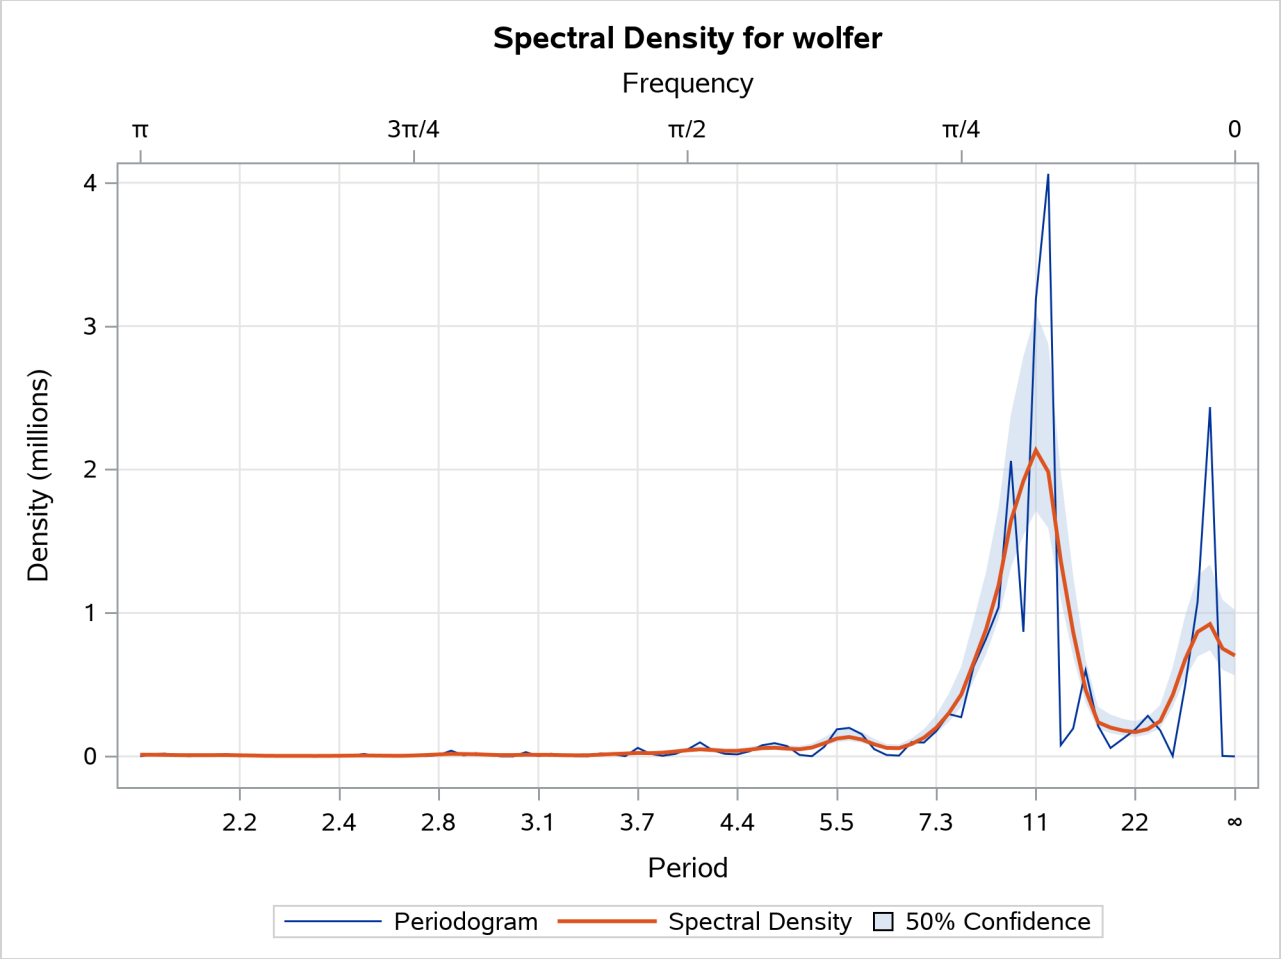
```
title "Wolfer's Sunspot Data";

proc timeseries data=sunspot plot=(series periodogram spectrum);
   var wolfer;
   id year interval=year;
   spectra freq period p s / adjmean bart c=1.5 expon=0.2;
run;
```

Output 38.4.1 Periodogram



Output 38.4.2 Spectral Density Plot



Example 38.5: Singular Spectrum Analysis

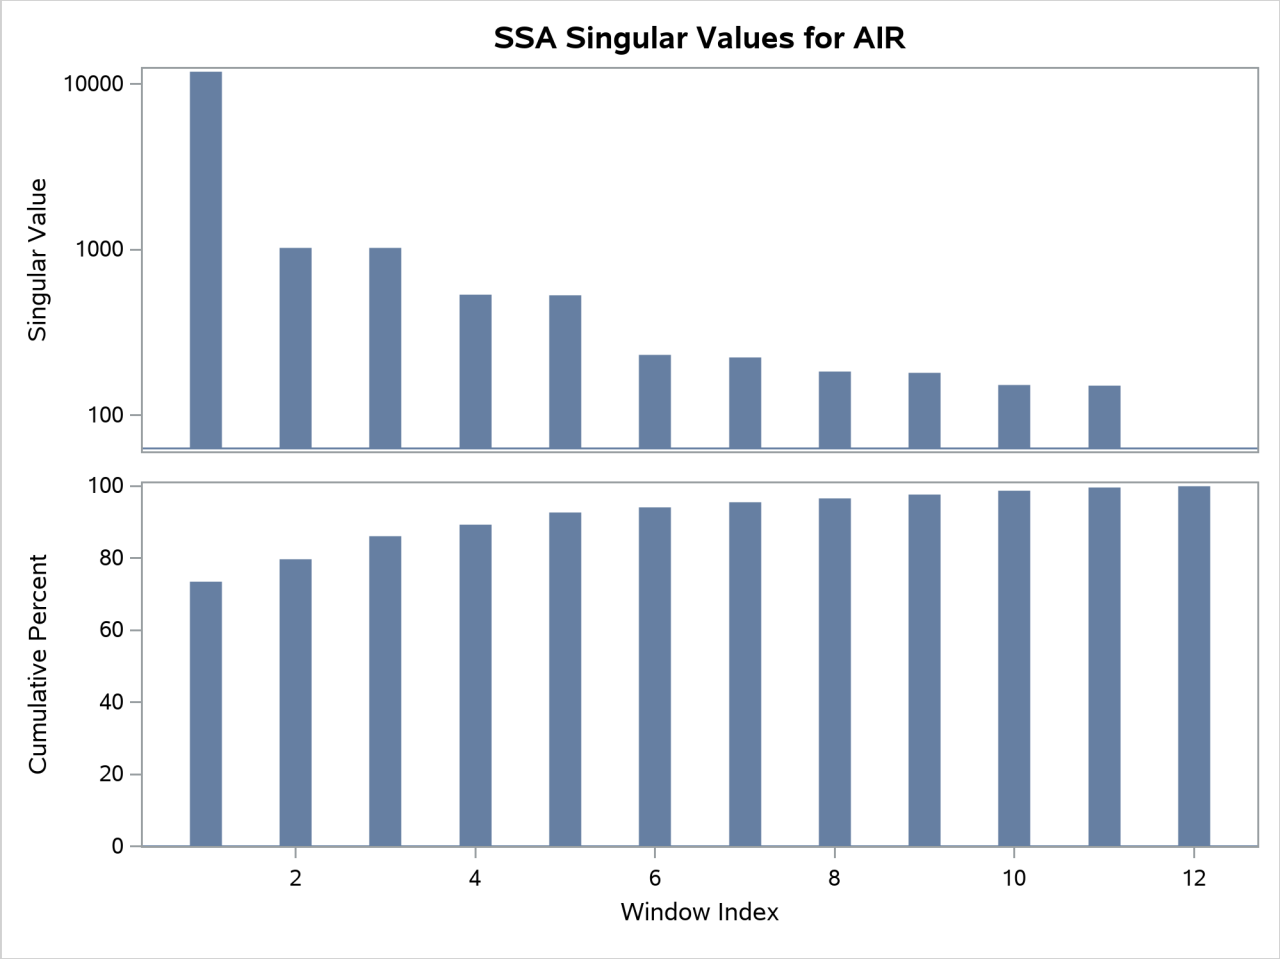
This example illustrates the use of singular spectrum analysis with different grouping steps.

The following statements extract two additive components from the Sashelp.Air time series by using the THRESHOLDPCT= option to specify that the first component represent 80% of the variability in the series (see Output 38.5.1). The resulting groupings, which consist of the first three and remaining nine singular value components, are presented in Output 38.5.2 through Output 38.5.4.

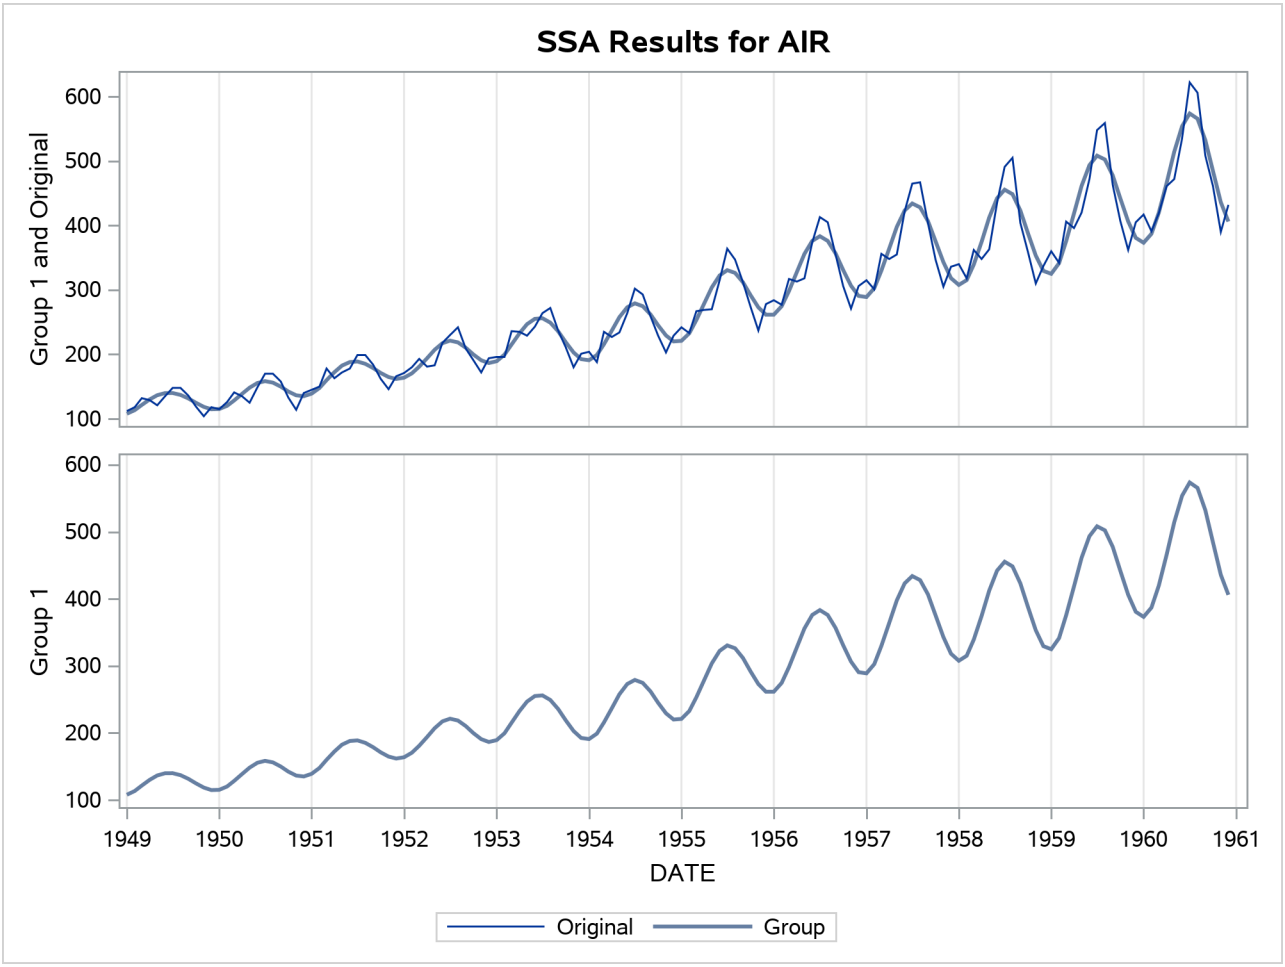
```
title "SSA of AIR Data";

proc timeseries data=sashelp.air plot=ssa;
   id date interval=month;
   var air;
   ssa / length=12 THRESHOLDPCT=80;
run;
```

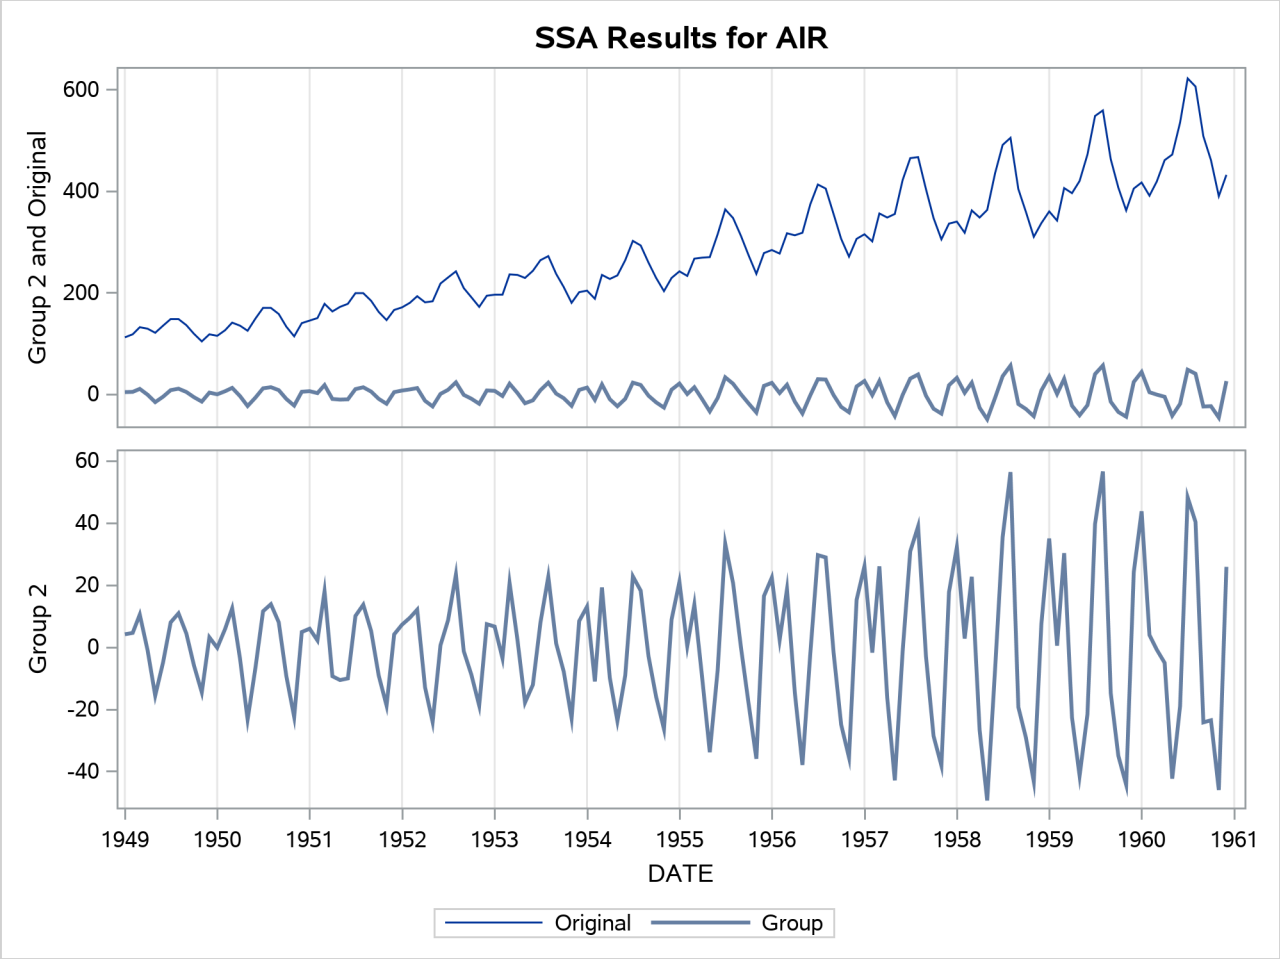
Output 38.5.1 Singular Values Plot



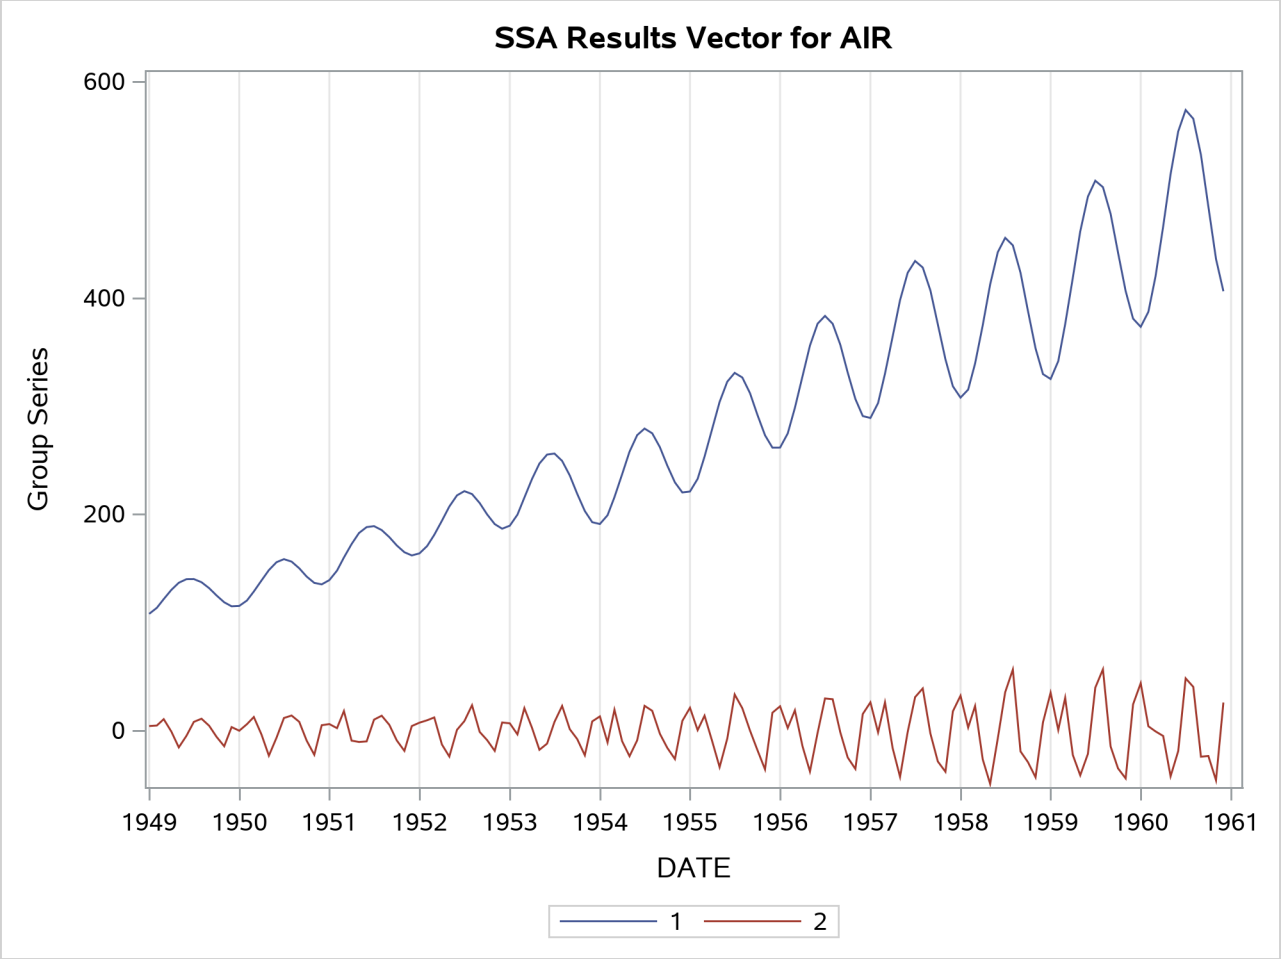
Output 38.5.2 Singular Value Grouping #1 Plot



Output 38.5.3 Singular Value Grouping #2 Plot



Output 38.5.4 Singular Value Components Plot



The following statements extract the first three important additive components from the Sashelp.Air time series by using the GROUPS=AUTO(3) option to apply SSA automatic grouping. The w-correlations are shown in Output 38.5.7. Large w-correlation values indicate that the procedure should select the corresponding singular value components as one group. The grouping results based on the w-correlations are shown in Output 38.5.5. The resulting groupings, which consist of the first (group 1), the second and third (group 2), and the fourth and fifth (group 3) singular value components, are presented in Output 38.5.8 through Output 38.5.11. According to Output 38.5.6, these three groups represent about 90% of the variability in the series. Finally, Output 38.5.12 shows the summation of the groups together with the original data.

```
title "SSA of AIR Data";

proc timeseries data=sashelp.air print=ssa plot=ssa;
   id date interval=month;
   var air;
   ssa / length=12 GROUPS=AUTO(3);
run;
```

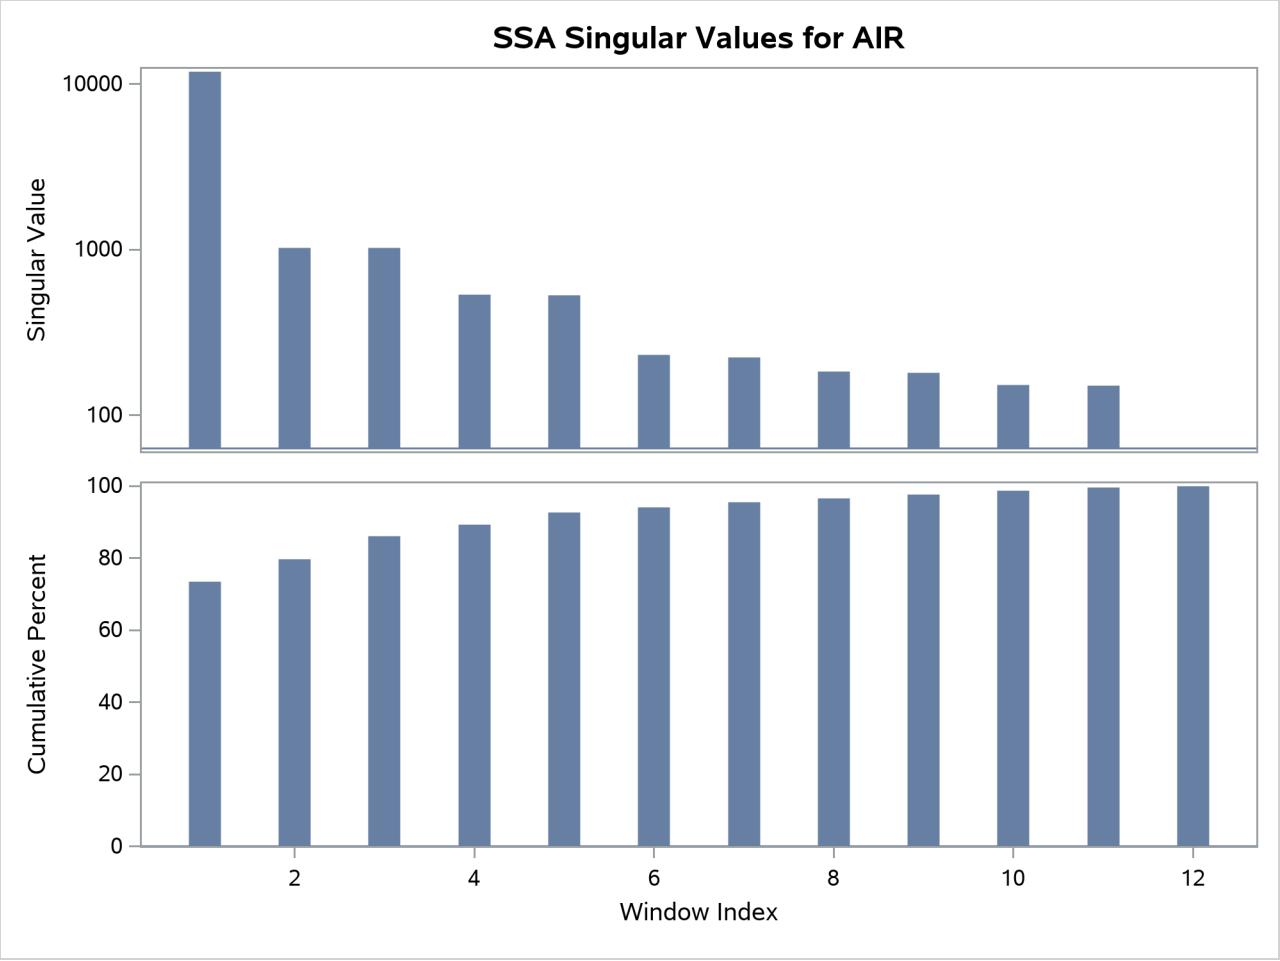
Output 38.5.5 SSA Groups

SSA of AIR Data

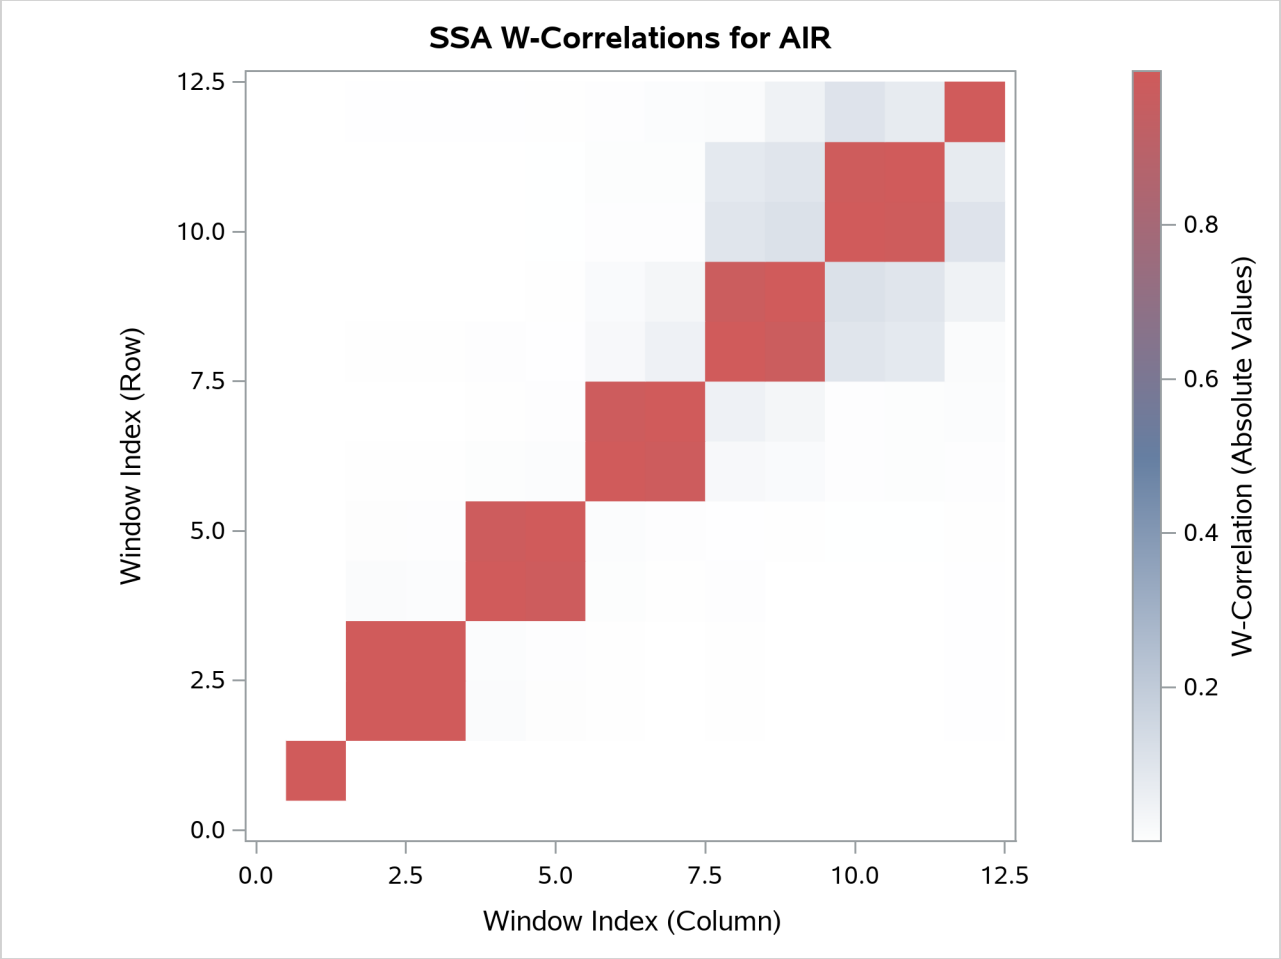
The TIMESERIES Procedure

SSA Groups	
Group Index	**Window Indices**
1	1
2	2, 3
3	4, 5

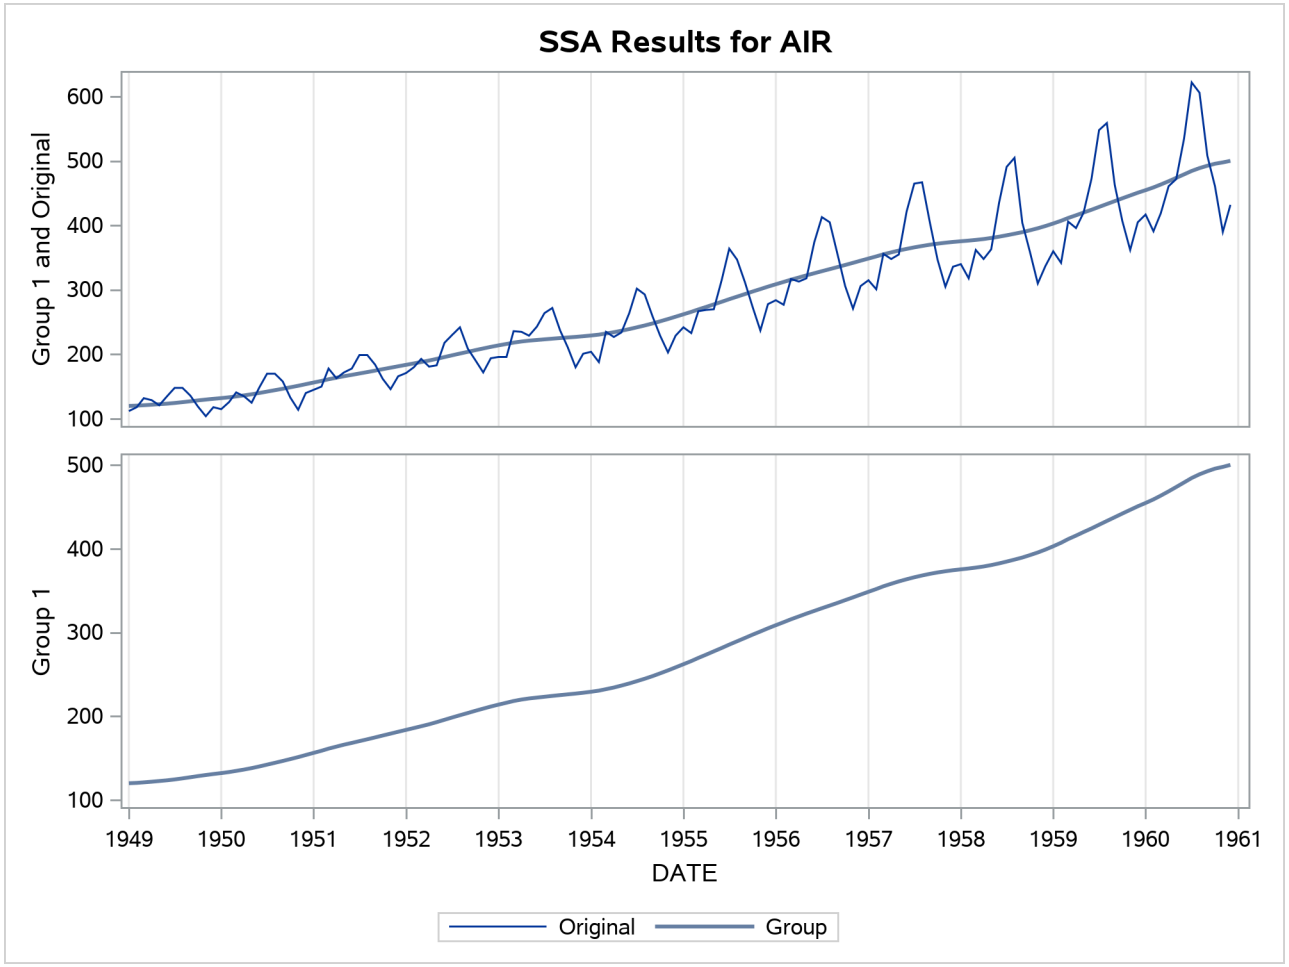
Output 38.5.6 Singular Values Plot



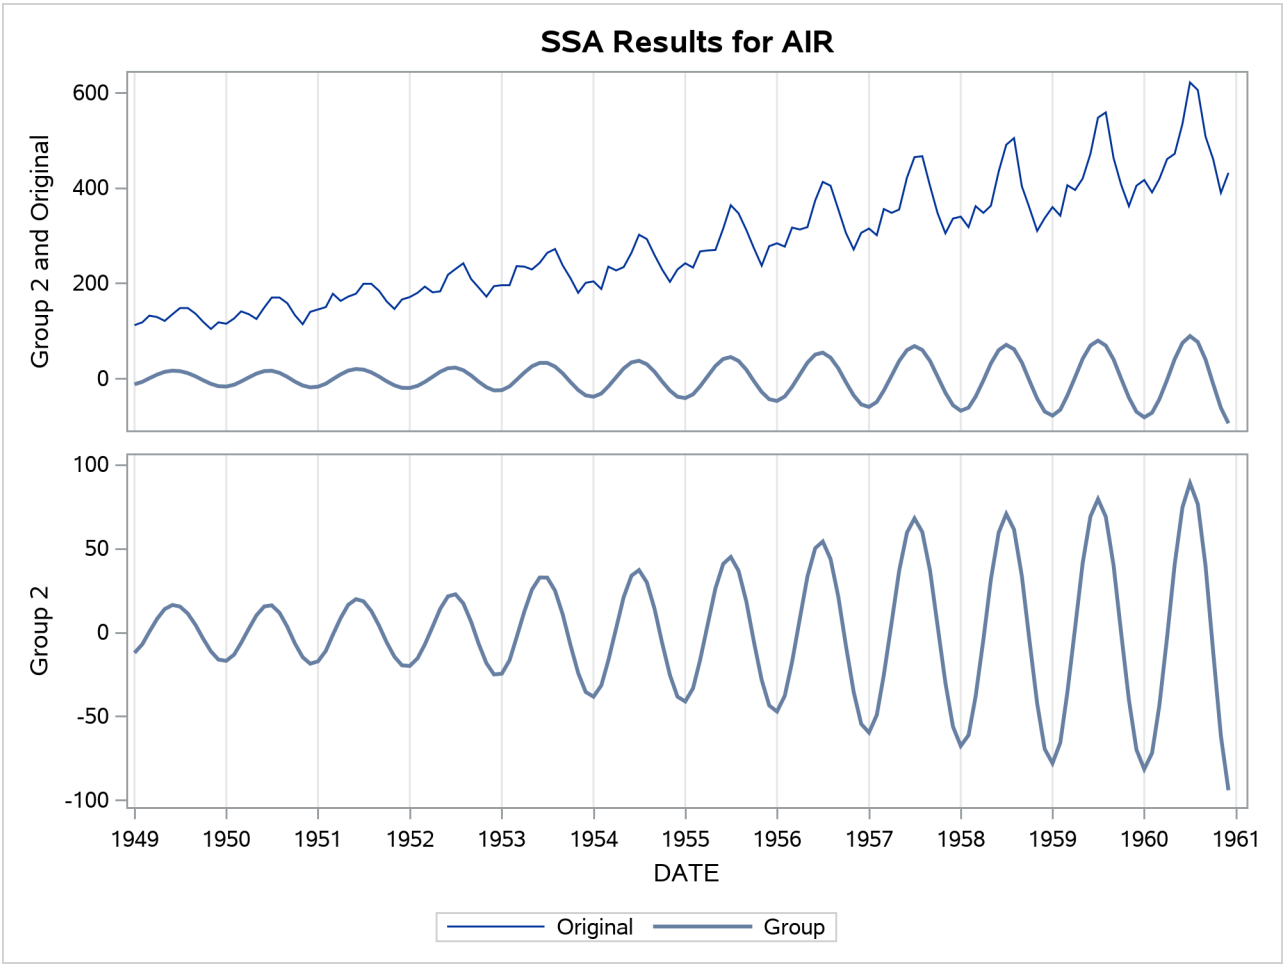
Output 38.5.7 W-Correlations Heat Map



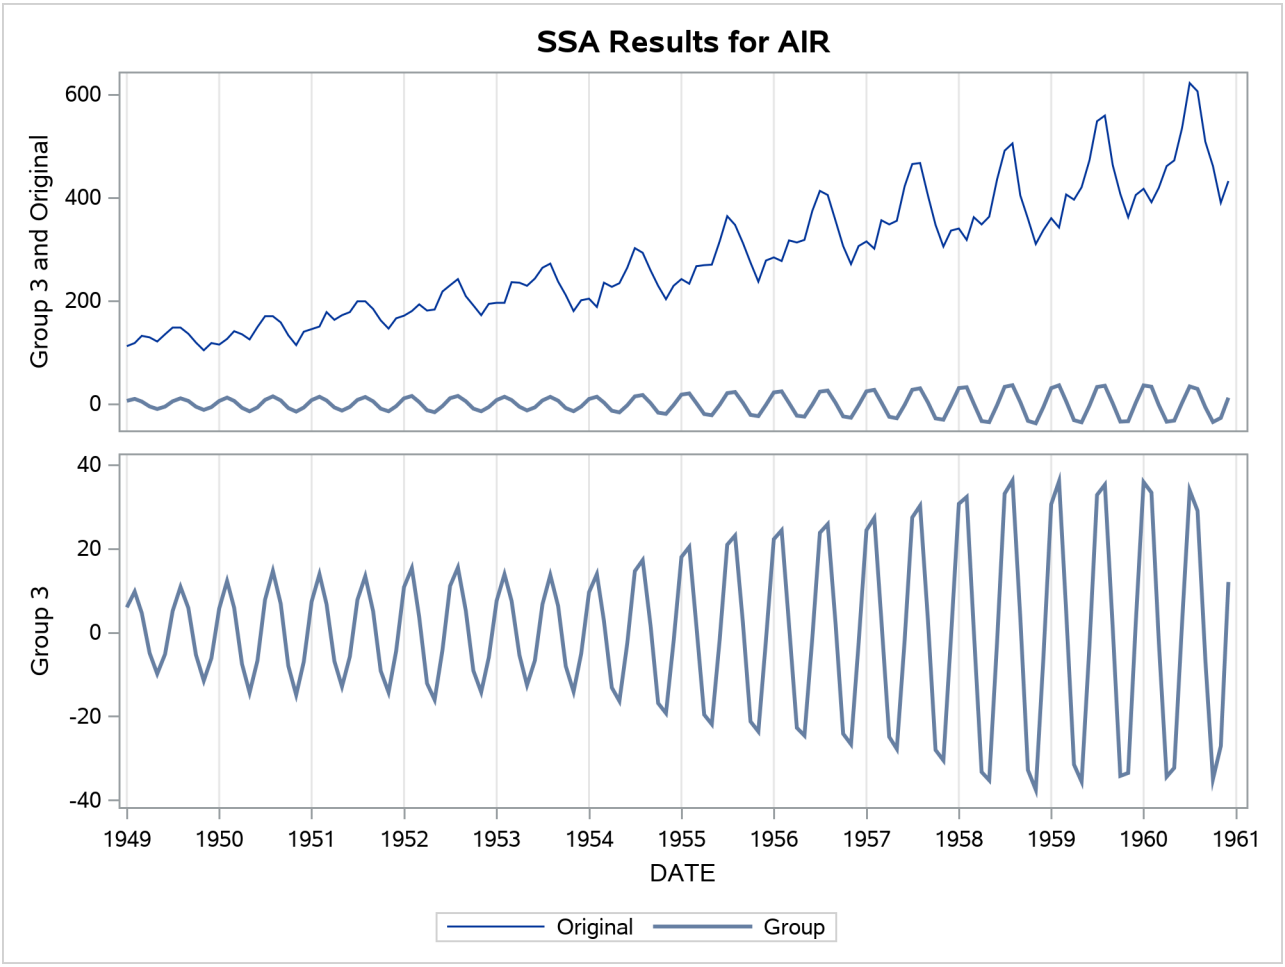
Output 38.5.8 Singular Value Grouping #1 Plot



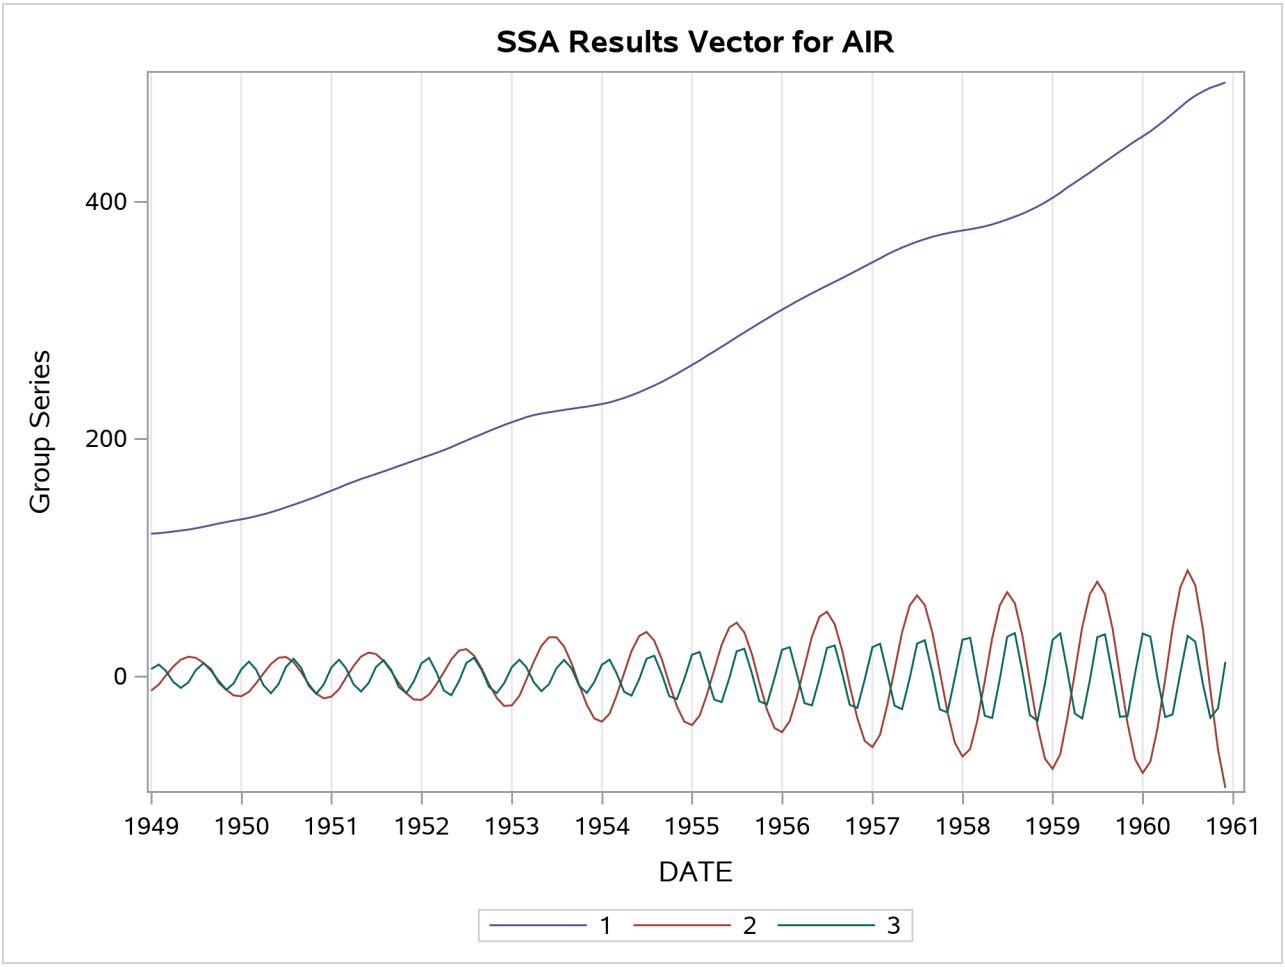
Output 38.5.9 Singular Value Grouping #2 Plot



Output 38.5.10 Singular Value Grouping #3 Plot



Output 38.5.11 Singular Value Components Plot



Output 38.5.12 SSA Groups Summation Plot

Overview: TMODEL Procedure

The TMODEL procedure is a new, experimental version of the MODEL procedure. The code that you use to perform nearly all analyses in PROC MODEL can be used unchanged in PROC TMODEL; however, PROC TMODEL incorporates high-performance computational techniques and offers new features that enhance the functionality of PROC MODEL. For an explanation of the capabilities and operation of both PROC MODEL and PROC TMODEL, see Chapter 24, "The MODEL Procedure."

Comparison of PROC TMODEL and PROC MODEL

PROC TMODEL includes changes to the underlying computational algorithms that are used in the majority of PROC MODEL analyses. The new algorithms improve the stability and convergence characteristics along with the computational efficiency for most problems; however, for some problems these improvements can cause PROC TMODEL to produce different results than PROC MODEL. In particular, both estimation and simulation tasks rely on matrix ordering and factorization algorithms that have been enhanced in PROC TMODEL to work more efficiently, especially for large problems. Also, PROC TMODEL processes input data in a different order than PROC MODEL to improve performance, and this can cause some estimation tasks to produce different results.

In addition to performance improvements, PROC TMODEL has the following new features:

- estimation and simulation of models that use panel data by specifying cross-sectional variables in the CROSSSECTION statement
- estimation of models with nonlinear random-effects parameters when cross-sectional variables are identified in the input data
- use of analytic expressions for Hessian matrices in the optimization process for most estimation methods by default
- use of the nonlinear programming (NLP) solver available in SAS/OR software for performing the optimizations during estimation tasks

The ability to specify cross-sectional variables in PROC TMODEL allows for the estimation of dynamic models by using multiple time series. By contrast, PROC MODEL can estimate dynamic models only for data that contain a single time series. Also, PROC TMODEL enhances the modeling capabilities of PROC MODEL by supporting models of the correlations among cross sections through the specification of random-effects parameters.

Models that depend on highly nonlinear parameters can cause the estimation process either to converge slowly or to fail to converge. PROC TMODEL includes two new features that address these problems. In PROC MODEL, a first-order approximation of the model problem's Hessian matrix is used in the parameter search. PROC TMODEL has the option to use exact Hessian matrix values in the parameter search. PROC TMODEL also supports the use of an alternative nonlinear programming solver that improves convergence characteristics for many estimation problems.

PROC TMODEL breaks computationally intensive operations into multiple, concurrent threads to reduce the time it takes to complete many of the estimation and simulation tasks available in PROC MODEL. PROC

MODEL performs all calculations sequentially. PROC TMODEL can break calculations up in the following ways:

- multithreading across partitions of the input data set
- multithreading across BY groups
- multithreading across repetitions in Monte Carlo simulations
- multithreading the optimization process in estimations across sets of initial estimates

For estimation tasks that do not involve dynamic models, PROC TMODEL breaks up the observed data into partitions and computes each partition's contribution to the estimation of parameters concurrently. When PROC TMODEL analyzes a model for many BY groups, the BY groups can be analyzed concurrently. In Monte Carlo simulations, the random perturbations of the model variables can be evaluated concurrently in PROC TMODEL. In problems that involve a numerical optimization, it is sometimes necessary to perform many local optimizations by using separate initial estimates in order to determine a global solution. PROC TMODEL can perform these local optimizations concurrently to find the global solution more quickly than PROC MODEL, which solves local optimization problems sequentially.

PROC MODEL Features Not Available in PROC TMODEL

The following features in PROC MODEL are not currently available in PROC TMODEL:

- some features in the model file used by the OUTMODEL= and MODEL= options
- BY groups in the SDATA= and ESTDATA= data sets
- covariance matrices in output data sets
- the OUTSUSED= data set
- some diagnostic information in output tables
- Durbin-Watson autocorrelation statistics
- some features in the CMP system, such as the RUN_MACRO function

Model specifications in either PROC MODEL or PROC TMODEL can be saved to a file for use in subsequent PROC MODEL or PROC TMODEL operations; however, there are some limitations to the model files that can be shared between PROC MODEL and PROC TMODEL. The specification of instrumental variables that is saved to a model file in PROC MODEL or PROC TMODEL cannot be used in PROC TMODEL or PROC MODEL estimation tasks, respectively.

Monte Carlo simulations in PROC MODEL can apply a different error covariance matrix, different parameter values, and a different parameter covariance matrix for each BY group in the DATA= data set through the specification of corresponding BY groups in the SDATA= and ESTDATA= data sets. Also, in PROC MODEL estimations, different initial parameter estimates for each BY group can be specified in the ESTDATA= data set. In contrast, PROC TMODEL does not currently support the use of BY groups in either the SDATA= or ESTDATA= data set. All BY groups share the same covariance matrices and parameter value specifications. PROC TMODEL will support BY groups in the SDATA= and ESTDATA= data sets in a future release.

PROC MODEL adds perturbations to parameter values during Monte Carlo simulations when a parameter covariance matrix is specified in the ESTDATA= data set. PROC TMODEL does not currently support perturbation of parameters, but this functionality will be available in a future release.

PROC MODEL stores both parameter estimates and parameter covariance matrices in the OUTEST= data set when the OUTCOV option is specified. PROC TMODEL does not support the output of covariance matrices in the OUTEST= data set; however, the COV option, which prints parameter covariance matrices, is supported.

Many tables that PROC MODEL produces are not available in PROC TMODEL because they fall into one or more of the following categories:

Not available	report the intermediate states of PROC MODEL calculations that are not available or are computed differently in PROC TMODEL.
Replaced	are replaced by equivalent diagnostic output in PROC TMODEL in a different format.
Future	are not yet available in PROC TMODEL but are planned for a future release.

The reason that each table is not available in PROC TMODEL is summarized in Table 39.1.

Table 39.1 ODS Tables Not Available in PROC TMODEL

ODS Table Name	Description	Reason[1]
ODS Tables Created by the FIT Statement		
AugGMMCovariance	Crossproducts matrix	F
ConfInterval	Profile likelihood confidence intervals	F
Crossproducts	Crossproducts matrix	F
DatasetOptions	Data sets used	F
DetResidCov	Determinant of the residuals	F
DWTest	Durbin-Watson test	F
EstSummaryMiss	Summary statistics for PAIRWISE option	F
GMMCovariance	Crossproducts matrix	F
GMMTestStats	GMM test statistics	F
Godfrey	Godfrey's serial correlation test	F
HausmanTest	Hausman's test table	F
InvXPXMat	X′X inverse for system	N
IterInfo	Iteration printing	N R
ObsSummary	Identifies observations that contain errors	R
ObsUsed	Observations read, used, and missing	R
ParmChange	Parameter change vector	N
SizeInfo	Storage requirement for estimation	F
XPXMat	X′X for system	N
YkVector	Marquardt iteration vector	N
ODS Tables Created by the SOLVE Statement		
DatasetOptions	Data sets used	F
DescriptiveStatistics	Descriptive statistics	F
FitStatistics	Fit statistics for simulation	F

[1] N - Not available, R - Replaced, F - Future

Table 39.1 *continued*

ODS Table Name	Description	Reason[1]
ObsSummary	Simulation trace output	R
ObsUsed	Observations read, used, and missing	R
SolutionVarList	Solution variable lists	F
TheilRelStats	Theil relative change error statistics	F
TheilStats	Theil forecast error statistics	F
ErrorVec	Iteration error vector	N
ResidualValues	Iteration residual values	N
PredictedValues	Iteration predicted values	N
SolutionValues	Iteration solved for variable values	N
ODS Tables Created by the FIT and SOLVE Statements		
AdjacencyMatrix	Adjacency graph	R
CodeDependency	Variable cross reference	N
CodeList	Listing of compiled program code	N
CrossReference	Cross-reference listing for program	N
DepStructure	Dependency structure of the system	N
FirstDerivatives	First derivative table	N
IterIntg	Integration iteration output	N
MemUsage	Memory usage statistics	F
MissingDependencies	Missing values by dependency	F
MissingObservations	Missing values by observation	F
MissingSymbols	Missing values by symbol	F
ParmReadIn	Parameter estimates read in	F
SortAdjacencyMatrix	Sorted adjacency graph	R
TransitiveClosure	Transitive closure graph	R

[1] N - Not available, R - Replaced, F - Future

You can find information in PROC TMODEL for the PROC MODEL tables in category R as follows:

- IterInfo displays iteration information for the optimization process in the log for the ORMP optimizer.
- ObsSummary displays diagnostic information for observations that produce missing values in the log.
- ObsUsed displays observation counts in the EstSummaryStats table.
- AdjacencyMatrix, SortAdjacencyMatrix, TransitiveClosure have dependency information that you display by using the ANALYZEDEPS= option in the SOLVE statement.

Getting Started: TMODEL Procedure

One of the most powerful enhancements in PROC TMODEL compared to PROC MODEL is the ability to reduce the time required to perform computationally intensive tasks, such as estimating parameters in a nonlinear ordinary differential equation (ODE) model. This estimation task requires both the numerical integration of derivative variables in the model over time steps and the repeated evaluation of the time steps during the estimation's minimization process. The following example estimates the parameters in a system of two coupled differential equations by using simulated data for four time series:

```
data soln;
   keep exprun t x y;
   length exprun $ 8;
   array experno[4] $ _temporary_ ( "one" "two" "three" "four" );
   call streaminit (1);
   do i = 1 to 4;
      exprun = experno[i];
      do t = 0 to 5 by 0.1;
         /* analytic solution for the ODE system */
         x = 1/2*(exp(-3*t) - exp(-t)) + rand('normal',0,0.01);
         y = 1/2*(exp(-3*t) + exp(-t)) + rand('normal',0,0.01);
         output;
      end;
   end;
run;

proc model outmodel=ode;
   endo x y;
   parms a b;
   g = exp (x + y);
   dert.x = -a*x - log (g);
   dert.y = -b*y - log (g);
quit;

proc model data=soln model=ode;
   fit / time=t dynamic;
quit;

proc tmodel data=soln model=ode;
   crosssection exprun;
   fit / time=t dynamic;
quit;
```

The model file Work.ODE is created and used in this example to avoid redundant specification of the model program. Although the ODE model and data are identical in the PROC MODEL and PROC TMODEL steps, you must specify the CROSSSECTION statement to take advantage of the multithreading capabilities of PROC TMODEL. Figure 39.1 shows how much faster PROC TMODEL performs this estimation by integrating the model over each of the four time series concurrently. Real time measures how long it takes to execute the PROC step, and CPU time is a measure of the computing resources that the PROC step consumes.

Figure 39.1 Performance Comparison of PROC MODEL and PROC TMODEL

```
NOTE: PROCEDURE MODEL used (Total process time):
      real time           4.18 seconds
      cpu time            4.10 seconds
NOTE: PROCEDURE TMODEL used (Total process time):
      real time           4.14 seconds
      cpu time            11.34 seconds
```

Syntax: TMODEL Procedure

The following statements are available in PROC TMODEL:

PROC TMODEL *options* **;**
ARRAY *arrayname variable-list . . .* **;**

The following sections describe statements that are available in PROC TMODEL but not in PROC MODEL or statements that have options in PROC TMODEL that are not available in PROC MODEL. For information about all other statements in the PROC TMODEL syntax, see Chapter 24, "The MODEL Procedure."

PROC TMODEL Statement

PROC TMODEL *options* **;**

The PROC TMODEL statement invokes the TMODEL procedure. The *options* that you can specify in the PROC TMODEL statement are the same as those you can specify in the PROC MODEL statement. For more information, see the section "PROC MODEL Statement" on page 1440 in Chapter 24, "The MODEL Procedure."

In addition to all the *options* described in PROC MODEL, you can specify the following *options*. These *options* can also be specified in a FIT statement or a SOLVE statement.

Options to Control the Solution of a System of Linear Equations

LUSOLVER=NUMPIVOT | STRUCTPIVOT | OLD | *n*

specifies the method to use to factor and solve systems of linear equations. These linear systems are encountered when the FIML option (which requests that the FIML method be used to estimate models) is specified in the FIT statement or the PROC TMODEL statement. These linear systems are also encountered when either the NEWTON or OPTIMIZE option is specified in the SOLVE statement (these options specify the numerical solution method). Also, model programs that include differential equations require the solution of linear systems of equations. You can specify the following values:

n	considers numerical values of matrix elements only every *n*th time a lower triangular times upper triangular (LU) matrix factorization is computed.
NUMPIVOT	considers numerical values of matrix elements each time an LU factorization is computed.
OLD	uses the factorization and solution algorithm that the MODEL procedure uses.
STRUCTPIVOT	considers only the structure of nonzero elements in the linear system for ordering equations in the LU factorization.

By default, LUSOLVER=NUMPIVOT.

CROSSSECTION Statement

CROSSSECTION *variables* **;**

The CROSSSECTION statement specifies the variables that identify observations in the input data set that form time series. This statement is useful when the input data set contains more than one time series and when a dynamic model is being estimated using the FIT statement or simulated using the SOLVE statement. When you use the CROSSSECTION statement, observations within each cross section must be grouped together, and the observations in each cross section must be sorted.

FIT Statement

FIT < *equations* > < **PARMS=(***parameter* < *values* > ... **)** > < **START=(***parameter values* ... **)** > < **DROP=(***parameter* ... **)** > < **INITIAL=(***variable* < = *parameter* | *constant* > ... **)** > < / *options* > **;**

PROC TMODEL includes additional options in the FIT statement to provide more control of the estimation process than PROC MODEL provides. For a complete description of the syntax of the FIT statement, see the section "FIT Statement" on page 1458 in Chapter 24, "The MODEL Procedure." The syntax for specifying the new options follows:

FIT < ... > < / **QUADHESS=LINEAR** | **ANALYTIC** | **FDA** < **OPTIMIZER=***type* < **(***ORMP-optimizer-options***)** > > > **;**

Options to Control the Estimation Process

QUADHESS=LINEAR | ANALYTIC | FDA (Experimental)
specifies which method to use to compute the Hessian matrix during the optimization process. For FIML and *t* distribution estimations, the HESSIAN= option is used to specify how the Hessian matrix is computed, and the QUADHESS= option has no effect.

ANALYTIC uses the exact analytical representation of the Hessian matrix during the optimization process. This option might improve convergence properties for certain nonlinear models. It is not available for feasible GLS estimations or random-effects estimations.

FDA uses a finite difference approximation to the Hessian matrix during the optimization process. This option is available only when the OPTIMIZER=ORMP option is specified.

LINEAR uses the crossproduct of the Jacobian matrix as an approximation to the Hessian matrix during the optimization process.

By default, QUADHESS=LINEAR.

Options to Control the Optimization Process

The following options control the optimization process. For more information about the optimizers available in PROC TMODEL, see the section "Nonlinear Optimization" on page 2817.

OPTIMIZER=*type***<(***ORMP-optimizer-options***)>**
specifies which optimizer to use to perform the numerical minimization. You can specify only one of the following *types*. By default, OPTIMIZER=ORMP.

ZOPT uses the optimizer that is used in PROC MODEL in the minimization.

You can also specify the following *options* after the slash in the FIT statement: CONVERGE=, MAXITER=, MAXSUBITER=, METHOD=.

ORMP uses the nonlinear programming solver available in SAS/OR software in the minimization. For more information about the ORMP nonlinear solver, see Chapter 10, "The Nonlinear Programming Solver" (*SAS/OR User's Guide: Mathematical Programming*).

You can specify the following *ORMP-optimizer-options*:

ALGORITHM=ACTIVESET | CONCURRENT | INTERIORPOINT
specifies the optimization technique to use to solve the problem. By default, ALGORITHM=INTERIORPOINT.

FEASTOL=ϵ
defines the feasible tolerance. By default, FEASTOL=1E–6.

MAXITER=*n*
requests that the NLP solver take at most *n* major iterations to determine an optimum. By default, MAXITER=5,000.

MAXTIME=*t*
specifies an upper limit of *t* units of time for the optimization process. If you do not specify this option, the NLP solver does not stop because of time elapsed.

MSBNDRANGE=*m*
defines the range from which each variable can take values during the sampling process. By default, MSBNDRANG=200.

MSDISTTOL=ϵ
specifies the tolerance by which two optimal points are considered distinct. Optimal points are considered distinct if the Euclidean distance between them is at least ϵ. By default, MSDISTTOL=1.0E–6.

MSMAXSTARTS=*n*
specifies the maximum number of starting points to use for local optimization. By default, MSMAXSTARTS=100.

MSMAXTIME=*t*

specifies the maximum time *t* (in seconds) for the NLP solver to locate the best local optimum in multistart mode. If you do not specify this option, the multistart algorithm does not stop because of the amount of time elapsed.

MULTISTART

enables multistart mode. In this mode, the local solver solves the problem from multiple starting points, possibly finding a better local minimum as a result. By default, this option is disabled.

OBJLIMIT=*m*

specifies a limit on the magnitude of the objective value. The algorithm terminates when the objective value becomes less than $-m$. The minimum acceptable value of m is 1E+8. If the specified value of m is less than 1E+8, the value is reset to the default value. By default, OBJLIMIT=1E+20.

OPTTOL=ϵ

defines the measure by which the ORMP optimizer decides whether the current iterate is an acceptable approximation of a local minimum, where ϵ is a positive real number. The ORMP optimizer determines that the current iterate is a local minimum when the norm of the scaled vector of the optimality conditions is less than ϵ and the true constraint violation is less than the value of the FEASTOL= option. By default OPTTOL=1E–6.

SEED=*n*

specifies a positive integer to use as the seed for generating random number sequences in multistart mode. To ensure reproducible results, specify a nonzero value. By default, SEED=0.

TIMETYPE=CPU | REAL

specifies the units of time that the MAXTIME= option uses. If you do not specify this option, the multistart algorithm does not stop because of the amount of time elapsed.

Options to Control the Solution of a System of Linear Equations

LUSOLVER=NUMPIVOT | STRUCTPIVOT | OLD | *n*

specifies the method to use to factor and solve systems of linear equations. These linear systems are encountered when the FIML option (which requests that the FIML method be used to estimate models) is specified in the FIT statement or the PROC TMODEL statement. These linear systems are also encountered when either the NEWTON or OPTIMIZE option is specified in the SOLVE statement (these options specify the numerical solution method). Also, model programs that include differential equations require the solution of linear systems of equations. You can specify the following values:

n	considers numerical values of matrix elements only every *n*th time a lower triangular times upper triangular (LU) matrix factorization is computed.
NUMPIVOT	considers numerical values of matrix elements each time an LU factorization is computed.
OLD	uses the factorization and solution algorithm that the MODEL procedure uses.

STRUCTPIVOT considers only the structure of nonzero elements in the linear system for ordering equations in the LU factorization.

By default, LUSOLVER=NUMPIVOT.

PERFORMANCE Statement

PERFORMANCE <**NTHREADS=***n*> <**BYPRIORITY=***priority*> <**REPPRIORITY=***priority*> <**MSPRIORITY** | **GRIDPRIORITY=***priority*> <**PARTPRIORITY=***priority* > **;**

The PERFORMANCE statement controls how an estimation or simulation task in PROC TMODEL uses multiple execution threads. You can specify two types of information in a PERFORMANCE statement: the *number* of threads and the *priority* of calculations to which the threads are assigned. Calculations with a higher priority are allocated a greater number of threads, and calculations with a lower priority are allocated fewer threads. When a calculation is assigned a priority of zero, it is executed in one thread. When priority options are not specified, PROC TMODEL assigns default priority values based on properties of the model program and data.

Each PERFORMANCE statement is associated with the FIT or SOLVE statement that precedes it. When there is no preceding FIT or SOLVE statement, the PERFORMANCE statement is associated with the FIT or SOLVE statement that follows it.

The following options apply to both estimation and simulation tasks:

BYPRIORITY=*priority*
specifies the priority for allocating the computation threads to process BY groups concurrently in the input data set. The value of *priority* must be between 0 and 1, where 0 specifies the lowest priority and 1 specifies the highest priority.

CPUCOUNT=*n*

NTHREADS=*n*
specifies the approximate number of concurrent computation threads to use. By default, the global CPUCOUNT= option is used to specify the number of threads. The actual number of threads that are used might vary from the value that you specify in the CPUCOUNT= or NTHREADS= option based on the properties of the model program, the properties of the input data set, and the priority options specified in the PERFORMANCE statement.

Options to Configure Estimation Threads

MSPRIORITY=*priority*

GRIDPRIORITY=*priority*
specifies the priority for allocating computation threads for the concurrent execution of the optimizer during the estimation process. Concurrent execution of the optimizer is possible when the OPTIMIZER=ORMP(MULTISTART) option or the START= option is specified in the FIT statement. The value of *priority* must be between 0 and 1, where 0 specifies the lowest priority and 1 specifies the highest priority.

PARTPRIORITY=*priority*
specifies the priority for allocating computation threads for concurrent execution across partitions of the input data set. The value of *priority* must be between 0 and 1, where 0 specifies the lowest priority and 1 specifies the highest priority.

Option to Configure Simulation Threads

REPPRIORITY=*priority*
specifies the priority for allocating computation threads for the concurrent execution of repetitions of the input data set when you are performing Monte Carlo simulations. The value of *priority* must be between 0 and 1, where 0 specifies the lowest priority and 1 specifies the highest priority.

For more information about multithreading in PROC TMODEL, see the section "Multithreaded Calculations" on page 2820.

RANDOM Statement (Experimental)

RANDOM *random-effects* ~ *distribution* < *options* > **;**

The RANDOM statement specifies which parameters in the model program are random effects and defines their distribution. The statement consists of a list of the random effects, a tilde (~), and then the distribution of the random effects. The RANDOM statement must also be accompanied by a CROSSSECTION statement, which specifies the subject variables. Only one RANDOM statement can be associated with each FIT statement.

The only distribution available for the random effects is normal(m,v), with mean m and variance v. This syntax is illustrated as follows for one effect:

```
random u ~ normal(0,s2u);
```

For multiple effects, you should specify bracketed vectors for m and v, the latter consisting of the lower triangular elements of the random-effects variance matrix listed in row order. This is illustrated for two random effects as follows:

```
random b1 b2 ~ normal([0,0],[g11,g21,g22]);
```

Similarly, the syntax for three random effects is illustrated as follows:

```
random b1 b2 b3 ~ normal([0,0,0],[g11,g21,g22,g31,g32,g33]);
```

The variables that you specify in the CROSSSECTION statement determine the unique realizations of the random effects. The observations for each value of the CROSSSECTION variables must be grouped together in the input data set. PROC TMODEL processes the input data set sequentially and considers an observation to be from a new cross section whenever the values of the CROSSSECTION variables change from the previous observation.

You can specify the following *options* in the RANDOM statement:

EBESOPT
specifies that the empirical Bayes estimates of the random effects that are computed for each value of the CROSSSECTION variables during the optimization process be computed by performing a nonlinear optimization. When you specify this option, the optimizer that you specify in the OPTIMIZER= option in the FIT statement is used to compute the empirical Bayes estimates. By default, a Newton search algorithm computes the empirical Bayes estimates.

NOPSD
specifies that the covariance matrix of random effects not be constrained to be positive semidefinite. This option might improve convergence properties for certain parameterizations of the random-effects covariance matrix.

NUMQUADPTS=*n*
specifies the number of quadrature points to use in the adaptive Gaussian quadrature approximation of the likelihood function. Each random effect is evaluated at *n* points during the approximation of the likelihood function, so if there are *r* random effects, the likelihood function is evaluated at n^r points. By default, NUMQUADPTS=1.

PSD
specifies that the covariance matrix of random effects be constrained to be positive semidefinite. PSD is the default.

SOLVE Statement

SOLVE *variables* < **SATISFY=** *equations* > < */options* > **;**

PROC TMODEL includes additional *options* in the SOLVE statement to provide more control of the solution process than PROC MODEL provides. For a complete description of the syntax of the SOLVE statement, see the section "SOLVE Statement" on page 1475 in Chapter 24, "The MODEL Procedure."

You can specify the following *options* after the slash.

Options to Control the Solution of a System of Linear Equations

LUSOLVER=NUMPIVOT | STRUCTPIVOT | OLD | *n*
specifies the method to use to factor and solve systems of linear equations. These linear systems are encountered when the FIML option (which requests that the FIML method be used to estimate models) is specified in the FIT statement or the PROC TMODEL statement. These linear systems are also encountered when either the NEWTON or OPTIMIZE option is specified in the SOLVE statement (these options specify the numerical solution method). Also, model programs that include differential equations require the solution of linear systems of equations. You can specify the following values:

n	considers numerical values of matrix elements only every *n*th time a lower triangular times upper triangular (LU) matrix factorization is computed.
NUMPIVOT	considers numerical values of matrix elements each time an LU factorization is computed.
OLD	uses the factorization and solution algorithm that the MODEL procedure uses.

STRUCTPIVOT considers only the structure of nonzero elements in the linear system for ordering equations in the LU factorization.

By default, LUSOLVER=NUMPIVOT.

Details: TMODEL Procedure

Panel Data

Panel data, also known as longitudinal data, consist of observations made over time for multiple subjects or cross sections. Data that are recorded in this form are often used to analyze dynamic models, which use past information to model the relationships among variables. In PROC TMODEL, you can analyze dynamic models that use panel data by identifying the cross-sectional variables in a CROSSSECTION statement. The following example illustrates how to use the CROSSSECTION statement to estimate an autoregressive model that has one parameter shared among five time series:

```
data d;
   length cs $ 8;
   array csname{5} $ _temporary_ ( 'first' 'second' 'third' 'fourth' 'fifth' );
   call streaminit (1);
   do pp = 1 to dim(csname);
      lagx = 0;
      do t = 1 to 10;
         x = 0.8*lagx + rand('normal');
         lagx = x;
         cs = csname[pp];
         output;
      end;
   end;
run;

proc tmodel data=d;
   endo x;
   crosssection cs;
   parms p;

   x = p*lag(x);
   fit;
quit;
```

In this example, PROC TMODEL skips the first observation in each time series because the first lag of *x* is not available. Figure 39.2 shows that only 45 of the 50 observations contribute to the estimation, because the first observation in each series is skipped.

Figure 39.2 Observation Counts in a Dynamic Model Estimation

The TMODEL Procedure

Number of Observations		Statistics for System	
Used	45	**Objective**	0.9694
Missing	0	**Objective*N**	43.623

Panel data are also treated differently from ordinary observational data for the purpose of multithreading. When no cross-sectional variables are specified, the observations in the DATA= data set are partitioned in a round-robin fashion among computational threads. Figure 39.3 shows how observations are partitioned among threads in the presence and absence of a cross-sectional variable specification.

Figure 39.3 Data Partitioning Strategies in a Multithreaded Environment

Original Data Set

OBS	CS	TIME
1	A	1
2	A	2
3	A	3
4	A	4
5	B	1
6	B	2
7	B	3
8	B	4
9	B	5
10	B	6

Round-Robin Partitioning

Thread #1			Thread #2			Thread #3			Thread #4		
OBS	CS	TIME	OBS	CS	TIME	OBS	CS	TIME	OBS	CS	TIME
1	A	1	2	A	2	3	A	3	4	A	4
5	B	1	6	B	2	7	B	3	8	B	4
9	B	5	10	B	6						

Partitioning with CROSSSECTION Statement

Thread #1			Thread #2			Thread #3			Thread #4		
OBS	CS	TIME	OBS	CS	TIME	OBS	CS	TIME	OBS	CS	TIME
1	A	1	5	B	1						
2	A	2	6	B	2						
3	A	3	7	B	3						
4	A	4	8	B	4						
			9	B	5						
			10	B	6						

In the case where no cross sectional-variables are specified and a dynamic model with lag terms is being analyzed, all the observations are processed sequentially in a single thread.

Another use for panel data is in random-effects models, which model the variation among subjects in the data. In these models, the grouping of observations into subjects is achieved by specifying cross-sectional variables in the same manner as in the other panel data applications in PROC TMODEL.

Random-Effects Models (Experimental)

The general nonlinear model that is estimated by PROC MODEL and PROC TMODEL can be extended to accommodate observations on M subjects as follows,

$$\mathbf{q}(\mathbf{y}_{it}, \mathbf{x}_{it}, \boldsymbol{\phi}, \mathbf{u}_i) = \boldsymbol{\epsilon}_{it}, \qquad i = 1, \ldots, M \quad t = 1, \ldots, M_i$$

where $\mathbf{q} \in R^g$ is a real-vector-valued function of $\mathbf{y}_{it} \in R^g$, $\mathbf{x}_{it} \in R^l$, $\boldsymbol{\phi} \in R^p$, and $\mathbf{u}_i \in R^r$, where g is the number of equations, l is the number of exogenous variables (lagged endogenous variables are considered exogenous here), p is the number of fixed parameters, r is the number of random effects, M is the number of subjects, and M_i is the number of observations on the ith subject. The random effects, $\mathbf{u}_i$, that are associated with the ith subject are distributed as follows,

$$\begin{aligned}
\mathbf{u}_i &\sim N(\boldsymbol{\mu}, \mathbf{D}) \\
\boldsymbol{\mu} &= \boldsymbol{\mu}(\boldsymbol{\xi}) \\
\mathbf{D} &= \mathbf{D}(\boldsymbol{\xi})
\end{aligned}$$

where $\boldsymbol{\mu}$ is an $r \times 1$ vector of means of the random effects, $\mathbf{D}$ is an $r \times r$ covariance matrix of the random effects, and $\boldsymbol{\xi}$ is a vector of parameters of the random-effects distribution.

The vector of unknown parameters for the random-effects models is $\boldsymbol{\theta} = [\boldsymbol{\phi}, \boldsymbol{\xi}]$. PROC TMODEL performs a maximum likelihood estimation of $\boldsymbol{\theta}$ and the covariance of $\boldsymbol{\theta}$ by using the following marginal distribution of $\mathbf{y}$ based on the joint distribution of $\mathbf{y}$ and the random effects, $\mathbf{u}_i$,

$$p(\boldsymbol{\theta}) = \prod_{i=1}^{M} \int p(\mathbf{y}_i | \mathbf{x}_i, \boldsymbol{\phi}, \mathbf{u}_i)\, p(\mathbf{u}_i | \boldsymbol{\xi})\, d\,\mathbf{u}_i$$

where $p(\mathbf{y}_i | \mathbf{x}_i, \boldsymbol{\phi}, \mathbf{u}_i)$ is the conditional distribution of $\mathbf{y}$ for the ith subject and $p(\mathbf{u}_i | \boldsymbol{\xi})$ is the conditional distribution of the random effects.

Random-Effects Estimation

Estimating the maximum likelihood values of $\boldsymbol{\theta}$ requires computation of an integral over the random effects. PROC TMODEL approximates this integral by using the adaptive Gaussian quadrature method described in Pinheiro and Bates (1995).

PROC TMODEL minimizes the following negative log-likelihood function to estimate the parameters in random-effects models,

$$-\log p(\boldsymbol{\theta}) \approx \sum_{i=1}^{M} \left(\frac{1}{2} \log |\mathbf{G}_i| - \log \sum_{q=1}^{Q} e^{\mathrm{obj}_{i,q}} \right) + \frac{M}{2} \left(\log |\mathbf{D}| + r \log 2\pi \right)$$

where

$$\begin{aligned}
\mathrm{obj}_{i,q} &= -\frac{1}{2} \sum_{j=1}^{M_i} \mathbf{q}_j'(\mathbf{v}_q) \mathbf{H}^{-1} \mathbf{q}_j(\mathbf{v}_q) + \mathbf{z}_q' \mathbf{z}_q + \sum_{k=1}^{r} \log w_k - \frac{1}{2} \mathbf{v}_q' \mathbf{D}^{-1} \mathbf{v}_q \\
\mathbf{H} &= \mathrm{diag}(h_1, \ldots, h_g) \\
\mathbf{v}_q &= \hat{\mathbf{u}}_i + \sqrt{2} \mathbf{G}_i^{-1/2} \mathbf{z}_q \\
\mathbf{G}_i &= -\nabla^2_{\mathbf{u}_i} \mathrm{obj}_i + \mathbf{D}^{-1}
\end{aligned}$$

where Q is the number of quadrature points used to approximate the integral, M_i is the number of observations on the ith subject, obj_i is the ith-subject-specific objective function evaluated at the empirical Bayes estimate of the random effects, $\mathrm{obj}_{i,q}$ is the objective function evaluated at the qth quadrature point, $\mathbf{q}_j$ is the vector of equation residuals, h_i is the variance specified for the ith equation, $\mathbf{z}_q$ is the qth quadrature point, w_k is the weight for the kth element of the quadrature point vector, $\mathbf{v}_q$ is the random-effects vector evaluated at the qth quadrature point, $\hat{\mathbf{u}}_i$ is the empirical Bayes estimate of the random effects for the ith subject, $\mathbf{G}_i$ is the random-effects scale matrix for the ith subject, and $\nabla^2_{\mathbf{u}_i}\mathrm{obj}_i$ is the Hessian of the empirical Bayes estimate of the random effects for the ith subject. The gradient of the negative log-likelihood function is computed analytically, and the Hessian is computed numerically.

This approach is also used by PROC NLMIXED. For more information about the implementation of the adaptive Gaussian quadrature method, see Chapter 89, "The NLMIXED Procedure" (*SAS/STAT User's Guide*).

The estimation of random-effects models in PROC TMODEL differs from that in PROC NLMIXED in the following ways:

- PROC TMODEL supports only the adaptive Gaussian quadrature method to compute the integral over random effects.
- PROC TMODEL does not compute the number of quadrature points adaptively.
- PROC TMODEL does not support models that contain variance parameters.
- PROC TMODEL constrains the covariance matrix of the random effects to be positive definite by imposing the nonlinear constraint $|\mathbf{D}| > 0$ in the optimization.
- PROC TMODEL does not support hierarchical random effects.
- PROC TMODEL supports models that have more than one endogenous variable.

Nonlinear Optimization

PROC TMODEL provides two numerical optimization systems, ZOPT and ORMP, to minimize the objective function associated with each of the available estimation methods. The ZOPT system is the same optimization system that PROC MODEL uses, and the nonlinear programming solver, ORMP, is the same optimization system that PROC OPTMODEL uses. The following sections summarize how both optimization systems address issues particular to the problem of estimating model parameters in PROC TMODEL.

Nonlinear Objective Function

The nonlinear dependence of model programs on parameters complicates the optimization process because it can cause the objective function to become a less predictable function of the parameters. The ZOPT optimizer provides the Gauss and Marquardt minimization methods to manage this nonlinear dependency during the numerical search for a minimum. The Gauss method implements a line search during the search process, and the Marquardt method improves the conditioning of the search for an optimum. The ORMP optimizer uses similar techniques to address nonlinearity and ill-conditioning of the minimization problem. In the ORMP optimizer, these techniques are implemented in a hybrid trust region and line-search algorithm.

Constraints on Parameters

Another difficulty occurs during the optimization process when constraints are placed on the parameters. In PROC TMODEL, linear and nonlinear constraints can be introduced through the use of the BOUNDS, RESTRICT, and TEST statements. The ZOPT optimizer handles constraints in the minimization by using an active set algorithm to keep track of and enforce constraints. The ORMP optimizer provides two algorithms to handle constraints, an active set algorithm and an interior point algorithm. The active set algorithm manages constraints during the optimization, which is similar to the approach used by the ZOPT optimizer. The interior point algorithm imposes constraints by using barrier functions.

Multiple Local Minima

Occasionally, characteristics of the data or model program can cause there to be more than one local minimum in the minimization problem. In such cases the optimization process must choose the best minimum from among multiple local minima. In PROC TMODEL, you can specify a grid of initial parameter estimates by using the START= option in the FIT statement, and PROC TMODEL solves the minimization problem by using each point in the grid as an initial estimate. The grid point optimization that converges to the smallest minimum is then selected as the global minimum. Either the ZOPT system or the ORMP system can be used in the grid search approach to solving the global minimization problem.

The ORMP system also supports a multistart algorithm for finding the global minimum. The multistart algorithm chooses the best global minimum from among many local minima, as in the grid search approach; however, the multistart algorithm does not require you to specify the initial grid point estimates.

Choosing an Optimizer

For most problems, there is no need to choose between the ZOPT and ORMP optimizers, because they both converge quickly to the same optimum. However, in cases where the optimizers yield different results, the following general guidelines can help you choose which optimizer to use for a particular problem.

Some considerations for choosing the ZOPT optimizer follow:

- compatibility with PROC MODEL estimation results, because the ZOPT system is also used in PROC MODEL
- faster solutions for smaller problems and for problems that are subject to neither extreme nonlinearities nor ill-conditioning

Some considerations for choosing the ORMP optimizer follow:

- more robust convergence properties for larger problems
- faster and more reliable convergence when there are many constraints on the parameters
- improved estimates in the presence of multiple local minima, or when there is insufficient information to choose initial grid point estimates

Hessian Evaluation (Experimental)

PROC MODEL uses a linear approximation to the Hessian for all estimation methods by default. In most cases, this linear approximation to the Hessian matrix is sufficient to ensure convergence of the optimization. However, for some combinations of models, data, estimation methods, and optimization methods, the estimates that PROC MODEL produces are sensitive to the linear approximation error in the Hessian. To correct for this shortcoming, PROC TMODEL computes an exact analytical representation of the Hessian for many of the estimation methods by default. The exact Hessian that PROC TMODEL uses also improves convergence properties of the ORMP optimizer for some problems. Table 39.2 summarizes estimation methods and exact analytical representations of the Hessian that are available in PROC TMODEL.

Table 39.2 PROC TMODEL Hessians for Estimation Methods

Method	Exact Hessian
OLS ITOLS	$\mathbf{X}'(\text{diag}(\mathbf{S})^{-1}\otimes\mathbf{I})\mathbf{X}+\frac{1}{2}(\mathbf{Q}'(\text{diag}(\mathbf{S})^{-1}\otimes\mathbf{I})\mathbf{r}+\mathbf{r}'(\text{diag}(\mathbf{S})^{-1}\otimes\mathbf{I})\mathbf{Q})$
SUR ITSUR	$\mathbf{X}'(\mathbf{S}^{-1}\otimes\mathbf{I})\mathbf{X}+\frac{1}{2}(\mathbf{Q}'(\mathbf{S}^{-1}\otimes\mathbf{I})\mathbf{r}+\mathbf{r}'(\mathbf{S}^{-1}\otimes\mathbf{I})\mathbf{Q})$
N2SLS ITN2SLS	$\mathbf{X}'(\text{diag}(\mathbf{S})^{-1}\otimes\mathbf{W})\mathbf{X}+\frac{1}{2}(\mathbf{Q}'(\text{diag}(\mathbf{S})^{-1}\otimes\mathbf{W})\mathbf{r}+\mathbf{r}'(\text{diag}(\mathbf{S})^{-1}\otimes\mathbf{W})\mathbf{Q})$
N3SLS ITN3SLS	$\mathbf{X}'(\mathbf{S}^{-1}\otimes\mathbf{W})\mathbf{X}+\frac{1}{2}(\mathbf{Q}'(\mathbf{S}^{-1}\otimes\mathbf{W})\mathbf{r}+\mathbf{r}'(\mathbf{S}^{-1}\otimes\mathbf{W})\mathbf{Q})$

The variables in this table are defined as follows:

- n the number of nonmissing observations
- g the number of equations
- k the number of instrumental variables
- p the number of parameters
- $\mathbf{r}$ the $ng \times 1$ vector of residuals for the g equations stacked together
- $\mathbf{S}$ a $g \times g$ matrix that estimates $\mathbf{\Sigma}$, the covariances of the errors across equations (referred to as the $\mathbf{S}$ matrix)
- $\mathbf{I}$ an $n \times n$ identity matrix
- $\mathbf{X}$ an $ng \times p$ matrix of partial derivatives of the residuals with respect to the parameters
- $\mathbf{Q}$ an $ng \times p \times p$ vector of matrices of second-order partial derivatives of the residuals with respect to the parameters
- $\mathbf{W}$ an $n \times n$ matrix, $\mathbf{Z}(\mathbf{Z}'\mathbf{Z})^{-1}\mathbf{Z}'$
- $\mathbf{Z}$ an $n \times k$ matrix of instruments

The exact analytic Hessians are not currently available for the FIML or GMM estimation methods or for models with random effects.

Multithreaded Calculations

PROC TMODEL uses concurrent computation threads to reduce the time it takes to perform estimation and simulation tasks. Because the characteristics of the input data, model program, and task can vary, PROC TMODEL uses different strategies for breaking its calculations into pieces that can be executed concurrently. For example, when you are estimating a simple model by using a data set with many observations, the most efficient multithreading strategy is to partition the observations and to evaluate the objective function concurrently across the partitions. However, for a highly nonlinear estimation problem with many parameters and fewer observations, the best strategy might be to execute the minimization problem concurrently for multiple regions of the parameter space and then choose the region that yields the optimal estimates.

PROC TMODEL automatically determines which threading strategy to use for each estimation or simulation modeling task by default. Alternatively, you can specify the threading strategy manually by specifying priority options in the PERFORMANCE statement. For each modeling task, the threading strategy is determined by the number of threads allocated to each job in the task. A job is an aspect or dimension of the task that can be executed concurrently with another job. The total number of threads that are used to complete each modeling task is determined as follows,

$$n^* = \prod_{i \in J} \text{ceil}(n \frac{p_i}{p_{\text{tot}}}) \qquad \text{for } p_{\text{tot}} = \sum_{k \in J} p_k$$

where n^* is the actual number of threads used, n is the number of threads specified, $p_i = \max(\text{priority}_i, 10^{-8})$, $\text{priority}_i \in [0, 1]$ is the priority specified for the ith job, and J is the set of all jobs in the modeling task. The allocation of threads to jobs in modeling tasks creates the same number or more threads than the number specified in the PERFORMANCE statement and CPUCOUNT= system option.

Multithreading Estimation Calculations

The following jobs in estimation tasks can be executed currently:

- BY-group processing
- grid search for optimal parameters specified using the START= option in the FIT statement, or multistart global optimization specified by the MULTISTART suboption of the OPTIMIZER= option in the FIT statement
- evaluation of the objective function across partitions of the DATA= data set

For model programs that use lagging functions, the observations in the DATA= data set must be processed sequentially to compute the objective function. In these cases, multithreading across partitions of the data is not possible unless you specify a CROSSSECTION statement or a RANDOM statement. The priority of each estimation job can be specified in the PERFORMANCE statement. When no priorities are specified, PROC TMODEL assigns jobs priorities based on the number of BY groups in the input data set, the number of observations in the input data set, the presence of a START= or MULTISTART option in the FIT statement, and the lag length of the model program.

Multithreading Simulation Calculations

The following jobs in simulation tasks can be executed concurrently:

- BY-group processing
- processing repetitions in Monte Carlo simulations that are specified using the RANDOM= option in the SOLVE statement

The priority of each simulation job can be specified in the PERFORMANCE statement. When no priorities are specified, PROC TMODEL assigns jobs priorities based on the number of BY groups in the input data set, the presence of a RANDOM= option, and the lag length of the model program.

Examples: TMODEL Procedure

Example 39.1: Thread Allocation Using the Performance Statement

This example illustrates how you can use the PERFORMANCE statement to improve the performance of parameter estimation for a data set that contains multiple BY groups. For clarity, a small data set and a simple model are used. In practice, the benefits of configuring the thread allocation strategy are realized only for larger data sets and more computationally demanding models.

In the following PROC TMODEL step, a linear model is estimated for 20 BY groups, each of which contains 1,001 observations:

```
data d;
   call streaminit(1);
   do iby = 1 to 2;
      do jby = 1 to 10;
         do x = -500 to 500;
            y = 2*x + 1 + rand('normal');
            output;
         end;
      end;
   end;
run;

proc tmodel data=d;
   performance nthreads=4 bypriority=1 partpriority=1 / threadconfig timings;
   y = a*x + b;
   by iby jby;
   fit y;
quit;
```

In this example, PROC TMODEL performs the estimations in two concurrent threads, where each thread performs the estimation for 10 BY groups. Also, within the estimation of each BY group, the 1,001 observations are processed concurrently in two partitions, one with 501 observations and the other with 500 observations. Figure 39.1.1 shows how PROC TMODEL divides this estimation problem into threads and the time it takes to complete all 20 estimations.

Output 39.1.1 Multithreading Performance for Two BY-Group Threads

The TMODEL Procedure

Multithreading Configuration		
Calculation Type	Concurrency Factor	Priority
BY Group Processing	2	1.00
Nonlinear Optimization	1	0
Data Partitioning	2	1.00

Performance Summary	
Threads Used	4
Task Time (sec)	6.786222
Program Run Time (sec)	0.352537
Data Time (sec)	0.331969

Another way to perform these estimation tasks is to divide the 20 BY groups into four concurrent threads, where the estimation of each BY group is performed on a single partition that contains all 1,001 observations. You can do this by setting the PARTPRIORITY= option to 0 in the following PERFORMANCE statement:

```
proc tmodel data=d;
   performance nthreads=4 bypriority=1 partpriority=0 / threadconfig timings;
   y = a*x + b;
   by iby jby;
   fit y;
quit;
```

Figure 39.1.2 shows that maximizing the number of BY-group threads improves the performance of this model and data set.

Output 39.1.2 Multithreading Performance for Four BY-Group Threads

The TMODEL Procedure

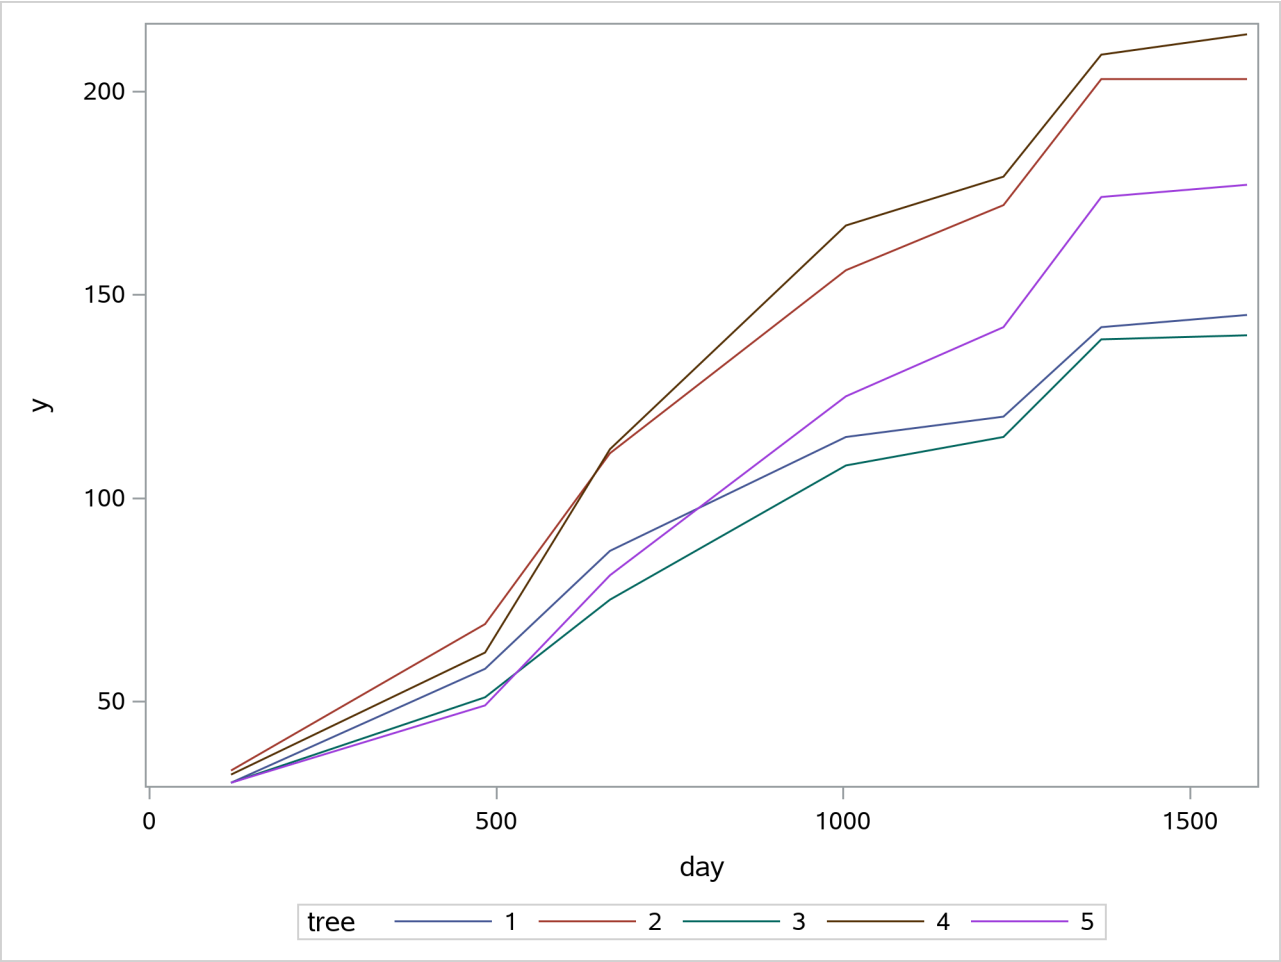
Multithreading Configuration		
Calculation Type	Concurrency Factor	Priority
BY Group Processing	4	1.00
Nonlinear Optimization	1	0
Data Partitioning	1	0

Performance Summary	
Threads Used	4
Task Time (sec)	5.798113
Program Run Time (sec)	0.372177
Data Time (sec)	0.359323

Example 39.2: Random-Effects Parameter Estimation (Experimental)

This example models the circumference of five orange trees over 1,600 days by using a logistic curve to represent the growth of each tree over time in conjunction with a random-effects parameter that accounts for variation among the trees. The tree data for this example come from Draper and Smith (1981) and are displayed in Output 39.2.1.

Output 39.2.1 Orange Tree Growth Curves



Lindstrom and Bates (1990) and Pinheiro and Bates (1995) propose the following logistic nonlinear mixed model for these data:

$$y_{ij} = \frac{b_1 + u_{i1}}{1 + \exp[-(d_{ij} - b_2)/b_3]} + e_{ij}$$

Here, y_{ij} represents the jth circumference measurement on the ith tree ($i = 1, \ldots, 5$; $j = 1, \ldots, 7$); d_{ij} is the corresponding day; b_1, b_2, and b_3 are the fixed-effects parameters; u_{i1} are the random-effect parameters assumed to be iid $N(0, \sigma_u^2)$; and e_{ij} are the residual errors assumed to be iid $N(0, \sigma_e^2)$ and independent of the u_{i1}. The random-effect parameters u_{i1} enter the model linearly.

The following PROC TMODEL step estimates the fixed-effects and random-effect parameters in this model:

```
proc tmodel data=tree;
   parms    b1  200
            b2  800
            b3  800
            s2u;
   num = b1 + u1;
   ex  = exp(-(day-b2)/b3);
   den = 1 + ex;
   y = num/den;
   crosssection tree;
   fit y;
   random u1 ~ normal(0,s2u) / nopsd;
quit;
```

The four SAS programming statements in this PROC TMODEL step specify the logistic model for tree growth. The variable u1 identifies the random effect in this model.

The CROSSSECTION statement defines a variable that indicates when new realizations of the random effect are encountered in the DATA= data set; in this case the variable tree is used.

The RANDOM statement defines the single random effect to be u1 and specifies that it follow a normal distribution with mean 0 and variance s2u. For models that have a nonlinear dependence on the random-effects variables, you can use the NUMQUADPTS= option to specify the number of Gaussian quadrature points to use in the approximation of the likelihood function. In this example, the model has a linear dependence on u1, so the default (NUMQUADPTS=1) is used.

For this example, as with many nonlinear random-effects models, the parameter optimization is sensitive to the selection of initial estimates. Therefore, in the PARMS statement, the values for the fixed-effects parameters are initialized with values based on a cursory examination of Output 39.2.1 to assure convergence. The parameter b1 represents an asymptotic limit for the circumference of an average tree. The parameters b2 and b3 are characteristic of the growth period for the orange trees.

Figure 39.2.2 shows the estimates for the fixed-effects and random-effect parameters together with their standard errors and approximate *t*-values.

Output 39.2.2 Fixed-Effects and Random-Effect Parameters for the Orange Tree Model

The TMODEL Procedure

Nonlinear Random Effects Estimates

Parameter	Estimate	Approx Std Err	t Value	Approx Pr > |t|
b1	192.0205	7.3253	26.21	<.0001
b2	727.7797	4.4848	162.28	<.0001
b3	347.8901	3.4471	100.92	<.0001
s2u	377.435	64.7305	5.83	<.0001

Overview: The TSCSREG Procedure

The TSCSREG (time series cross section regression) procedure analyzes a class of linear econometric models that commonly arise when time series and cross-sectional data are combined. The TSCSREG procedure deals with panel data sets that consist of time series observations on each of several cross-sectional units.

The TSCSREG procedure is very similar to the PANEL procedure; for a full description, syntax details, models, and estimation methods, see Chapter 25, "The PANEL Procedure." The TSCSREG procedure is no longer being updated, and it shares the code base with the PANEL procedure.

The original TSCSREG procedure was developed by Douglas J. Drummond and A. Ronald Gallant, and contributed to the Version 5 SUGI Supplemental Library in 1979. The original code was changed substantially over the years. Additional new methods as well as other new features are currently included in the PANEL PROCEDURE. SAS Institute would like to thank Dr. Drummond and Dr. Gallant for their contribution of the original version of the TSCSREG procedure.

Getting Started: The TSCSREG Procedure

Specifying the Input Data

The input data set used by the TSCSREG procedure must be sorted by cross section and by time within each cross section. Therefore, the first step in using PROC TSCSREG is to make sure that the input data set is sorted. Normally, the input data set contains a variable that identifies the cross section for each observation and a variable that identifies the time period for each observation.

To illustrate, suppose that you have a data set A that contains data over time for each of several states. You want to regress the variable Y on regressors X1 and X2. Cross sections are identified by the variable STATE, and time periods are identified by the variable DATE. The following statements sort the data set A appropriately:

```
proc sort data=a;
   by state date;
run;
```

The next step is to invoke the TSCSREG procedure and specify the cross section and time series variables in an ID statement. List the variables in the ID statement exactly as they are listed in the BY statement.

```
proc tscsreg data=a;
   id state date;
```

Alternatively, you can omit the ID statement and use the CS= and TS= options in the PROC TSCSREG statement to specify the number of cross sections in the data set and the number of time series observations in each cross section.

Unbalanced Data

In the case of fixed-effects and random-effects models, the TSCSREG procedure is capable of processing data with different numbers of time series observations across different cross sections. You must specify the ID statement to estimate models that use unbalanced data. The missing time series observations are recognized by the absence of time series ID variable values in some of the cross sections in the input data set. Moreover, if an observation with a particular time series ID value and cross-sectional ID value is present in the input data set, but one or more of the model variables are missing, that time series point is treated as missing for that cross section.

Specifying the Regression Model

Next, specify the linear regression model with a MODEL statement, as shown in the following statements:

```
proc tscsreg data=a;
   id state date;
   model y = x1 x2;
run;
```

The MODEL statement in PROC TSCSREG is specified like the MODEL statement in other SAS regression procedures: the dependent variable is listed first, followed by an equal sign, followed by the list of regressor variables.

The reason for using PROC TSCSREG instead of other SAS regression procedures is that you can incorporate a model for the structure of the random errors. It is important to consider what kind of error structure model is appropriate for your data and to specify the corresponding option in the MODEL statement.

The error structure options supported by the TSCSREG procedure are FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, and DASILVA. For more information about these methods and the error structures they assume, see the section "Details: The TSCSREG Procedure" on page 2838.

By default, the two-way random-effects error model structure is used while Fuller-Battese and Wansbeek-Kapteyn methods are used for the estimation of variance components in balanced data and unbalanced data, respectively. Thus, the preceding example is the same as specifying the RANTWO option, as shown in the following statements:

```
proc tscsreg data=a;
   id state date;
   model y = x1 x2 / rantwo;
run;
```

You can specify more than one error structure option in the MODEL statement; the analysis is repeated using each method specified. You can use any number of MODEL statements to estimate different regression models or estimate the same model by using different options.

In order to aid in model specification within this class of models, the procedure provides two specification test statistics. The first is an F statistic that tests the null hypothesis that the fixed-effects parameters are all zero. The second is a Hausman m-statistic that provides information about the appropriateness of the random-effects specification. It is based on the idea that, under the null hypothesis of no correlation between the effects variables and the regressors, OLS and GLS are consistent, but OLS is inefficient. Hence, a test can be based on the result that the covariance of an efficient estimator with its difference from an inefficient estimator is zero. Rejection of the null hypothesis might suggest that the fixed-effects model is more appropriate.

The procedure also provides the Buse R-square measure, which is the most appropriate goodness-of-fit measure for models estimated by using GLS. This number is interpreted as a measure of the proportion of the transformed sum of squares of the dependent variable that is attributable to the influence of the independent variables. In the case of OLS estimation, the Buse R-square measure is equivalent to the usual R-square measure.

Estimation Techniques

If the effects are fixed, the models are essentially regression models with dummy variables that correspond to the specified effects. For fixed-effects models, ordinary least squares (OLS) estimation is equivalent to best linear unbiased estimation.

The output from PROC TSCSREG is identical to what one would obtain from creating dummy variables to represent the cross-sectional and time (fixed) effects. The output is presented in this manner to facilitate comparisons to the least squares dummy variables estimator (LSDV). As such, the inclusion of a intercept term implies that one dummy variable must be dropped. The actual estimation of the fixed-effects models is not LSDV. LSDV is much too cumbersome to implement. Instead, PROC TSCSREG operates in a two-step fashion. In the first step, the following occurs:

- *One-way fixed-effects model*: In the one-way fixed-effects model, the data are transformed by removing the cross-sectional means from the dependent and independent variables. The following is true:

$$\tilde{y}_{it} = y_{it} - \bar{y}_{i\cdot}$$

$$\tilde{\mathbf{x}}_{it} = \mathbf{x}_{it} - \bar{\mathbf{x}}_{i\cdot}$$

- *Two-way fixed-effects model*: In the two-way fixed-effects model, the data are transformed by removing the cross-sectional and time means and adding back the overall means,

$$\tilde{y}_{it} = y_{it} - \bar{y}_{i\cdot} - \bar{y}_{\cdot t} + \bar{\bar{y}}$$

$$\tilde{\mathbf{x}}_{it} = \mathbf{x}_{it} - \bar{\mathbf{x}}_{i\cdot} - \bar{\mathbf{x}}_{\cdot t} + \bar{\bar{\mathbf{x}}}$$

where y_{it} and $\mathbf{x}_{it}$ are the dependent variable (a scalar) and the explanatory variables (a vector whose columns are the explanatory variables, not including a constant), respectively; $\bar{y}_{i\cdot}$ and $\bar{\mathbf{x}}_{i\cdot}$ are cross section means; $\bar{y}_{\cdot t}$ and $\bar{\mathbf{x}}_{\cdot t}$ are time means; and $\bar{\bar{y}}$ and $\bar{\bar{\mathbf{x}}}$ are the overall means.

The second step consists of running OLS on the properly de-meaned series, provided that the data are balanced. The unbalanced case is slightly more difficult, because the structure of the missing data must be retained. For this case, PROC TSCSREG uses a slight specialization on Wansbeek and Kapteyn.

The other alternative is to assume that the effects are random. In the one-way case, $E(v_i) = 0$, $E(v_i^2) = \sigma_v^2$, and $E(v_i v_j) = 0$ for $i \neq j$, and v_i is uncorrelated with ϵ_{it} for all i and t. In the two-way case, in addition to all of the preceding, $E(e_t) = 0$, $E(e_t^2) = \sigma_e^2$, and $E(e_t e_s) = 0$ for $t \neq s$, and the e_t are uncorrelated with the v_i and the ϵ_{it} for all i and t. Thus, the model is a variance components model, with the variance components σ_v^2, σ_e^2, and σ_ϵ^2, to be estimated. A crucial implication of such a specification is that the effects are independent of the regressors. For random-effects models, the estimation method is an estimated generalized least squares (EGLS) procedure that involves estimating the variance components in the first stage and using the estimated variance covariance matrix thus obtained to apply generalized least squares (GLS) to the data.

Introductory Example

This example uses the cost function data from Greene (1990) to estimate the variance components model. The variable OUTPUT is the log of output in millions of kilowatt-hours, and the variable COST is the log of cost in millions of dollars. For more information, see Greene (1990).

```
title1;
data greene;
   input firm year output cost @@;
   df1 = firm = 1;
   df2 = firm = 2;
   df3 = firm = 3;
   df4 = firm = 4;
   df5 = firm = 5;
   d60 = year = 1960;
   d65 = year = 1965;
   d70 = year = 1970;
datalines;
    1 1955   5.36598   1.14867  1 1960   6.03787   1.45185

... more lines ...
```

Usually you cannot explicitly specify all the explanatory variables that affect the dependent variable. The omitted or unobservable variables are summarized in the error disturbances. The TSCSREG procedure used with the RANTWO option specifies the two-way random-effects error model where the variance components are estimated by the Fuller-Battese method, because the data are balanced and the parameters are efficiently estimated by using the GLS method. The variance components model used by the Fuller-Battese method is

$$y_{it} = \sum_{k=1}^{K} X_{itk}\boldsymbol{\beta}_k + v_i + e_t + \epsilon_{it} \quad i = 1,\ldots,N, \;\; t = 1,\ldots,T$$

The following statements fit this model:

```
proc sort data=greene;
   by firm year;
run;

proc tscsreg data=greene;
   model cost = output / rantwo;
   id firm year;
run;
```

The TSCSREG procedure output is shown in Figure 40.1. A model description is printed first; it reports the estimation method used and the number of cross sections and time periods. The variance components estimates are printed next. Finally, the table of regression parameter estimates shows the estimates, standard errors, and t tests.

PROC TSCSREG Statement

PROC TSCSREG *options* **;**

The following options can be specified in the PROC TSCSREG statement:

DATA=*SAS-data-set*
names the input data set. The input data set must be sorted by cross section and by time period within cross section. If you omit the DATA= option, the most recently created SAS data set is used.

TS=*number*
specifies the number of observations in the time series for each cross section. The TS= option value must be greater than 1. The TS= option is required unless an ID statement is used. Note that the number of observations for each time series must be the same for each cross section and must cover the same time period.

CS=*number*
specifies the number of cross sections. The CS= option value must be greater than 1. The CS= option is required unless an ID statement is used.

OUTEST=*SAS-data-set*
the parameter estimates. When the OUTEST= option is not specified, the OUTEST= data set is not created.

OUTCOV
COVOUT
writes the covariance matrix of the parameter estimates to the OUTEST= data set.

OUTCORR
CORROUT
writes the correlation matrix of the parameter estimates to the OUTEST= data set.

In addition, any of the following MODEL statement options can be specified in the PROC TSCSREG statement: CORRB, COVB, FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, DASILVA, NOINT, NOPRINT, M=, PHI, RHO, and SINGULAR=. When specified in the PROC TSCSREG statement, these options are equivalent to specifying the options for every MODEL statement.

BY Statement

BY *variables* **;**

A BY statement can be used with PROC TSCSREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the input data set must be sorted by the BY variables as well as by cross section and time period within the BY groups.

When both an ID statement and a BY statement are specified, the input data set must be sorted first with respect to BY variables and then with respect to the cross section and time series ID variables. For example:

```
proc sort data=a;
   by byvar1 byvar2 csid tsid;
run;

proc tscsreg data=a;
   by byvar1 byvar2;
   id csid tsid;
   ...
run;
```

When both a BY statement and an ID statement are used, the data set might have a different number of cross sections or a different number of time periods in each BY group. If no ID statement is used, the CS=N and TS=T options must be specified and each BY group must contain $N \times T$ observations.

ID Statement

ID *cross-section-id-variable time-series-id-variable* **;**

The ID statement is used to specify variables in the input data set that identify the cross section and time period for each observation.

When an ID statement is used, the TSCSREG procedure verifies that the input data set is sorted by the cross section ID variable and by the time series ID variable within each cross section. The TSCSREG procedure also verifies that the time series ID values are the same for all cross sections.

To make sure the input data set is correctly sorted, use PROC SORT with a BY statement with the variables listed exactly as they are listed in the ID statement to sort the input data set. For example:

```
proc sort data=a;
   by csid tsid;
run;

proc tscsreg data=a;
   id csid tsid;
   ... etc. ...
run;
```

If the ID statement is not used, the TS= and CS= options must be specified in the PROC TSCSREG statement. Note that the input data must be sorted by time within cross section, regardless of whether the cross section structure is given by an ID statement or by the options TS= and CS=.

If an ID statement is specified, the time series length T is set to the minimum number of observations for any cross section, and only the first T observations in each cross section are used. If both the ID statement and the TS= and CS= options are specified, the TS= and CS= options are ignored.

MODEL Statement

MODEL *response = regressors / options* **;**

The MODEL statement specifies the regression model and the error structure assumed for the regression residuals. The response variable on the left side of the equal sign is regressed on the independent variables listed after the equal sign. Any number of MODEL statements can be used. For each model statement, only one response variable can be specified on the left side of the equal sign.

The error structure is specified by the FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, and DASILVA options. More than one of these options can be used, in which case the analysis is repeated for each error structure model specified.

Models can be given labels up to 32 characters in length. Model labels are used in the printed output to identify the results for different models. If no label is specified, the response variable name is used as the label for the model. The model label is specified as follows:

label: **MODEL** *response = regressors / options* **;**

The following options can be specified in the MODEL statement after a slash (/):

CORRB

CORR

prints the matrix of estimated correlations between the parameter estimates.

COVB

VAR

prints the matrix of estimated covariances between the parameter estimates.

FIXONE

specifies that a one-way fixed-effects model be estimated with the one-way model that corresponds to group effects only.

FIXTWO

specifies that a two-way fixed-effects model be estimated.

RANONE

specifies that a one-way random-effects model be estimated.

RANTWO

specifies that a two-way random-effects model be estimated.

FULLER
specifies that the model be estimated by using the Fuller-Battese method, which assumes a variance components model for the error structure.

PARKS
specifies that the model be estimated by using the Parks method, which assumes a first-order autoregressive model for the error structure.

DASILVA
specifies that the model be estimated by using the Da Silva method, which assumes a mixed variance-component moving-average model for the error structure.

M=*number*
specifies the order of the moving-average process in the Da Silva method. The M= value must be less than $T - 1$. The default is M=1.

PHI
prints the Φ matrix of estimated covariances of the observations for the Parks method. The PHI option is relevant only when the PARKS option is used.

RHO
prints the estimated autocorrelation coefficients for the Parks method.

NOINT
NOMEAN
suppresses the intercept parameter from the model.

NOPRINT
suppresses the normal printed output.

SINGULAR=*number*
specifies a singularity criterion for the inversion of the matrix. The default depends on the precision of the computer system.

TEST Statement

TEST *equation* < , *equation . . .* > < / *options* > ;

The TEST statement performs F tests of linear hypotheses about the regression parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. All hypotheses in one TEST statement are tested jointly. Variable names in the equations must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT refers to the coefficient of the intercept.

The following statements illustrate the use of the TEST statement:

```
proc tscsreg;
   model y = x1 x2 x3;
   test x1 = 0, x2 * .5 + 2 * x3= 0;
   test_int: test intercept=0, x3 = 0;
```

Note that a test of the following form is not permitted:

```
test_bad: test x2 / 2 + 2 * x3= 0;
```

Do not use the division sign in the TEST statement.

Details: The TSCSREG Procedure

Models, estimators, and methods are covered in detail in Chapter 25, "The PANEL Procedure."

ODS Table Names

PROC TSCSREG assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 40.2.

Table 40.2 ODS Tables Produced in PROC TSCSREG

ODS Table Name	Description	Options
ODS Tables Created by the MODEL Statement		
ModelDescription	Model description	Default
FitStatistics	Fit statistics	Default
FixedEffectsTest	*F* test for no fixed effects	FIXONE, FIXTWO, RANONE, RANTWO

Overview: UCM Procedure

The UCM procedure analyzes and forecasts equally spaced univariate time series data by using an unobserved components model (UCM). The UCMs are also called *structural models* in the time series literature. A UCM decomposes the response series into components such as trend, seasonals, cycles, and the regression effects due to predictor series. The components in the model are supposed to capture the salient features of the series that are useful in explaining and predicting its behavior. Harvey (1989) and Pelagatti (2015) are good references for time series modeling that use the UCMs. Harvey calls the components in a UCM the "stylized facts" about the series under consideration. Traditionally, the ARIMA models and, to some limited extent, the exponential smoothing models have been the main tools in the analysis of this type of time series data. It is fair to say that the UCMs capture the versatility of the ARIMA models while possessing the interpretability of the smoothing models. A thorough discussion of the correspondence between the ARIMA models and the UCMs, and the relative merits of UCM and ARIMA modeling, is given in Harvey (1989). The UCMs are also very similar to another set of models, called the *dynamic models*, that are popular in the Bayesian time series literature (West and Harrison 1999). In SAS/ETS, you can use PROC SSM for multivariate (and more general univariate) UCMs (see Chapter 33, "The SSM Procedure"), PROC ARIMA for ARIMA modeling (see Chapter 7, "The ARIMA Procedure"), and PROC ESM for exponential smoothing modeling (see Chapter 14, "The ESM Procedure").

You can use the UCM procedure to fit a wide range of UCMs that can incorporate complex trend, seasonal, and cyclical patterns and can include multiple predictors. It provides a variety of diagnostic tools to assess the fitted model and to suggest the possible extensions or modifications. The components in the UCM provide a succinct description of the underlying mechanism governing the series. You can print, save, or plot the estimates of these component series. Along with the standard forecast and residual plots, the study of these component plots is an essential part of time series analysis using the UCMs. Once a suitable UCM is found

for the series under consideration, it can be used for a variety of purposes. For example, it can be used for the following:

- forecasting the values of the response series and the component series in the model
- obtaining a model-based seasonal decomposition of the series
- obtaining a "denoised" version and interpolating the missing values of the response series in the historical period
- obtaining the full sample or "smoothed" estimates of the component series in the model

Getting Started: UCM Procedure

The analysis of time series using the UCMs involves recognizing the salient features present in the series and modeling them suitably. The UCM procedure provides a variety of models for estimating and forecasting the commonly observed features in time series. These models are discussed in detail later in the section "An Introduction to Unobserved Component Models" on page 2883. First the procedure is illustrated using an example.

A Seasonal Series with Linear Trend

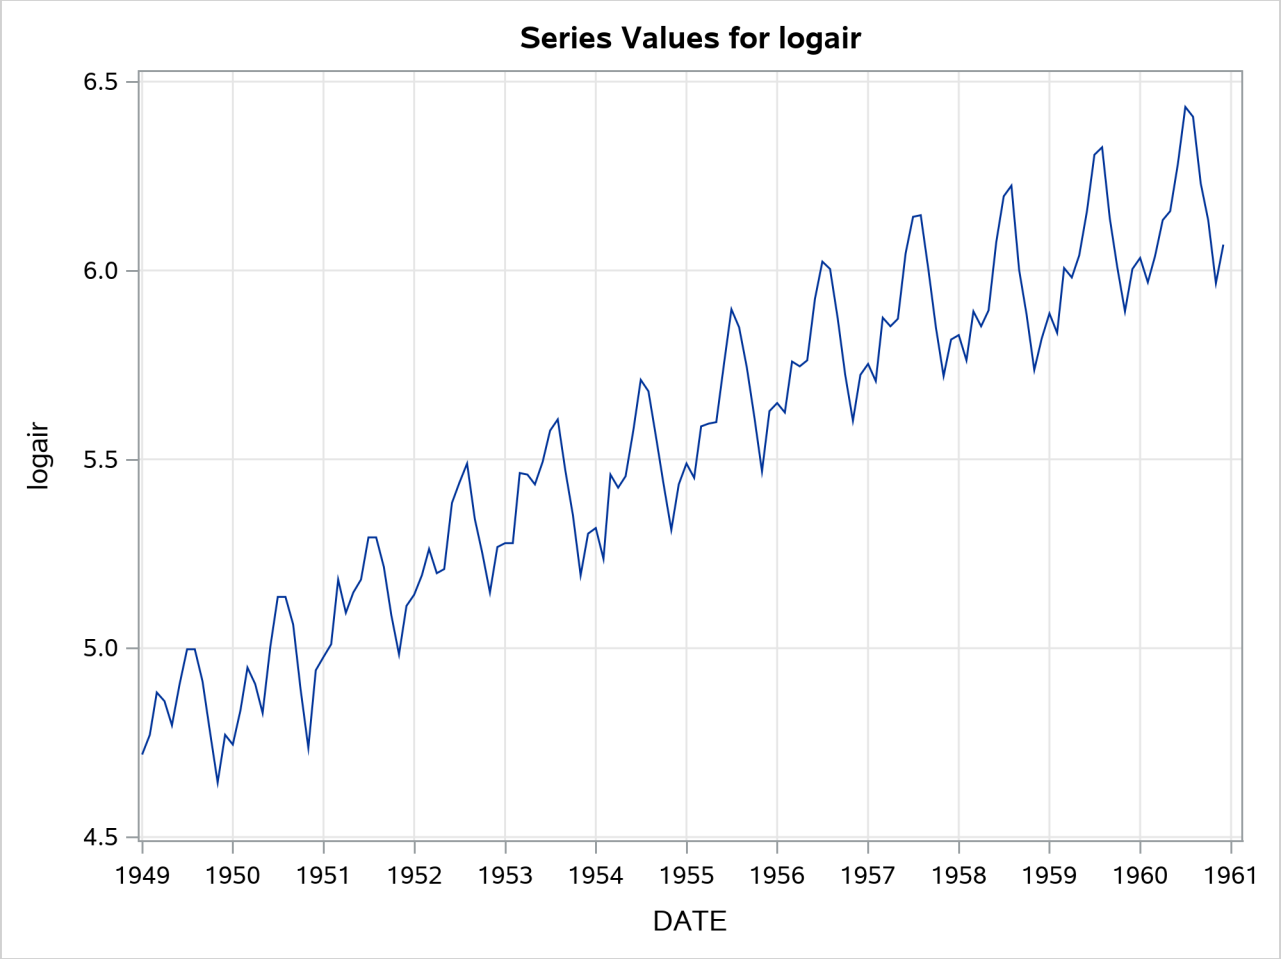
The airline passenger series, given as Series G in Box and Jenkins (1976), is often used in time series literature as an example of a nonstationary seasonal time series. This series is a monthly series consisting of the number of airline passengers who traveled during the years 1949 to 1960. Its main features are a steady rise in the number of passengers from year to year and the seasonal variation in the numbers during any given year. It also exhibits an increase in variability around the trend. A log transformation is used to stabilize this variability. The following DATA step prepares the log-transformed passenger series analyzed in this example:

```
data seriesG;
   set sashelp.air;
   logair = log( air );
run;
```

The following statements produce a time series plot of the series by using the TIMESERIES procedure (see Chapter 38, "The TIMESERIES Procedure"). The trend and seasonal features of the series are apparent in the plot in Figure 41.1.

```
proc timeseries data=seriesG plot=series;
   id date interval=month;
   var logair;
run;
```

Figure 41.1 Series Plot of Log-Transformed Airline Passenger Series



In this example this series is modeled using an unobserved component model called the basic structural model (BSM). The BSM models a time series as a sum of three stochastic components: a trend component μ_t, a seasonal component γ_t, and random error ϵ_t. Formally, a BSM for a response series y_t can be described as

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

Each of the stochastic components in the model is modeled separately. The random error ϵ_t, also called the *irregular component*, is modeled simply as a sequence of independent, identically distributed (iid) zero-mean Gaussian random variables. The trend and the seasonal components can be modeled in a few different ways. The model for trend used here is called a *locally linear time trend*. This trend model can be written as follows:

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, \quad & \eta_t &\sim \text{iid } N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim \text{iid } N(0, \sigma_\xi^2) \end{aligned}$$

These equations specify a trend where the level μ_t as well as the slope β_t is allowed to vary over time. This variation in slope and level is governed by the variances of the disturbance terms η_t and ξ_t in their respective equations. Some interesting special cases of this model arise when you manipulate these disturbance variances.

For example, if the variance of ξ_t is zero, the slope will be constant (equal to β_0); if the variance of η_t is also zero, μ_t will be a deterministic trend given by the line $\mu_0 + \beta_0 t$. The seasonal model used in this example is called a trigonometric seasonal. The stochastic equations governing a trigonometric seasonal are explained later (see the section "Modeling Seasons" on page 2885). However, it is interesting to note here that this seasonal model reduces to the familiar regression with deterministic seasonal dummies if the variance of the disturbance terms in its equations is equal to zero. The following statements specify a BSM with these three components:

```
proc ucm data=seriesG;
   id date interval=month;
   model logair;
   irregular;
   level;
   slope;
   season length=12 type=trig print=smooth;
   estimate;
   forecast lead=24 print=decomp;
run;
```

The PROC UCM statement signifies the start of the UCM procedure, and the input data set, seriesG, containing the dependent series is specified there. The optional ID statement is used to specify a date, datetime, or time identification variable, date in this example, to label the observations. The INTERVAL=MONTH option in the ID statement indicates that the measurements were collected on a monthly basis. The model specification begins with the MODEL statement, where the response series is specified (logair in this case). After this the components in the model are specified using separate statements that enable you to control their individual properties. The irregular component ϵ_t is specified using the IRREGULAR statement and the trend component μ_t is specified using the LEVEL and SLOPE statements. The seasonal component γ_t is specified using the SEASON statement. The specifics of the seasonal characteristics such as the season length, its stochastic evolution properties, etc., are specified using the options in the SEASON statement. The seasonal component used in this example has a season length of 12, corresponding to the monthly seasonality, and is of the *trigonometric* type. Different types of seasonals are explained later (see the section "Modeling Seasons" on page 2885).

The parameters of this model are the variances of the disturbance terms in the evolution equations of μ_t, β_t, and γ_t and the variance of the irregular component ϵ_t. These parameters are estimated by maximizing the likelihood of the data. The ESTIMATE statement options can be used to specify the span of data used in parameter estimation and to display and save the results of the estimation step and the model diagnostics. You can use the estimated model to obtain the forecasts of the series as well as the components. The options in the individual component statements can be used to display the component forecasts—for example, PRINT=SMOOTH option in the SEASON statement requests the displaying of smoothed forecasts of the seasonal component γ_t. The series forecasts and forecasts of the sum of components can be requested using the FORECAST statement. The option PRINT=DECOMP in the FORECAST statement requests the printing of the smoothed trend μ_t and the trend plus seasonal component $(\mu_t + \gamma_t)$.

The parameter estimates for this model are displayed in Figure 41.2.

Figure 41.2 BSM for the Logair Series

The UCM Procedure

Final Estimates of the Free Parameters

Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > |t|
Irregular	Error Variance	0.00023436	0.0001079	2.17	0.0298
Level	Error Variance	0.00029828	0.0001057	2.82	0.0048
Slope	Error Variance	8.47929E-13	6.2271E-10	0.00	0.9989
Season	Error Variance	0.00000356	1.32347E-6	2.69	0.0072

The estimates suggest that except for the slope component, the disturbance variances of all the components are significant—that is, all these components are *stochastic*. The slope component, however, appears to be deterministic because its error variance is quite insignificant. It might then be useful to check if the slope component can be dropped from the model—that is, if $\beta_0 = 0$. This can be checked by examining the significance analysis table of the components given in Figure 41.3.

Figure 41.3 Component Significance Analysis for the Logair Series

Significance Analysis of Components (Based on the Final State)

Component	DF	Chi-Square	Pr > ChiSq
Irregular	1	0.08	0.7747
Level	1	117867	<.0001
Slope	1	43.78	<.0001
Season	11	507.75	<.0001

This table provides the significance of the components in the model at the end of the estimation span. If a component is deterministic, this analysis is equivalent to checking whether the corresponding regression effect is significant. However, if a component is stochastic, then this analysis pertains only to the portion of the series near the end of the estimation span. In this example the slope appears quite significant and should be retained in the model, possibly as a deterministic component. Note that, on the basis of this table, the irregular component's contribution appears insignificant toward the end of the estimation span; however, since it is a stochastic component, it cannot be dropped from the model on the basis of this analysis alone. The slope component can be made deterministic by holding the value of its error variance fixed at zero. This is done by modifying the SLOPE statement as follows:

```
slope variance=0 noest;
```

After a tentative model is fit, its adequacy can be checked by examining different goodness-of-fit measures and other diagnostic tests and plots that are based on the model residuals. Once the model appears satisfactory, it can be used for forecasting. An interesting feature of the UCM procedure is that, apart from the series forecasts, you can request the forecasts of the individual components in the model. The plots of component forecasts can be useful in understanding their contributions to the series. The following statements illustrate some of these features:

```
proc ucm data=seriesG;
   id date interval = month;
   model logair;
   irregular;
```

```
   level plot=smooth;
   slope variance=0 noest;
   season length=12 type=trig
       plot=smooth;
   estimate;
   forecast lead=24 plot=decomp;
run;
```

The table given in Figure 41.4 shows the goodness-of-fit statistics that are computed by using the one-step-ahead prediction errors (see the section "Statistics of Fit" on page 2923). These measures indicate a good agreement between the model and the data. Additional diagnostic measures are also printed by default but are not shown here.

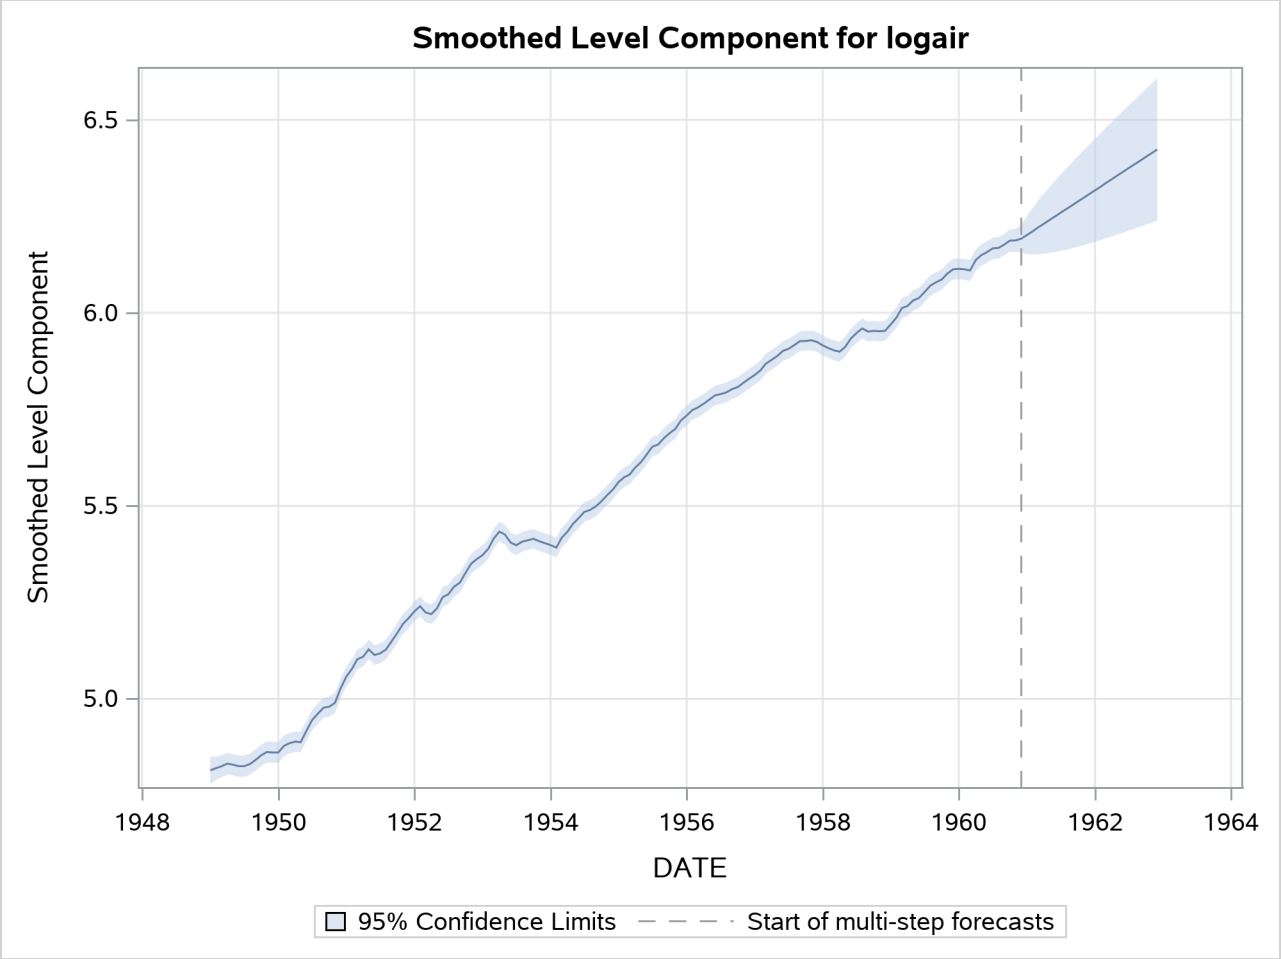
Figure 41.4 Fit Statistics for the Logair Series

The UCM Procedure

Fit Statistics Based on Residuals	
Mean Squared Error	0.00147
Root Mean Squared Error	0.03830
Mean Absolute Percentage Error	0.54132
Maximum Percent Error	2.19097
R-Square	0.99061
Adjusted R-Square	0.99046
Random Walk R-Square	0.87288
Amemiya's Adjusted R-Square	0.99017
Number of non-missing residuals used for computing the fit statistics = 131	

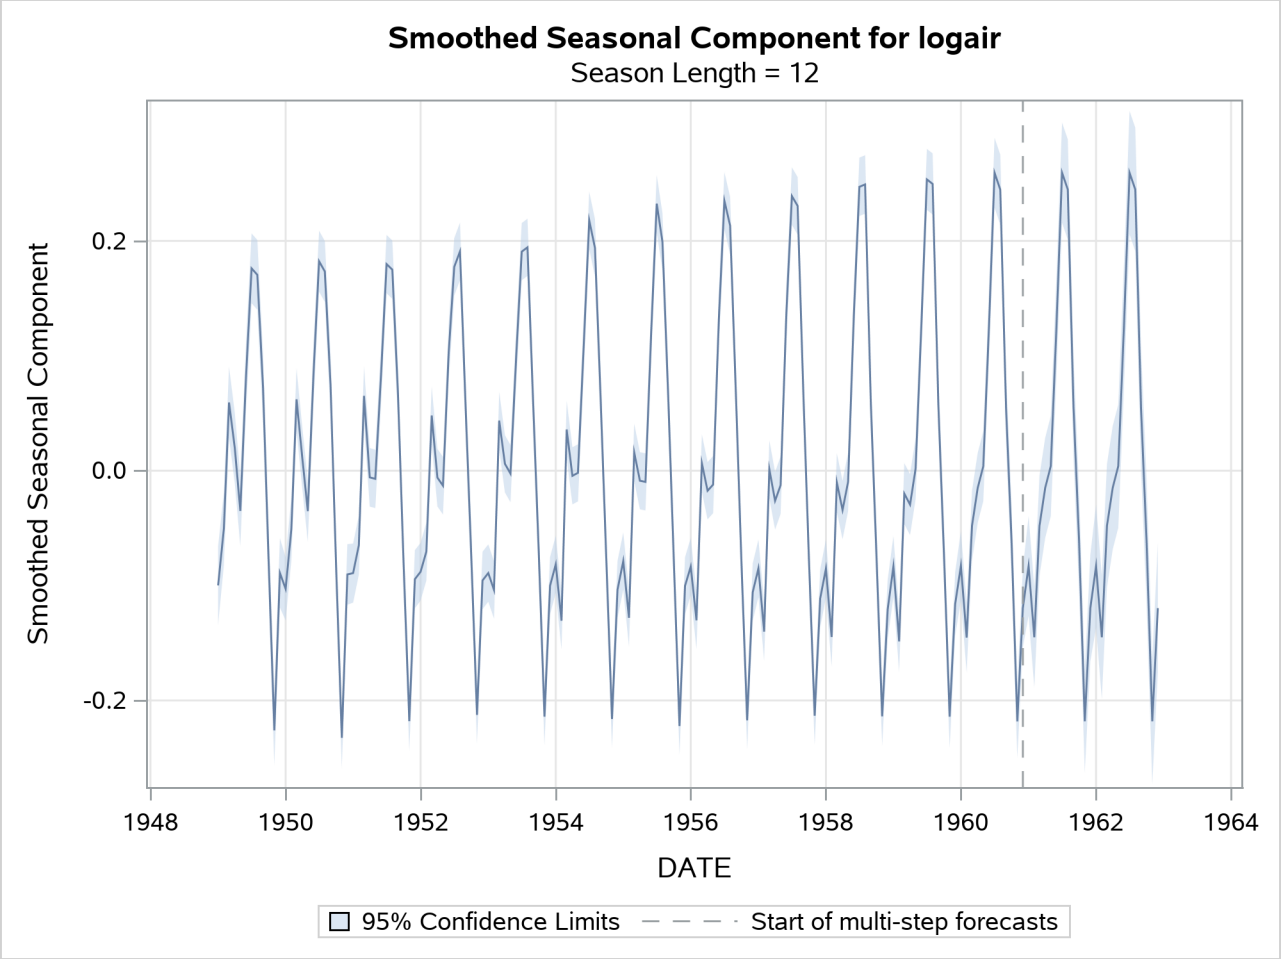
The first plot, shown in Figure 41.5, is produced by the PLOT=SMOOTH option in the LEVEL statement, it shows the smoothed level of the series.

Figure 41.5 Smoothed Trend in the Logair Series



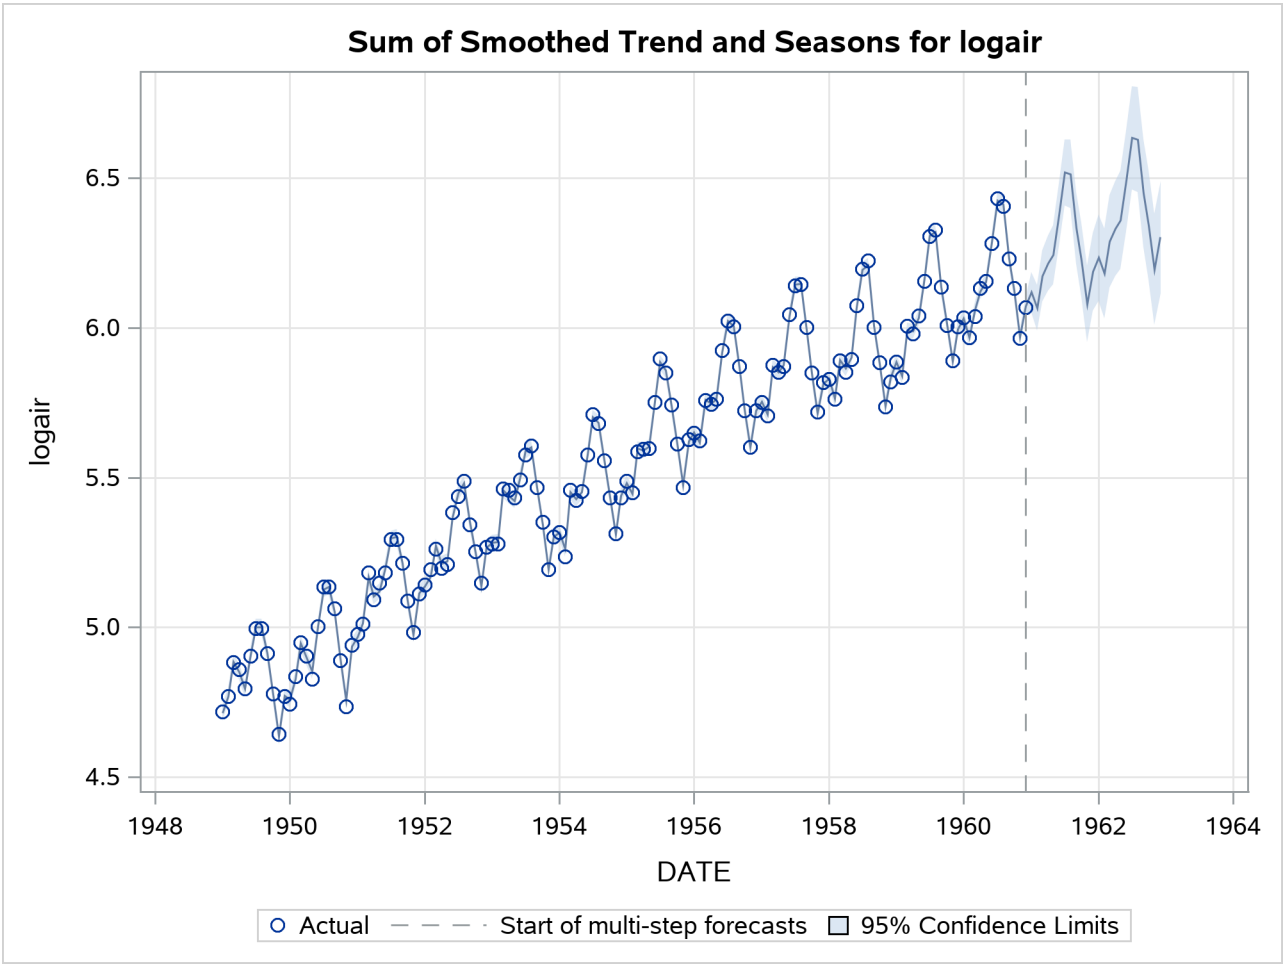
The second plot (Figure 41.6), produced by the PLOT=SMOOTH option in the SEASON statement, shows the smoothed seasonal component by itself.

Figure 41.6 Smoothed Seasonal in the Logair Series



The plot of the sum of the trend and seasonal component, produced by the PLOT=DECOMP option in the FORECAST statement, is shown in Figure 41.7. You can see that, at least visually, the model seems to fit the data well. In all these decomposition plots the component estimates are extrapolated for two years in the future based on the LEAD=24 option specified in the FORECAST statement.

Figure 41.7 Smoothed Trend plus Seasonal in the Logair Series



Syntax: UCM Procedure

The UCM procedure uses the following statements:

```
PROC UCM < options > ;
    AUTOREG < options > ;
    BLOCKSEASON options ;
    BY variables ;
    CYCLE < options > ;
    DEPLAG options ;
    ESTIMATE < options > ;
    FORECAST < options > ;
    ID variable options ;
    IRREGULAR < options > ;
    LEVEL < options > ;
    MODEL dependent variable < = regressors > ;
    NLOPTIONS options ;
    PERFORMANCE options ;
    OUTLIER options ;
    RANDOMREG regressors < / options > ;
    SEASON options ;
    SLOPE < options > ;
    SPLINEREG regressor < options > ;
    SPLINESEASON options ;
    TF regressor < options > ;
```

The PROC UCM and MODEL statements are required. In addition, the model must contain at least one component with nonzero disturbance variance.

Functional Summary

The statements and options controlling the UCM procedure are summarized in Table 41.1. Most commonly needed scenarios are listed; see the individual statements for additional details. You can use the PRINT= and PLOT= options in the individual component statements for printing and plotting the corresponding component forecasts.

Turn off all the plotting for the procedure	PROC UCM	PLOTS=NONE
Turn on all the plotting options for the procedure	PROC UCM	PLOTS=ALL
Turn on a variety of plotting options for the procedure	PROC UCM	PLOTS=

Table 41.1 *continued*

Description	Statement	Option
ID Specify a variable that provides the time index for the series values	ID	

PROC UCM Statement

PROC UCM < *options* > **;**

The PROC UCM statement is required. The following options can be used in the PROC UCM statement:

DATA=*SAS-data-set*
specifies the name of the SAS data set containing the time series. If the DATA= option is not specified in the PROC UCM statement, the most recently created SAS data set is used.

NOPRINT
turns off all the printing for the procedure. The subsequent print options in the procedure are ignored.

PLOTS< (*global-plot-options***) > < = ***plot-request* < **(***options***)** > **>**

PLOTS< (*global-plot-options***) > < = (***plot-request* < **(***options***)** > **< . . .** *plot-request* < **(***options***)** > **>) >**
controls the plots produced with ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request.

Here are some examples:

```
plots=none
plots=all
plots=residuals(acf loess)
plots(noclm)=(smooth(decomp) residual(panel loess))
```

For general information about ODS Graphics, see Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

```
proc ucm;
   model y = x;
   irregular;
   level;
run;

proc ucm plots=all;
   model y = x;
   irregular;
   level;
run;
```

The first PROC UCM step does not specify the PLOTS= option, so the default plot that displays the series forecasts in the forecast region is produced. The PLOTS=ALL option in the second PROC UCM step produces all the plots that are appropriate for the specified model.

In addition to the PLOTS= option in the PROC UCM statement, you can request plots by using the PLOT= option in other statements of the UCM procedure. This way of requesting plots provides finer control over the plot production. If you do not specify any specific plot request, then PROC UCM produces the plot of series forecasts in the forecast horizon by default.

Global Plot Options

The *global-plot-options* apply to all relevant plots generated by the UCM procedure. The following *global-plot-option* is supported:

NOCLM
suppresses the confidence limits in all the component and forecast plots.

Specific Plot Options

The following list describes the specific plots and their options:

ALL
produces all plots appropriate for the particular analysis.

NONE
suppresses all plots.

FILTER (< *filter-plot-options* **>)**
produces time series plots of the filtered component estimates. The following *filter-plot-options* are available:

ALL
produces all the filtered component estimate plots appropriate for the particular analysis.

LEVEL
produces a time series plot of the filtered level component estimate, provided the model contains the level component.

SLOPE
produces a time series plot of the filtered slope component estimate, provided the model contains the slope component.

CYCLE
produces time series plots of the filtered cycle component estimates for all cycle components in the model, if there are any.

SEASON
produces time series plots of the filtered season component estimates for all seasonal components in the model, if there are any.

DECOMP
produces time series plots of the filtered estimates of the series decomposition.

RESIDUAL (< *residual-plot-options* **>)**
produces the residuals plots. The following *residual-plot-options* are available:

ALL
produces all the residual diagnostics plots appropriate for the particular analysis.

ACF
produces the autocorrelation plot of residuals.

CUSUM
produces the plot of cumulative residuals against time.

CUSUMSQ
produces the plot of cumulative squared residuals against time.

HISTOGRAM
produces the histogram of residuals.

LOESS
produces a scatter plot of residuals against time, which has an overlaid loess-fit.

PACF
produces the partial-autocorrelation plot of residuals.

PANEL
produces a summary panel of the residual diagnostics consisting of the following:

- histogram of residuals
- normal quantile plot of residuals
- the residual-autocorrelation-plot
- the residual-partial-autocorrelation-plot

QQ
produces a normal quantile plot of residuals.

RESIDUAL
produces a needle plot of residuals against time.

WN
produces the plot of Ljung-Box white-noise test p-values at different lags (in log scale).

SMOOTH (< *smooth-plot-options* >)
produces time series plots of the smoothed component estimates. The following *smooth-plot-options* are available:

ALL
produces all the smoothed component estimate plots appropriate for the particular analysis.

LEVEL
produces time series plot of the smoothed level component estimate, provided the model contains the level component.

SLOPE
produces time series plot of the smoothed slope component estimate, provided the model contains the slope component.

CYCLE
produces time series plots of the smoothed cycle component estimates for all cycle components in the model, if there are any.

SEASON
produces time series plots of the smoothed season component estimates for all season components in the model, if there are any.

DECOMP
produces time series plots of the smoothed estimates of the series decomposition.

PRINTALL
turns on all the printing options for the procedure. The subsequent NOPRINT options in the procedure are ignored.

AUTOREG Statement

AUTOREG < *options* > **;**

The AUTOREG statement specifies an autoregressive component in the model. An autoregressive component is a special case of cycle that corresponds to the frequency of zero or π. It is modeled separately for easier interpretation. A stochastic equation for an autoregressive component r_t can be written as follows:

$$r_t = \rho r_{t-1} + \nu_t, \quad \nu_t \sim \text{iid } N(0, \sigma_\nu^2)$$

The damping factor ρ can take any value in the interval (–1, 1), including –1 but excluding 1. If $\rho = 1$, the autoregressive component cannot be distinguished from the random walk level component. If $\rho = -1$, the autoregressive component corresponds to a seasonal component with a season length of 2, or a nonstationary cycle with period 2. If $|\rho| < 1$, then the autoregressive component is stationary. The following example illustrates the AUTOREG statement. This statement includes an autoregressive component in the model. The damping factor ρ and the disturbance variance σ_ν^2 are estimated from the data.

```
autoreg;
```

NOEST=RHO

NOEST=VARIANCE

NOEST=(RHO VARIANCE)
fixes the values of ρ and σ_v^2 to those specified in the RHO= and VARIANCE= options.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(<FILTER> <SMOOTH>)
requests plotting of the filtered or smoothed estimate of the autoreg component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(<FILTER> <SMOOTH>)
requests printing of the filtered or smoothed estimate of the autoreg component.

RHO=*value*
specifies an initial value for the damping factor ρ during the parameter estimation process. The value of ρ must be in the interval (–1, 1), including –1 but excluding 1.

VARIANCE=*value*
specifies an initial value for the disturbance variance σ_v^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

BLOCKSEASON Statement

BLOCKSEASON NBLOCKS=*integer* **BLOCKSIZE=***integer* <*options*> **;**

The BLOCKSEASON or BLOCKSEASONAL statement is used to specify a seasonal component γ_t that has a special block structure. The seasonal γ_t is called a *block seasonal* of block size m and number of blocks k if its season length, s, can be factored as $s = m * k$ and its seasonal effects have a block form—that is, the first m seasonal effects are all equal to some number τ_1, the next m effects are all equal to some number τ_2, and so on.

This type of seasonal structure can be appropriate in some cases; for example, consider a series that is recorded on an hourly basis. Further assume that, in this particular case, the hour-of-the-day effect and the day-of-the-week effect are additive. In this situation the hour-of-the-week seasonality, having a season length of 168, can be modeled as a sum of two components. The hour-of-the-day effect is modeled using a simple seasonal of season length 24, while the day-of-the-week is modeled as a block seasonal component that has the days of the week as blocks. This day-of-the-week block seasonal component has seven blocks, each of size 24.

A block seasonal specification requires, at the minimum, the block size m and the number of blocks in the seasonal k. These are specified using the BLOCKSIZE= and NBLOCKS= option, respectively. In addition, you might need to specify the position of the first observation of the series by using the OFFSET= option if it is not at the beginning of one of the blocks. In the example just considered, this corresponds to a situation

where the first series measurement is not at the start of the day. Suppose that the first measurement of the series corresponds to the hour between 6:00 and 7:00 a.m., which is the seventh hour within that day or at the seventh position within that block. This is specified as OFFSET=7.

The other options in this statement are very similar to the options in the SEASON statement; for example, a block seasonal can also be of one of the two types, DUMMY and TRIG. There can be more than one block seasonal component in the model, each specified using a separate BLOCKSEASON statement. No two block seasonals in the model can have the same NBLOCKS= and BLOCKSIZE= specifications. The following example illustrates the use of the BLOCKSEASON statement to specify the additive, hour-of-the-week seasonal model:

```
season length=24 type=trig;
blockseason nblocks=7 blocksize=24;
```

BLOCKSIZE=*integer*
: specifies the block size, *m*. This is a required option in this statement. The block size can be any integer larger than or equal to two. Typical examples of block sizes are 24, corresponding to the hours of the day when a day is being used as a block in hourly data, or 60, corresponding to the minutes in an hour when an hour is being used as a block in data recorded by minutes, etc.

NBLOCKS=*integer*
: specifies the number of blocks, *k*. This is a required option in this statement. The number of blocks can be any integer greater than or equal to two.

NOEST
: fixes the value of the disturbance variance parameter to the value specified in the VARIANCE= option.

OFFSET=*integer*
: specifies the position of the first measurement within the block, if the first measurement is not at the start of a block. The OFFSET= value must be between one and the block size. The default value is one. The first measurement refers to the start of the estimation span and the forecast span. If these spans differ, their starting measurements must be separated by an integer multiple of the block size.

PLOT=FILTER

PLOT=SMOOTH

PLOT=F_ANNUAL

PLOT=S_ANNUAL

PLOT=(< *plot-request* **> . . . <** *plot-request* **>)**
: requests plots of the season component. When you specify only one *plot-request*, you can omit the parentheses around it. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the season component γ_t. You can use the F_ANNUAL and S_ANNUAL options to get the plots of "annual" variation in the filtered and smoothed estimates of γ_t. The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here "month" and "year" are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years. The first period in each block is plotted over the years.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)
requests the printing of the filtered or smoothed estimate of the block seasonal component γ_t.

TYPE=DUMMY | TRIG
specifies the type of the block seasonal component. The default type is DUMMY.

VARIANCE=*value*
specifies an initial value for the disturbance variance, σ_ω^2, in the γ_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

BY Statement

BY *variables* **;**

A BY statement can be used in the UCM procedure to process a data set in groups of observations defined by the BY variables. The model specified using the MODEL and other component statements is applied to all the groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. The variables are one or more variables in the input data set.

CYCLE Statement

CYCLE < *options* > **;**

The CYCLE statement is used to specify a cycle component, ψ_t, in the model. The stochastic equation governing a cycle component of period p and damping factor ρ is

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos\lambda & \sin\lambda \\ -\sin\lambda & \cos\lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} \nu_t \\ \nu_t^* \end{bmatrix}$$

where ν_t and ν_t^* are independent, zero-mean, Gaussian disturbances with variance σ_ν^2 and $\lambda = 2 * \pi / p$ is the angular frequency of the cycle. Any p strictly greater than two is an admissible value for the period, and the damping factor ρ can be any value in the interval (0, 1), including one but excluding zero. The cycles with frequency zero and π, which correspond to the periods equal to infinity and two, respectively, can be specified using the AUTOREG statement. The values of ρ less than one give rise to a stationary cycle, while $\rho = 1$ gives rise to a nonstationary cycle. As a default, values of ρ, p, and σ_ν^2 are estimated from the data. However, if necessary, you can fix the values of some or all of these parameters.

There can be multiple cycles in a model, each specified using a separate CYCLE statement. The examples that follow illustrate the use of the CYCLE statement.

The following statements request including two cycles in the model. The parameters of each of these cycles are estimated from the data.

```
cycle;
cycle;
```

The following statement requests inclusion of a nonstationary cycle in the model. The cycle period p and the disturbance variance σ_ν^2 are estimated from the data.

```
cycle rho=1 noest=rho;
```

In the following statement, a nonstationary cycle with a fixed period of 12 is specified. Moreover, a starting value is supplied for σ_ν^2.

```
cycle period=12 rho=1 variance=4 noest=(rho period);
```

NOEST=PERIOD

NOEST=RHO

NOEST=VARIANCE

NOEST=(< RHO > < PERIOD > < VARIANCE >)

fixes the values of the component parameters to those specified in the RHO=, PERIOD=, and VARIANCE= options. This option enables you to fix any combination of parameter values.

ORDER=*integer* (Experimental)

enables you to specify a higher-order cycle. A higher-order cycle (a cycle whose order is greater than 1) is a generalization of the stochastic cycle described at the beginning of this section, which can be thought of as a first-order cycle. Higher-order cycles are well explained in Trimbur (2005) and Pelagatti (2015, sect. 3.3.3). A cycle whose order is greater than 2 is rarely needed, and specifying cycles of large orders (for example, an order greater than 4) can lead to computational instability. See Example 41.9 for an example of the use of higher-order cycles.

PERIOD=*value*

specifies an initial value for the cycle period during the parameter estimation process. Period value must be strictly greater than 2.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

requests plotting of the filtered or smoothed estimate of the cycle component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests the printing of a filtered or smoothed estimate of the cycle component ψ_t.

RHO=*value*

specifies an initial value for the damping factor in this component during the parameter estimation process. Any value in the interval (0, 1), including one but excluding zero, is an acceptable initial value for the damping factor.

VARIANCE=*value*

specifies an initial value for the disturbance variance parameter, σ_v^2, to be used during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

DEPLAG Statement

DEPLAG LAGS=*order* < **PHI=***value* ... > < **NOEST** > **;**

The DEPLAG statement is used to specify the lags of the dependent variable to be included as predictors in the model. The following examples illustrate the use of the DEPLAG statement.

If the dependent series is denoted by y_t, the following statement specifies the inclusion of $\phi_1 y_{t-1} + \phi_2 y_{t-2}$ in the model. The parameters ϕ_1 and ϕ_2 are estimated from the data.

```
deplag lags=2;
```

The following statement requests including $\phi_1 y_{t-1} + \phi_2 y_{t-4} - \phi_1\phi_2 y_{t-5}$ in the model. The values of ϕ_1 and ϕ_2 are fixed at 0.8 and –1.2.

```
deplag lags=(1)(4) phi=0.8 -1.2 noest;
```

The dependent lag parameters are not constrained to lie in any particular region. In particular, this implies that a UCM that contains only an irregular component and dependent lags, resulting in a traditional autoregressive model, is not constrained to be a stationary model. In the DEPLAG statement, if an initial value is supplied for any one of the parameters, the initial values must also be supplied for all other parameters.

LAGS=*order*

LAGS=(*lag, ..., lag* **)...(***lag, ..., lag* **)**

is a required option in this statement. LAGS=($l_1, l_2, \ldots, l_k$) defines a model with specified lags of the dependent variable included as predictors. LAGS=*order* is equivalent to LAGS=(1, 2, ..., *order*).

A concatenation of parenthesized lists specifies a factored model. For example, LAGS=(1)(12) specifies that the lag values, 1, 12, and 13, corresponding to the following polynomial in the backward shift operator, be included in the model:

$$(1 - \phi_{1,1} B)(1 - \phi_{2,1} B^{12})$$

Note that, in this case, the coefficient of the thirteenth lag is constrained to be the product of the coefficients of the first and twelfth lags.

NOEST

fixes the values of the parameters to those specified in PHI= option.

PHI=*value* **...**

lists starting values for the coefficients of the lagged dependent variable. The order of the values listed corresponds with the order of the lags specified in the LAGS= option.

ESTIMATE Statement

ESTIMATE < *options* > **;**

The ESTIMATE statement is an optional statement used to control the overall model-fitting environment. Using this statement, you can control the span of observations used to fit the model by using the SKIPFIRST= and BACK= options. This can be useful in model diagnostics. You can request a variety of goodness-of-fit statistics and other model diagnostic information including different residual diagnostic plots. Note that the ESTIMATE statement is not used to control the nonlinear optimization process itself. That is done using the NLOPTIONS statement, where you can control the number of iterations, choose between the different optimization techniques, and so on. You can save the estimated parameters and other related information in a data set by using the OUTEST= option. You can request the optimization of the profile likelihood, the likelihood obtained by concentrating out a disturbance variance, for parameter estimation by using the PROFILE option. The following example illustrates the use of this statement:

```
estimate skipfirst=12 back=24;
```

This statement requests that the initial 12 measurements and the last 24 measurements be excluded during the model-fitting process. The actual observation span used to fit the model is decided as follows: Suppose that n_0 and n_1 are the observation numbers of the first and the last nonmissing values of the response variable, respectively. As a result of SKIPFIRST=12 and BACK=24, the measurements between observation numbers $n_0 + 12$ and $n_1 - 24$ form the estimation span. Of course, the model fitting might not take place if there are insufficient data in the resulting span. The model fitting does not take place if there are regressors in the model that have missing values in the estimation span.

BACK=*integer*

SKIPLAST=*integer*

indicates that some ending part of the data needs to be ignored during the parameter estimation. This can be useful when you want to study the forecasting performance of a model on the observed data. BACK=10 results in skipping the last 10 measurements of the response series during the parameter estimation. The default is BACK=0.

LIKE=DIFFUSE | MARGINAL

specifies the type of likelihood to use for parameter estimation. You can specify the following values:

DIFFUSE uses diffuse likelihood.

MARGINAL uses marginal likelihood.

For more information about likelihood types, see the section "Likelihood Computation and Model-Fitting Phase" on page 2439 in Chapter 33, "The SSM Procedure." For an example of the use of LIKE=MARGINAL option, see Example 41.10. By default, LIKE=DIFFUSE.

EXTRADIFFUSE=*k*

enables continuation of the diffuse filtering iterations for k additional iterations beyond the first instance where the initialization of the diffuse state would have otherwise taken place. If the specified k is larger than the sample size, the diffuse iterations continue until the end of the sample. Note that one-step-ahead residuals are produced only after the diffuse state is initialized. Delaying the initialization leads to a reduction in the number of one-step-ahead residuals available for computing the residual diagnostic measures. This option is useful when you want to ignore the first few one-step-ahead residuals that often have large variance.

NOPROFILE
requests that the usual likelihood be optimized for parameter estimation. For more information, see the section "Parameter Estimation by Profile Likelihood Optimization" on page 2901.

OUTEST=*SAS-data-set*
specifies an output data set for the estimated parameters.

In the ESTIMATE statement, the PLOT= option is used to obtain different residual diagnostic plots. The different possibilities are as follows:

PLOT=ACF
PLOT=MODEL
PLOT=LOESS
PLOT=HISTOGRAM
PLOT=PACF
PLOT=PANEL
PLOT=QQ
PLOT=RESIDUAL
PLOT=WN
PLOT=(*< plot-request >* **. . .** *< plot-request >* **)**
requests different residual diagnostic plots. The different options are as follows:

ACF
produces the residual-autocorrelation plot.

CUSUM
produces the plot of cumulative residuals against time.

CUSUMSQ
produces the plot of cumulative squared residuals against time.

MODEL
produces the plot of one-step-ahead forecasts in the estimation span.

HISTOGRAM
produces the histogram of residuals.

LOESS
produces a scatter plot of residuals against time, which has an overlaid loess-fit.

PACF
produces the residual-partial-autocorrelation plot.

PANEL
produces a summary panel of the residual diagnostics consisting of the following:

- histogram of residuals
- normal quantile plot of residuals
- the residual-autocorrelation-plot
- the residual-partial-autocorrelation-plot

QQ
produces a normal quantile plot of residuals.

RESIDUAL
produces a needle plot of residuals against time.

WN
produces a plot of *p*-values, in log-scale, at different lags for the Ljung-Box portmanteau white noise test statistics.

PRINT=NONE
suppresses all the printed output related to the model fitting, such as the parameter estimates, the goodness-of-fit statistics, and so on.

PROFILE
requests that the profile likelihood, obtained by concentrating out one of the disturbance variances from the likelihood, be optimized for parameter estimation. By default, the profile likelihood is not optimized if any of the disturbance variance parameters is held fixed to a nonzero value. For more information see the section "Parameter Estimation by Profile Likelihood Optimization" on page 2901.

SKIPFIRST=*integer*
indicates that some early part of the data needs to be ignored during the parameter estimation. This can be useful if there is a reason to believe that the model being estimated is not appropriate for this portion of the data. SKIPFIRST=10 results in skipping the first 10 measurements of the response series during the parameter estimation. The default is SKIPFIRST=0.

FORECAST Statement

FORECAST < *options* > **;**

The FORECAST statement is an optional statement that is used to specify the overall forecasting environment for the specified model. It can be used to specify the span of observations, the historical period, to use to compute the forecasts of the future observations. This is done using the SKIPFIRST= and BACK= options. The number of periods to forecast beyond the historical period, and the significance level of the forecast confidence interval, is specified using the LEAD= and ALPHA= options. You can request one-step-ahead series and component forecasts by using the PRINT= option. You can save the series forecasts, and the model-based decomposition of the series, in a data set by using the OUTFOR= option. You can use the BOOTSTRAP option to request the computation of bootstrap prediction standard errors and the associated confidence intervals. The following example illustrates the use of this statement:

```
forecast skipfirst=12 back=24 lead=30;
```

This statement requests that the initial 12 and the last 24 response values be excluded during the forecast computations. The forecast horizon, specified using the LEAD= option, is 30 periods; that is, multistep forecasting begins at the end of the historical period and continues for 30 periods. The actual observation span used to compute the multistep forecasting is decided as follows: Suppose that n_0 and n_1 are the observation numbers of the first and the last nonmissing values of the response variable, respectively. As a result of SKIPFIRST=12 and BACK=24, the historical period, or the forecast span, begins at $n_0 + 12$ and ends at $n_1 - 24$. Multistep forecasts are produced for the next 30 periods—that is, for the observation numbers

$n_1 - 23$ to $n_1 + 6$. Of course, the forecast computations can fail if the model has regressor variables that have missing values in the forecast span. If the regressors contain missing values in the forecast horizon—that is, between the observations $n_1 - 23$ and $n_1 + 6$—the forecast horizon is reduced accordingly.

ALPHA=*value*

specifies the significance level of the forecast confidence intervals; for example, ALPHA=0.05, which is the default, results in a 95% confidence interval.

BACK=*integer*

SKIPLAST=*integer*

specifies the holdout sample for the evaluation of the forecasting performance of the model. For example, BACK=10 results in treating the last 10 observed values of the response series as unobserved. A post-sample-prediction-analysis table is produced for comparing the predicted values with the actual values in the holdout period. The default is BACK=0.

BOOTSTRAP(NREP=*integer* **< SEED=***integer* **>)** (Experimental)

enables the computation of bootstrap prediction standard errors based on the specified number of replications (NREP). The value of NREP must be at least 2. Optionally, you can specify the random number seed that is associated with the first replication by using the SEED= option. The seeds for the subsequent replications are assigned sequentially. The default seed value that is associated with the first replication is 123. The BOOTSTRAP option has no effect if the number of parameters to be estimated is zero (that is, all the model parameters are known). Note that this option is computationally expensive. The computational cost of NREP replications is comparable to the cost of estimating parameters NREP times.

EXTRADIFFUSE=*k*

enables continuation of the diffuse filtering iterations for k additional iterations beyond the first instance where the initialization of the diffuse state would have otherwise taken place. If the specified k is larger than the sample size, the diffuse iterations continue until the end of the sample. Note that one-step-ahead forecasts are produced only after the diffuse state is initialized. Delaying the initialization leads to reduction in the number of one-step-ahead forecasts. This option is useful when you want to ignore the first few one-step-ahead forecasts that often have large variance.

LEAD=*integer*

specifies the number of periods to forecast beyond the historical period defined by the SKIPFIRST= and BACK= options; for example, LEAD=10 results in the forecasting of 10 future values of the response series. The default is LEAD=12.

OUTFOR=*SAS-data-set*

specifies an output data set for the forecasts. The output data set contains the ID variable (if specified), the response and predictor series, the one-step-ahead and out-of-sample response series forecasts, the forecast confidence intervals, the smoothed values of the response series, and the smoothed forecasts produced as a result of the model-based decomposition of the series.

PLOT=DECOMP

PLOT=DECOMPVAR

PLOT=FDECOMP

PLOT=FDECOMPVAR

PLOT=FORECASTS

PLOT=TREND

PLOT=(< *plot-request* **> . . . <** *plot-request* **>)**

requests forecast and model decomposition plots. The FORECASTS option provides the plot of the series forecasts, the TREND and DECOMP options provide the plots of the smoothed trend and other decompositions, the DECOMPVAR option can be used to plot the variance of these components, and the FDECOMP and FDECOMPVAR options provide the same plots for the filtered decomposition estimates and their variances.

PRINT=DECOMP

PRINT=FDECOMP

PRINT=FORECASTS

PRINT=NONE

PRINT=(< *print-request* **> . . . <** *print-request* **>)**

controls the printing of the series forecasts and the printing of smoothed model decomposition estimates. By default, the series forecasts are printed only for the forecast horizon specified by the LEAD= option; that is, the one-step-ahead predicted values are not printed. You can request forecasts for the entire forecast span by specifying the PRINT=FORECASTS option. Using PRINT=DECOMP, you can get smoothed estimates of the following effects: trend, trend plus regression, trend plus regression plus cycle, and sum of all components except the irregular. If some of these effects are absent in the model, then they are ignored. Similarly, you can get filtered estimates of these effects by using PRINT=FDECOMP. You can use PRINT=NONE to suppress the printing of all the forecast output.

SKIPFIRST=*integer*

indicates that some early part of the data needs to be ignored during the forecasting calculations. This can be useful if there is a reason to believe that the model being used for forecasting is not appropriate for this portion of the data. SKIPFIRST=10 results in skipping the first 10 measurements of the response series during the forecast calculations. The default is SKIPFIRST=0.

ID Statement

ID *variable* **INTERVAL**=*value* < **ALIGN=***value* > **;**

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable's values are assumed to be SAS date, time, or datetime values. In addition, the ID statement specifies the frequency associated with the time series. The ID statement options also specify how the observations are aligned to form the time series. If the ID statement is specified, the INTERVAL= option must also be specified. If the ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID. The values of the ID variable are extrapolated for the forecast observations based on the values of the INTERVAL= option.

ALIGN=*value*
controls the alignment of SAS dates used to identify output observations. The ALIGN= option has the following possible values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. The default is BEGINNING. The ALIGN= option is used to align the ID variable with the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

INTERVAL=*value*
specifies the time interval between observations. This option is required in the ID statement. INTERVAL=*value* is used in conjunction with the ID variable to check that the input data are in order and have no gaps. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data. For a complete discussion of the intervals supported, see Chapter 4, "Date Intervals, Formats, and Functions."

IRREGULAR Statement

IRREGULAR < *options* > **;**

The IRREGULAR statement includes an irregular component in the model. There can be at most one IRREGULAR statement in the model specification. The irregular component corresponds to the overall random error ϵ_t in the model. By default the irregular component is modeled as white noise—that is, as a sequence of independent, identically distributed, zero-mean, Gaussian random variables. However, you can also model it as an autoregressive moving average (ARMA) process. The options for specifying an ARMA model for the irregular component are given in a separate subsection: "ARMA Specification" on page 2869.

The options in this statement enable you to specify the model for the irregular component and to output its estimates. Two examples of the IRREGULAR statement are given next. In the first example the statement is in its simplest form, resulting in the inclusion of an irregular component that is white noise with unknown variance:

```
irregular;
```

The following statement provides a starting value for the white noise variance σ_ϵ^2 to be used in the nonlinear parameter estimation process. It also requests the printing of smoothed estimates of ϵ_t. The smoothed irregulars are useful in model diagnostics.

```
irregular variance=4 print=smooth;
```

NOEST
fixes the value of σ_ϵ^2 to the value specified in the VARIANCE= option. Also see the NOEST= option in the subsection "ARMA Specification" on page 2869.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)
requests plotting of the filtered or smoothed estimate of the irregular component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

requests printing of the filtered or smoothed estimate of the irregular component.

VARIANCE=*value*

specifies an initial value for σ_ϵ^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

ARMA Specification

This section details the options for specifying an ARMA model for the irregular component. The specification of ARMA models requires some notation, which is explained first.

Let B denote the backshift operator—that is, for any sequence ϵ_t, $B\epsilon_t = \epsilon_{t-1}$. The higher powers of B represent larger shifts (for example, $B^3\epsilon_t = \epsilon_{t-3}$). A random sequence ϵ_t follows a zero-mean ARMA(p,q)×(P,Q)$_s$ model with nonseasonal autoregressive order p, seasonal autoregressive order P, nonseasonal moving average order q, and seasonal moving average order Q, if it satisfies the following difference equation specified in terms of the polynomials in the backshift operator where a_t is a white noise sequence and s is the season length:

$$\phi(B)\Phi(B^s)\epsilon_t = \theta(B)\Theta(B^s)a_t$$

The polynomials ϕ, Φ, θ, and Θ are of orders p, P, q, and Q, respectively, which can be any nonnegative integers. The season length s must be a positive integer. For example, ϵ_t satisfies an ARMA(1,1) model (that is, $p = 1, q = 1, P = 0$, and $Q = 0$) if

$$\epsilon_t = \phi_1\epsilon_{t-1} + a_t - \theta_1 a_{t-1}$$

for some coefficients ϕ_1 and θ_1 and a white noise sequence a_t. Similarly, ϵ_t satisfies an ARMA(1,1)×(1,1)$_{12}$ model if

$$\epsilon_t = \phi_1\epsilon_{t-1} + \Phi_1\epsilon_{t-12} - \phi_1\Phi_1\epsilon_{t-13} + a_t - \theta_1 a_{t-1} - \Theta_1 a_{t-12} + \theta_1\Theta_1 a_{t-13}$$

for some coefficients ϕ_1, Φ_1, θ_1, and Θ_1 and a white noise sequence a_t. The ARMA process is stationary and invertible if the defining polynomials ϕ, Φ, θ, and Θ have all their roots outside the unit circle—that is, their absolute values are strictly larger than 1.0. It is assumed that the ARMA model specified for the irregular component is stationary and invertible—that is, the coefficients of the polynomials ϕ, Φ, θ, and Θ are constrained so that the stationarity and invertibility conditions are satisfied. The unknown coefficients of these polynomials become part of the model parameter vector that is estimated using the data.

The notation for a closely related class of models, autoregressive integrated moving average (ARIMA) models, is also given here. A random sequence y_t is said to follow an ARIMA(p,d,q)×(P,D,Q)$_s$ model if, for some nonnegative integers d and D, the differenced series $\epsilon_t = (1-B)^d(1-B^s)^D y_t$ follows an ARMA(p,q)×(P,Q)$_s$ model. The integers d and D are called nonseasonal and seasonal differencing orders, respectively. You can specify ARIMA models by using the DEPLAG statement for specifying the differencing orders and by using the IRREGULAR statement for the ARMA specification. For an example of ARIMA(0,1,1)×(0,1,1)$_{12}$ model specification, see Example 41.8. Brockwell and Davis (1991) can be consulted for additional information about ARIMA models.

You can use options of the IRREGULAR statement to specify the desired ARMA model and to request printed and graphical output. A few examples of the IRREGULAR statement are given next.

The following statement specifies an irregular component that is modeled as an ARMA(1,1) process. It also requests plotting its smoothed estimate.

```
irregular p=1 q=1 plot=smooth;
```

The following statement specifies an ARMA(1,1)×(1,1)$_{12}$ model. It also fixes the coefficient of the first-order seasonal moving average polynomial to 0.1. The other coefficients and the white noise variance are estimated using the data.

```
irregular p=1 sp=1 q=1 sq=1 s=12 sma=0.1 noest=(sma);
```

AR=$\phi_1\ \phi_2\ \ldots\phi_p$
lists the starting values of the coefficients of the nonseasonal autoregressive polynomial

$$\phi(B) = 1 - \phi_1 B - \cdots - \phi_p B^p$$

where the order p is specified in the P= option. The coefficients ϕ_i must define a stationary autoregressive polynomial.

MA=$\theta_1\ \theta_2\ \ldots\theta_q$
lists the starting values of the coefficients of the nonseasonal moving average polynomial

$$\theta(B) = 1 - \theta_1 B - \cdots - \theta_q B^q$$

where the order q is specified in the Q= option. The coefficients θ_i must define an invertible moving average polynomial.

NOEST=(<VARIANCE> <AR> <SAR> <MA> <SMA>)
fixes the values of the ARMA parameters and the value of the white noise variance to those specified in the AR=, SAR=, MA=, SMA=, or VARIANCE= options.

P=*integer*
specifies the order of the nonseasonal autoregressive polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1, 2, or 3.

Q=*integer*
specifies the order of the nonseasonal moving average polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1, 2, or 3.

S=*integer*
specifies the season length used during the specification of the seasonal autoregressive or seasonal moving average polynomial. The season length can be any positive integer; for example, S=4 might be an appropriate value for a quarterly series. The default value is S=1.

SAR=$\Phi_1\ \Phi_2\ \ldots\Phi_P$
lists the starting values of the coefficients of the seasonal autoregressive polynomial

$$\Phi(B^s) = 1 - \Phi_1 B^s - \cdots - \Phi_P B^{sP}$$

where the order P is specified in the SP= option and the season length s is specified in the S= option. The coefficients Φ_i must define a stationary autoregressive polynomial.

SMA=$\Theta_1\ \Theta_2\ \ldots\ \Theta_Q$
lists the starting values of the coefficients of the seasonal moving average polynomial

$$\Theta(B^s) = 1 - \Theta_1 B^s - \cdots - \Theta_Q B^{sQ}$$

where the order Q is specified in the SQ= option and the season length s is specified in the S= option. The coefficients Θ_i must define an invertible moving average polynomial.

SP=*integer*
specifies the order of the seasonal autoregressive polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1 or 2.

SQ=*integer*
specifies the order of the seasonal moving average polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1 or 2.

LEVEL Statement

LEVEL < *options* > **;**

The LEVEL statement is used to include a level component in the model. The level component, either by itself or together with a slope component (see the SLOPE statement), forms the trend component, μ_t, of the model. If the slope component is absent, the resulting trend is a random walk (RW) specified by the following equations:

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim \text{iid}\ \ N(0, \sigma_\eta^2)$$

If the slope component is present, signified by the presence of a SLOPE statement, a locally linear trend (LLT) is obtained. The equations of LLT are as follows:

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, \quad & \eta_t &\sim \text{iid}\ \ N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim \text{iid}\ \ N(0, \sigma_\xi^2) \end{aligned}$$

In either case, the options in the LEVEL statement are used to specify the value of σ_η^2 and to request forecasts of μ_t. The SLOPE statement is used for similar purposes in the case of slope β_t. The following examples illustrate the use of the LEVEL statement. Assuming that a SLOPE statement is not added subsequently, a simple random walk trend is specified by the following statement:

```
level;
```

The following statements specify a locally linear trend with value of σ_η^2 fixed at 4. It also requests printing of filtered values of μ_t. The value of σ_ξ^2, the disturbance variance in the slope equation, is estimated from the data.

```
level variance=4 noest print=filter;
slope;
```

CHECKBREAK
turns on the checking of breaks in the level component.

NOEST
fixes the value of σ_η^2 to the value specified in the VARIANCE= option.

PLOT=FILTER
PLOT=SMOOTH
PLOT=(< FILTER > < SMOOTH >)
requests plotting of the filtered or smoothed estimate of the level component.

PRINT=FILTER
PRINT=SMOOTH
PRINT=(< FILTER > < SMOOTH >)
requests printing of the filtered or smoothed estimate of the level component.

VARIANCE=*value*
specifies an initial value for σ_η^2, the disturbance variance in the μ_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

MODEL Statement

MODEL *dependent* < **=** *regressors* > **;**

The MODEL statement specifies the response variable and, optionally, the predictor or regressor variables for the UCM model. This is a required statement in the UCM procedure. The predictors specified in the MODEL statement are assumed to have a linear and time-invariant relationship with the response. The predictors that have time-varying regression coefficients are specified separately in the RANDOMREG statement. Similarly, the predictors that have a nonlinear effect on the response variable are specified separately in the SPLINEREG statement. Only one MODEL statement can be specified.

NLOPTIONS Statement

NLOPTIONS < *options* > **;**

PROC UCM uses the nonlinear optimization (NLO) subsystem to perform the nonlinear optimization of the likelihood function during the estimation of model parameters. You can use the NLOPTIONS statement to control different aspects of this optimization process. For most problems the default settings of the optimization process are adequate. However, in some cases it might be useful to change the optimization technique or to change the maximum number of iterations. This can be done by using the TECH= and MAXITER= options in the NLOPTIONS statement as follows:

```
nloptions tech=dbldog maxiter=200;
```

This sets the maximum number of iterations to 200 and changes the optimization technique to DBLDOG rather than the default technique, TRUREG, used in PROC UCM. A discussion of the full range of options that can be used with the NLOPTIONS statement is given in Chapter 6, "Nonlinear Optimization Methods." In PROC UCM, all these options are available except the options related to the printing of the optimization history. In this version of PROC UCM all the printed output from the NLO subsystem is suppressed.

OUTLIER Statement

OUTLIER < *options* > **;**

The OUTLIER statement enables you to control the reporting of the additive outliers (AO) and level shifts (LS) in the response series. The AOs are searched by default. You can turn on the search for LSs by using the CHECKBREAK option in the LEVEL statement.

ALPHA=*significance-level*
specifies the significance level for reporting the outliers. The default is 0.05.

MAXNUM=*number*
limits the number of outliers to search. The default is MAXNUM=5.

MAXPCT=*number*
is similar to the MAXNUM= option. In the MAXPCT= option you can limit the number of outliers to search for according to a percentage of the series length. The default is MAXPCT=1. When both of these options are specified, the minimum of the two search numbers is used.

PRINT=SHORT | DETAIL
enables you to control the printed output of the outlier search. The PRINT=SHORT option, which is the default, produces an outlier summary table containing the most significant outliers, either AO or LS, discovered in the outlier search. The PRINT=DETAIL option produces, in addition to the outlier summary table, separate tables containing the AO and LS structural break chi-square statistics computed at each time point in the estimation span.

PERFORMANCE Statement

PERFORMANCE *options* **;**

The PERFORMANCE statement defines performance parameters for distributed and multithreaded computing and passes variables that describe the distributed computing environment. In the UCM procedure, this statement is applicable only if you specify the BOOTSTRAP option in the FORECAST statement. In addition, the number of nodes that you specify in the NODES= option in the PERFORMANCE statement must be strictly smaller than the number of bootstrap replications that you specify in the BOOTSTRAP option. The following statements illustrate how you can use this statement to perform bootstrap computations that use 10 nodes on a grid named *hpa.sas.com*:

```
proc ucm data=seriesG;
   id date interval=month;
   model logair;
   irregular;
   level;
   forecast lead=24 bootstrap(nrep=50 seed=1234);
   performance nodes=10 host="hpa.sas.com";
run;
```

For more information about the PERFORMANCE statement, see the section "PERFORMANCE Statement" (Chapter 21, *SAS/STAT User's Guide*).

RANDOMREG Statement

RANDOMREG *regressors* < / *options* > **;**

The RANDOMREG statement is used to specify regressors with time-varying regression coefficients. Each regression coefficient—for example, β_t—is assumed to evolve as a random walk:

$$\beta_t = \beta_{t-1} + \eta_t, \quad \eta_t \sim \text{iid } N(0, \sigma^2)$$

Of course, if the random walk disturbance variance σ^2 is zero, then the regression coefficient is not time varying, and it reduces to the standard regression setting. There can be multiple RANDOMREG statements, and each statement can contain one or more regressors. The regressors in a given RANDOMREG statement form a group that is assumed to share the same disturbance variance parameter. The random walks associated with different regressors are assumed to be independent. For an example of using this statement see Example 41.4. For additional information about the way parameter estimates are reported for this type of regressors, see the section "Reporting Parameter Estimates for Random Regressors" on page 2897.

NOEST
fixes the value of σ^2 to the value specified in the VARIANCE= option.

PLOT=FILTER
PLOT=SMOOTH
PLOT=(< FILTER > < SMOOTH >)
requests plotting of filtered or smoothed estimate of the time-varying regression coefficient.

PRINT=FILTER
PRINT=SMOOTH
PRINT=(< FILTER > < SMOOTH >)
requests printing of the filtered or smoothed estimate of the time-varying regression coefficient.

VARIANCE=*value*
specifies an initial value for σ^2 during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SEASON Statement

SEASON LENGTH=*integer* < *options* > **;**

The SEASON or SEASONAL statement is used to specify a seasonal component, γ_t, in the model. A seasonal component can be one of the two types, DUMMY or TRIG. A DUMMY seasonal with season length s satisfies the following stochastic equation:

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \qquad \omega_t \sim \text{iid } N(0, \sigma_\omega^2)$$

The equations for a TRIG (short for trigonometric) seasonal component are as follows

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if s is even and $(s-1)/2$ if it is odd. The sinusoids, also called *harmonics*, $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma^*_{j,t} \end{bmatrix} = \begin{bmatrix} \cos\lambda_j & \sin\lambda_j \\ -\sin\lambda_j & \cos\lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma^*_{j,t-1} \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega^*_{j,t} \end{bmatrix}$$

where the disturbances $\omega_{j,t}$ and $\omega^*_{j,t}$ are assumed to be independent and, for fixed j, $\omega_{j,t}$ and $\omega^*_{j,t} \sim N(0, \sigma^2_\omega)$. If s is even, then the equation for $\gamma^*_{s/2,t}$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

In the TRIG seasonal case, the option KEEPH= or DROPH= can be used to obtain *subset trigonometric* seasonals that contain only a subset of the full set of harmonics $\gamma_{j,t}$, $j = 1, 2, \ldots, [s/2]$. This is particularly useful when the season length s is large and the seasonal pattern is relatively smooth.

Note that whether the seasonal type is DUMMY or TRIG, there is only one parameter, the disturbance variance σ^2_ω, in the seasonal model.

There can be more than one seasonal component in the model, necessarily with different season lengths if the seasons are full. You can have multiple *subset* season components with the same season length, if you need to use separate disturbance variances for different sets of harmonics. Each seasonal component is specified using a separate SEASON statement. A model with multiple seasonal components can easily become quite complex and might need a large amount of data and computing resources for its estimation and forecasting. The examples that follow illustrate the use of SEASON statement.

The following statement specifies a DUMMY type (default) seasonal component with a season length of four, corresponding to the quarterly seasonality. The disturbance variance σ^2_ω is estimated from the data.

```
season length=4;
```

The following statement specifies a trigonometric seasonal with monthly seasonality. It also provides a starting value for σ^2_ω.

```
season length=12 type=trig variance=4;
```

DROPHARMONICS | DROPH=*number-list* **|** *n* **TO** *m* **BY** *p*
enables you to drop some harmonics $\gamma_{j,t}$ from the full set of harmonics used to obtain a trigonometric seasonal. The drop list can include any integer between 1 and $[s/2]$, s being the season length. For example, the following specification results in a specification of a trigonometric seasonal with a season length 12 that consists of only the first four harmonics $\gamma_{j,t}$, $j = 1, 2, 3, 4$:

```
season length=12 type=trig DROPH=5 6;
```

The last two *high*-frequency harmonics are dropped. The DROPH= option cannot be used with the KEEPH= option.

KEEPHARMONICS | KEEPH=*number-list* **|** *n* **TO** *m* **BY** *p*
enables you to keep only the harmonics $\gamma_{j,t}$ listed in the option to obtain a trigonometric seasonal. The keep list can include any integer between 1 and $[s/2]$, s being the season length. For example, the following specification results in a specification of a trigonometric seasonal with a season length of 12 that consists of all six harmonics $\gamma_{j,t}$, $j = 1, \ldots, 6$:

```
season length=12 type=trig KEEPH=1 to 3;
season length=12 type=trig KEEPH=4 to 6;
```

However, these six harmonics are grouped into two groups, each having its own disturbance variance parameter. The DROPH= option cannot be used with the KEEPH= option.

LENGTH=*integer*

specifies the season length, s. This is a required option in this statement. The season length can be any integer greater than or equal to 2. Typical examples of season lengths are 12, corresponding to the monthly seasonality, or 4, corresponding to the quarterly seasonality.

NOEST

fixes the value of the disturbance variance parameter to the value specified in the VARIANCE= option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=F_ANNUAL

PLOT=S_ANNUAL

PLOT=(<*plot-request***> . . . <***plot-request***>)**

requests plots of the season component. When you specify only one *plot-request*, you can omit the parentheses around it. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the season component γ_t. You can use the F_ANNUAL and S_ANNUAL options to get the plots of "annual" variation in the filtered and smoothed estimates of γ_t. The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here "month" and "year" are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years.

PRINT=HARMONICS

requests printing of the summary of harmonics present in the seasonal component. This option is valid only for the trigonometric seasonal component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< *print-request* **> . . . <** *print-request* **>)**

requests printing of the filtered or smoothed estimate of the seasonal component γ_t.

TYPE=DUMMY | TRIG

specifies the type of the seasonal component. The default type is DUMMY.

VARIANCE=*value*

specifies an initial value for the disturbance variance, σ_ω^2, in the γ_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SLOPE Statement

SLOPE < *options* > **;**

The SLOPE statement is used to include a slope component in the model. The slope component cannot be used without the level component (see the LEVEL statement). The level and slope specifications jointly define the trend component of the model. A SLOPE statement without the accompanying LEVEL statement is ignored. The equations of the trend, defined jointly by the level μ_t and slope β_t, are as follows:

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, \quad \eta_t \sim \text{iid } N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, \quad \xi_t \sim \text{iid } N(0, \sigma_\xi^2) \end{aligned}$$

The SLOPE statement is used to specify the value of the disturbance variance, σ_ξ^2, in the slope equation, and to request forecasts of β_t. The following examples illustrate this statement:

```
level;
slope;
```

The preceding statements fit a model with a locally linear trend. The disturbance variances σ_η^2 and σ_ξ^2 are estimated from the data. You can request a locally linear trend with fixed slope by using the following statements:

```
level;
slope variance=0 noest;
```

NOEST
fixes the value of the disturbance variance, σ_ξ^2, to the value specified in the VARIANCE= option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)
requests plotting of the filtered or smoothed estimate of the slope component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)
requests printing of the filtered or smoothed estimate of the slope component β_t.

VARIANCE=*value*
specifies an initial value for the disturbance variance, σ_ξ^2, in the β_t equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SPLINEREG Statement

SPLINEREG *regressor* < *options* > **;**

The SPLINEREG statement is used to specify a regressor that has a nonlinear relationship with the dependent series that can be approximated by a given B-spline. If the specified spline has degree d and is based on n internal knots, then it is known that it can be written as a linear combination of $(n + d + 1)$ regressors that are derived from the original regressor. The span of these $(n + d + 1)$ derived regressors includes constant; therefore, to avoid multicollinearity with the level component, one of these regressors is dropped. Specifying the SPLINEREG statement is equivalent to specifying a RANDOMREG statement with these derived regressors. There can be multiple SPLINEREG statements. You must specify at least one interior knot, either using the NKNOTS= option or the KNOTS= option. For more information about splines, see Chapter 126, "The TRANSREG Procedure" (*SAS/STAT User's Guide*). For an example of using this statement, see Example 41.6. For additional information about the way parameter estimates are reported for this type of regressors, see the section "Reporting Parameter Estimates for Random Regressors" on page 2897.

DEGREE=*integer*

specifies the degree of the spline. It can be any integer larger than or equal to zero. The default value is 3. The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

KNOTS=*number-list* | *n* **TO** *m* **BY** *p*

specifies the interior knots or break points. The values in the knot list must be nondecreasing and must lie between the minimum and the maximum of the spline regressor values in the input data set. The first time you specify a value in the knot list, it indicates a discontinuity in the nth (from DEGREE=n) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the $(n - 1)$th derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the KNOTS= option with the NKNOTS= option. You should keep the number of knots small.

NKNOTS=*m*

creates m knots, the first at the $100/(m + 1)$ percentile, the second at the $200/(m + 1)$ percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if NKNOTS=3, knots are placed at the 25th percentile, the median, and the 75th percentile. The value specified for the NKNOTS= option must be ≥ 1. You cannot use the NKNOTS=option with the KNOTS= option.

NOTE: Specifying knots by using the NKNOTS= option can result in different sets of knots in the estimation and forecast stages if the distributions of regressor values in the estimation and forecast spans differ. The estimation span is based on the BACK= and SKIPFIRST= options in the ESTIMATE statement, and the forecast span is based on the BACK= and SKIPFIRST= options in the FORECAST statement.

NOEST
fixes the value of the regression coefficient random walk disturbance variance to the value specified in the VARIANCE= option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)
requests plotting of filtered or smoothed estimate of the time-varying regression coefficient.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)
requests printing of filtered or smoothed estimate of the time-varying regression coefficient.

VARIANCE=*value*
specifies an initial value for the regression coefficient random walk disturbance variance during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

SPLINESEASON Statement

SPLINESEASON LENGTH=*integer* **KNOTS=***integer*$_1$ *integer*$_2$ **...** < *options* > **;**

The SPLINESEASON statement is used to specify a seasonal pattern that is to be approximated by a given B-spline. If the specified spline has degree d and is based on n internal knots, then it can be written as a linear combination of $(n + d)$ regressors that are derived from the seasonal dummy regressors. The SPLINESEASON specification is equivalent to specifying a RANDOMREG specification with these derived regressors. Such approximation is useful only if the season length is relatively large, at least larger than $(n+d)$. For additional information about splines, see Chapter 126, "The TRANSREG Procedure" (*SAS/STAT User's Guide*). For an example of using this statement, see Example 41.3.

DEGREE=*integer*
specifies the degree of the spline. It can be any integer greater than or equal to zero. The default value is 3.

KNOTS=*integer*$_1$ *integer*$_2$ **...**
lists the *internal* knots. This list of values must be a nondecreasing sequence of integers within the range of 2 to $(s - 1)$, where s is the season length specified in the LENGTH= option. This is a required option in this statement.

LENGTH=*integer*
specifies the season length, *s*. This is a required option in this statement. The length can be any integer greater than or equal to three.

NOEST
fixes the value of the regression coefficient random walk disturbance variance to the value specified in the VARIANCE= option.

OFFSET=*integer*
specifies the position of the first measurement within the season, if the first measurement is not at the start of the season. The OFFSET= value must be between one and the season length. The default value is one. The first measurement refers to the start of the estimation span and the forecast span. If these spans differ, their starting measurements must be separated by an integer multiple of the season length.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)
requests plots of the season component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the season component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)
requests the printing of the filtered or smoothed estimate of the spline season component.

RKNOTS=(*knot, . . . , knot* **) . . . (***knot, . . . , knot* **)**
specifies a grouping of knots such that the knots within the same group have identical seasonal values. The knots specified in this option must already be present in the list specified by the KNOTS= option. The knot groups must be non-overlapping and without any repeated knots.

VARIANCE=*value*
specifies an initial value for the regression coefficient random walk disturbance variance during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

TF Statement (Experimental)

TF *regressor* < *options* > **;**

The TF statement specifies a regressor that has a transfer-function relationship with the dependent series. A transfer function is useful for capturing the contributions from lagged values of the regressor. Box and Jenkins (1976) popularized ARIMA models that have transfer-function inputs. In the UCM procedure, you can specify a transfer function of the following type (assuming the regression variable is x):

$$\frac{(\gamma_0 + \gamma_1 B^{l1} + \gamma_2 B^{l2} + \cdots) B^d}{(1 - \delta_1 B - \delta_2 B^2 - \cdots - \delta_m B^m)(1 - \omega_1 B^s - \omega_2 B^{2s} - \cdots - \omega_n B^{ns})} x_t$$

This transfer function is specified by using the ratio of polynomials in the backshift operator B. The numerator polynomial orders $(l1, l2, \cdots)$ are positive integers, possibly with gaps (for example, 1, 3). The numerator term B^d signifies the *delay* of order d. The denominator polynomial can have two factors: a nonseasonal factor, $(1 - \delta_1 B - \delta_2 B^2 - \cdots - \delta_m B^m)$, and a seasonal factor whose season length is s, $(1 - \omega_1 B^s - \omega_2 B^{2s} - \cdots - \omega_n B^{ns})$. The orders of the terms in the denominator factors cannot have gaps;

that is, if 5 is the maximum order of the nonseasonal factor, then all terms of orders 1 through 5 are present. By design, the denominator factors are restricted to be stable polynomials (their roots are strictly larger than 1 in absolute value). As an example, consider the following transfer function specification:

$$\frac{(\gamma_0 + \gamma_1 B^1 + \gamma_2 B^2) B^3}{(1 - \delta_1 B - \delta_2 B^2)(1 - \omega_1 B^4)} x_t$$

You can specify this transfer function as follows:

```
tf x num=(1 2) den=2 sden=1 s=4 delay=3;
```

Since the numerator polynomial orders do not have any gaps, the following simpler specification is also available:

```
tf x num=2 den=2 sden=1 s=4 delay=3;
```

Because the denominator factors do not permit gaps in their orders, only the maximum orders need to be provided in their specification.

A state space representation of a transfer-function relationship is described in the section "State Space Form of a Transfer Function Relationship" on page 2897. You can specify multiple TF statements, each one with a separate regressor. A regressor that is specified in any transfer function specification must not appear in any other regression specifications, such as in the right-hand side of the MODEL statement or in the RANDOMREG and SPLINEREG statements.

NOTE: The mathematical form of the transfer function considered by PROC UCM is similar to the one considered in the ARIMA procedure (Chapter 7, "The ARIMA Procedure"). However, there are some differences:

- The sign convention of the coefficients of the nonzero-order terms in the numerator polynomial in the UCM procedure is opposite to that of the ARIMA procedure.
- The ARIMA procedure permits multiple polynomial factors in both the numerator and the denominator. The UCM procedure permits only one numerator factor and at most two denominator factors.
- The ARIMA procedure permits full control over the terms present in each of the polynomial factors. The UCM procedure does not permit such fine control over the terms in the polynomials.
- In the UCM procedure, you cannot fix the coefficients of the numerator polynomial. They are always estimated from the data.
- In the UCM procedure, if both nonseasonal and seasonal factors are present in the denominator, you must specify starting values for their coefficients either for both factors or for neither.

You can specify the following *options* in the TF statement:

DELAY=*integer*
specifies the delay order, which must be a positive integer. By default, DELAY= 0.

DEN=*integer*
specifies the maximum order of the nonseasonal factor of the denominator polynomial. By default, DEN=0.

DENVAL=*val1 val2* **...**
specifies the starting values of the coefficients of the nonseasonal factor of the denominator polynomial. The number of values supplied in the DENVAL= option must match the value of the DEN= option. Moreover, the resulting polynomial must be stable.

NOEST
fixes the values of the denominator polynomial coefficients to those specified in the DENVAL= and SDENVAL= specifications.

NUM=*argument*
specifies the positive orders of the terms in the numerator polynomial. You can specify the *argument* in either of the following forms:

integer	includes all orders from 1 to *integer*.
(*lag1*, *lag2*, . . .)	specifies a more general list of orders.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)
requests plots of the transfer-function component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the transfer-function component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)
requests the printing of the filtered or smoothed estimate of the transfer-function component. When you specify only one print request, you can omit the parentheses around the print request. You can use the FILTER and SMOOTH options to print the filtered and smoothed estimates of the transfer-function component.

S=*integer*
specifies the season length that is used in the specification of the seasonal factor of the denominator polynomial. The season length can be any positive integer; for example, S=4 might be an appropriate value for a quarterly series. By default, S=1.

SDEN=*integer*
specifies the maximum order of the seasonal factor of the denominator polynomial. By default, SDEN=0.

SDENVAL=*val1 val2* **...**
specifies the starting values of the coefficients of the seasonal factor of the denominator polynomial. The number of values supplied in this option must match the value of the SDEN= option. Moreover, the resulting polynomial must be stable.

TFSTART=*value*
specifies the value of the transfer function at the start of the sample (the first time ID). By default, the value of this option is a missing value that is estimated from the data. This option is often used when the past values of the transfer function can be inferred because of the structure of the problem or when it is useful to set these values (usually to 0) to achieve identifiability of the overall model. For more information, see the section "State Space Form of a Transfer Function Relationship" on page 2897. See Example 41.10 for an example of the use of this option.

Details: UCM Procedure

An Introduction to Unobserved Component Models

A UCM decomposes the response series into components such as trend, seasons, cycles, and the regression effects due to predictor series. The following model shows a possible scenario:

$$\begin{aligned} y_t &= \mu_t + \gamma_t + \psi_t + \sum_{j=1}^{m} \beta_j x_{jt} + \epsilon_t \\ \epsilon_t &\sim \text{iid } N(0, \sigma_\epsilon^2) \end{aligned}$$

The terms μ_t, γ_t, and ψ_t represent the trend, seasonal, and cyclical components, respectively. In fact the model can contain multiple seasons and cycles, and the seasons can be of different types. For simplicity of discussion the preceding model contains only one of each of these components. The regression term, $\sum_{j=1}^{m} \beta_j x_{jt}$, includes contribution of regression variables with *fixed* regression coefficients. A model can also contain regression variables that have *time-varying* regression coefficients or that have a nonlinear or a transfer-function relationship with the dependent series (see "Incorporating Predictors of Different Types" on page 2896). The disturbance term ϵ_t, also called the *irregular* component, is usually assumed to be Gaussian white noise. In some cases it is useful to model the irregular component as a stationary ARMA process. For additional information, see the section "Modeling the Irregular Component" on page 2887.

By controlling the presence or absence of various terms and by choosing the proper flavor of the included terms, the UCMs can generate a rich variety of time series patterns. A UCM can be applied to variables after transforming them by transforms such as *log* and *difference*.

The components μ_t, γ_t, and ψ_t model structurally different aspects of the time series. For example, the trend μ_t models the natural tendency of the series in the absence of any other perturbing effects such as seasonality, cyclical components, and the effects of exogenous variables, while the seasonal component γ_t models the correction to the level due to the seasonal effects. These components are assumed to be statistically independent of each other and independent of the irregular component. All of the component models can be thought of as stochastic generalizations of the relevant deterministic patterns in time. This

way the deterministic cases emerge as special cases of the stochastic models. The different models available for these unobserved components are discussed next.

Modeling the Trend

As mentioned earlier, the trend in a series can be loosely defined as the natural tendency of the series in the absence of any other perturbing effects. The UCM procedure offers two ways to model the trend component μ_t. The first model, called the random walk (RW) model, implies that the trend remains roughly constant throughout the life of the series without any persistent upward or downward drift. In the second model the trend is modeled as a locally linear time trend (LLT). The RW model can be described as

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim \text{iid } N(0, \sigma_\eta^2)$$

Note that if $\sigma_\eta^2 = 0$, then the model becomes $\mu_t = constant$. In the LLT model the trend is locally linear, consisting of both the *level* and *slope*. The LLT model is

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim \text{iid } N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim \text{iid } N(0, \sigma_\xi^2) \end{aligned}$$

The disturbances η_t and ξ_t are assumed to be independent. There are some interesting special cases of this model obtained by setting one or both of the disturbance variances σ_η^2 and σ_ξ^2 equal to zero. If σ_ξ^2 is set equal to zero, then you get a linear trend model with fixed slope. If σ_η^2 is set to zero, then the resulting model usually has a smoother trend. If both the variances are set to zero, then the resulting model is the deterministic linear time trend: $\mu_t = \mu_0 + \beta_0 t$.

You can incorporate these trend patterns in your model by using the LEVEL and SLOPE statements.

Modeling a Cycle

A deterministic cycle ψ_t with frequency λ, $0 < \lambda < \pi$, can be written as

$$\psi_t = \alpha \cos(\lambda t) + \beta \sin(\lambda t)$$

If the argument t is measured on a continuous scale, then ψ_t is a periodic function with period $2\pi/\lambda$, amplitude $\gamma = (\alpha^2 + \beta^2)^{1/2}$, and phase $\phi = \tan^{-1}(\beta/\alpha)$. Equivalently, the cycle can be written in terms of the amplitude and phase as

$$\psi_t = \gamma \cos(\lambda t - \phi)$$

Note that when ψ_t is measured only at the integer values, it is not exactly periodic, unless $\lambda = (2\pi j)/k$ for some integers j and k. The cycles in their pure form are not used very often in practice. However, they are very useful as building blocks for more complex periodic patterns. It is well known that the periodic pattern of any complexity can be written as a sum of pure cycles of different frequencies and amplitudes. In time series situations it is useful to generalize this simple cyclical pattern to a stochastic cycle that has a fixed expected period but time-varying amplitude and phase. The stochastic cycle considered here is motivated by the following recursive formula for computing ψ_t,

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \begin{bmatrix} \cos\lambda & \sin\lambda \\ -\sin\lambda & \cos\lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix}$$

starting with $\psi_0 = \alpha$ and $\psi_0^* = \beta$. Note that ψ_t and ψ_t^* satisfy the relation

$$\psi_t^2 + \psi_t^{*2} = \alpha^2 + \beta^2 \quad \text{for all } t$$

A stochastic generalization of the cycle ψ_t can be obtained by adding random noise to this recursion and by introducing a damping factor, ρ, for additional modeling flexibility. This model can be described as follows,

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos\lambda & \sin\lambda \\ -\sin\lambda & \cos\lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} \nu_t \\ \nu_t^* \end{bmatrix}$$

where $0 \le \rho \le 1$, and the disturbances ν_t and ν_t^* are independent $N(0, \sigma_\nu^2)$ variables. The resulting stochastic cycle has a fixed expected period but time-varying amplitude and phase. The stationarity properties of the random sequence ψ_t depend on the damping factor ρ. If $\rho < 1$, ψ_t has a stationary distribution with mean zero and variance $\sigma_\nu^2/(1-\rho^2)$. If $\rho = 1$, ψ_t is nonstationary.

You can incorporate a cycle in a UCM by specifying a CYCLE statement. You can include multiple cycles in the model by using separate CYCLE statements for each included cycle.

As mentioned before, the cycles are very useful as building blocks for constructing more complex periodic patterns. Periodic patterns of almost any complexity can be created by superimposing cycles of different periods and amplitudes. In particular, the seasonal patterns, general periodic patterns with integer periods, can be constructed as sums of cycles. This important topic of modeling the seasonal components is considered next.

Modeling Seasons

Seasonal fluctuations are a common source of variation in time series data. These fluctuations arise because of the regular changes in seasons or some other periodic events. The seasonal effects are regarded as corrections to the general trend of the series due to the seasonal variations, and these effects sum to zero when summed over the full season cycle. Therefore the seasonal component γ_t is modeled as a stochastic periodic pattern of an integer period s such that the sum $\sum_{i=0}^{s-1} \gamma_{t-i}$ is always zero in the mean. The period s is called the season length. Two different models for the seasonal component are considered here. The first model is called the *dummy* variable form of the seasonal component. It is described by the equation

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \qquad \omega_t \sim \text{iid } N(0, \sigma_\omega^2)$$

The other model is called the *trigonometric* form of the seasonal component. In this case γ_t is modeled as a sum of cycles of different frequencies. This model is given by

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if s is even and $(s-1)/2$ if it is odd. The cycles $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma_{j,t}^* \end{bmatrix} = \begin{bmatrix} \cos\lambda_j & \sin\lambda_j \\ -\sin\lambda_j & \cos\lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma_{j,t-1}^* \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega_{j,t}^* \end{bmatrix}$$

where the disturbances $\omega_{j,t}$ and $\omega^*_{j,t}$ are assumed to be independent and, for fixed j, $\omega_{j,t}$ and $\omega^*_{j,t} \sim N(0, \sigma^2_\omega)$. If s is even, then the equation for $\gamma^*_{s/2,t}$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

The cycles $\gamma_{j,t}$ are called *harmonics*. If the seasonal component is deterministic, the decomposition of the seasonal effects into these harmonics is identical to its Fourier decomposition. In this case the sum of squares of the seasonal factors equals the sum of squares of the amplitudes of these harmonics. In many practical situations, the contribution of the high-frequency harmonics is negligible and can be ignored, giving rise to a simpler description of the seasonal. In the case of stochastic seasonals, the situation might not be so transparent; however, similar considerations still apply. Note that if the disturbance variance $\sigma^2_\omega = 0$, then both the dummy and the trigonometric forms of seasonal components reduce to constant seasonal effects. That is, the seasonal component reduces to a deterministic function that is completely determined by its first $s - 1$ values.

In the UCM procedure you can specify a seasonal component in a variety of ways, the SEASON statement being the simplest of these. The dummy and the trigonometric seasonal components discussed so far can be considered as *saturated* seasonal components that put no restrictions on the $s - 1$ seasonal values. In some cases a more parsimonious representation of the seasonal might be more appropriate. This is particularly useful for seasonal components with large season lengths. In the UCM procedure you can obtain parsimonious representations of the seasonal components by one of the following ways:

- Use a *subset* trigonometric seasonal component obtained by deleting a few of the $[s/2]$ harmonics used in its sum. For example, a slightly smoother seasonal component of length 12, corresponding to the monthly seasonality, can be obtained by deleting the highest-frequency harmonic of period 2. That is, such a seasonal component will be a sum of five stochastic cycles that have periods 12, 6, 4, 3, and 2.4. You can specify such subset seasonal components by using the KEEPH= or DROPH= option in the SEASON statement.

- Approximate the seasonal pattern by a suitable spline approximation. You can do this by using the SPLINESEASON statement.

- A *block-seasonal* pattern is a seasonal pattern where the pattern is divided into a few blocks of equal length such that the season values within a block are the same—for example, a monthly seasonal pattern that has only four different values, one for each quarter. In some situations a long seasonal pattern can be approximated by the sum of block season and a simple season, the length of the simple season being equal to the block length of the block season. You can obtain such approximation by using a combination of BLOCKSEASON and SEASON statements.

- Consider a seasonal component of a large season length as a sum of two or more seasonal components that are each of much smaller season lengths. This can be done by specifying more than one SEASON statements.

Note that the preceding techniques of obtaining parsimonious seasonal components can also enable you to specify seasonal components that are more *general* than the simple saturated seasonal components. For example, you can specify a saturated trigonometric seasonal component that has some of its harmonics evolving according to one disturbance variance parameter while the others evolve with another disturbance variance parameter.

Modeling an Autoregression

An autoregression of order one can be thought of as a special case of a cycle when the frequency λ is either 0 or π. Modeling this special case separately helps interpretation and parameter estimation. The autoregression component r_t is modeled as

$$r_t = \rho r_{t-1} + \nu_t, \quad \nu_t \sim \text{iid } N(0, \sigma_\nu^2)$$

where $-1 \leq \rho < 1$. An autoregression can also provide an alternative to the IRREGULAR component when the model errors show some autocorrelation. You can incorporate an autoregression in your model by using the AUTOREG statement.

Modeling Regression Effects

A predictor variable can affect the response variable in a variety of ways. The UCM procedure enables you to model several different types of predictor-response relationships:

- The predictor-response relationship is *linear*, and the regression coefficient does not change with time. This is the simplest kind of relationship and such predictors are specified in the MODEL statement.
- The predictor-response relationship is *linear*, but the regression coefficient does change with time. Such predictors are specified in the RANDOMREG statement. Here the regression coefficient is assumed to evolve as a random walk.
- The predictor-response relationship is *nonlinear* and the relationship can change with time. This type of relationship can be approximated by an appropriate time-varying spline. Such predictors are specified in the SPLINEREG statement.
- The response depends on contemporaneous and lagged values of the predictor. This type of relationship is called transfer-function relationship, which can be specified in the TF statement.

A response variable can depend on its own past values—that is, lagged dependent values. Such a relationship can be specified in the DEPLAG statement.

Modeling the Irregular Component

The components—such as trend, seasonal and regression effects, and nonstationary cycles—are used to capture the structural dynamics of a response series. In contrast, the stationary cycles and the autoregression are used to capture the transient aspects of the response series that are important for its short-range prediction but have little impact on its long-term forecasts. The irregular component represents the residual variation remaining in the response series that is modeled using an appropriate selection of structural and transient effects. In most cases, the irregular component can be assumed to be simply Gaussian white noise. In some other cases, however, the residual variation can be more complicated. In such situations, it might be necessary to model the irregular component as a stationary ARMA process. Moreover, you can use the ARMA irregular component together with the dependent lag specification (see the DEPLAG statement) to specify an ARIMA$(p,d,q)\times(P,D,Q)_s$ model for the response series. For an explanation of the ARIMA notation, see the IRREGULAR statement. For an example of modeling a series by using an ARIMA$(0,1,1)\times(0,1,1)_{12}$ model, see Example 41.8.

The Model Parameters

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression, and the regression coefficients in the regression terms. These parameters are estimated by maximizing the likelihood. It is possible to restrict the values of the model parameters to user-specified values.

Model Specification

A UCM is specified by describing the components in the model. For example, consider the model

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

consisting of the irregular, level, slope, and seasonal components. This model is called the basic structural model (BSM) by Harvey (1989). The syntax for a BSM with monthly seasonality of trigonometric type is as follows:

```
model y;
irregular;
level;
slope;
season length=12 type=trig;
```

Similarly, the following syntax specifies a BSM with a response variable y, a regressor x, and dummy-type monthly seasonality:

```
model y = x;
irregular;
level;
slope variance=0 noest;
season length=12 type=dummy;
```

Moreover, the disturbance variance of the slope component is restricted to zero, giving rise to a local linear trend with fixed slope.

A model can contain multiple cycle and seasonal components. In such cases the model syntax contains a separate statement for each of these multiple cycle or seasonal components; for example, the syntax for a model containing irregular and level components along with two cycle components could be as follows:

```
model y = x;
irregular;
level;
cycle;
cycle;
```

The UCMs as State Space Models

The UCMs considered in PROC UCM are special cases of more general models, called (linear) state space models (SSM). The section "State Space Model and Notation" on page 2430 in Chapter 33, "The SSM Procedure," provides an elaborate notation for such models. However, for most of the UCMs considered in PROC UCM, much simpler notation suffices. This section describes a treatment of UCMs in terms of this simplified notation. At times the description and mathematical treatment (such as the expressions of likelihood) of state space models in PROC UCM and PROC SSM can appear different. However, these differences are only notational and the underlying mathematical quantities coincide. For example, the diffuse Kalman filter (DKF) described in this section is called the *exact initial* Kalman filter whereas the DKF described in the section "Filtering, Smoothing, Likelihood, and Structural Break Detection" on page 2438 in Chapter 33, "The SSM Procedure," is called the *augmented* Kalman filter. Both of these algorithms produce the same final output (see Durbin and Koopman (2012, chap. 5) for more information).

An SSM can be described as follows:

$$\begin{aligned} y_t &= Z_t \alpha_t \\ \alpha_{t+1} &= T_t \alpha_t + \zeta_{t+1}, \qquad \zeta_t \sim \mathrm{N}(0, Q_t) \\ \alpha_1 &\sim \mathrm{N}(0, P) \end{aligned}$$

The first equation, called the *observation equation*, relates the response series y_t to a state vector α_t that is usually unobserved. The second equation, called the *state equation*, describes the evolution of the state vector in time. The system matrices Z_t and T_t are of appropriate dimensions and are known, except possibly for some unknown elements that become part of the parameter vector of the model. The noise series ζ_t consists of independent, zero-mean, Gaussian vectors with covariance matrices Q_t. For most of the UCMs considered here, the system matrices Z_t and T_t, and the noise covariances Q_t, are time invariant—that is, they do not depend on time. In a few cases, however, some or all of them can depend on time. The initial state vector α_1 is assumed to be independent of the noise series, and its covariance matrix P can be partially diffuse. A random vector has a partially diffuse covariance matrix if it can be partitioned such that one part of the vector has a properly defined probability distribution, while the covariance matrix of the other part is infinite—that is, you have no prior information about this part of the vector. The covariance of the initial state α_1 is assumed to have the form

$$P = P_* + \kappa P_\infty$$

where P_* and P_∞ are nonnegative definite, symmetric matrices and κ is a constant that is assumed to be close to ∞. In the case of UCMs considered here, P_∞ is always a diagonal matrix that consists of zeros and ones, and, if a particular diagonal element of P_∞ is one, then the corresponding row and column in P_* are zero.

The state space formulation of a UCM has many computational advantages. In this formulation there are convenient algorithms for estimating and forecasting the unobserved states $\{\alpha_t\}$ by using the observed series $\{y_t\}$. These algorithms also yield the in-sample and out-of-sample forecasts and the likelihood of $\{y_t\}$. The state space representation of a UCM does not need to be unique. In the representation used here, the unobserved components in the UCM often appear as elements of the state vector. This makes the elements of the state interpretable and, more important, the sample estimates and forecasts of these unobserved components are easily obtained. For additional information about the computational aspects of the state

space modeling, see Durbin and Koopman (2012). Next, some notation is developed to describe the essential quantities computed during the analysis of the state space models.

Let $\{y_t, t = 1, \ldots, n\}$ be the observed sample from a series that satisfies a state space model. Next, for $1 \leq t \leq n$, let the one-step-ahead forecasts of the series, the states, and their variances be defined as follows, using the usual notation to denote the conditional expectation and conditional variance:

$$\begin{aligned}
\hat{\alpha}_t &= \mathrm{E}(\alpha_t | y_1, y_2, \ldots, y_{t-1}) \\
\Gamma_t &= \mathrm{Var}(\alpha_t | y_1, y_2, \ldots, y_{t-1}) \\
\hat{y}_t &= \mathrm{E}(y_t | y_1, y_2, \ldots, y_{t-1}) \\
F_t &= \mathrm{Var}(y_t | y_1, y_2, \ldots, y_{t-1})
\end{aligned}$$

These are also called the *filtered* estimates of the series and the states. Similarly, for $t \geq 1$, let the following denote the full-sample estimates of the series and the state values at time t:

$$\begin{aligned}
\tilde{\alpha}_t &= \mathrm{E}(\alpha_t | y_1, y_2, \ldots, y_n) \\
\Delta_t &= \mathrm{Var}(\alpha_t | y_1, y_2, \ldots, y_n) \\
\tilde{y}_t &= \mathrm{E}(y_t | y_1, y_2, \ldots, y_n) \\
G_t &= \mathrm{Var}(y_t | y_1, y_2, \ldots, y_n)
\end{aligned}$$

If the time t is in the historical period—that is, if $1 \leq t \leq n$—then the full-sample estimates are called the *smoothed* estimates, and if t lies in the future then they are called out-of-sample forecasts. Note that if $1 \leq t \leq n$, then $\tilde{y}_t = y_t$ and $G_t = 0$, unless y_t is missing.

All the filtered and smoothed estimates ($\hat{\alpha}_t, \tilde{\alpha}_t, \ldots, G_t$, and so on) are computed by using the Kalman filtering and smoothing (KFS) algorithm, which is an iterative process. If the initial state is diffuse, as is often the case for the UCMs, its treatment requires modification of the traditional KFS, which is called the diffuse KFS (DKFS). The details of DKFS implemented in the UCM procedure can be found in De Jong and Chu-Chun-Lin (2003). Additional information on the state space models can be found in Durbin and Koopman (2012). The likelihood formulas described in this section are taken from the latter reference.

In the case of diffuse initial condition, the effect of the improper prior distribution of α_1 manifests itself in the first few filtering iterations. During these initial filtering iterations the distribution of the filtered quantities remains diffuse; that is, during these iterations the one-step-ahead series and state forecast variances F_t and Γ_t have the following form:

$$\begin{aligned}
F_t &= F_{*t} + \kappa F_{\infty t} \\
\Gamma_t &= \Gamma_{*t} + \kappa \Gamma_{\infty t}
\end{aligned}$$

The actual number of iterations—for example, I—affected by this improper prior depends on the nature of the vectors Z_t, the number of nonzero diagonal elements of P_∞, and the pattern of missing values in the dependent series. After I iterations, $\Gamma_{\infty t}$ and $F_{\infty t}$ become zero and the one-step-ahead series and state forecasts have proper distributions. These first I iterations constitute the *initialization* phase of the DKFS algorithm. The post-initialization phase of the DKFS and the traditional KFS is the same. In the state space modeling literature the pre-initialization and post-initialization phases are some times called *pre-collapse* and *post-collapse* phases of the diffuse Kalman filtering. In certain missing value patterns it is possible for I to

exceed the sample size; that is, the sample information can be insufficient to create a proper prior for the filtering process. In these cases, parameter estimation and forecasting is done on the basis of this improper prior, and some or all of the series and component forecasts can have infinite variances (or zero precision). The forecasts that have infinite variance are set to missing. The same situation can occur if the specified model contains components that are essentially multicollinear. In these situations no residual analysis is possible; in particular, no residuals-based goodness-of-fit statistics are produced.

The log likelihood of the sample (L_∞), which takes account of this diffuse initialization step, is computed by using the one-step-ahead series forecasts as follows,

$$L_\infty(y_1,\ldots,y_n) = -\frac{(n-d)}{2}\log 2\pi - \frac{1}{2}\sum_{t=1}^{I} w_t - \frac{1}{2}\sum_{t=I+1}^{n}(\log F_t + \frac{v_t^2}{F_t})$$

where d is the number of diffuse elements in the initial state α_1, $v_t = y_t - Z_t\hat{\alpha}_t$ are the one-step-ahead residuals, and

$$\begin{aligned} w_t &= \log F_{\infty t} && \text{if } F_{\infty t} > 0 \\ &= \log F_{*t} + \frac{v_t^2}{F_{*t}} && \text{if } F_{\infty t} = 0 \end{aligned}$$

If y_t is missing at some time t, then the corresponding summand in the log likelihood expression is deleted, and the constant term is adjusted suitably. Moreover, if the initialization step does not complete—that is, if I exceeds the sample size—then the value of d is reduced to the number of diffuse states that are successfully initialized.

The portion of the log likelihood that corresponds to the post-initialization period is called the nondiffuse log likelihood (L_0). The nondiffuse log likelihood is given by

$$L_0(y_1,\ldots,y_n) = -\frac{1}{2}\sum_{t=I+1}^{n}(\log F_t + \frac{v_t^2}{F_t})$$

In the case of UCMs considered in PROC UCM, it often happens that the diffuse part of the likelihood, $\sum_{t=1}^{I} w_t$, does not depend on the model parameters, and in these cases the maximization of nondiffuse and diffuse likelihoods is equivalent. However, in some cases, such as when the model consists of dependent lags, the diffuse part does depend on the model parameters. In these cases the maximization of the diffuse and nondiffuse likelihood can produce different parameter estimates.

In some situations it is convenient to reparameterize the nondiffuse initial state covariance P_* as $\sigma^2 P_*$ and the state noise covariance Q_t as $\sigma^2 Q_t$ for some common scalar parameter σ^2. In this case the preceding log-likelihood expression, up to a constant, can be written as

$$L_\infty(y_1,\ldots,y_n) = -\frac{1}{2}\sum_{t=1}^{I} w_t - \frac{1}{2}\sum_{t=I+1}^{n}\log F_t - \frac{1}{2\sigma^2}\sum_{t=I+1}^{n}\frac{v_t^2}{F_t} - \frac{(n-d)}{2}\log\sigma^2$$

Solving analytically for the optimum, the maximum likelihood estimate of σ^2 can be shown to be

$$\hat{\sigma}^2 = \frac{1}{(n-d)}\sum_{t=I+1}^{n}\frac{v_t^2}{F_t}$$

When this expression of σ^2 is substituted back into the likelihood formula, an expression called the *profile likelihood* (L_{profile}) of the data is obtained:

$$-2L_{\text{profile}}(y_1,\ldots,y_n) = \sum_{t=1}^{I} w_t + \sum_{t=I+1}^{n} \log F_t + (n-d)\log(\sum_{t=I+1}^{n} \frac{v_t^2}{F_t})$$

In some situations the parameter estimation is done by optimizing the profile likelihood (see the section "Parameter Estimation by Profile Likelihood Optimization" on page 2901 and the PROFILE option in the ESTIMATE statement).

You can also request that parameter estimation be based on an alternate form of the likelihood, called the marginal likelihood ($\mathbf{L}_m(\mathbf{Y},\boldsymbol{\theta})$). You can switch to the marginal-likelihood-based parameter estimation by specifying LIKE=MARGINAL in the ESTIMATE statement. This alternate likelihood and two additional likelihoods are described in the section "Likelihood Computation and Model-Fitting Phase" on page 2439 in Chapter 33, "The SSM Procedure." The diffuse likelihood, L_∞, described in this section is equivalent to the diffuse likelihood, $\mathbf{L}_d(\mathbf{Y},\boldsymbol{\theta})$, described in that section. However, do not confuse the profile likelihood, L_{profile}, described in this section with the profile likelihood, $\mathbf{L}_p(\mathbf{Y},\boldsymbol{\theta})$, described in that section. The profiling in $\mathbf{L}_p(\mathbf{Y},\boldsymbol{\theta})$ refers to the profiling of the diffuse effects, whereas the profiling in L_{profile} refers to the profiling of a common scalar parameter σ^2. For each of the three likelihoods—diffuse, marginal and profile—that are described in that section, it is possible to profile out (also called concentrate out) a common scalar parameter σ^2 and obtain expressions similar to the L_{profile} likelihood that is described in this section. In fact, when you request that parameter estimation be based on the marginal likelihood by specifying LIKE=MARGINAL in the ESTIMATE statement, the profile version of marginal likelihood ($\mathbf{L}_m(\mathbf{Y},\boldsymbol{\theta})$) is used if the PROFILE option is in effect (by default or when the PROFILE option is specified). The discussion in the section "Parameter Estimation by Profile Likelihood Optimization" on page 2901 also applies to marginal likelihood. As explained in the section "Likelihood Computation and Model-Fitting Phase" on page 2439 in Chapter 33, "The SSM Procedure," the estimates that are based on marginal likelihood and the estimates that are based on diffuse likelihood coincide in many cases. In PROC UCM, estimates that are based on marginal likelihood and diffuse likelihood will differ only if at least one of the following conditions holds:

- The DEPLAG statement is present and the NOEST option is not specified.
- In a TF statement, at least one denominator factor is present and the NOEST option is not specified.
- In a CYCLE statement, RHO is fixed at 1 and the period is to be estimated—that is, RHO=1 and NOEST=RHO or NOEST=(RHO VARIANCE).

Whenever you specify LIKE=MARGINAL in the ESTIMATE statement, the FitSummary table that displays the likelihood-based fit statistics includes fit statistics and information criteria that are based on the marginal likelihood in addition to fit statistics that are based on diffuse likelihood.

In the remainder of this section, the state space formulation of UCMs is further explained by using some particular UCMs as examples. The examples show that the state space formulation of the UCMs depends on the components in the model in a simple fashion; for example, the system matrix T is usually a block diagonal matrix with blocks that correspond to the components in the model. The only exception to this pattern is the UCMs that consist of the lags of dependent variable. This case is considered at the end of the section.

In what follows, $\text{Diag}\,[a,b,\ldots]$ denotes a diagonal matrix with diagonal entries $[a,b,\ldots]$, and the transpose of a matrix T is denoted as T'.

Locally Linear Trend Model

Recall that the dynamics of the locally linear trend model are

$$\begin{aligned} y_t &= \mu_t + \epsilon_t \\ \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t \\ \beta_t &= \beta_{t-1} + \xi_t \end{aligned}$$

Here y_t is the response series and ϵ_t, η_t, and ξ_t are independent, zero-mean Gaussian disturbance sequences with variances $\sigma_\epsilon^2, \sigma_\eta^2$, and σ_ξ^2, respectively. This model can be formulated as a state space model where the state vector $\alpha_t = [\ \epsilon_t\ \mu_t\ \beta_t\ ]'$ and the state noise $\zeta_t = [\ \epsilon_t\ \eta_t\ \xi_t\ ]'$. Note that the elements of the state vector are precisely the unobserved components in the model. The system matrices T and Z and the noise covariance Q corresponding to this choice of state and state noise vectors can be seen to be time invariant and are given by

$$Z = [\ 1\ 1\ 0\ ],\quad T = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix} \text{ and } Q = \text{Diag}\left[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2\right]$$

The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}\left[\sigma_\epsilon^2, 0, 0\right]$ and $P_\infty = \text{Diag}\,[0, 1, 1]$. The parameter vector θ consists of all the disturbance variances—that is, $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2)$.

Basic Structural Model

The basic structural model (BSM) is obtained by adding a seasonal component, γ_t, to the local level model. In order to economize on the space, the state space formulation of a BSM with a relatively short season length, season length = 4 (quarterly seasonality), is considered here. The pattern for longer season lengths such as 12 (monthly) and 52 (weekly) is easy to see.

Let us first consider the dummy form of seasonality. In this case the state and state noise vectors are $\alpha_t = \left[\ \epsilon_t\ \mu_t\ \beta_t\ \gamma_{1,t}\ \gamma_{2,t}\ \gamma_{3,t}\ \right]'$ and $\zeta_t = [\ \epsilon_t\ \eta_t\ \xi_t\ \omega_t\ 0\ 0\ ]'$, respectively. The first three elements of the state vector are the irregular, level, and slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component γ_t. $\gamma_{1,t}$ corresponds to lag zero—that is, the same as γ_t, $\gamma_{2,t}$ to lag 1 and $\gamma_{3,t}$ to lag 2. The system matrices are

$$Z = [\ 1\ 1\ 0\ 1\ 0\ 0\ ],\quad T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & -1 & -1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

and $Q = \text{Diag}\left[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, 0, 0\right]$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}\left[\sigma_\epsilon^2, 0, 0, 0, 0, 0\right]$ and $P_\infty = \text{Diag}\,[0, 1, 1, 1, 1, 1]$.

In the case of the trigonometric type of seasonality, $\alpha_t = \left[\ \epsilon_t\ \mu_t\ \beta_t\ \gamma_{1,t}\ \gamma_{1,t}^*\ \gamma_{2,t}\ \right]'$ and $\zeta_t = \left[\ \epsilon_t\ \eta_t\ \xi_t\ \omega_{1,t}\ \omega_{1,t}^*\ \omega_{2,t}\ \right]'$. The disturbance sequences, $\omega_{j,t}, 1 \le j \le 2$, and $\omega_{1,t}^*$, are independent, zero-

mean, Gaussian sequences with variance σ^2_ω. The system matrices are

$$Z = [\,1\;1\;0\;1\;0\;1\,],\quad T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cos\lambda_1 & \sin\lambda_1 & 0 \\ 0 & 0 & 0 & -\sin\lambda_1 & \cos\lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos\lambda_2 \end{bmatrix}$$

and $Q = \mathrm{Diag}\left[\sigma^2_\epsilon, \sigma^2_\eta, \sigma^2_\xi, \sigma^2_\omega, \sigma^2_\omega, \sigma^2_\omega\right]$. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \mathrm{Diag}\left[\sigma^2_\epsilon, 0, 0, 0, 0, 0\right]$ and $P_\infty = \mathrm{Diag}\,[0, 1, 1, 1, 1, 1]$. The parameter vector in both the cases is $\theta = (\sigma^2_\epsilon, \sigma^2_\eta, \sigma^2_\xi, \sigma^2_\omega)$.

Seasons with Blocked Seasonal Values

Block seasonals are special seasonal components that impose a special block structure on the seasonal effects. Let us consider a BSM with monthly seasonality that has a quarterly block structure—that is, months within the same quarter are assumed to have identical effects except for some random perturbation. Such a seasonal component is a block seasonal with block size m equal to 3 and the number of blocks k equal to 4. The state space structure for such a model with dummy-type seasonality is as follows: The state and state noise vectors are $\alpha_t = \left[\,\epsilon_t\;\mu_t\;\beta_t\;\gamma_{1,t}\;\gamma_{2,t}\;\gamma_{3,t}\,\right]'$ and $\zeta_t = [\,\epsilon_t\;\eta_t\;\xi_t\;\omega_t\;0\;0\,]'$, respectively. The first three elements of the state vector are the irregular, level, and slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component γ_t. $\gamma_{1,t}$ corresponds to lag zero—that is, the same as γ_t, $\gamma_{2,t}$ to lag m and $\gamma_{3,t}$ to lag $2m$. All the system matrices are time invariant, except the matrix T. They can be seen to be $Z = [\,1\;1\;0\;1\;0\;0\,]$, $Q = \mathrm{Diag}\left[\sigma^2_\epsilon, \sigma^2_\eta, \sigma^2_\xi, \sigma^2_\omega, 0, 0\right]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & -1 & -1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

when t is a multiple of the block size m, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

otherwise. Note that when t is not a multiple of m, the portion of the T_t matrix corresponding to the seasonal is identity. The distribution of the initial state vector α_1 is diffuse, with $P_* = \mathrm{Diag}\left[\sigma^2_\epsilon, 0, 0, 0, 0, 0\right]$ and $P_\infty = \mathrm{Diag}\,[0, 1, 1, 1, 1, 1]$.

Similarly, in the case of the trigonometric form of seasonality, $\alpha_t = \left[\,\epsilon_t\;\mu_t\;\beta_t\;\gamma_{1,t}\;\gamma^*_{1,t}\;\gamma_{2,t}\,\right]'$ and $\zeta_t = \left[\,\epsilon_t\;\eta_t\;\xi_t\;\omega_{1,t}\;\omega^*_{1,t}\;\omega_{2,t}\,\right]'$. The disturbance sequences, $\omega_{j,t}, 1 \le j \le 2$, and $\omega^*_{1,t}$, are independent, zero-mean, Gaussian sequences with variance σ^2_ω. $Z = [\,1\;1\;0\;1\;0\;1\,]$, $Q = \mathrm{Diag}\left[\sigma^2_\epsilon, \sigma^2_\eta, \sigma^2_\xi, \sigma^2_\omega, \sigma^2_\omega, \sigma^2_\omega\right]$,

and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cos\lambda_1 & \sin\lambda_1 & 0 \\ 0 & 0 & 0 & -\sin\lambda_1 & \cos\lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos\lambda_2 \end{bmatrix}$$

when t is a multiple of the block size m, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

otherwise. As before, when t is not a multiple of m, the portion of the T_t matrix corresponding to the seasonal is identity. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}\left[\sigma_\epsilon^2, 0, 0, 0, 0, 0\right]$ and $P_\infty = \text{Diag}\left[0, 1, 1, 1, 1, 1\right]$. The parameter vector in both the cases is $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2)$.

Cycles and Autoregression

The preceding examples have illustrated how to build a state space model corresponding to a UCM that includes components such as irregular, trend, and seasonal. There you can see that the state vector and the system matrices have a simple block structure with blocks corresponding to the components in the model. Therefore, here only a simple model consisting of a single cycle and an irregular component is considered. The state space form for more complex UCMs consisting of multiple cycles and other components can be easily deduced from this example.

Recall that a stochastic cycle ψ_t with frequency λ, $0 < \lambda < \pi$, and damping coefficient ρ can be modeled as

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos\lambda & \sin\lambda \\ -\sin\lambda & \cos\lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} \nu_t \\ \nu_t^* \end{bmatrix}$$

where ν_t and ν_t^* are independent, zero-mean, Gaussian disturbances with variance σ_ν^2. In what follows, a state space form for a model consisting of such a stochastic cycle and an irregular component is given.

The state vector $\alpha_t = \begin{bmatrix} \epsilon_t & \psi_t & \psi_t^* \end{bmatrix}'$, and the state noise vector $\zeta_t = \begin{bmatrix} \epsilon_t & \nu_t & \nu_t^* \end{bmatrix}'$. The system matrices are

$$Z = [\,1\ 1\ 0\,] \quad T = \begin{bmatrix} 0 & 0 & 0 \\ 0 & \rho\cos\lambda & \rho\sin\lambda \\ 0 & -\rho\sin\lambda & \rho\cos\lambda \end{bmatrix} \quad Q = \text{Diag}\left[\sigma_\epsilon^2, \sigma_\nu^2, \sigma_\nu^2\right]$$

The distribution of the initial state vector α_1 is proper, with $P_* = \text{Diag}\left[\sigma_\epsilon^2, \sigma_\psi^2, \sigma_\psi^2\right]$, where $\sigma_\psi^2 = \sigma_\nu^2(1-\rho^2)^{-1}$. The parameter vector $\theta = (\sigma_\epsilon^2, \rho, \lambda, \sigma_\nu^2)$.

An autoregression r_t can be considered as a special case of cycle with frequency λ equal to 0 or π. In this case the equation for ψ_t^* is not needed. Therefore, for a UCM consisting of an autoregressive component and an irregular component, the state space model simplifies to the following form.

The state vector $\alpha_t = [\ \epsilon_t\ r_t\ ]'$, and the state noise vector $\zeta_t = [\ \epsilon_t\ \nu_t\ ]'$. The system matrices are

$$Z = [\ 1\ 1\ ],\quad T = \begin{bmatrix} 0 & 0 \\ 0 & \rho \end{bmatrix} \text{ and } Q = \text{Diag}\left[\sigma_\epsilon^2, \sigma_\nu^2\right]$$

The distribution of the initial state vector α_1 is proper, with $P_* = \text{Diag}\left[\sigma_\epsilon^2, \sigma_r^2\right]$, where $\sigma_r^2 = \sigma_\nu^2(1-\rho^2)^{-1}$. The parameter vector $\theta = (\sigma_\epsilon^2, \rho, \sigma_\nu^2)$.

Incorporating Predictors of Different Types

In the UCM procedure, you can incorporate predictors in a UCM in a variety of ways: you can specify simple time-invariant linear predictors in the MODEL statement, you can specify predictors that have time-varying coefficients in the RANDOMREG statement, and you can specify predictors that have a nonlinear relationship with the response variable in the SPLINEREG statement. You can also specify a transfer-function relationship by using the TF statement. As with earlier examples, the first part of this section uses a simple special case to show how to obtain a state space form of a UCM that consists of a variety of predictors (except the transfer-function relationship). The state space form that is associated with a transfer-function relationship is described in the section "State Space Form of a Transfer Function Relationship" on page 2897.

Consider a random walk trend model that has predictors x, u_1, u_2, and v. Assume that x is a simple regressor that is specified in the MODEL statement, u_1 and u_2 are random regressors with time-varying regression coefficients that are specified in the same RANDOMREG statement, and v is a nonlinear regressor that is specified in a SPLINEREG statement. Further assume that the spline that is associated with v has degree one and is based on two internal knots. As explained in the section "SPLINEREG Statement" on page 2878, using v is equivalent to using $(n\ knots + degree) = (2+1) = 3$ derived (random) regressors: for example, s_1, s_2, s_3. There are $(1+2+3) = 6$ regressors in all, the first one being a simple regressor and the others being time-varying coefficient regressors. The time-varying regressors are in two groups: the first group consists of u_1 and u_2, and the other group consists of s_1, s_2, and s_3. The dynamics of this model are as follows:

$$\begin{aligned}
y_t &= \mu_t + \beta x_t + \kappa_{1t}u_{1t} + \kappa_{2t}u_{2t} + \sum_{i=1}^{3}\gamma_{it}s_{it} + \epsilon_t \\
\mu_t &= \mu_{t-1} + \eta_t \\
\kappa_{1t} &= \kappa_{1(t-1)} + \xi_{1t} \\
\kappa_{2t} &= \kappa_{2(t-1)} + \xi_{2t} \\
\gamma_{1t} &= \gamma_{1(t-1)} + \zeta_{1t} \\
\gamma_{2t} &= \gamma_{2(t-1)} + \zeta_{2t} \\
\gamma_{3t} &= \gamma_{3(t-1)} + \zeta_{3t}
\end{aligned}$$

All the disturbances $\epsilon_t, \eta_t, \xi_{1t}, \xi_{2t}, \zeta_{1t}, \zeta_{2t}$, and ζ_{3t} are independent, zero-mean, Gaussian variables, where ξ_{1t}, ξ_{2t} share a common variance parameter σ_ξ^2 and $\zeta_{1t}, \zeta_{2t}, \zeta_{3t}$ share a common variance σ_ζ^2. These dynamics can be captured in the state space form by taking state $\alpha_t = [\ \epsilon_t\ \mu_t\ \beta\ \kappa_{1t}\ \kappa_{2t}\ \gamma_{1t}\ \gamma_{2t}\ \gamma_{3t}\ ]'$, state disturbance $\zeta_t = [\ \epsilon_t\ \eta_t\ 0\ \xi_{1t}\ \xi_{2t}\ \zeta_{1t}\ \zeta_{2t}\ \zeta_{3t}\ ]'$, and the system matrices

$$\begin{aligned}
Z_t &= [\ 1\ 1\ x_t\ u_{1t}\ u_{2t}\ s_{1t}\ s_{2t}\ s_{3t}\ ] \\
T &= \text{Diag}\,[0,\ 1,\ 1,\ 1,\ 1,\ 1,\ 1,\ 1] \\
Q &= \text{Diag}\left[\sigma_\epsilon^2,\ \sigma_\eta^2,\ 0,\ \sigma_\xi^2,\ \sigma_\xi^2,\ \sigma_\zeta^2,\ \sigma_\zeta^2,\ \sigma_\zeta^2\right]
\end{aligned}$$

Note that the regression coefficients are elements of the state vector and that the system vector Z_t is not time-invariant. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}\left[\sigma_\epsilon^2, 0, 0, 0, 0, 0, 0, 0\right]$ and $P_\infty = \text{Diag}\,[0, 1, 1, 1, 1, 1, 1, 1]$. The parameters of this model are the disturbance variances, σ_ϵ^2, σ_η^2, σ_ξ^2, and σ_ζ^2, which are estimated by maximizing the likelihood. The regression coefficients, time-invariant β, and time-varying $\kappa_{1t}, \kappa_{2t}, \gamma_{1t}, \gamma_{2t}$ and γ_{3t} are implicitly estimated during the state estimation (smoothing).

State Space Form of a Transfer Function Relationship

This section illustrates the state space form of a simple transfer-function relationship. The state space form of more complicated transfer-function relationships can be deduced using the same logic. Suppose that a predictor x enters the model for a response variable y as

$$\begin{aligned} y_t &= f_t + \epsilon_t \\ f_t &= \frac{(\gamma_0 + \gamma_1 B)}{(1 - \delta_1 B - \delta_2 B^2)} x_t \end{aligned}$$

where f_t is the transfer-function component and ϵ_t is a sequence of independent, zero-mean, Gaussian variables. In this description, the transfer-function component is described using the backward shift operator B. Alternatively, it can be described as follows:

$$f_t = \delta_1 f_{t-1} + \delta_2 f_{t-2} + \gamma_0 x_t + \gamma_1 x_{t-1}$$

This model can be easily put in a state space form by taking state $\boldsymbol{\alpha}_t = (\epsilon_t \;\; f_t \;\; f_{t-1} \;\; \gamma_0 \;\; \gamma_1)'$, state disturbance $\boldsymbol{\zeta}_t = (\epsilon_t \;\; 0 \;\; 0 \;\; 0 \;\; 0)'$, the system matrices $Z = [1 \;\; 1 \;\; 0 \;\; 0 \;\; 0]$, $Q = \text{Diag}[\sigma_\epsilon^2 \;\; 0 \;\; 0 \;\; 0 \;\; 0]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & \delta_1 & \delta_2 & x_{t+1} & x_t \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

The initial state $\boldsymbol{\alpha}_1$ is partially diffuse. The precise form of the initial state depends on the value of the TFSTART= option in the TF statement. If the TFSTART option is not specified, all elements of $\boldsymbol{\alpha}_1$ except for the first element (ϵ_1) are treated as diffuse. On the other hand, if a value is specified in the TFSTART= option, the initial transfer function values (f_1 and f_0) in $\boldsymbol{\alpha}_1$ are fixed at that specified value. In this formulation of the model, the numerator coefficients of the transfer-function relationship (γ_0 and γ_1) are part of the state. They are implicitly estimated during the state estimation (smoothing). On the other hand, the denominator coefficients (δ_1 and δ_2) and the noise variance (σ_ϵ^2) are estimated by maximizing the likelihood.

Reporting Parameter Estimates for Random Regressors

If the random walk disturbance variance that is associated with a random regressor is held fixed at 0, then its coefficient is no longer time-varying. In the UCM procedure, the random regressor parameter estimates are reported differently if the random walk disturbance variance that is associated with a random regressor is held fixed at 0. The following points explain how the parameter estimates are reported in the parameter estimates table and in the OUTEST= data set:

- If the random walk disturbance variance that is associated with a random regressor is not held fixed, then its estimate is reported in the parameter estimates table and in the OUTEST= data set.

- If more that one random regressor is specified in a RANDOMREG statement, then the first regressor in the list is used as a representative of the list when the corresponding common variance parameter estimate is reported.
- If the random walk disturbance variance is held fixed at 0, then the parameter estimates table and the OUTEST= data set contain the corresponding regression parameter estimate rather than the variance parameter estimate.
- Similar considerations apply in the case of the derived random regressors that are associated with a spline regressor.

Forecasting with Predictor Variables

If regression effects are included in the model (in a MODEL statement or in one or more of the RANDOMREG, SPLINEREG, and TF statements) and the FORECAST statement is used to compute multistep forecasts, then future values of the predictor variables must be included in the DATA= data set for the forecast horizon that is defined by the BACK= and LEAD= options in the FORECAST statement. For more information about how the forecast horizon is defined, see the FORECAST statement.

ARMA Irregular Component

The state space form for the irregular component that follows an ARMA(*p*,*q*)×(*P*,*Q*)$_s$ model is described in this section. The notation for ARMA models is explained in the IRREGULAR statement. A number of alternate state space forms are possible in this case; the one given here is based on Jones (1980). With slight abuse of notation, let $p = p + sP$ denote the effective autoregressive order and $q = q + sQ$ denote the effective moving average order of the model. Similarly, let ϕ be the effective autoregressive polynomial and θ be the effective moving average polynomial in the backshift operator with coefficients $\phi_1, \ldots, \phi_p$ and $\theta_1, \ldots, \theta_q$, obtained by multiplying the respective nonseasonal and seasonal factors. Then, a random sequence ϵ_t that follows an ARMA(*p*,*q*)×(*P*,*Q*)$_s$ model with a white noise sequence a_t has a state space form with state vector of size $m = \max(p, q+1)$. The system matrices, which are time invariant, are as follows: $Z = [1\ 0\ \ldots\ 0]$. The state transition matrix T, in a blocked form, is given by

$$T = \begin{bmatrix} 0 & I_{m-1} \\ \phi_m\ \ldots & \phi_1 \end{bmatrix}$$

where $\phi_i = 0$ if $i > p$ and I_{m-1} is an $(m-1)$ dimensional identity matrix. The covariance of the state disturbance matrix $Q = \sigma^2 \psi \psi'$ where σ^2 is the variance of the white noise sequence a_t and the vector $\psi = [\psi_0 \ldots \psi_{m-1}]'$ contains the first m values of the impulse response function—that is, the first m coefficients in the expansion of the ratio θ/ϕ. Since ϵ_t is a stationary sequence, the initial state is nondiffuse and $P_\infty = 0$. The description of P_*, the covariance matrix of the initial state, is a little involved; the details are given in Jones (1980).

Models with Dependent Lags

The state space form of a UCM consisting of the lags of the dependent variable is quite different from the state space forms considered so far. Let us consider an example to illustrate this situation. Consider a model that has random walk trend, two simple time-invariant regressors, and that also includes a few—for example,

k—lags of the dependent variable. That is,

$$\begin{aligned} y_t &= \sum_{i=1}^{k} \phi_i y_{t-i} + \mu_t + \beta_1 x_{1t} + \beta_2 x_{2t} + \epsilon_t \\ \mu_t &= \mu_{t-1} + \eta_t \end{aligned}$$

The state space form of this augmented model can be described in terms of the state space form of a model that has random walk trend with two simple time-invariant regressors. A superscript dagger (†) has been added to distinguish the augmented model state space entities from the corresponding entities of the state space form of the random walk with predictors model. With this notation, the state vector of the augmented model $\alpha_t^{\dagger} = \begin{bmatrix} \alpha_t' & y_t & y_{t-1} & \ldots & y_{t-k+1} \end{bmatrix}'$ and the new state noise vector $\zeta_t^{\dagger} = \begin{bmatrix} \zeta_t' & u_t & 0 \ldots & 0 \end{bmatrix}'$, where u_t is the matrix product $Z_t \zeta_t$. Note that the length of the new state vector is $k + \text{length}(\alpha_t) = k + 4$. The new system matrices, in block form, are

$$Z_t^{\dagger} = [\, 0\, 0\, 0\, 0\, 1 \ \ldots\ 0\,], \quad T_t^{\dagger} = \begin{bmatrix} T_t & 0 & \ldots & 0 \\ Z_{t+1} T_t & \phi_1 & \ldots & \phi_k \\ 0 & I_{k-1,k-1} & & 0 \end{bmatrix}$$

where $I_{k-1,k-1}$ is the $k-1$ dimensional identity matrix and

$$Q_t^{\dagger} = \begin{bmatrix} Q_t & Q_t Z_t' & 0 \\ Z_t Q_t & Z_t Q_t Z_t' & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

Note that the T and Q matrices of the random walk with predictors model are time invariant, and in the expressions above their time indices are kept because they illustrate the pattern for more general models. The initial state vector is diffuse, with

$$P_*^{\dagger} = \begin{bmatrix} P_* & 0 \\ 0 & 0 \end{bmatrix}, \quad P_{\infty}^{\dagger} = \begin{bmatrix} P_{\infty} & 0 \\ 0 & I_{k,k} \end{bmatrix}$$

The parameters of this model are the disturbance variances σ_{ϵ}^2 and σ_{η}^2, the lag coefficients $\phi_1, \phi_2, \ldots, \phi_k$, and the regression coefficients β_1 and β_2. As before, the regression coefficients get estimated during the state smoothing, and the other parameters are estimated by maximizing the likelihood.

Outlier Detection

In time series analysis it is often useful to detect changes over time in the characteristics of the response series. In the UCM procedure you can search for two types of changes, additive outliers (AO) and level shifts (LS). An additive outlier is an unusual value in the series, the cause of which might be a data recording error or a temporary shock to the series generation process. A level shift represents a permanent shift, either up or down, in the level of the series. You can control different aspects of the outlier search, such as the significance level of the reported outliers, by choosing different options in the OUTLIER statement. The search for AOs is done by default, whereas the CHECKBREAK option in the LEVEL statement must be used to turn on the search for LSs.

The outlier detection process implemented in the UCM procedure is based on De Jong and Penzer (1998). In this approach the fitted model is taken to be the *null* model, and the series values and level shifts that are

not adequately accounted for by the null model are flagged as outliers. The unusualness of a response series value at a particular time point t_0, with respect to the fitted model, can be judged by estimating its value based on the rest of the data (that is, the series obtained by *deleting* the series value at t_0) and comparing the estimated value to the observed value. If the difference between the estimated and observed values is statistically significant, then such value can be regarded as an AO. Note that this difference between the estimated and observed values is also the regression coefficient of a *dummy* regressor that takes the value 1.0 at t_0 and is 0.0 elsewhere, assuming such a regressor is added to the null model. In this way the series value at t_0 is regarded as AO if the regression coefficient of this dummy regressor is significant. Similarly, you can say that a level shift has occurred at a time point t_0 if the regression coefficient of a regressor, which is 0.0 before t_0 and 1.0 at t_0 and thereafter, is statistically significant. De Jong and Penzer (1998) provide an efficient way to compute such AO and LS regression coefficients and their standard errors at all time points in the series. The outlier summary table, which is produced by default, simply lists the most statistically significant candidates among these.

Missing Values

Embedded missing values in the dependent variable usually cause no problems in UCM modeling. However, no missing values are allowed in the predictor variables. Certain patterns of missing values in the dependent variable can lead to failure of the initialization step of the diffuse Kalman filtering for some models. For example, if in a monthly series all values are missing for a certain month—such as May—then a BSM with monthly seasonality leads to such a situation. However, in this case the initialization step can complete successfully for a nonseasonal model such as local linear model.

Parameter Estimation

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression, the lag coefficients of the dependent lags, and the regression coefficients in the regression terms. The regression coefficients are always part of the state vector and are estimated by state smoothing. The remaining parameters are estimated by maximizing either the full diffuse likelihood or the nondiffuse likelihood. The decision to use the full diffuse likelihood or the nondiffuse likelihood depends on the presence or absence of the dependent lag coefficients in the parameter vector. If the parameter vector does not contain any dependent lag coefficients, then the full diffuse likelihood is used. If, on the other hand, the parameter vector does contain some dependent lag coefficients, then the parameters are estimated by maximizing the nondiffuse likelihood. The optimization of the full diffuse likelihood is often unstable when the parameter vector contains dependent lag coefficients. In this sense, when the parameter vector contains dependent lag coefficients, the parameter estimates are not true maximum likelihood estimates.

The optimization of the likelihood, either full or nondiffuse, is carried out using one of several nonlinear optimization algorithms. The user can control many aspects of the optimization process by using the NLOPTIONS statement and by providing the starting values of the parameters while specifying the corresponding components. However, in most cases the default settings work quite well. The optimization process is not guaranteed to converge to a maximum likelihood estimate. In most cases the difficulties in parameter estimation are associated with the specification of a model that is not appropriate for the series being modeled.

Parameter Estimation by Profile Likelihood Optimization

If a disturbance variance, such as the disturbance variance of the irregular component, is a part of the UCM and is a free parameter, then it can be profiled out of the likelihood. This means solving analytically for its optimum and plugging this expression back into the likelihood formula, giving rise to the so-called *profile* likelihood. The expression of the profile likelihood and the MLE of the profiled variance are given earlier in the section "The UCMs as State Space Models" on page 2889, where the computation of the likelihood of the state space model is also discussed.

In some situations the optimization of the profile likelihood can be more efficient because the number of parameters to optimize is reduced by one; however, for a variety of reasons such gains might not always be observed. Moreover, in theory the estimates obtained by optimizing the profile likelihood and the usual likelihood should be the same, but in practice this might not hold because of numerical rounding and other conditions.

In the UCM procedure, by default the usual likelihood is optimized if any of the disturbance variance parameters is held fixed to a nonzero value by using the NOEST option in the corresponding component statement. In other cases the decision whether to optimize the profile likelihood or the usual likelihood is based on several factors that are difficult to document. You can choose which likelihood to optimize during parameter estimation by specifying the PROFILE option for the profile likelihood optimization or the NOPROFILE option for the usual likelihood optimization. In the presence of the PROFILE option, the disturbance variance to profile is checked in a specific order, so that if the irregular component disturbance variance is free then it is always chosen. The situation in other cases is more complicated.

Profiling in the Presence of Fixed Variance Parameters

Note that when the parameter estimation is done by optimizing the profile likelihood, the interpretation of the variance parameters that are held fixed to nonzero values changes. In the presence of the PROFILE option, the disturbance variances that are held at a fixed value by using the NOEST option in their respective component statements are interpreted as being restricted to be that fixed multiple of the profiled variance rather than being fixed at that nominal value. That is, implicitly, the parameter estimation is done under the restriction of holding the disturbance variance *ratio* fixed at a given value rather than the disturbance variance itself. For an example of this type of restriction to obtain a UC model that is equivalent to the famous Hodrick-Prescott filter, see Example 41.5.

t Values

The *t* values reported in the table of parameter estimates are approximations whose accuracy depends on the validity of the model, the nature of the model, and the length of the observed series. The distributional properties of the maximum likelihood estimates of general unobserved components models have not been explored fully; therefore the probability values that correspond to a *t* distribution should be interpreted carefully, as they can be misleading. This is particularly true if the parameters in question are close to the boundary of the parameter space. The two sources by Harvey (1989, 2001) are good references for information about this topic. For some parameters, such as the cycle period, the reported *t* values are uninformative because comparison of the estimated parameter with zero is never needed. In such cases the *t* values and the corresponding probability values should be ignored.

Bootstrap Prediction Intervals (Experimental)

By default, the UCM procedure computes the standard errors of the series and component forecasts (both the filtered and smoothed estimates) by assuming that the estimated parameters are in fact the true parameters. Rodriguez and Ruiz (2010) describe a bootstrap-based procedure to compute the standard errors of the series and component forecasts that takes into account the uncertainty of parameter estimation. As an experimental feature in this release, you can request the computation of standard errors based on this bootstrap-based procedure by specifying the BOOTSTRAP option in the FORECAST statement. Subsequently, the confidence intervals for the series and component forecasts are based on these bootstrap standard errors. The algorithm that PROC UCM uses closely follows the first procedure described in Section 3 of Rodriguez and Ruiz (2010). Note that this bootstrap algorithm is computationally expensive. The computational burden increases with the number of bootstrap replications and is comparable to the computational burden of fitting the specified model as many times as the number of replications. Fortunately, these replications can be executed in parallel, and the UCM procedure can use multiple cores and multiple grid nodes (if they are available) to complete these calculations faster. For a single machine with multiple cores, the procedure automatically detects and uses all the cores. If a grid environment with multiple machines is available (with the appropriate SAS license), you must use the PERFORMANCE statement to supply the necessary information to the UCM procedure.

Computational Issues

Convergence Problems

As explained in the section "Parameter Estimation" on page 2900, the model parameters are estimated by nonlinear optimization of the likelihood. This process is not guaranteed to succeed. For some data sets, the optimization algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data. It is also possible for the algorithm to converge to a point that is not the global optimum of the likelihood.

If you experience convergence problems, the following points might be helpful:

- Data that are extremely large or extremely small can adversely affect results because of the internal tolerances used during the filtering steps of the likelihood calculation. Rescaling the data can improve stability.
- Examine your model for redundancies in the included components and regressors. If some of the included components or regressors are nearly collinear to each other, then the optimization process can become unstable.
- Experimenting with different options offered by the NLOPTIONS statement can help.
- Lack of convergence can indicate model misspecification or a violation of the normality assumption.

Computer Resource Requirements

The computing resources required for the UCM procedure depend on several factors. The memory requirement for the procedure is largely dependent on the number of observations to be processed and the size of the state vector underlying the specified model. If n denotes the sample size and m denotes the size of the state vector, the memory requirement for the smoothing stage of the Kalman filter is of the order of $6 \times 8 \times n \times m^2$ bytes, ignoring the lower-order terms. If the smoothed component estimates are not needed then the memory requirement is of the order of $6 \times 8 \times (m^2 + n)$ bytes. Besides m and n, the computing time for the parameter estimation depends on the type of components included in the model. For example, the parameter estimation is usually faster if the model parameter vector consists only of disturbance variances, because in this case there is an efficient way to compute the likelihood gradient.

Displayed Output

The default printed output produced by the UCM procedure is described in the following list:

- brief information about the input data set, including the data set name and label, and the name of the ID variable specified in the ID statement
- summary statistics for the data in the estimation and forecast spans, including the names of the variables in the model, their categorization as dependent or predictor, the index of the beginning and ending observations in the spans, the total number of observations and the number of missing observations, the smallest and largest measurements, and the mean and standard deviation
- information about the model parameters at the start of the model-fitting stage, including the fixed parameters in the model and the initial estimates of the free parameters in the model
- convergence status of the likelihood optimization process if any parameter estimation is done
- estimates of the free parameters at the end of the model fitting-stage, including the parameter estimates, their approximate standard errors, t statistics, and the approximate p-value
- the likelihood-based goodness-of-fit statistics, including the full likelihood, the portion of the likelihood corresponding to the diffuse initialization, the sum of squares of residuals normalized by their standard errors, and the information criteria: AIC, AICC, HQIC, BIC, and CAIC
- the fit statistics that are based on the raw residuals (observed minus predicted), including the mean squared error (MSE), the root mean squared error (RMSE), the mean absolute percentage error (MAPE), the maximum percentage error (MAXPE), the R-square, the adjusted R-square, the random walk R-square, and Amemiya's R-square
- the significance analysis of the components included in the model that is based on the estimation span
- brief information about the components included in the model
- additive outliers in the series, if any are detected
- the multistep series forecasts
- post-sample-prediction analysis table that compares the multistep forecasts with the observed series values, if the BACK= option is used in the FORECAST statement

Statistical Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

This section provides information about the basic ODS statistical graphics produced by the UCM procedure.

You can obtain most plots relevant to the specified model by using the global PLOTS= option in the PROC UCM statement. The plot of series forecasts in the forecast horizon is produced by default. You can further control the production of individual plots by using the PLOT= options in the different statements.

The main types of plots available are as follows:

- Time series plots of the component estimates, either filtered or smoothed, can be requested by using the PLOT= option in the respective component statements. For example, the use of PLOT=SMOOTH option in a CYCLE statement produces a plot of smoothed estimate of that cycle.
- Residual plots for model diagnostics can be obtained by using the PLOT= option in the ESTIMATE statement.
- Plots of series forecasts and model decompositions can be obtained by using the PLOT= option in the FORECAST statement.

The following example is a simple illustration of the available plot options.

Analysis of Sunspot Data: Illustration of ODS Graphics

In this example a well-known series, Wolfer's sunspot data (Anderson 1971), is considered. The data consist of yearly sunspot numbers recorded from 1749 to 1924. These sunspot numbers are known to have a cyclical pattern with a period of about eleven years. The following DATA step creates the input data set:

```
data sunspot;
   input year wolfer @@;
   year = mdy(1,1, year);
   format year year4.;
datalines;
1749  809 1750  834 1751  477 1752  478 1753  307 1754  122 1755   96
1756  102 1757  324 1758  476 1759  540 1760  629 1761  859 1762  612
1763  451 1764  364 1765  209 1766  114 1767  378 1768  698 1769 1061

   ... more lines ...
```

The following statements specify a UCM that includes a cycle component and a random walk trend component:

```
proc ucm data=sunspot;
   id year interval=year;
   model wolfer;
   irregular;
   level ;
   cycle plot=(filter smooth);
   estimate back=24 plot=(loess panel cusum wn);
   forecast back=24 lead=24 plot=(forecasts decomp);
run;
```

The following subsections explain the graphics produced by the preceding statements.

Component Plots

The plots in Figure 41.8 and Figure 41.9, produced by specifying PLOT=(FILTER SMOOTH) in the CYCLE statement, show the filtered and smoothed estimates, respectively, of the cycle component in the model. Note that the smoothed estimate appears smoother than the filtered estimate. This is always true because the filtered estimate of a component at time t is based on the observations prior to time t—that is, it uses measurements from the first observation up to the $(t-1)$th observation. On the other hand, the corresponding smoothed estimate uses all the available observations—that is, all the measurements from the first observation to the last. This makes the smoothed estimate of the component more precise than the filtered estimate for the time points within historical period. In the forecast horizon, both filtered and smoothed estimates are identical, being based on the same set of observations.

Figure 41.8 Sunspots Series: Filtered Cycle

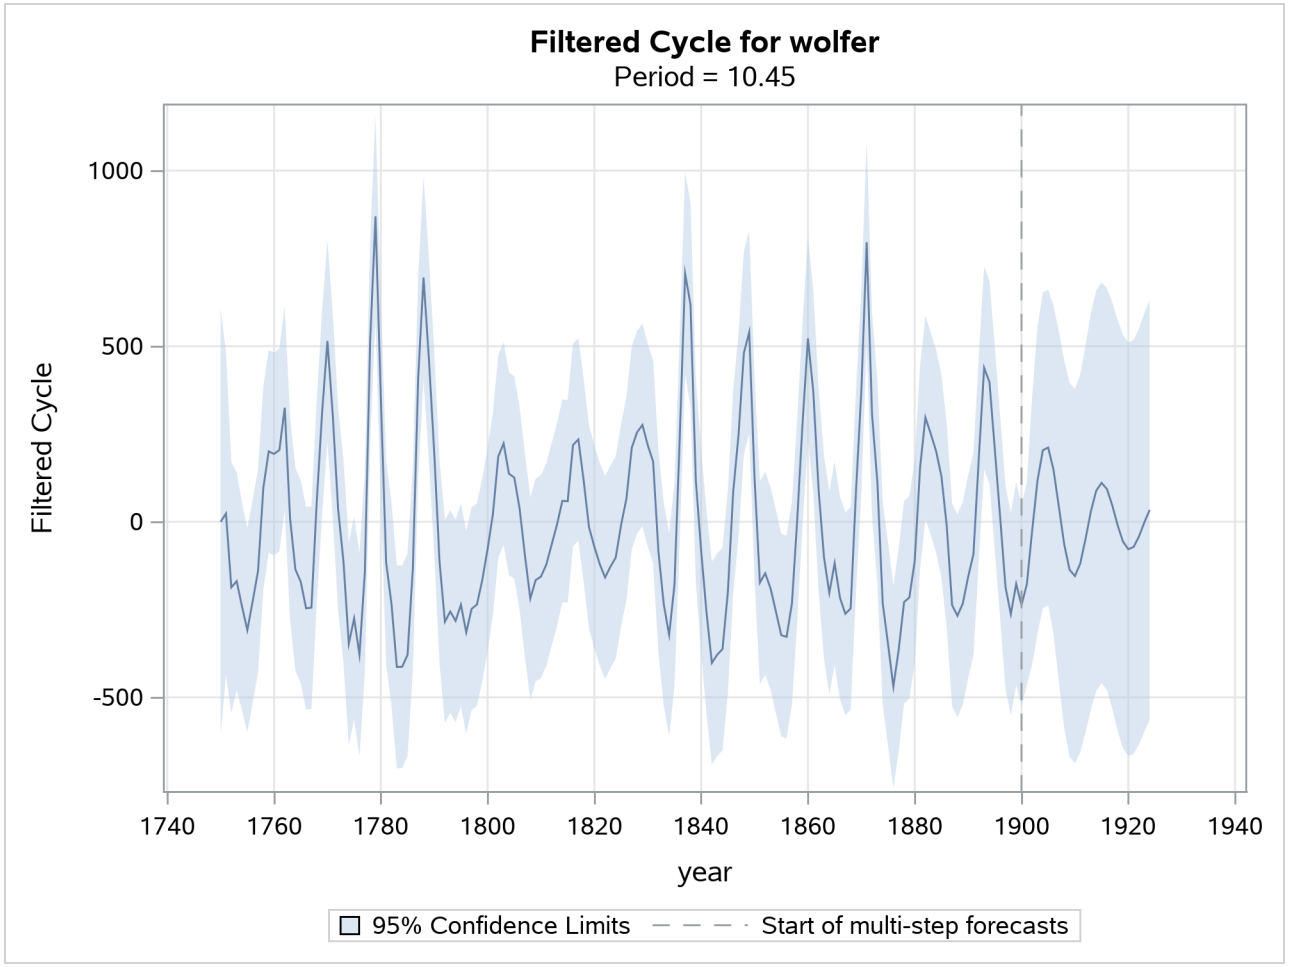

Figure 41.9 Sunspots Series: Smoothed Cycle

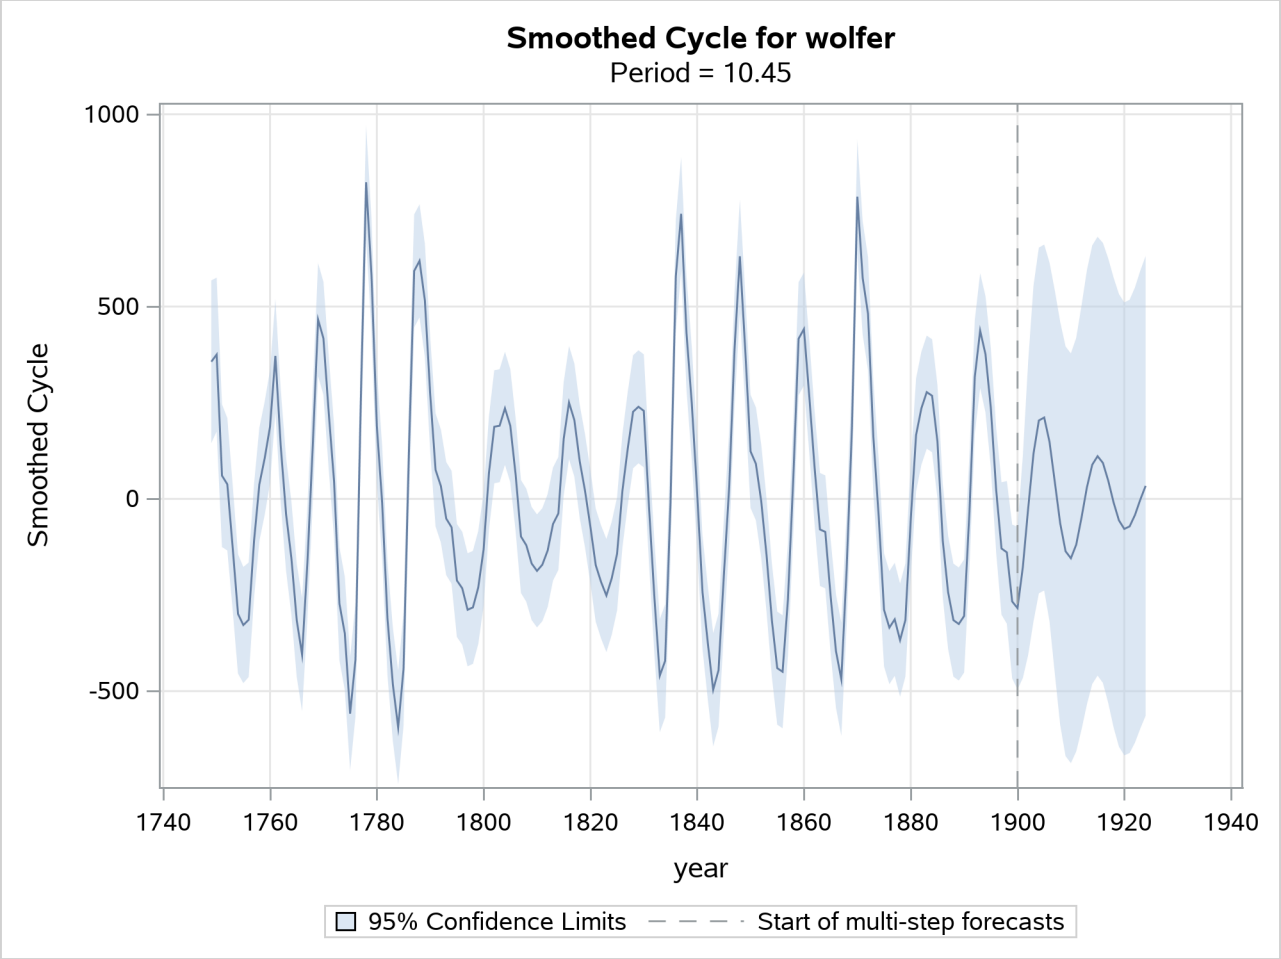
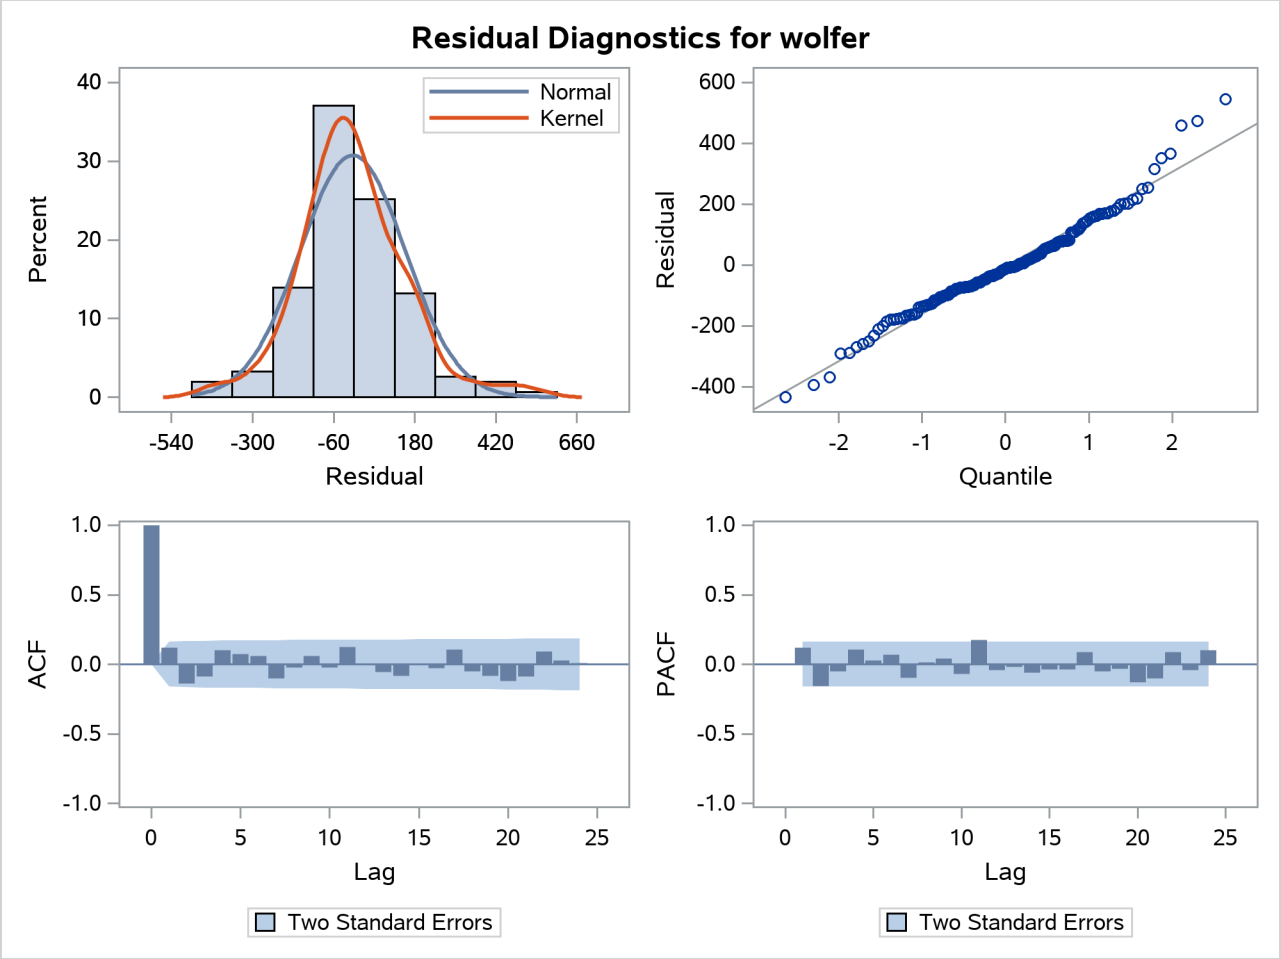


Residual Diagnostics

If the fitted model is appropriate for the given data, then the corresponding one-step-ahead residuals should be approximately *white*—that is, uncorrelated—and approximately normal. Moreover, the residuals should not display any discernible pattern. You can detect departures from these conditions graphically. Different residual diagnostic plots can be requested by using the PLOT= option in the ESTIMATE statement.

The normality can be checked by examining the histogram and the normal quantile plot of residuals. The whiteness can be checked by examining the ACF and PACF plots that show the sample autocorrelation and sample partial-autocorrelation at different lags. The diagnostic panel shown in Figure 41.10, produced by specifying PLOT=PANEL, contains these four plots.

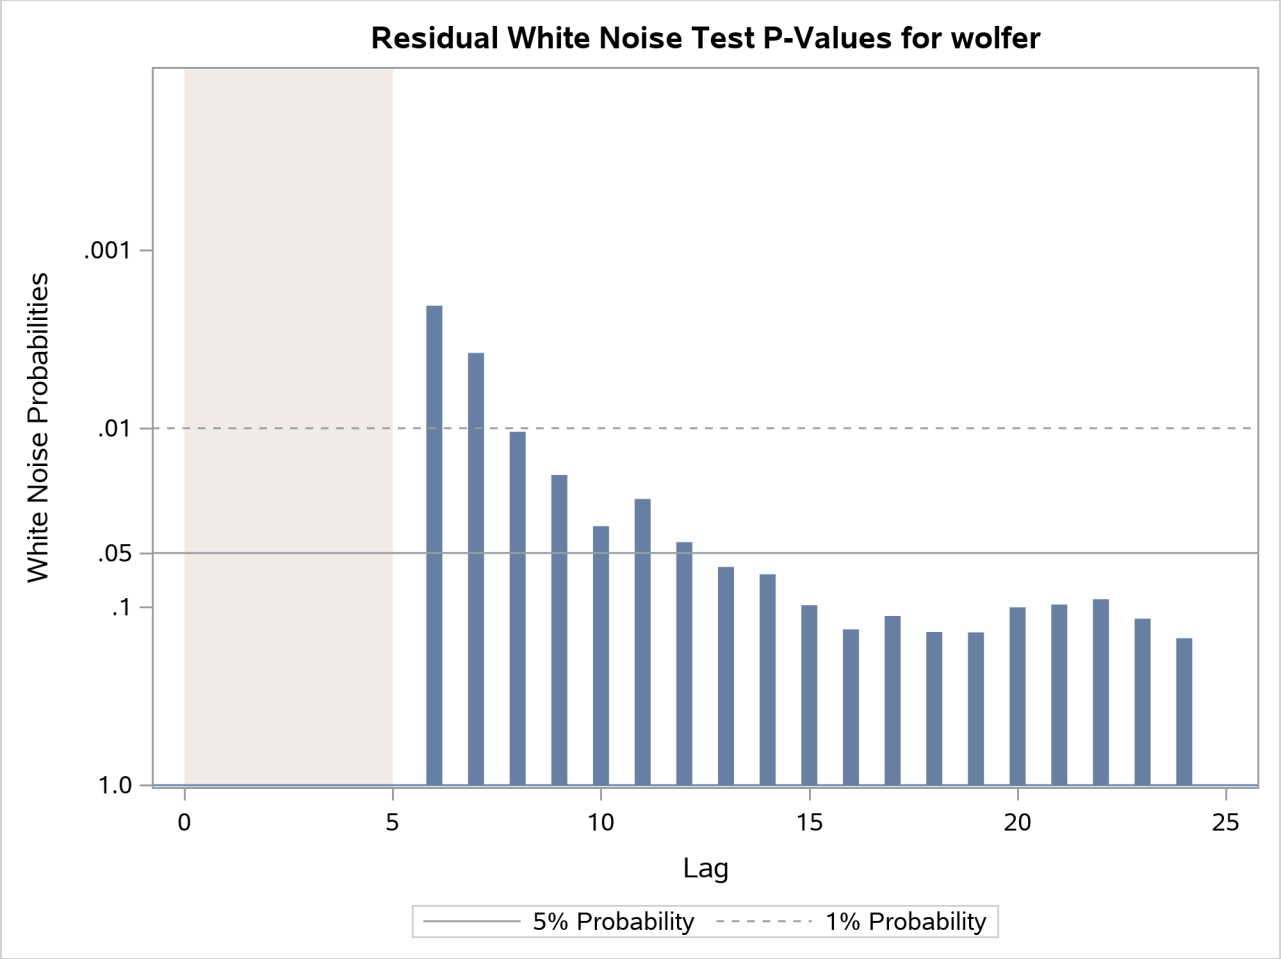
Figure 41.10 Sunspots Series: Residual Diagnostics



The residual histogram and Q-Q plot show no serious violation of normality. The histogram appears reasonably symmetric and follows the overlaid normal density curve reasonably closely. Similarly, in the Q-Q plot the residuals follow the reference line fairly closely. The ACF and PACF plots also do not exhibit any violation of the whiteness assumption; the correlations at all nonzero lags seem to be insignificant.

The residual whiteness can also be formally tested by using the Ljung-Box portmanteau test. The plot in Figure 41.11, produced by specifying PLOT=WN, shows the p-values of the Ljung-Box test statistics at different lags. In these plots the p-values for the first few lags, equal to the number of estimated parameters in the model, are not shown because they are always missing. This portion of the plot is shaded blue to indicate this fact. In the case of this model, five parameters are estimated so the p-values for the first five lags are not shown. The p-values are displayed on a log scale in such a way that higher bars imply more extreme test statistics. In this plot some early p-values appear extreme. However, these p-values are based on large sample theory, which suggests that these statistics should be examined for lags larger than the square root of sample size. In this example it means that the p-values for the first $\sqrt{154} \approx 12$ lags can be ignored. With this consideration, the plot shows no violation of whiteness since the p-values after the 12th lag do not appear extreme.

Figure 41.11 Sunspots Series: Ljung-Box Portmanteau Test

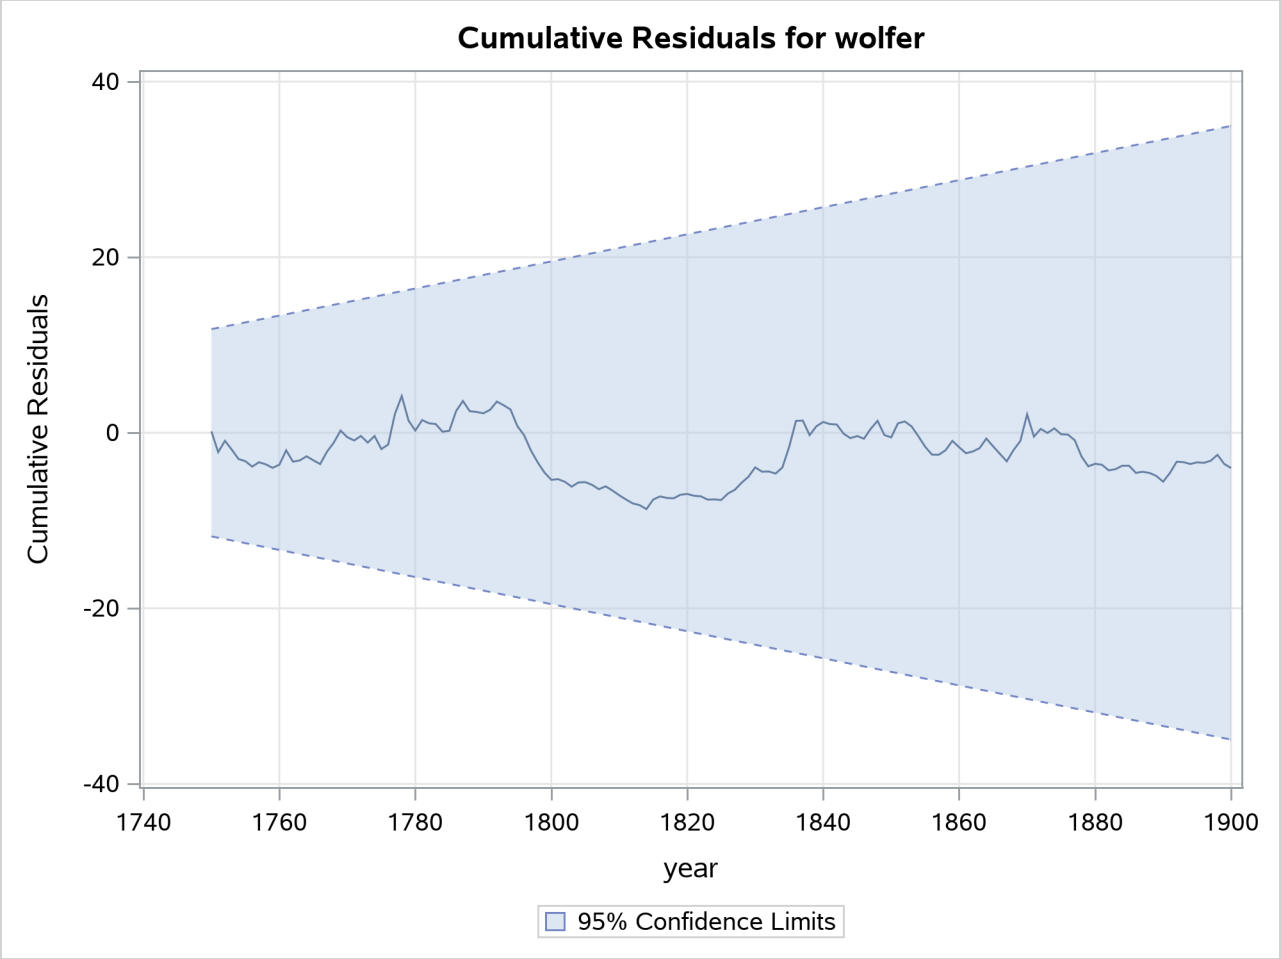


The plot in Figure 41.12, produced by specifying PLOT=LOESS, shows the residuals plotted against time with an overlaid loess curve. This plot is useful for checking whether any discernible pattern remains in the residuals. Here again, no significant pattern appears to be present.

Figure 41.12 Sunspots Series: Residual Loess Plot

The plot in Figure 41.13, produced by specifying PLOT=CUSUM, shows the cumulative residuals plotted against time. This plot is useful for checking structural breaks. Here, there appears to be no evidence of structural break since the cumulative residuals remain within the confidence band throughout the sample period. Similarly, you can request a plot of the squared cumulative residuals by specifying PLOT=CUSUMSQ.

Figure 41.13 Sunspots Series: CUSUM Plot



Brockwell and Davis (1991) can be consulted for additional information on diagnosing residuals. For more information about CUSUM and CUSUMSQ plots, you can consult Harvey (1989).

Forecast and Series Decomposition Plots

You can use the PLOT= option in the FORECAST statement to obtain the series forecast plot and the series decomposition plots. The series decomposition plots show the result of successively adding different components in the model starting with the trend component. The IRREGULAR component is left out of this process. The following two plots, produced by specifying PLOT=DECOMP, show the results of successive component addition for this example. The first plot, shown in Figure 41.14, shows the smoothed trend component and the second plot, shown in Figure 41.15, shows the sum of smoothed trend and cycle.

Figure 41.14 Sunspots Series: Smoothed Trend

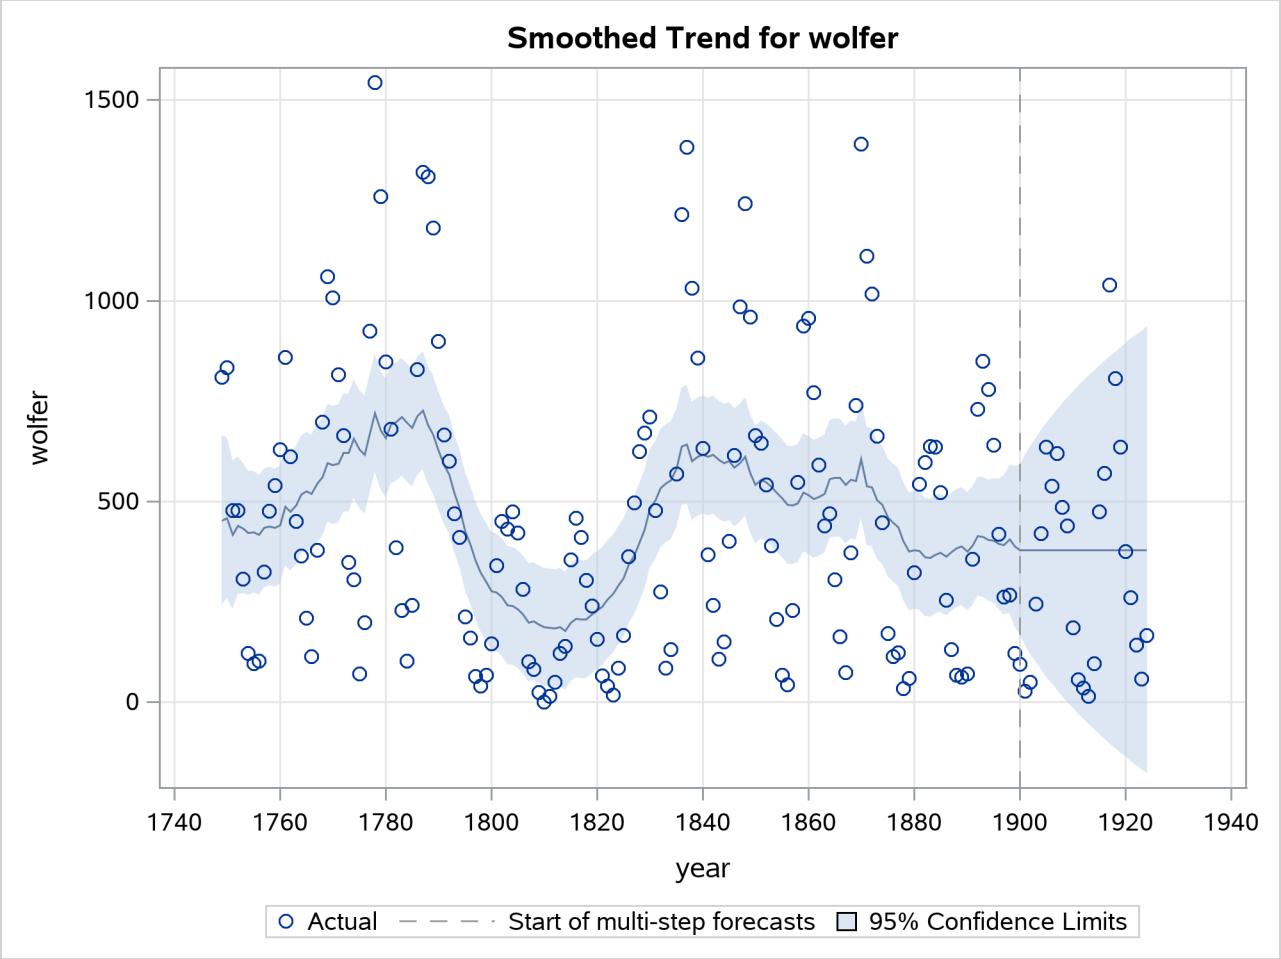


Figure 41.15 Sunspots Series: Smoothed Trend plus Cycle

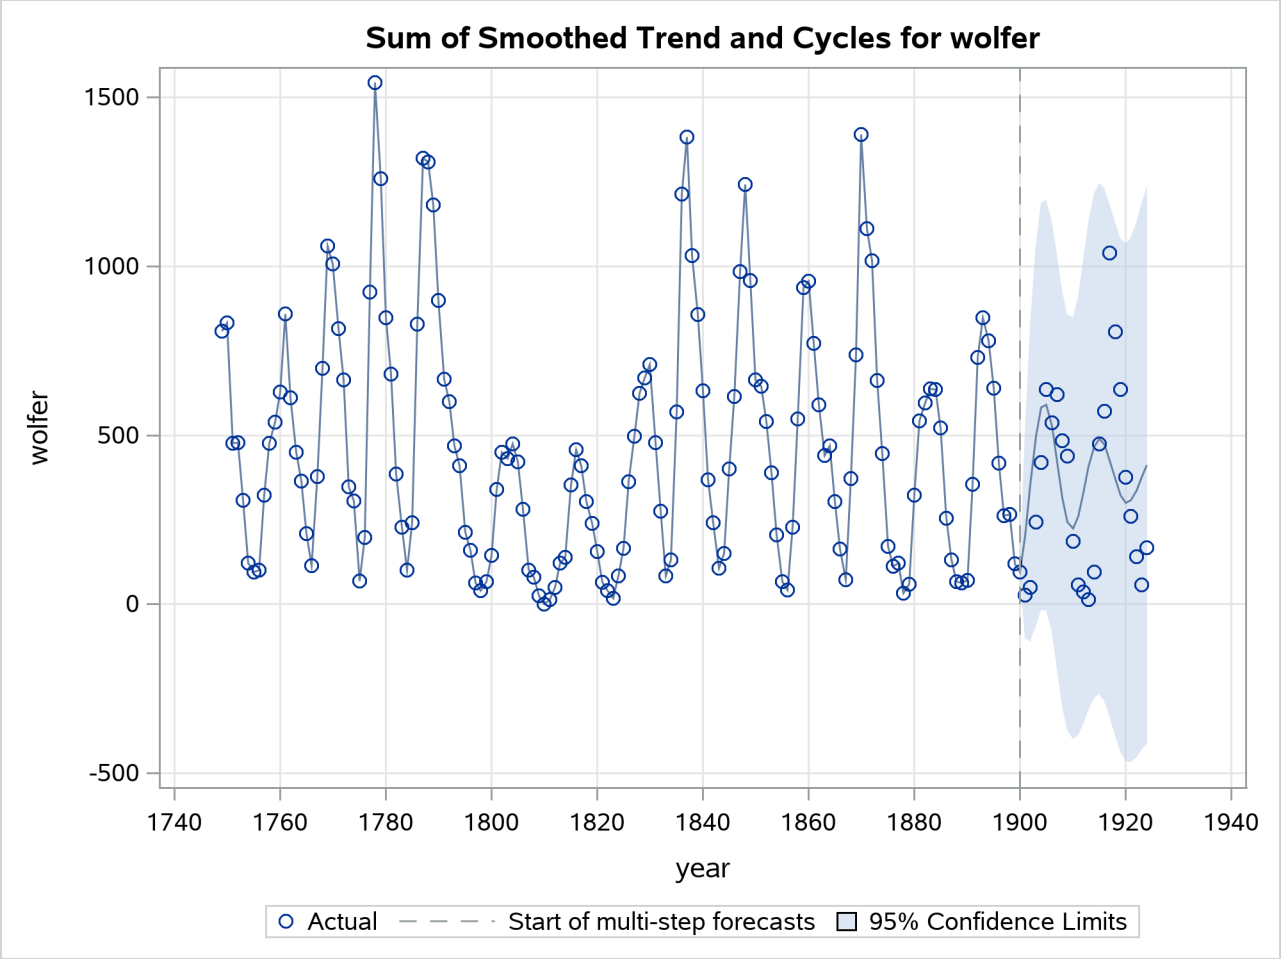
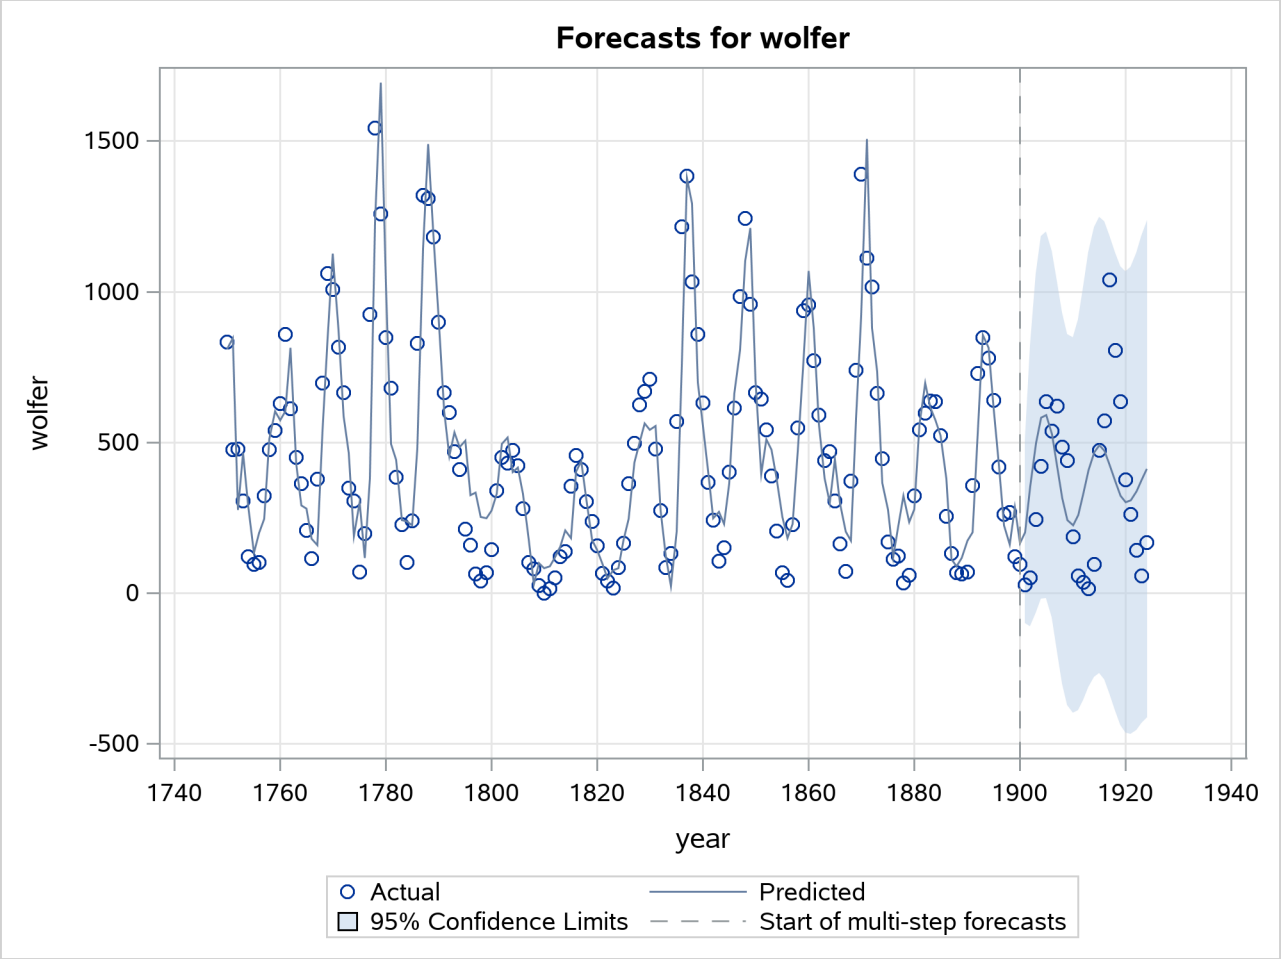


Finally, Figure 41.16 shows the forecast plot.

Figure 41.16 Sunspots Series: Series Forecasts



ODS Table Names

The UCM procedure assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 41.2.

Table 41.2 ODS Tables Produced by PROC UCM

ODS Table Name	Description	Statement	Option
Tables Summarizing the Estimation and Forecast Spans			
EstimationSpan	Estimation span summary information		Default
ForecastSpan	Forecast span summary information		Default

Table 41.2 *continued*

ODS Table Name	Description	Statement	Option
Tables Related to Model Parameters			
ConvergenceStatus	Convergence status of the estimation process		Default
FixedParameters	Fixed parameters in the model		Default
InitialParameters	Initial estimates of the free parameters		Default
ParameterEstimates	Final estimates of the free parameters		Default
Tables Related to Model Information and Diagnostics			
BlockSeasonDescription	Information about the block seasonals in the model		Default
ComponentSignificance	Significance analysis of the components in the model		Default
CycleDescription	Information about the cycles in the model		Default
FitStatistics	Fit statistics based on the one-step-ahead predictions		Default
FitSummary	Likelihood-based fit statistics		Default
OutlierSummary	Summary table of the detected outliers		Default
AdditiveOutliers	AO statistics computed at each time point in the estimation span	OUTLIER	PRINT=DETAIL
LevelShifts	LS statistics computed at each time point in the estimation span	OUTLIER	PRINT=DETAIL
SeasonDescription	Information about the seasonals in the model		Default
SeasonHarmonics	Summary of harmonics in a trigonometric seasonal component	SEASON	PRINT=HARMONICS
SplineSeasonDescription	Information about the spline-seasonals in the model		Default
TrendInformation	Summary information of the level and slope components		Default
Tables Related to Filtered Component Estimates			
FilteredAutoReg	Filtered estimate of an autoreg component	AUTOREG	PRINT=FILTER
FilteredBlockSeason	Filtered estimate of a block seasonal component	BLOCKSEASON	PRINT=FILTER

Table 41.2 *continued*

ODS Table Name	Description	Statement	Option
FilteredCycle	Filtered estimate of a cycle component	CYCLE	PRINT=FILTER
FilteredIrregular	Filtered estimate of the irregular component	IRREGULAR	PRINT=FILTER
FilteredLevel	Filtered estimate of the level component	LEVEL	PRINT=FILTER
FilteredRandomReg	Filtered estimate of the time-varying random-regression coefficient	RANDOMREG	PRINT=FILTER
FilteredSeason	Filtered estimate of a seasonal component	SEASON	PRINT=FILTER
FilteredSlope	Filtered estimate of the slope component	SLOPE	PRINT=FILTER
FilteredSplineReg	Filtered estimate of the time-varying spline-regression coefficient	SPLINEREG	PRINT=FILTER
FilteredSplineSeason	Filtered estimate of a spline-seasonal component	SPLINESEASON	PRINT=FILTER
Tables Related to Smoothed Component Estimates			
SmoothedAutoReg	Smoothed estimate of an autoreg component	AUTOREG	PRINT=SMOOTH
SmoothedBlockSeason	Smoothed estimate of a block seasonal component	BLOCKSEASON	PRINT=SMOOTH
SmoothedCycle	Smoothed estimate of the cycle component	CYCLE	PRINT=SMOOTH
SmoothedIrregular	Smoothed estimate of the irregular component	IRREGULAR	PRINT=SMOOTH
SmoothedLevel	Smoothed estimate of the level component	LEVEL	PRINT=SMOOTH
SmoothedRandomReg	Smoothed estimate of the time-varying random-regression coefficient	RANDOMREG	PRINT=SMOOTH
SmoothedSeason	Smoothed estimate of a seasonal component	SEASON	PRINT=SMOOTH
SmoothedSlope	Smoothed estimate of the slope component	SLOPE	PRINT=SMOOTH
SmoothedSplineReg	Smoothed estimate of the time-varying spline-regression coefficient	SPLINEREG	PRINT=SMOOTH
SmoothedSplineSeason	Smoothed estimate of a spline-seasonal component	SPLINESEASON	PRINT=SMOOTH

Table 41.2 *continued*

ODS Table Name	Description	Statement	Option
Tables Related to Series Decomposition and Forecasting			
FilteredAllExceptIrreg	Filtered estimate of sum of all components except the irregular component	FORECAST	PRINT=FDECOMP
FilteredTrend	Filtered estimate of trend	FORECAST	PRINT= FDECOMP
FilteredTrendReg	Filtered estimate of trend plus regression	FORECAST	PRINT=FDECOMP
FilteredTrendRegCyc	Filtered estimate of trend plus regression plus cycles and autoreg	FORECAST	PRINT=FDECOMP
Forecasts	Dependent series forecasts		Default
PostSamplePrediction	Forecasting performance in the holdout period	FORECAST	BACK=
SmoothedAllExceptIrreg	Smoothed estimate of sum of all components except the irregular component	FORECAST	PRINT=DECOMP
SmoothedTrend	Smoothed estimate of trend	FORECAST	PRINT= DECOMP
SmoothedTrendReg	Smoothed estimate of trend plus regression	FORECAST	PRINT=DECOMP
SmoothedTrendRegCyc	Smoothed estimate of trend plus regression plus cycles and autoreg	FORECAST	PRINT=DECOMP

NOTE: The tables are related to a single series within a BY group. In the case of models that contain multiple cycles, seasonal components, or block seasonal components, the corresponding component estimate tables are sequentially numbered. For example, if a model contains two cycles and a seasonal component and the PRINT=SMOOTH option is used for each of them, the ODS tables containing the smoothed estimates will be named SmoothedCycle1, SmoothedCycle2, and SmoothedSeason. Note that the seasonal table is not numbered because there is only one seasonal component. There are some exceptions to this numbering rule: the tables, FilteredRandomReg, SmoothedRandomReg, FilteredSplineReg, and SmoothedSplineReg, are always numbered starting with zero.

ODS Graph Names

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, "Statistical Graphics Using ODS" (*SAS/STAT User's Guide*).

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section "Enabling and Disabling ODS Graphics" in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section "A Primer on ODS Statistical Graphics" in that chapter.

You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC UCM generates are listed in Table 41.3, along with the required statements and options.

Table 41.3 ODS Graphics Produced by PROC UCM

ODS Graph Name	Description	Statement	Option
Plots Related to Residual Analysis			
ErrorACFPlot	Prediction error autocorrelation plot	ESTIMATE	PLOT=ACF
ErrorPACFPlot	Prediction error partial-autocorrelation plot	ESTIMATE	PLOT=PACF
ErrorHistogram	Prediction error histogram	ESTIMATE	PLOT=NORMAL
ErrorQQPlot	Prediction error normal quantile plot	ESTIMATE	PLOT=QQ
ErrorPlot	Plot of prediction errors	ESTIMATE	PLOT=RESIDUAL

OUTFOR= Data Set

You can use the OUTFOR= option in the FORECAST statement to store the series and component forecasts produced by the procedure. This data set contains the following columns:

- the BY variables
- the ID variable. If an ID variable is not specified, then a numerical variable, _ID_, is created that contains the observation numbers from the input data set.
- the dependent series and the predictor series
- FORECAST, a numerical variable containing the one-step-ahead predicted values and the multistep forecasts
- RESIDUAL, a numerical variable containing the difference between the actual and forecast values
- STD, a numerical variable containing the standard error of prediction
- LCL and UCL, numerical variables containing the lower and upper forecast confidence limits
- S_SERIES and VS_SERIES, numerical variables containing the smoothed values of the dependent series and their variances
- S_IRREG and VS_IRREG, numerical variables containing the smoothed values of the irregular component and their variances. These variables are present only if the model has an irregular component.
- F_LEVEL, VF_LEVEL, S_LEVEL, and VS_LEVEL, numerical variables containing the filtered and smoothed values of the level component and the respective variances. These variables are present only if the model has a level component.
- F_SLOPE, VF_SLOPE, S_SLOPE, and VS_SLOPE, numerical variables containing the filtered and smoothed values of the slope component and the respective variances. These variables are present only if the model has a slope component.
- F_AUTOREG, VF_AUTOREG, S_AUTOREG, and VS_AUTOREG, numerical variables containing the filtered and smoothed values of the autoreg component and the respective variances. These variables are present only if the model has an autoreg component.

- F_CYCLE, VF_CYCLE, S_CYCLE, and VS_CYCLE, numerical variables containing the filtered and smoothed values of the cycle component and the respective variances. If there are multiple cycles in the model, these variables are sequentially numbered as F_CYCLE1, F_CYCLE2, and so on. These variables are present only if the model has at least one cycle component.

- F_SEASON, VF_SEASON, S_SEASON, and VS_SEASON, numerical variables containing the filtered and smoothed values of the season component and the respective variances. If there are multiple seasons in the model, these variables are sequentially numbered as F_SEASON1, F_SEASON2, and so on. These variables are present only if the model has at least one season component.

- F_BLKSEAS, VF_BLKSEAS, S_BLKSEAS, and VS_BLKSEAS, numerical variables containing the filtered and smoothed values of the blockseason component and the respective variances. If there are multiple block seasons in the model, these variables are sequentially numbered as F_BLKSEAS1, F_BLKSEAS2, and so on.

- F_SPLSEAS, VF_SPLSEAS, S_SPLSEAS, and VS_SPLSEAS, numerical variables containing the filtered and smoothed values of the splineseason component and the respective variances. If there are multiple spline seasons in the model, these variables are sequentially numbered as F_SPLSEAS1, F_SPLSEAS2, and so on. These variables are present only if the model has at least one splineseason component.

- Filtered and smoothed estimates, and their variances, of the time-varying regression coefficients of the variables that are specified in the RANDOMREG and SPLINEREG statements. A variable is not included if its coefficient is time-invariant, that is, if the associated disturbance variance is zero.

- F_TF, VF_TF, S_TF, and VS_TF, numerical variables that contain the filtered and smoothed values of the transfer-function component and their variances. If there are multiple transfer-function components in the model, these variables are sequentially numbered as F_TF1, F_TF2, and so on. These variables are present only if the model has at least one transfer-function component.

- S_TREG and VS_TREG, numerical variables containing the smoothed values of level plus regression component and their variances. These variables are present only if the model has at least one predictor variable or has dependent lags.

- S_TREGCYC and VS_TREGCYC, numerical variables containing the smoothed values of level plus regression plus cycle component and their variances. These variables are present only if the model has at least one cycle or an autoreg component.

- S_NOIRREG and VS_NOIRREG, numerical variables containing the smoothed values of the sum of all components except the irregular component and their variances. These variables are present only if the model has at least one seasonal or block seasonal component.

OUTEST= Data Set

You can use the OUTEST= option in the ESTIMATE statement to store the model parameters and the related estimation details. This data set contains the following columns:

- the BY variables
- COMPONENT, a character variable containing the name of the component corresponding to the parameter being described
- PARAMETER, a character variable containing the parameter name
- TYPE, a character variable indicating whether the parameter value was fixed by the user or estimated
- _STATUS_, a character variable indicating whether the parameter estimation process converged or failed or there was an error of some other kind
- ESTIMATE, a numerical variable containing the parameter estimate
- STD, a numerical variable containing the standard error of the parameter estimate. This has a missing value if the parameter value is fixed.
- TVALUE, a numerical variable containing the *t*-statistic. This has a missing value if the parameter value is fixed.
- PVALUE, a numerical variable containing the *p*-value. This has a missing value if the parameter value is fixed.

Statistics of Fit

This section explains the goodness-of-fit statistics reported to measure how well the specified model fits the data.

First the various statistics of fit that are computed using the prediction errors, $y_t - \hat{y}_t$, are considered. In these formulas, n is the number of nonmissing prediction errors and k is the number of fitted parameters in the model. Moreover, the sum of squared errors, $\mathrm{SSE} = \sum (y_t - \hat{y}_t)^2$, and the total sum of squares for the series corrected for the mean, $\mathrm{SST} = \sum (y_t - \overline{y})^2$, where $\overline{y}$ is the series mean, and the sums are over all the nonmissing prediction errors.

Mean Squared Error
The mean squared prediction error, $\mathrm{MSE} = \frac{1}{n}\mathrm{SSE}$

Root Mean Squared Error
The root mean square error, RMSE = $\sqrt{\mathrm{MSE}}$

Mean Absolute Percent Error
The mean absolute percent prediction error, MAPE = $\frac{100}{n} \sum_{t=1}^{n} |(y_t - \hat{y}_t)/y_t|$.
The summation ignores observations where $y_t = 0$.

R-Square
The R-square statistic, $R^2 = 1 - \mathrm{SSE}/\mathrm{SST}$.
If the model fits the series badly, the model error sum of squares, SSE, might be larger than SST and the R-square statistic will be negative.

Adjusted R-Square
The adjusted R-square statistic, $1 - (\frac{n-1}{n-k})(1 - R^2)$

Amemiya's Adjusted R-Square
Amemiya's adjusted R-square, $1 - (\frac{n+k}{n-k})(1 - R^2)$

Random Walk R-Square
The random walk R-square statistic (Harvey's R-square statistic that uses the random walk model for comparison), $1 - (\frac{n-1}{n})\mathrm{SSE}/\mathrm{RWSSE}$, where $\mathrm{RWSSE} = \sum_{t=2}^{n}(y_t - y_{t-1} - \mu)^2$, and $\mu = \frac{1}{n-1}\sum_{t=2}^{n}(y_t - y_{t-1})$

Maximum Percent Error
The largest percent prediction error, $100\max((y_t - \hat{y}_t)/y_t)$. In this computation the observations where $y_t = 0$ are ignored.

The likelihood-based fit statistics are reported separately (see the section "The UCMs as State Space Models" on page 2889). They include the full log likelihood (L_∞), the diffuse part of the log likelihood, the normalized residual sum of squares, and several information criteria: AIC, AICC, HQIC, BIC, and CAIC. Let q denote the number of estimated parameters, n be the number of nonmissing measurements in the estimation span, and d be the number of diffuse elements in the initial state vector that are successfully initialized during the Kalman filtering process. Moreover, let $n^* = (n - d)$. The reported information criteria, all in smaller-is-better form, are described in Table 41.4:

Table 41.4 Information Criteria

Criterion	Formula	Reference
AIC	$-2L_\infty + 2q$	Akaike (1974)
AICC	$-2L_\infty + 2qn^*/(n^* - q - 1)$	Hurvich and Tsai (1989) Burnham and Anderson (1998)
HQIC	$-2L_\infty + 2q\log\log(n^*)$	Hannan and Quinn (1979)
BIC	$-2L_\infty + q\log(n^*)$	Schwarz (1978)
CAIC	$-2L_\infty + q(\log(n^*) + 1)$	Bozdogan (1987)

Examples: UCM Procedure

Example 41.1: The Airline Series Revisited

The series in this example, the monthly airline passenger series, has already been discussed earlier; see the section "A Seasonal Series with Linear Trend" on page 2843. Recall that the series consists of monthly numbers of international airline travelers (from January 1949 to December 1960). Here additional output features of the UCM procedure are illustrated, such as how to use the ESTIMATE and FORECAST statements to limit the span of the data used in parameter estimation and forecasting. The following statements fit a BSM to the logarithm of the airline passenger numbers. The disturbance variance for the slope component is held fixed at value 0; that is, the trend is locally linear with constant slope. In order to evaluate the performance of the fitted model on observed data, some of the observed data are withheld during parameter estimation and forecast computations. The observations in the last two years, years 1959 and 1960, are not used in parameter estimation, while the observations in the last year, year 1960, are not used in the forecasting computations. This is done using the BACK= option in the ESTIMATE and FORECAST statements. In addition, a panel of residual diagnostic plots is obtained using the PLOT=PANEL option in the ESTIMATE statement.

```
data seriesG;
   set sashelp.air;
   logair = log(air);
run;

proc ucm data = seriesG;
   id date interval = month;
   model logair;
   irregular;
   level;
   slope var = 0 noest;
   season length = 12 type=trig;
   estimate back=24 plot=panel;
   forecast back=12 lead=24 print=forecasts;
run;
```

The following tables display the summary of data used in estimation and forecasting (Output 41.1.1 and Output 41.1.2). These tables provide simple summary statistics for the estimation and forecast spans; they include useful information such as the beginning and ending dates of the span, the number of nonmissing values, and so on.

Output 41.1.1 Observation Span Used in Parameter Estimation (partial output)

Variable	Type	First	Last	Nobs	Mean
logair	Dependent	JAN1949	DEC1958	120	5.43035

Output 41.1.2 Observation Span Used in Forecasting (partial output)

Variable	Type	First	Last	Nobs	Mean
logair	Dependent	JAN1949	DEC1959	132	5.48654

The following tables display the fixed parameters in the model, the preliminary estimates of the free parameters, and the final estimates of the free parameters (Output 41.1.3, Output 41.1.4, and Output 41.1.5).

Output 41.1.3 Fixed Parameters in the Model

The UCM Procedure

Fixed Parameters in the Model		
Component	**Parameter**	**Value**
Slope	**Error Variance**	0

Output 41.1.4 Starting Values for the Parameters to Be Estimated

Preliminary Estimates of the Free Parameters		
Component	**Parameter**	**Estimate**
Irregular	**Error Variance**	6.64120
Level	**Error Variance**	2.49045
Season	**Error Variance**	1.26676

Output 41.1.5 Maximum Likelihood Estimates of the Free Parameters

Final Estimates of the Free Parameters					
Component	**Parameter**	**Estimate**	**Approx Std Error**	**t Value**	**Approx Pr > |t|**
Irregular	**Error Variance**	0.00018686	0.0001212	1.54	0.1233
Level	**Error Variance**	0.00040314	0.0001566	2.57	0.0100
Season	**Error Variance**	0.00000350	1.66319E-6	2.10	0.0354

Two types of goodness-of-fit statistics are reported after a model is fit to the series (see Output 41.1.6 and Output 41.1.7). The first type is the likelihood-based goodness-of-fit statistics, which include the full likelihood of the data, the diffuse portion of the likelihood (see the section "Details: UCM Procedure" on page 2883), and the information criteria. The second type of statistics is based on the raw residuals, residual = observed – predicted. If the model is nonstationary, then one-step-ahead predictions are not available for some initial observations, and the number of values used in computing these fit statistics will be different from those used in computing the likelihood-based test statistics.

Output 41.1.6 Likelihood-Based Fit Statistics for the Airline Data

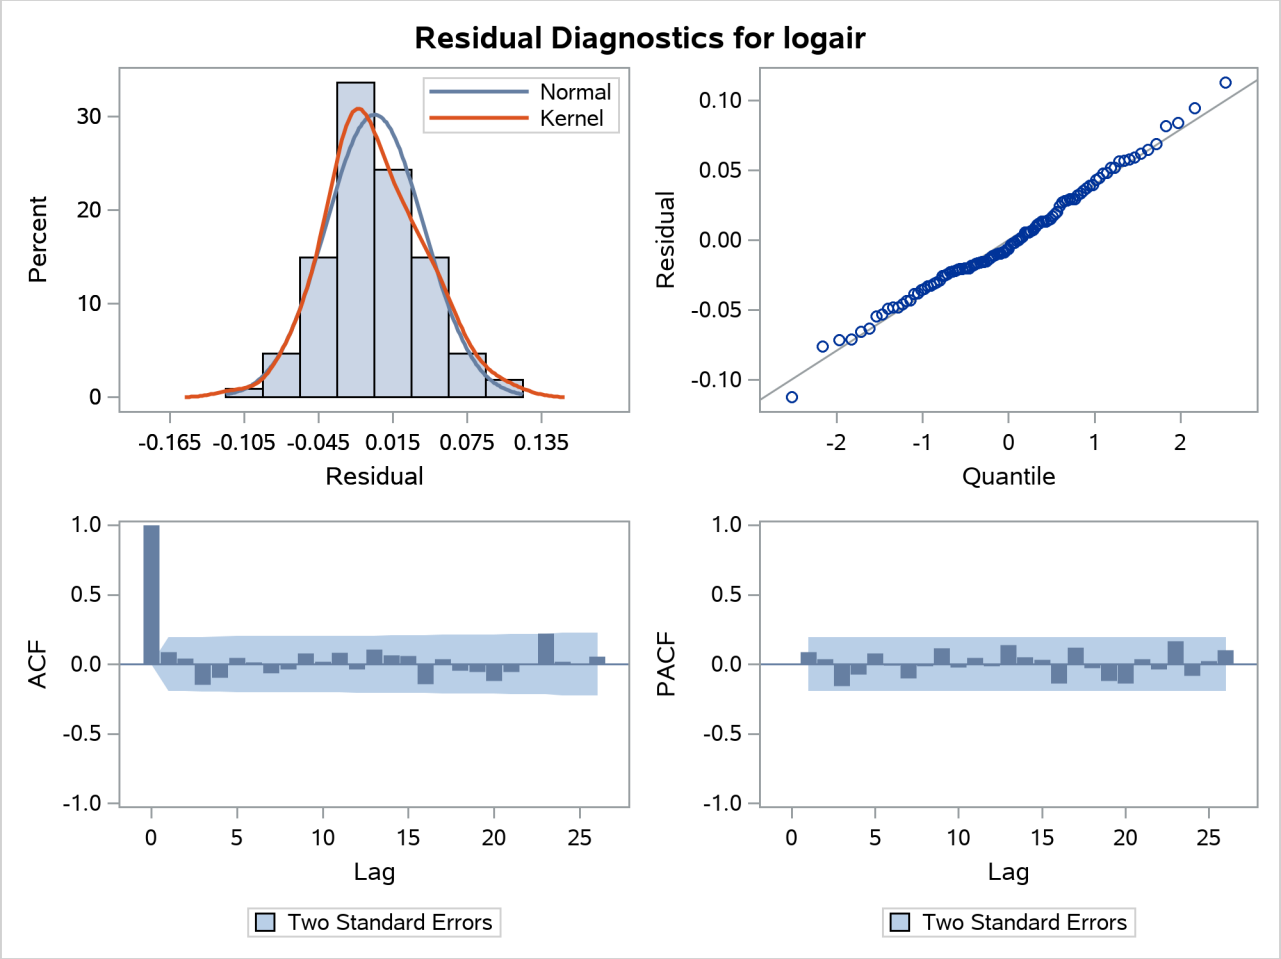
Likelihood Based Fit Statistics	
Statistic	**Value**
Diffuse Log Likelihood	180.63
Diffuse Part of Log Likelihood	-13.93
Non-Missing Observations Used	120
Estimated Parameters	3
Initialized Diffuse State Elements	13
Normalized Residual Sum of Squares	107
AIC (smaller is better)	-355.3
BIC (smaller is better)	-347.2
AICC (smaller is better)	-355
HQIC (smaller is better)	-352
CAIC (smaller is better)	-344.2

Output 41.1.7 Residuals-Based Fit Statistics for the Airline Data

Fit Statistics Based on Residuals	
Mean Squared Error	0.00156
Root Mean Squared Error	0.03944
Mean Absolute Percentage Error	0.57677
Maximum Percent Error	2.19396
R-Square	0.98705
Adjusted R-Square	0.98680
Random Walk R-Square	0.86370
Amemiya's Adjusted R-Square	0.98630
Number of non-missing residuals used for computing the fit statistics = 107	

The diagnostic plots based on the one-step-ahead residuals are shown in Output 41.1.8. The residual histogram and the Q-Q plot show no reasons to question the approximate normality of the residual distribution. The remaining plots check for the *whiteness* of the residuals. The sample correlation plots, the autocorrelation function (ACF) and the partial autocorrelation function (PACF), also do not show any significant violations of the whiteness of the residuals. Therefore, on the whole, the model seems to fit the data well.

Output 41.1.8 Residual Diagnostics for the Airline Series Using a BSM



The forecasts are given in Output 41.1.9. In order to save the space, the upper and lower confidence limit columns are dropped from the output, and only the rows corresponding to the year 1960 are shown. Recall that the actual measurements in the years 1959 and 1960 were withheld during the parameter estimation, and the ones in 1960 were not used in the forecast computations.

Output 41.1.9 *continued*

Output 41.1.9 Forecasts for the Airline Data

Obs	date	Forecast	StdErr	logair	Residual
133	JAN60	6.050	0.038	6.033	-0.017
134	FEB60	5.996	0.044	5.969	-0.027

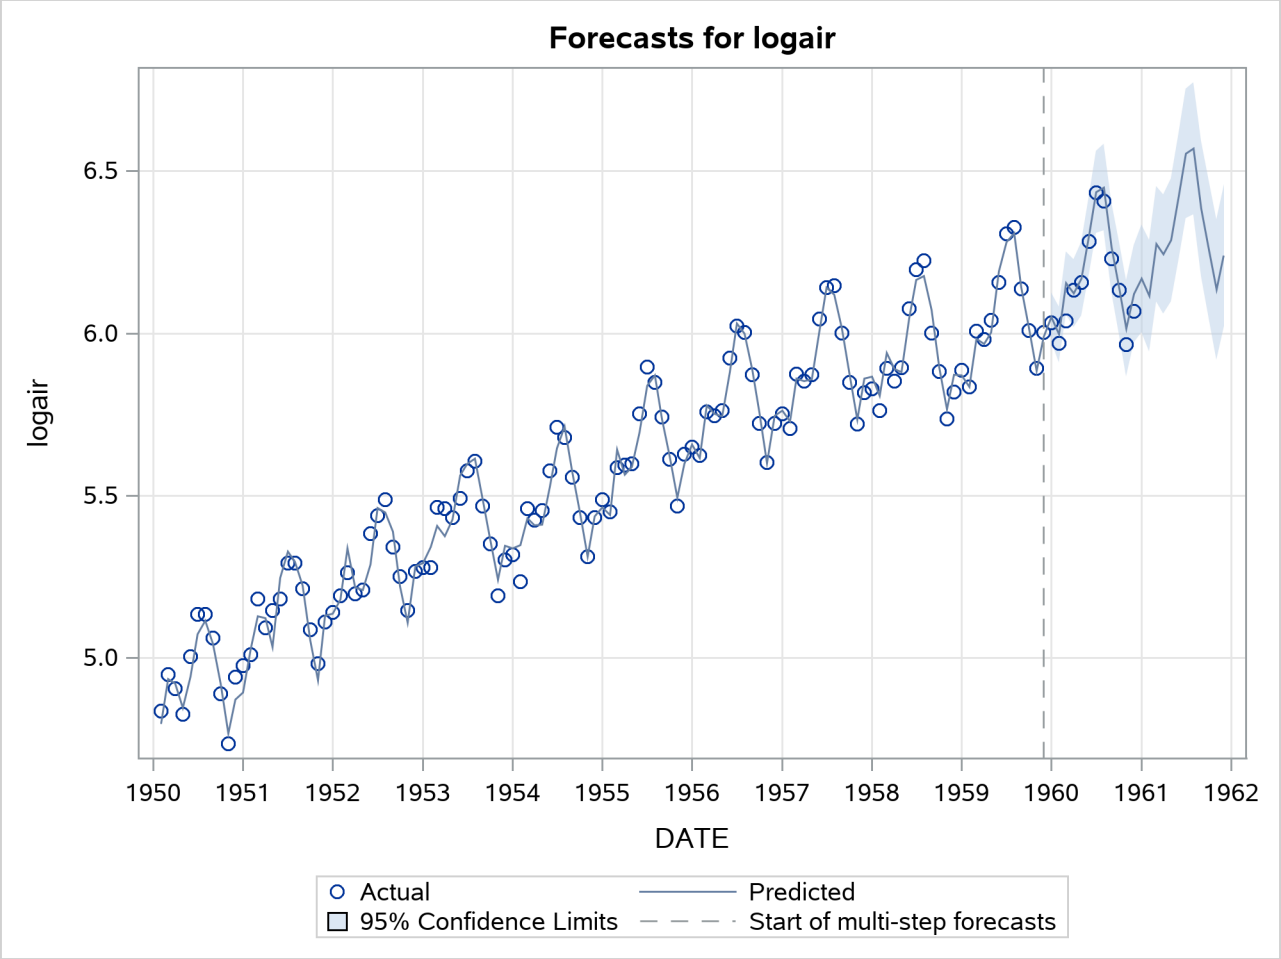
143	NOV60	6.015	0.075	5.966	-0.049
144	DEC60	6.121	0.077	6.068	-0.053

Output 41.1.10 shows the forecast plot. The forecasts in the year 1960 show that the model predictions were quite good.

Output 41.1.10 Forecast Plot of the Airline Series Using a BSM



Example 41.2: Variable Star Data

The series in this example is studied in detail in Bloomfield (2000). This series consists of brightness measurements (magnitude) of a variable star taken at midnight for 600 consecutive days. The data can be downloaded from a time series archive maintained by the University of York, England (http://www.york.ac.uk/depts/maths/data/ts/welcome.htm (series number 26)). The following DATA step statements read the data in a SAS data set:

```
data star;
   input magnitude @@;
   day = _n_;
datalines;
  25  28  31  32  33  33  32  31  28   25   22   18
  14  10   7   4   2   0   0   0   2    4    8   11
  15  19  23  26  29  32  33  34  33   32   30   27
  24  20  17  13  10   7   5   3   3    3    4    5
   7  10  13  16  19  22  24  26  27   28   29   28
  27  25  24  21  19  17  15  13  12   11   11   10
```

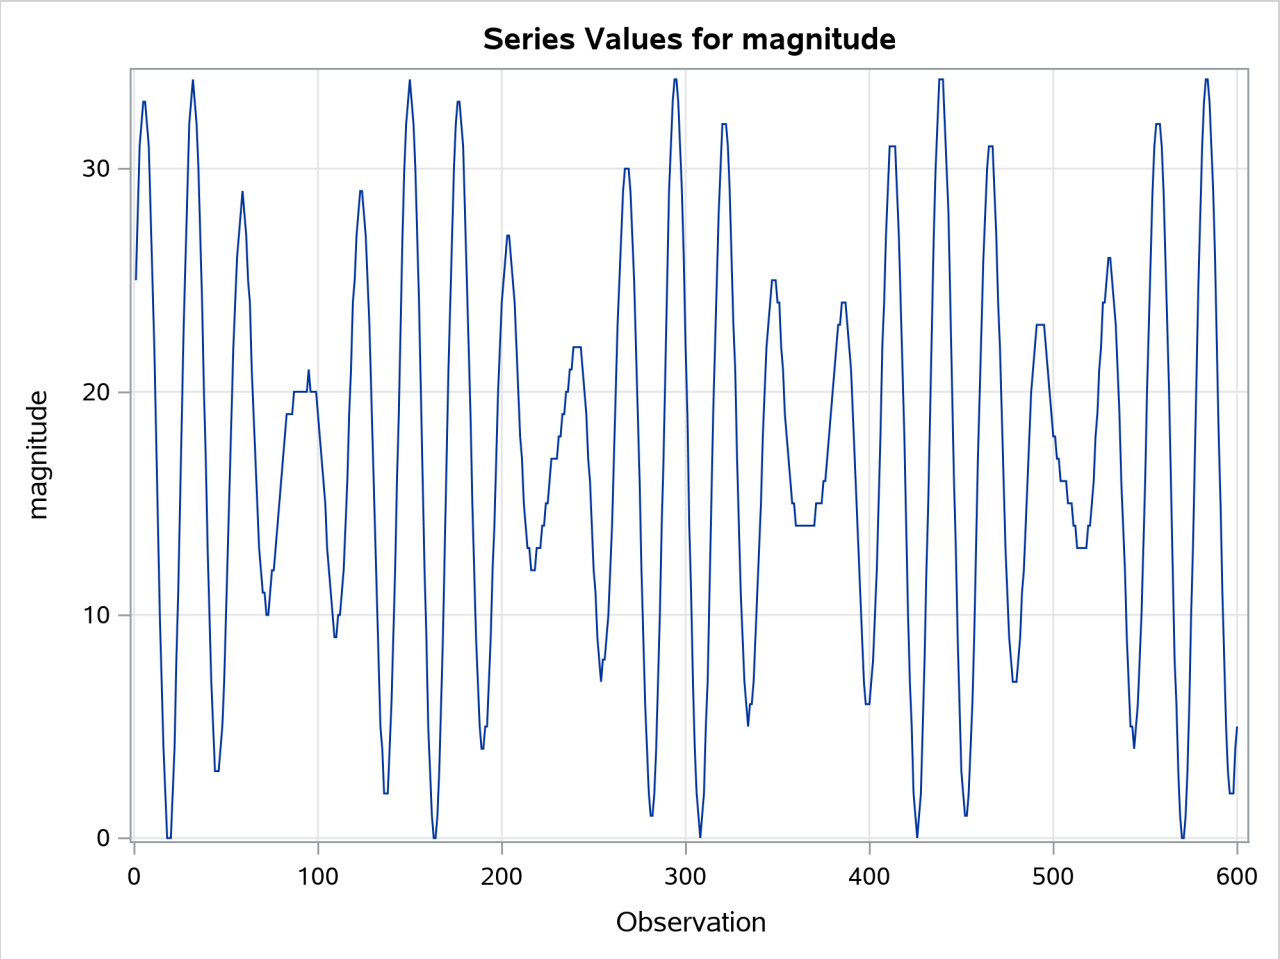
```
 10  11  12  12  13  14  15  16  17   18   19   19

  ... more lines ...
```

The following statements use the TIMESERIES procedure to get a timeseries plot of the series (see Output 41.2.1):

```
proc timeseries data=star plot=series;
   var magnitude;
run;
```

Output 41.2.1 Plot of Star Brightness on Successive Days



The plot clearly shows the cyclic nature of the series. Bloomfield shows that the series is very well explained by a model that includes two deterministic cycles that have periods 29.0003 and 24.0001 days, a constant term, and a simple error term. He also mentions the difficulty involved in estimating the periods from the data (Bloomfield 2000, Chapter 3). In his case the cycle periods are estimated by least squares, and the sum of squares surface has multiple local optima and ridges. The following statements show how to use the UCM procedure to fit this two-cycle model to the series. The constant term in the model is specified by holding the variance parameter of the level component to zero.

```
proc ucm data=star;
   model magnitude;
   irregular;
   level var=0 noest;
   cycle;
   cycle;
   estimate;
run;
```

The final parameter estimates and the goodness-of-fit statistics are shown in Output 41.2.2 and Output 41.2.3, respectively. The model fit appears to be good.

Output 41.2.2 Two-Cycle Model: Parameter Estimates

The UCM Procedure

Final Estimates of the Free Parameters

Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > |t|
Irregular	Error Variance	0.09257	0.0053845	17.19	<.0001
Cycle_1	Damping Factor	1.00000	1.81175E-7	5519514	<.0001
Cycle_1	Period	29.00036	0.0022709	12770.4	<.0001
Cycle_1	Error Variance	0.00000882	5.27213E-6	1.67	0.0944
Cycle_2	Damping Factor	1.00000	2.11939E-7	4718334	<.0001
Cycle_2	Period	24.00011	0.0019128	12547.2	<.0001
Cycle_2	Error Variance	0.00000535	3.56374E-6	1.50	0.1330

Output 41.2.3 Two-Cycle Model: Goodness of Fit

Fit Statistics Based on Residuals	
Mean Squared Error	0.12072
Root Mean Squared Error	0.34745
Mean Absolute Percentage Error	2.65141
Maximum Percent Error	36.38991
R-Square	0.99850
Adjusted R-Square	0.99849
Random Walk R-Square	0.97281
Amemiya's Adjusted R-Square	0.99847
Number of non-missing residuals used for computing the fit statistics = 599	

A summary of the cycles in the model is given in Output 41.2.4.

Output 41.2.4 Two-Cycle Model: Summary

Name	Type	period	Rho	ErrorVar
Cycle_1	Stationary	29.00036	1.00000	0.00000882
Cycle_2	Stationary	24.00011	1.00000	0.00000535

Note that the estimated periods are the same as in Bloomfield's model, the damping factors are nearly equal

to 1.0, and the disturbance variances are very close to zero, implying persistent deterministic cycles. In fact, this model is identical to Bloomfield's model.

Example 41.3: Modeling Long Seasonal Patterns

This example illustrates some of the techniques you can use to model long seasonal patterns in a series. If the seasonal pattern is of moderate length and the underlying dynamics are simple, then it is easily modeled by using the basic settings of the SEASON statement and these additional techniques are not needed. However, if the seasonal pattern has a long season length and/or has a complex stochastic dynamics, then the techniques discussed here can be useful. You can obtain parsimonious models for a long seasonal pattern by using an appropriate subset of trigonometric harmonics, or by using a suitable spline function, or by using a block-season pattern in combination with a seasonal component of much smaller length. You can also vary the disturbance variances of the subcomponents that combine to form the seasonal component.

The time series used in this example consists of number of calls received per shift at a call center. Each shift is six hours long, and the first shift of the day begins at midnight, resulting in four shifts per day. The observations are available from December 15, 1999, to April 30, 2000. This series is seasonal with season length 28, which is moderate, and in fact there is no particular need to use pattern approximation techniques in this case. However, it is adequate for demonstration purposes. The plan of this example is as follows. First an initial model with a full seasonal component is created. This model is used as a baseline for comparing alternate models created by the techniques that are being illustrated. In practice any candidate model is first checked for adequacy by using various diagnostic procedures. In this illustration the main focus is on the different ways a long seasonal pattern can be modeled and no model diagnostics are done for the models being entertained. The alternate models are compared by using the sum of absolute prediction errors in the holdout region.

The following DATA step statements create the input data set used in this example:

```
data callCenter;
   input calls @@;
   label calls= "Number of Calls Received in a 6 Hour Shift";
   start = '15dec99:00:00'dt;
   datetime = INTNX( 'dthour6', start, _n_-1 );
   format datetime datetime10.;
datalines;
  18    122    244    128     19    113    230    119     17    112
 219     93     14     73    139     53     11     32     74     56
  15    137    289    153     20    125    227    106     16    101
 201     92     14     94    187     69     11     59     94     21

   ... more lines ...
```

Initial exploration of the series clearly indicates that the series does not show any significant trend, and time of day and day of the week have a significant influence on the number of calls received. These considerations suggest a simple random walk trend model along with a seasonal component of season length 28, the total number of shifts in a week. The following statements specify this model. Note the PRINT=HARMONICS option in the SEASON statement, which produces a table that lists the full set of harmonics contributing to the seasonal along with the significance of their contribution. This table will be useful later in choosing a subset trigonometric model. The BACK=28 and LEAD=28 specifications in the FORECAST statement

create a holdout region of 28 observations. The sum of absolute prediction errors (SAE) in this holdout region is used to compare the different models.

```
proc ucm data=callCenter;
   id datetime interval=dthour6;
   model calls;
   irregular;
   level;
   season length=28 type=trig
      print=(harmonics);
   estimate back=28;
   forecast back=28 lead=28;
run;
```

The forecasting performance of this model in the holdout region is shown in Output 41.3.1. The SAE is 516.22, which appears in the last row of the holdout analysis table.

Now that a baseline model is created, the exploration for alternate models can begin. The review of the harmonic table in Output 41.3.2 shows that all but the last three harmonics are significant, and deleting

any of them to form a subset trigonometric seasonal component will lead to a poorer model. The last three harmonics, 12th, 13th, and 14th, with periods of 2.333, 2.15 and 2.0, respectively, do appear to be possible choices for deletion. Note that the disturbance variance of the seasonal component is not very insignificant (see Output 41.3.3); therefore the seasonal component is stochastic and the preceding logic, which is based on the final state estimate, provides only a rough guideline.

Output 41.3.2 Harmonic Analysis of the Season: Initial Model

The UCM Procedure

Harmonic Analysis of Trigonometric Seasons (Based on the Final State)

Name	Season Length	Harmonic	Period	Chi-Square	DF	Pr > ChiSq
Season	28	1	28.00000	234.19	2	<.0001
Season	28	2	14.00000	264.19	2	<.0001
Season	28	3	9.33333	95.65	2	<.0001
Season	28	4	7.00000	105.64	2	<.0001
Season	28	5	5.60000	146.74	2	<.0001
Season	28	6	4.66667	121.93	2	<.0001
Season	28	7	4.00000	4299.12	2	<.0001

Output 41.3.3 Parameter Estimates: Initial Model

Final Estimates of the Free Parameters

Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > |t|
Irregular	Error Variance	92.14591	13.10986	7.03	<.0001
Level	Error Variance	44.83595	10.65465	4.21	<.0001
Season	Error Variance	0.01250	0.0065153	1.92	0.0551

The following statements fit a subset trigonometric model formed by dropping the last three harmonics by specifying the DROPH= option in the SEASON statement:

```
proc ucm data=callCenter;
   id datetime interval=dthour6;
   model calls;
   irregular;
   level;
   season length=28 type=trig droph=12 13 14;
   estimate back=28;
   forecast back=28 lead=28;
run;
```

The last row of the holdout region prediction analysis table for the preceding model is shown in Output 41.3.4. It shows that the subset trigonometric model has better prediction performance in the holdout region than the full trigonometric model; its SAE is 471.53, compared to an SAE of 516.22 for the full model.

Output 41.3.4 SAE for the Subset Trigonometric Model

Obs	datetime	Actual	Forecast	Error	SAE
552	30APR00:18	61	40.836	20.164	471.534

The following statements illustrate a spline approximation to this seasonal component. In the spline specification the knot placement is quite important, and usually some experimentation is needed. In the following model the knots are placed at the beginning and the middle of each day. Note that the knots at the beginning and end of the season, 1 and 28 in this case, should not be listed in the knot list because knots are always placed there anyway.

```
proc ucm data=callCenter;
   id datetime interval=dthour6;
   model calls;
   irregular;
   level;
   splineseason length=28
      knots=3 5 7 9 11 13 15 17 19 21 23 25 27
      degree=3;
   estimate back=28;
   forecast back=28 lead=28;
run;
```

The spline season model takes about half the time to fit that the baseline model takes. The last row of the holdout region prediction analysis table for this model is shown in Output 41.3.5, which shows that the spline season model performs even better than the previous two models in the holdout region; its SAE is 313.79, compared to an SAE of 471.53 for the previous model.

Output 41.3.5 SAE for the Spline Season Model

Obs	datetime	Actual	Forecast	Error	SAE
552	30APR00:18	61	23.350	37.650	313.792

The following statements illustrate yet another way to approximate a long seasonal component. Here a combination of BLOCKSEASON and SEASON statements results in a seasonal component that is a sum of two seasonal patterns: one seasonal pattern is simply a regular season with season length 4 that captures the *within-day* seasonal pattern, and the other seasonal pattern is a block seasonal pattern that remains constant during the day but varies from day to day within a week. Note the use of the NLOPTIONS statement to change the optimization technique during the parameter estimation to DBLDOG, which in this case performs better than the default technique, TRUREG.

```
proc ucm data=callCenter;
   id datetime interval=dthour6;
   model calls;
   irregular;
   level;
   season length=4 type=trig;
```

```
   blockseason nblocks=7 blocksize=4
      type=trig;
   estimate back=28;
   forecast back=28 lead=28;
   nloptions tech=dbldog;
run;
```

This model also takes about half the time to fit that the baseline model takes. The last row of the holdout region prediction analysis table for this model is shown in Output 41.3.6, which shows that the block season model does slightly better than the baseline model but not as well as the other two models; its SAE is 508.52, compared to an SAE of 516.22 for the baseline model.

Output 41.3.6 SAE for the Block Season Model

Obs	datetime	Actual	Forecast	Error	SAE
552	30APR00:18	61	39.339	21.661	508.522

This example showed a few different ways to model a long seasonal pattern. It showed that parsimonious models for long seasonal patterns can be useful, and in some cases even more effective than the full model. Moreover, for very long seasonal patterns the high memory requirements and long computing times might make full models impractical.

Example 41.4: Modeling Time-Varying Regression Effects

In April 1979, the Albuquerque Police Department began a special enforcement program aimed at reducing the number of DWI (driving while intoxicated) accidents. The program was administered by a squad of police officers, who used breath alcohol testing (BAT) devices and a van that houses a BAT device (Batmobile). These data were collected by the Division of Governmental Research of the University of New Mexico, under a contract with the National Highway Traffic Safety Administration of the U.S. Department of Transportation, to evaluate the Batmobile program. The first 29 observations are for a control period, and the next 23 observations are for the experimental (Batmobile) period. The data consist of two variables: ACC, which represents injuries and fatalities from Wednesday to Saturday nighttime accidents, and FUEL, which represents fuel consumption (millions of gallons) in Albuquerque. The variables are measured quarterly starting from the first quarter of 1972 up to the last quarter of 1984, covering the span of 13 years. The following DATA step statements create the input data set:

```
data bat;
   input ACC FUEL @@;
   batProgram = 0;
   if _n_ > 29 then batProgram = 1;
   date = INTNX( 'qtr', '1jan1972'd, _n_- 1 );
   format date qtr8.;
datalines;
192    32.592    238    37.250    232    40.032
246    35.852    185    38.226    274    38.711
266    43.139    196    40.434    170    35.898
234    37.111    272    38.944    234    37.717
210    37.861    280    42.524    246    43.965
248    41.976    269    42.918    326    49.789
342    48.454    257    45.056    280    49.385
```

```
290    42.524    356    51.224    295    48.562
279    48.167    330    51.362    354    54.646
331    53.398    291    50.584    377    51.320
327    50.810    301    46.272    269    48.664
314    48.122    318    47.483    288    44.732
242    46.143    268    44.129    327    46.258
253    48.230    215    46.459    263    50.686
319    49.681    263    51.029    206    47.236
286    51.717    323    51.824    306    49.380
230    47.961    304    46.039    311    55.683
292    52.263
;
```

There are a number of ways to study these data and the question of the effectiveness of the BAT program. One possibility is to study the *before-after* difference in the injuries and fatalities per million gallons of fuel consumed, by regressing ACC on FUEL and the dummy variable BATPROGRAM, which is zero before the program began and one while the program is in place. However, it is possible that the effect of the Batmobiles might well be cumulative, because as awareness of the program becomes dispersed, its effectiveness as a deterrent to driving while intoxicated increases. This suggests that the regression coefficient of the BATPROGRAM variable might be *time-varying*. The following program fits a model that incorporates these considerations. A seasonal component is included in the model since it is easy to see that the data show strong quarterly seasonality.

```
proc ucm data=bat;
   model acc = fuel;
   id date interval=qtr;
   irregular;
   level var=0 noest;
   randomreg batProgram / plot=smooth;
   season length=4 var=0 noest plot=smooth;
   estimate plot=(panel residual);
   forecast plot=forecasts lead=0;
run;
```

The model seems to fit the data adequately. No data are withheld for model validation because the series is relatively short. The plot of the time-varying coefficient of BATPROGRAM is shown in Output 41.4.1. As expected, it shows that the effectiveness of the program increases as awareness of the program becomes dispersed. The effectiveness eventually seems to level off. The residual diagnostic plots are shown in Output 41.4.2 and Output 41.4.3, the forecast plot is in Output 41.4.4, the goodness-of-fit statistics are in Output 41.4.5, and the parameter estimates are in Output 41.4.6.

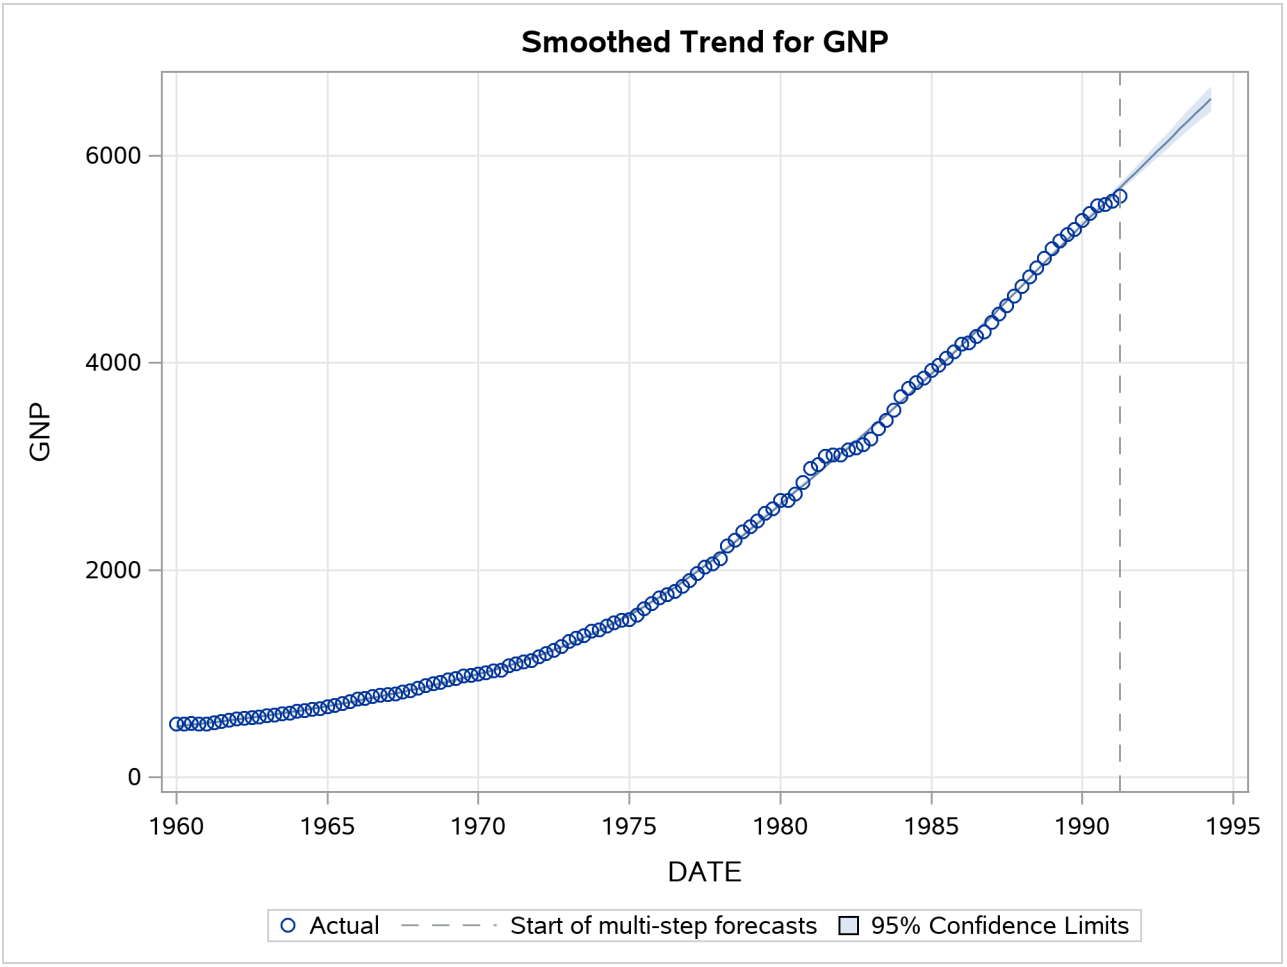
Example 41.5: Trend Removal Using the Hodrick-Prescott Filter

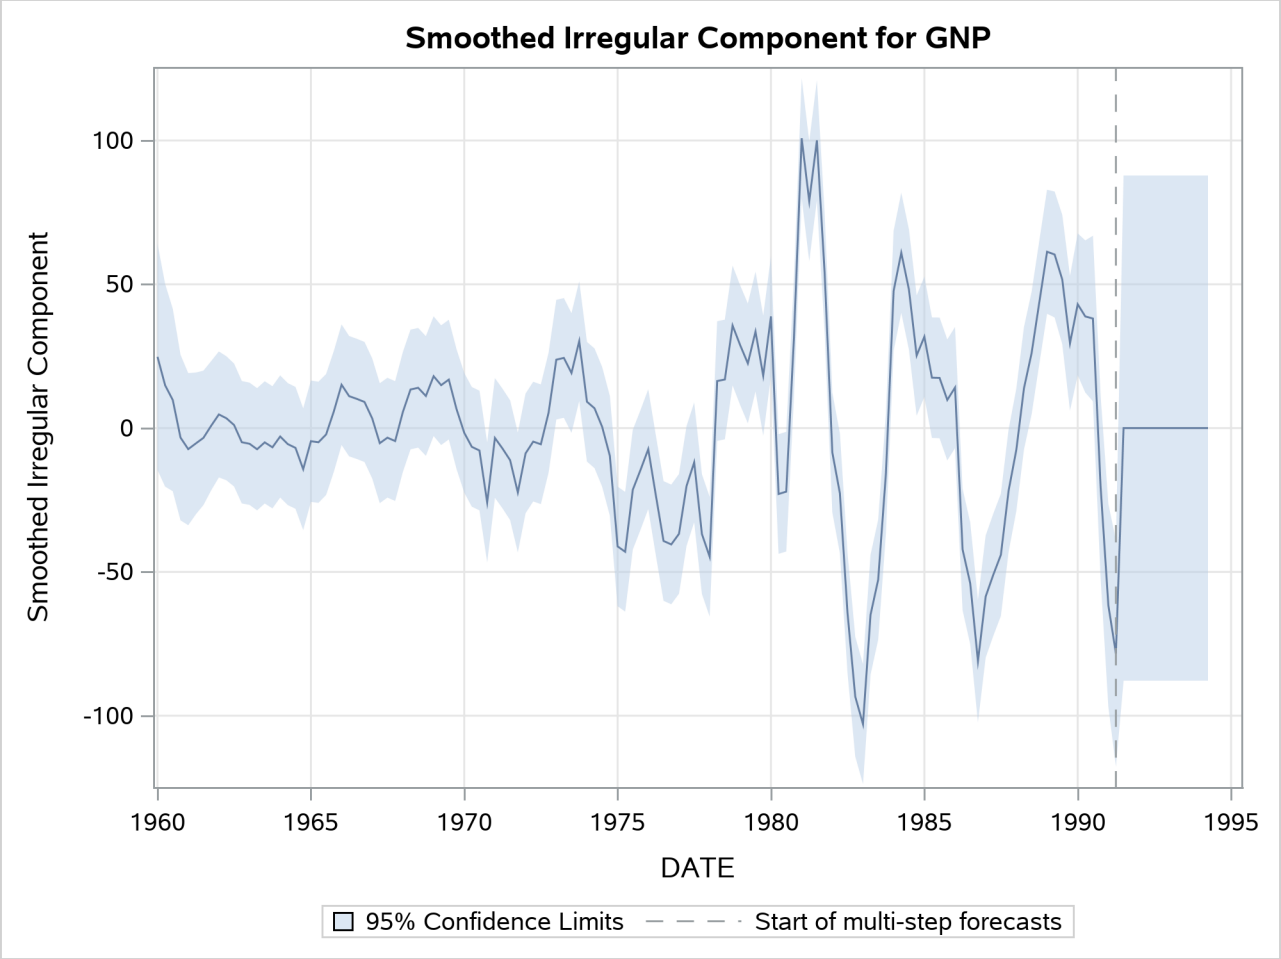
The Hodrick-Prescott filter (Hodrick and Prescott 1997) is a popular tool in macroeconomics for fitting a smooth trend to time series. It is well known that the trend computation according to this filter is equivalent to fitting the local linear trend plus irregular model with the level disturbance variance restricted to zero and the slope disturbance variance restricted to be a suitable multiple of the irregular component variance. The multiple used depends on the frequency of the series; for example, for quarterly series the commonly recommended multiple is $1/1600 = 0.000625$. For other intervals there is no consensus, but a frequently suggested value for monthly series is $1/14400$ and the value for an annual series can range from $1/400 = 0.0025$ to $1/7 = 0.15$. The data set considered in this example consists of quarterly GNP values for the United States from 1960 to 1991. In the UCM procedure statements that follow, the presence of the PROFILE option in the ESTIMATE statement implies that the restriction that the disturbance variance of the slope component be fixed at 0.000625 is interpreted differently: it implies that the disturbance variance of the slope component be restricted to be 0.000625 *times* the estimated irregular component variance, as needed for the Hodrick-Prescott filter. The plot of the fitted trend is shown in Output 41.5.1, and the plot of the smoothed irregular component, which corresponds to the detrended series, is given in Output 41.5.2. The detrended series can be further analyzed for business cycles.

```
proc ucm data=sashelp.gnp;
   id date interval=qtr;
   model gnp;
   irregular plot=smooth;
   level var=0 noest plot=smooth;
   slope var=0.000625 noest;
   estimate PROFILE;
   forecast plot=(decomp);
run;
```

Output 41.5.1 Smoothed Trend for the GNP Series as per the Hodrick-Prescott Filter



Output 41.5.2 Detrended GNP Series



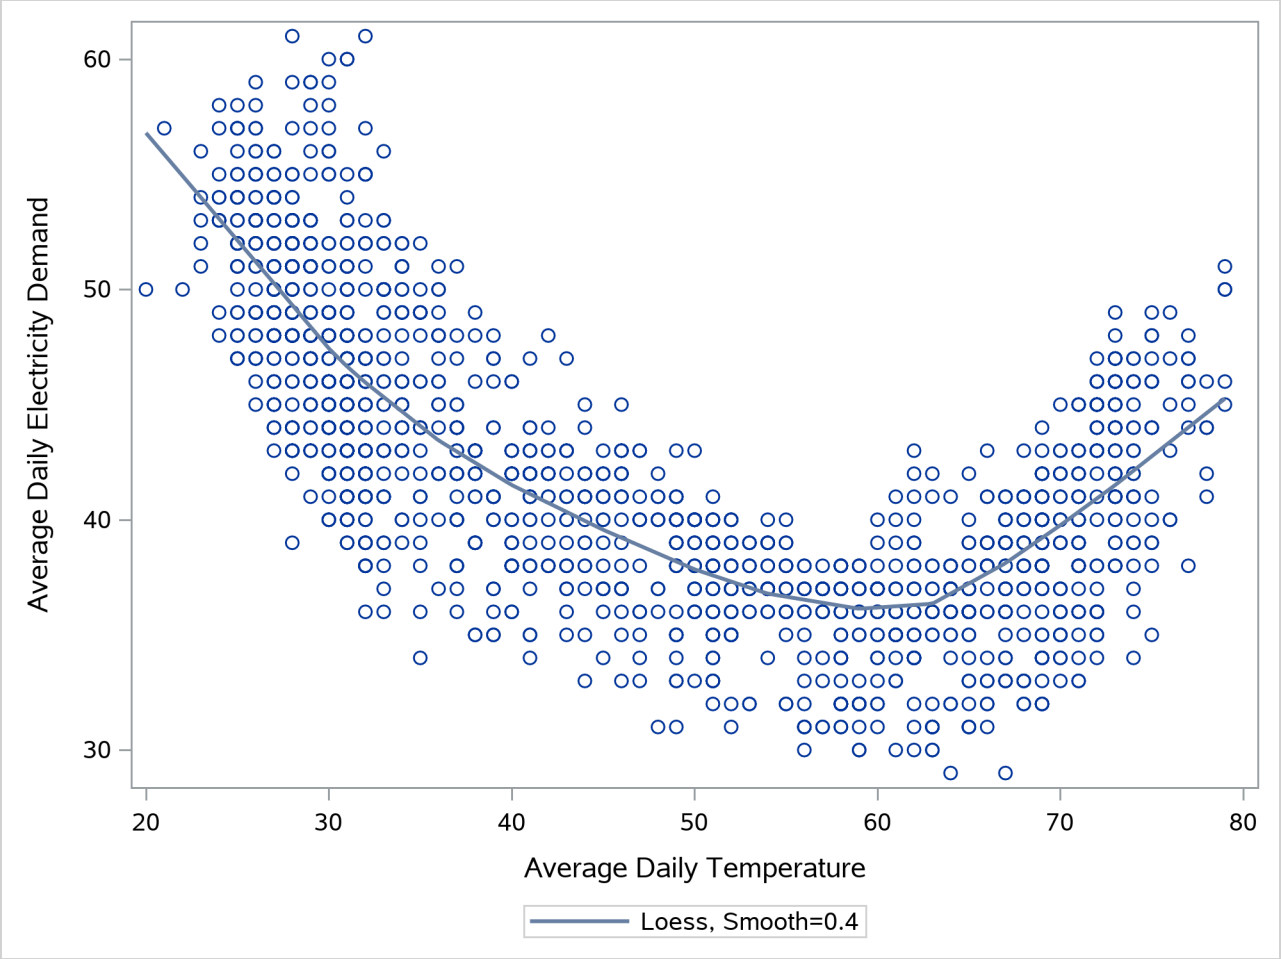
Example 41.6: Using Splines to Incorporate Nonlinear Effects

The data in this example are created to mirror the electricity demand and temperature data recorded at a utility company in the midwest region of the United States. The data set (not shown), utility, has three variables: load, temp, and date. The load column contains the daily electricity demand, the temp column has the average daily temperature readings, and the date column records the observation date.

The following statements produce a plot, shown in Output 41.6.1, of electricity load versus temperature. Clearly the relationship is smooth but nonlinear: the load generally increases when the temperatures are away from the comfortable sixties.

```
proc sgplot data=utility;
    loess x=temp y=load / smooth=0.4;
run;
```

Output 41.6.1 Load versus Temperature Plot



The time series plot of the load (not shown) also shows that, apart from a day-of-the-week seasonal effect, there are no additional easily identifiable patterns in the series. The series has no apparent upward or downward trend. The following statements fit a UCM to the series that takes into account these observations. The particular choice of the model is a result of a little modeling exercise that compared a small number of competing models. The chosen model is adequate but by no means the best possible. The temperature effect is modeled by a deterministic three-degree spline with knots at 30, 40, 50, 60, and 75. The knot locations and the degree were chosen by visual inspection of the plot (Output 41.6.1). An autoreg component is used in place of the simple irregular component, which improved the residual analysis. The last 60 days of data are withheld for out-of-sample forecast evaluation (note the BACK= option in both the ESTIMATE and FORECAST statements). The OUTLIER statement is used to increase the number of outliers reported to 10. Since no CHECKBREAK option is used in the LEVEL statement, only the additive outliers are searched. In this example the use of the EXTRADIFFUSE= option in the ESTIMATE and FORECAST statements is useful for discarding some early one-step-ahead forecasts and residuals with large variance.

```
proc ucm data=utility;
   id date interval=day;
   model load;
   autoreg;
   level plot=smooth;
```

```
   splinereg temp knots=30 40 50 65 75 degree=3
      variance=0 noest;
   season length=7 var=0 noest;
   estimate plot=panel back=60
      extradiffuse=50;
   outlier maxnum=10;
   forecast back=60 lead=60
      extradiffuse=50;
run;
```

The parameter estimates are given in Output 41.6.2, and the residual goodness-of-fit statistics are shown in Output 41.6.3. The residual diagnostic plots are shown in Output 41.6.4. The ACF and PACF plots appear satisfactory, but the normality plots, particularly the Q-Q plot, show possible violations. It appears that, at least in part, this nonnormal behavior of the residuals might be attributable to the outliers in the series. The outlier summary table, Output 41.6.5, shows the most likely outlying observations. Notice that most of these outliers are holidays, like July 4th, when the electricity load is lower than usual for that day of the week.

Output 41.6.2 Electricity Load: Parameter Estimates

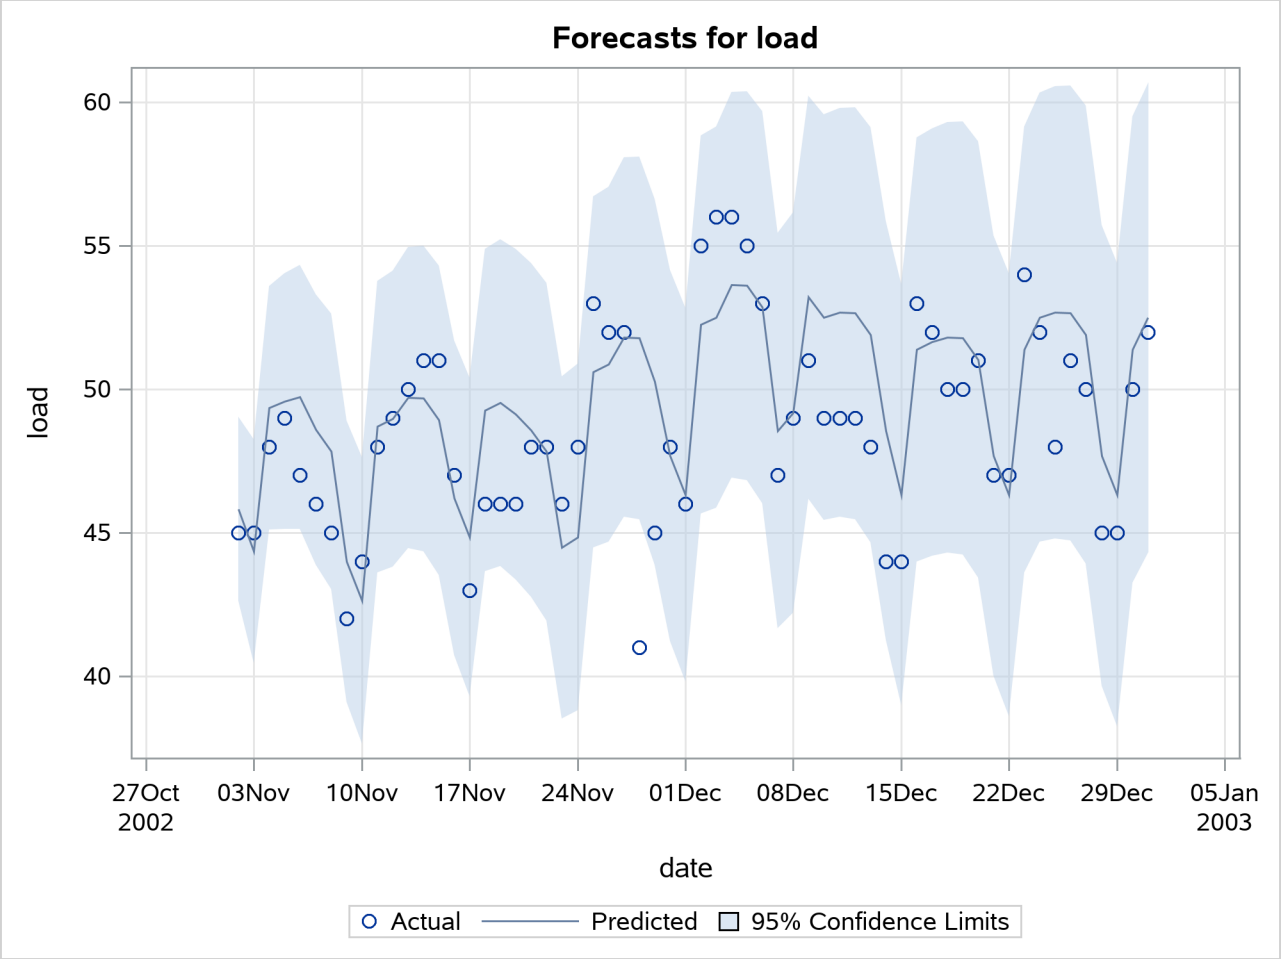
Output 41.6.6 Electricity Load: Forecast Evaluation of the Withheld Data



Example 41.7: Detection of Level Shift

The series in this example consists of the yearly water level readings of the Nile River recorded at Aswan, Egypt (Cobb 1978; De Jong and Penzer 1998). The readings are from the years 1871 to 1970. The series does not show any apparent trend or any other distinctive patterns; however, there is a shift in the water level starting at the year 1899. This shift could be attributed to the start of construction of a dam near Aswan in that year. A time series plot of this series is given in Output 41.7.1. The following DATA step statements create the input data set:

```
data nile;
   input waterlevel @@;
   year = intnx( 'year', '1jan1871'd, _n_-1 );
   format year year4.;
datalines;

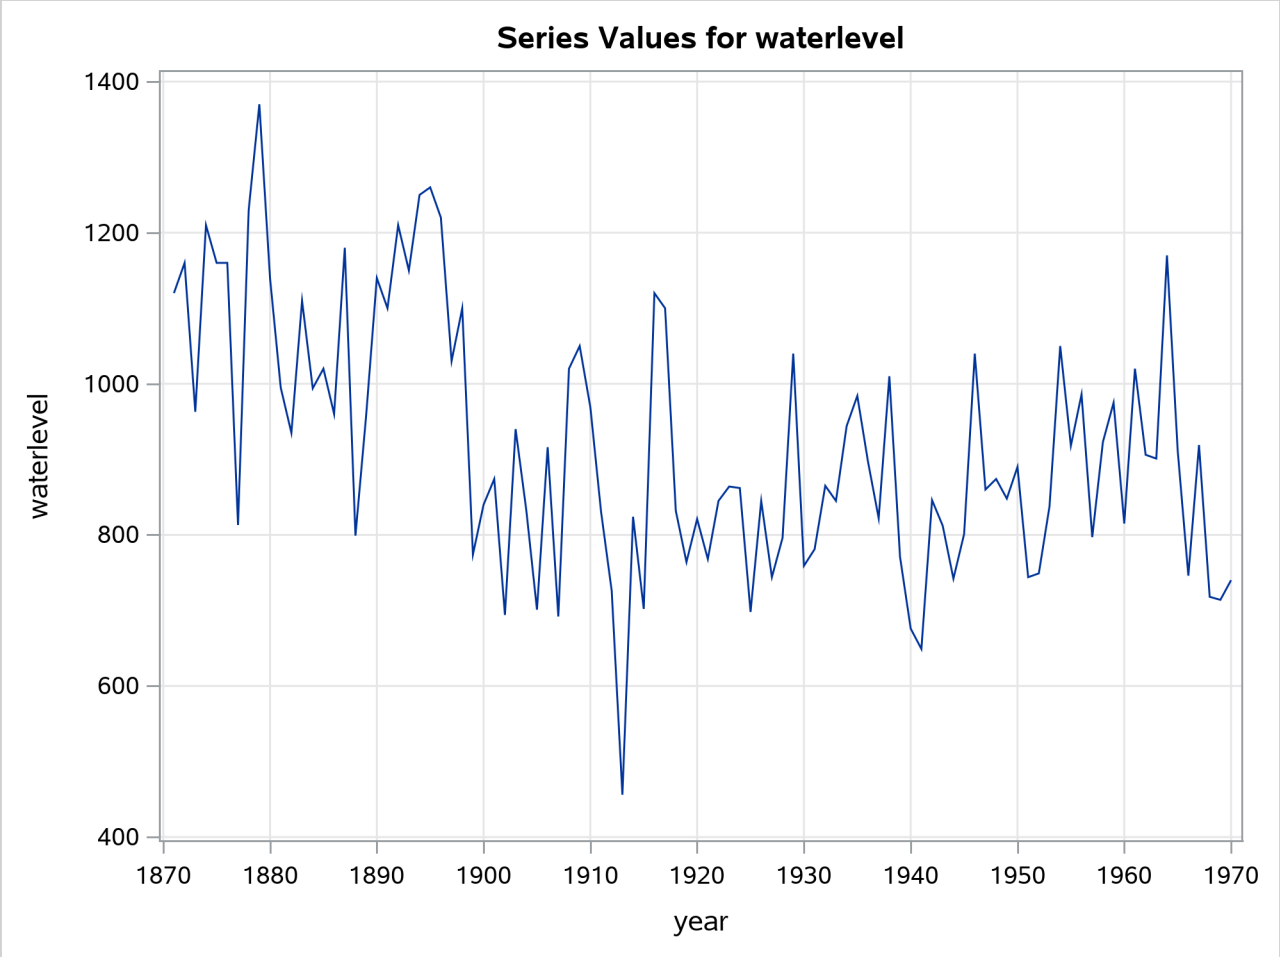
proc timeseries data=nile plot=series;
   id year interval=year;
   var waterlevel;
run;
```

Output 41.7.1 Nile Water Level

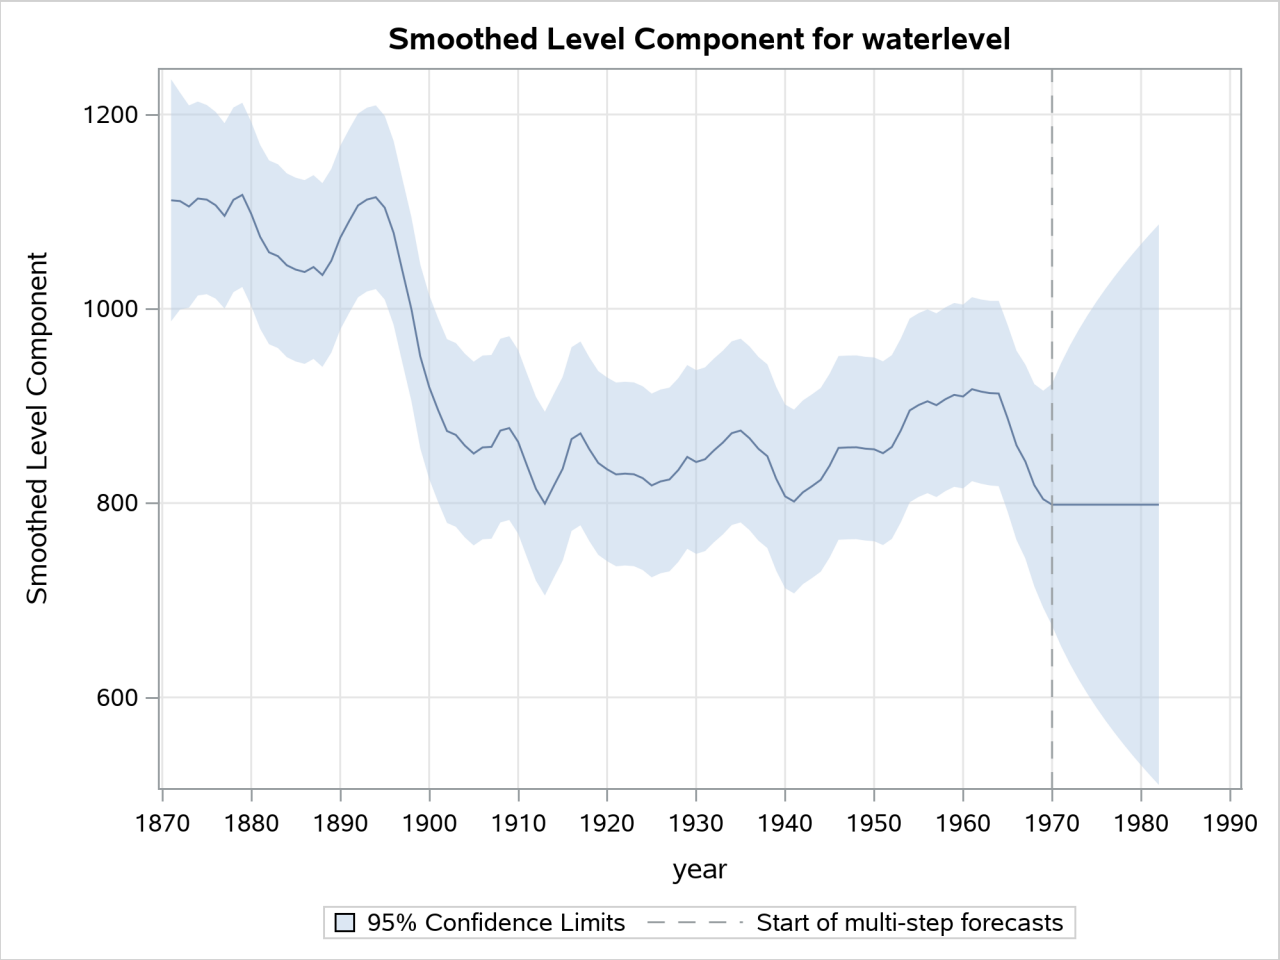


In this situation it is known that a shift in the water level occurred within the span of the series, and its effect can be easily taken into account by including an appropriate indicator variable as a regressor. However, in many situation such prior information is not available, and it is useful to detect such a shift in a data analytic fashion. You can check for breaks in the level by using the CHECKBREAK option in the LEVEL statement. The following statements fit a simple locally constant level plus error model to the series:

```
proc ucm data=nile;
   id year interval=year;
   model waterlevel;
   irregular;
   level plot=smooth checkbreak;
   estimate;
   forecast plot=decomp;
run;
```

The plot in Output 41.7.2 shows a noticeable drop in the smoothed water level around 1899.

Output 41.7.2 Smoothed Trend without the Shift of 1899



The "Outlier Summary" table in Output 41.7.3 shows the most likely types of breaks and their locations within the series span. The shift of 1899 is easily detected.

Output 41.7.3 Detection of Structural Breaks in the Nile River Level

Outlier Summary

Obs	year	Break Type	Estimate	Standard Error	Chi-Square	DF	Pr > ChiSq
29	**1899**	**Level**	-315.73791	97.639753	10.46	1	0.0012

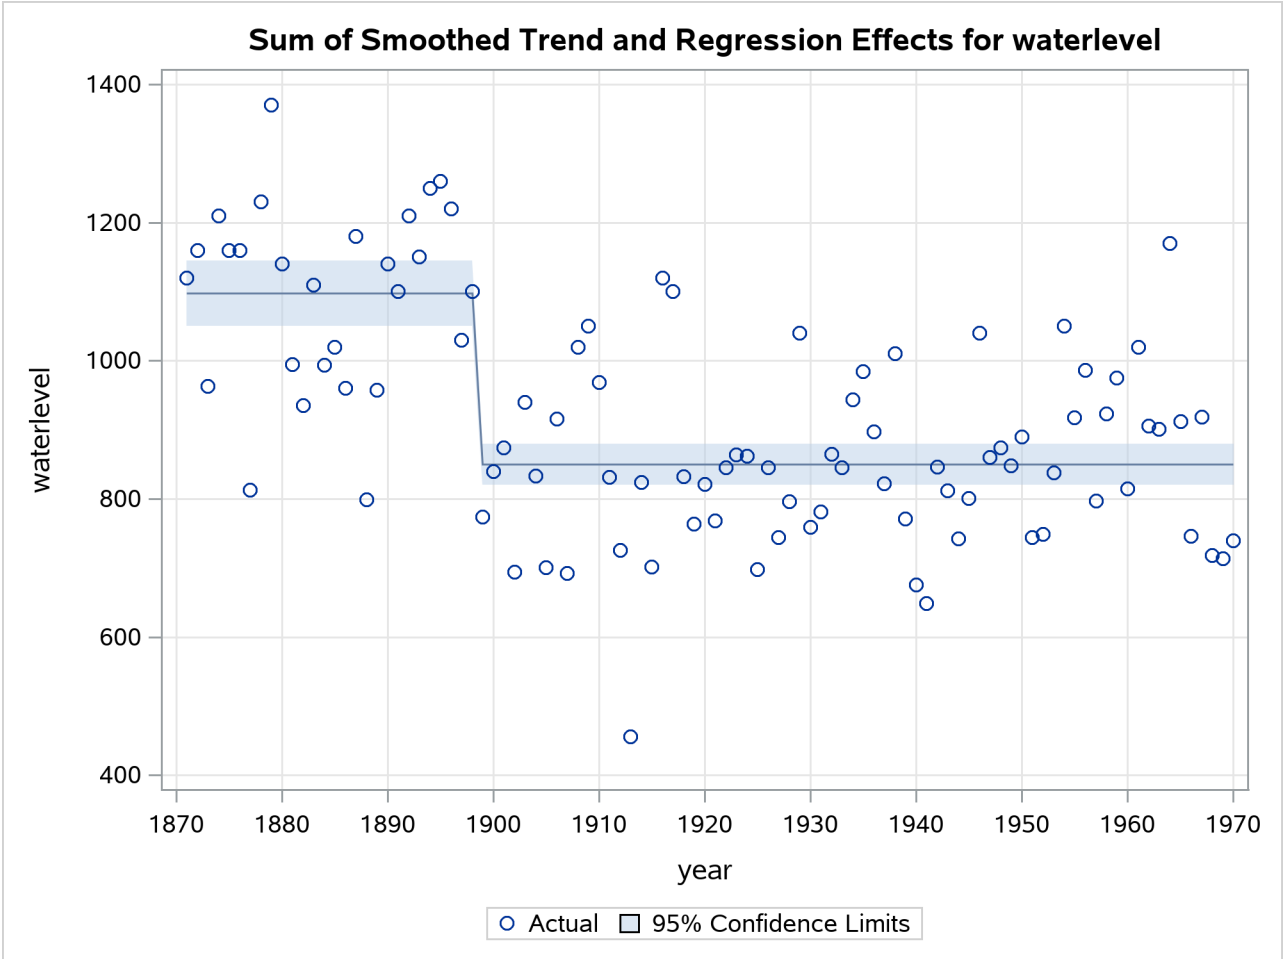
The following statements specify a UCM that models the level of the river as a locally constant series with a shift in the year 1899, represented by a dummy regressor (SHIFT1899):

```
data nile;
   set nile;
   shift1899 = ( year >= '1jan1899'd );
run;

proc ucm data=nile;
   id year interval=year;
   model waterlevel = shift1899;
   irregular;
   level;
   estimate;
   forecast plot=decomp;
run;
```

The plot in Output 41.7.4 shows the smoothed trend, including the correction due to the shift in the year 1899. Notice the simplicity in the shape of the smoothed curve after the incorporation of the shift information.

Output 41.7.4 Smoothed Trend plus Shift of 1899



Example 41.8: ARIMA Modeling

This example shows how you can use the UCM procedure for ARIMA modeling. The parameter estimates and predictions for ARIMA models obtained by using PROC UCM will be close to those obtained by using PROC ARIMA (in the presence of the ML option in its ESTIMATE statement) if the model is stationary or if the model is nonstationary and there are no missing values in the data. For more information about the ARIMA procedure, see Chapter 7, "The ARIMA Procedure." However, if there are missing values in the data and the model is nonstationary, then the UCM and ARIMA procedures can produce significantly different parameter estimates and predictions. An article by Kohn and Ansley (1986) suggests a statistically sound method of estimation, prediction, and interpolation for nonstationary ARIMA models with missing data. This method is based on an algorithm that is equivalent to the Kalman filtering and smoothing algorithm used in the UCM procedure. The results of an illustrative example in their article are reproduced here using the UCM procedure. In this example an ARIMA$(0,1,1)\times(0,1,1)_{12}$ model is applied to the logarithm of the air series in the sashelp.air data set. Four different missing value patterns are considered to highlight different aspects of the problem:

- *Data1.* The full data set of 144 observations.
- *Data2.* The set of 78 observations that omit January through November in each of the last 6 years.
- *Data3.* The data set with the 5 observations July 1949, June, July, and August 1957, and July 1960 missing.
- *Data4.* The data set with all July observations missing and June and August 1957 also missing.

The following DATA steps create these data sets:

```
data Data1;
   set sashelp.air;
   logair = log(air);
run;

data Data2;
   set data1;
   if year(date) >= 1955 and month(date) < 12 then logair = .;
run;

data Data3;
   set data1;
   if (year(date) = 1949 and month(date) = 7) then logair = .;
   if ( year(date) = 1957 and
        (month(date) = 6 or month(date) = 7 or month(date) = 8))
        then logair = .;
   if (year(date) = 1960 and month(date) = 7) then logair = .;
run;

data Data4;
   set data1;
   if month(date) = 7 then logair = .;
   if year(date) = 1957 and (month(date) = 6 or month(date) = 8)
```

```
      then logair = .;
run;
```

The following statements specify the ARIMA$(0,1,1) \times (0,1,1)_{12}$ model for the logair series in the first data set (Data1):

```
proc ucm data=Data1;
   id date interval=month;
   model logair;
   irregular q=1 sq=1 s=12;
   deplag lags=(1)(12) phi=1 1 noest;
   estimate outest=est1;
   forecast outfor=for1;
run;
```

Note that the moving average part of the model is specified by using the Q=, SQ=, and S= options in the IRREGULAR statement and the differencing operator, $(1-B)(1-B^{12})$, is specified by using the DEPLAG statement. The model does not contain an intercept term; therefore no LEVEL statement is needed. The parameter estimates are saved in a data set EST1 by using the OUTEST= option in the ESTIMATE statement and the forecasts and the component estimates are saved in a data set FOR1 by using the OUTFOR= option in the FORECAST statement. The same analysis is performed on the other three data sets, but is not shown here.

Output 41.8.1 resembles Table 1 in Kohn and Ansley (1986). This table is generated by merging the parameter estimates from the four analyses. Only the moving average parameter estimates and their standard errors are reported. The columns EST1 and STD1 correspond to the estimates for Data1. The parameter estimates and their standard errors for other three data sets are similarly named. Note that the parameter estimates closely match the parameter estimates in the article. However, their standard errors differ slightly. This difference could be the result of different ways of computing the Hessian at the optimum. The white noise error variance estimates are not reported here, but they agree quite closely with those in the article.

Output 41.8.1 Data Sets 1–4: Parameter Estimates and Standard Errors

PARAMETER	est1	std1	est2	std2	est3	std3	est4	std4
MA_1	0.402	0.090	0.457	0.121	0.408	0.092	0.431	0.091
SMA_1	0.557	0.073	0.758	0.236	0.566	0.075	0.573	0.074

Output 41.8.2 resembles Table 2 in Kohn and Ansley (1986). It contains forecasts and their standard errors for the four data sets. The numbers are very close to those in the article.

Output 41.8.2 Data Sets 1–4: Forecasts and Standard Errors

DATE	for1	std1	for2	std2	for3	std3	for4	std4
JAN61	6.110	0.037	6.084	0.052	6.110	0.037	6.111	0.037

DEC61	6.168	0.082	6.174	0.086	6.168	0.082	6.169	0.080

Output 41.8.3 is based on Data2. It resembles Table 3 in Kohn and Ansley (1986). The columns S_SERIES and VS_SERIES in the OUTFOR= data set contain the interpolated values of logair and their variances. The estimate column in Output 41.8.3 reports interpolated values (which are the same as S_SERIES), and the std column reports their standard errors (which are computed as square root of VS_SERIES) for January–November 1957. The actual logair values for these months, which are missing in Data2, are also provided for comparison. The numbers are very close to those in the article.

Output 41.8.3 Data Set 2: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JAN57	5.753	5.733	0.045
FEB57	5.707	5.738	0.049
MAR57	5.875	5.893	0.052
