For more information about the estimates of parameters of interest, policy evaluation, and policy comparison, see the sections “[Full-Population Average Effect Parameters](#)” on page 934, “[Subpopulation Average Effect Parameters](#)” on page 936, and “[Policy Evaluation and Comparison](#)” on page 937.

Syntax: DEEPCAUSAL Procedure

The following statements are available in the DEEPCAUSAL procedure. Items within angle brackets (<>) are optional.

```
PROC DEEPCAUSAL options ;
  DNN options ;
  ID variable ;
  INFER <options> ;
  MODEL outcome-variable <=covariates> </options> ;
  PSMODEL treatment-variable <=covariates> </options> ;
  SCORE options ;
```

Functional Summary

The statements and options available in the DEEPCAUSAL procedure are summarized in [Table 15.1](#). The sections after the table provide a description of each statement in alphabetical order, following the PROC DEEPCAUSAL statement.

Table 15.1 Functional Summary

Description	Statement	Option
Input Data Table Option		
Specifies the input data table	PROC DEEPCAUSAL	DATA=
Specifies the input data table for $\alpha(\cdot)$ estimation information	SCORE	INA=
Specifies the input data table for $\beta(\cdot)$ estimation information	SCORE	INB=
Specifies the input data table for outcome model information	SCORE	INO=
Specifies the input data table for propensity score model information	SCORE	INPS=
Output Data Table Options		
Writes the estimation of the parameters of interest, policy evaluation, and policy comparison to an output data set	INFER	OUTEST=
Writes the details of the estimation, including $\alpha(\cdot)$, $\beta(\cdot)$, $p(\cdot)$, the residual, and influence functions for each unit, to an output data set	INFER	OUTDETAILS=
Writes the $\alpha(\cdot)$ estimation information to the specified output data set	SCORE	OUTA=
Writes the $\beta(\cdot)$ estimation information to the specified output data set	SCORE	OUTB=

Table 15.1 *continued*

Description	Statement	Option
Writes the outcome model information to the specified output data set	SCORE	OUTO=
Writes the propensity score model information to the specified output data set	SCORE	OUTPS=
ID Variable		
Specifies the identifying variable	ID	
Deep Neural Network (DNN) Options		
Specifies the parameters of the DNN for the propensity score model	PSMODEL	DNN=
Specifies the parameters of the DNN for the outcome model	MODEL	DNN=
Specifies the number of nodes for all hidden layers of the DNN for the propensity score model and outcome model	DNN	NODES=
Specifies the training options of the DNN for the propensity score model and outcome model	DNN	TRAIN=
Outcome Model Variables		
Specifies the outcome variable	MODEL	<i>outcome-variable</i>
Specifies the covariates for the outcome model	MODEL	<i>covariates</i>
Propensity Score Model Variables		
Specifies the treatment variable	PSMODEL	<i>treatment-variable</i>
Specifies the covariates for the propensity score model	PSMODEL	<i>covariates</i>
Inference Options		
Specifies the list of policy variables to be evaluated	INFER	POLICY=
Specifies the parameters for policy comparison	INFER	POLICYCOMPARISON=

PROC DEEPCAUSAL Statement

PROC DEEPCAUSAL *options* ;

The PROC DEEPCAUSAL statement invokes the DEEPCAUSAL procedure. You must specify the following *option*:

DATA=*libref.data-table*

names the input data table for PROC DEEPCAUSAL to use. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section “Using CAS Sessions and CAS Engine Librefs” on page 909.

data-table specifies the name of the input data table.

NOTE: The input data table must not contain any of the reserved variables (case-insensitive): *_PSHAT_*, *_YHAT_*, *_Y0_*, *_Y1_*, *_AVGPX_*, *_px_*, *_alpha_*, *_beta_*, *_rho00_*, *_rho01_*, *_rho10_*, *_rho11_*, *_att_*, *_deltaX_*, *_atu_*, or *_delta_*.

DNN Statement

DNN *< options >* ;

The DNN statement specifies the parameters for the deep neural network (DNN). It includes options that are related to the DNNs for the propensity score model and outcome models. You can specify the following *options*:

NODES=*(numeric-list)*

specifies the number of nodes for each hidden layer in the DNN, where each value in the *numeric-list* must be a positive number and values are separated by commas or spaces. The length of the list specifies the number of layers, and each value specifies the number of nodes for the corresponding layer. If the length of the list is denoted by n , the i th ($1 \leq i \leq n$) value denotes the number of nodes for the i th layer. By default, NODES=(32 32 32 32), which yields four hidden layers, with 32 nodes in each layer.

TRAIN=*(train-options)*

specifies the train options for the DNN. You can specify one or more of the following *train-options*:

GPU=*(< gpu-options >)*

specifies that the DNN perform calculations by using graphics processing unit (GPU) hardware. You can specify the following *gpu-options*:

DEVICE=(*numeric-list*)

DEVICES=(*numeric-list*)

specifies a list of GPU devices to use.

PRECISION=FP16 | FP32

specifies the computational precision in forward-backward computations. You can specify the following values:

FP16 uses half-precision (16-bit floating-point) computations to train and score the DNN. The lower computational precision in forward-backward computations can encourage tensor core engagements.

FP32 uses single-precision (32-bit floating-point) computations to train and score the DNN.

By default, PRECISION=FP32.

USEEXCLUSIVE

specifies that only GPU devices be used.

USETensorRT

enables the use of the TensorRT software development kit for fast inference.

MISSING=MAX | MEAN | MIN | NONE

specifies the policy to use for replacing missing input covariate values with imputed values. You can specify one of the following values:

MAX replaces missing values with the maximum of the corresponding covariate.

MEAN replaces missing values with the mean of the corresponding covariate.

MIN replaces missing values with the minimum of the corresponding covariate.

NONE ignores observations that have missing values.

By default, MISSING=MEAN. The MISSING= option is for DNN training only. In the later inference, observations that have missing covariates are removed.

NTHREADS=*number*

specifies the number of threads to use for the DNN.

OPTIMIZATION=(*optimizer-options*)

OPTIMIZE=(*optimizer-options*)

OPTIMIZER=(*optimizer-options*)

specifies the settings for the optimization algorithm, optimization mode, and other settings, such as a seed, the maximum number of epochs, and so on. You can specify the following *optimizer-options*:

ALGORITHM=*algorithm-keyword*<(common-algorithm-options)>

specifies the optimization algorithm and the corresponding options. First, you can specify some common options of all the optimization algorithms, *common-algorithm-options*, in the parentheses that follow the *algorithm-keyword*. They are as follows:

CLIPGRADMAX=*number*

specifies the maximum gradient value. All gradient values that exceed the specified maximum value are set to the specified maximum value. The *number* should be greater than or equal to 0.

CLIPGRADMIN=*number*

specifies the minimum gradient value. All gradient values that are less than the specified minimum value are set to the specified minimum value. The *number* should be less than or equal to 0.

FCMPEARLYSTOPPING=*symbol-name***FCMPES=***symbol-name*

specifies the FCMP early stopping function.

FCMPLEARNINGRATE=*symbol-name***FCMPLR=***symbol-name*

specifies the FCMP learning rate function.

GAMMA=*number*

specifies the gamma value for the learning rate policy. The *number* must be between 0 and 100. By default, GAMMA=0.1.

LEARNINGRATE=*number*

specifies the learning rate (a positive value) for stochastic gradient descent (SGD). By default, LEARNINGRATE=0.001.

LEARNINGRATEPOLICY=FIXED | INV | MULTISTEP | POLY | STEP**LRPOLICY=**FIXED | INV | MULTISTEP | POLY | STEP

specifies the learning rate policy. You can specify one of the following values:

FIXED

specifies a fixed learning rate.

INV

sets the learning rate option value after each epoch, according to the initial learning rate, the value of the GAMMA= option, and the value of the POWER= option. The rate is calculated as $\text{learningRate} * (1 + \text{gamma} * \text{currentEpoch})^{-\text{power}}$.

MULTISTEP

sets the learning rate after each of the epochs that you specify in the STEPS= option. The updated learning rate is the product of the previous learning rate value and the GAMMA= option value.

POLY

sets the learning rate option value after each epoch, according to the initial learning rate, the maximum number of epochs, and the value of the POWER= option. The rate is calculated as $\text{learningRate} * (1 - \text{currentEpoch}/\text{maxEpochs})^{\text{power}}$.

STEP sets the learning rate option by multiplying the current learning rate option value by the GAMMA= option value. The number of steps is specified in the STEPSIZE= option. The configured learning rate is recalculated for each group of epochs, according to the step size.

By default, LEARNINGRATEPOLICY=FIXED.

NOUSELOCKING

specifies that gradients be computed asynchronously with multiple threads.

POWER=number

specifies the power for the learning rate policy. The *number* must be nonnegative. By default, POWER=0.75.

STEPS=(numeric-list)

specifies a list of epoch counts. When the current epoch matches one of the specified steps, the learning rate is multiplied by the value of the GAMMA= option. For example, if you specify STEPS=(5 9 13), then the learning rate is multiplied by gamma after the 5th, 9th, and 13th epochs.

STEPSIZE=number

specifies the step size (a value greater than or equal to 1) when the learning rate policy is set to STEP. By default, STEPSIZE=10.

For the ALGORITHM= option, you can specify one of the following *algorithm-keywords* and its associated options:

ADAM<(adam-options)>

ADAMSGD<(adam-options)>

specifies the ADAM optimization algorithm. For the *adam-options*, you can specify one or more of the *common-algorithm-options*. You can also specify the following *adam-options*:

BETA1=number

specifies the exponential decay rate for the first moment in an ADAM learning algorithm. The *number* must be in the range [0, 1). By default, BETA1=0.9.

BETA2=number

specifies the exponential decay rate for the second moment in an ADAM learning algorithm. The *number* must be in the range [0, 1). By default, BETA2=0.999.

LARS<(lars-options)>

specifies the LARS optimization algorithm. For the *lars-options*, you can specify one or more of the *common-algorithm-options*. You can also specify one or more of the following *lars-options*:

LAYERRATES=(*numeric-list*)

LOCALRATES=(*numeric-list*)

produces an array of values that specifies the learning rate for each model layer. You cannot specify this option in the DNN statement; you can specify it only in the PSMODEL or MODEL statement. In the PSMODEL statement, the number of local learning rates that you specify in the *numeric-list* must equal $m + 2$, where m is the number of hidden layers of the DNN for the propensity score model. In the MODEL statement, the number of local learning rates that you specify in the *numeric-list* must equal $n + 9$, where n is the number of hidden layers of the DNN for the outcome model.

MOMENTUM=*number*

specifies the momentum parameter value for stochastic gradient descent (SGD). The *number* must be in the range $[0, 1]$. By default, MOMENTUM=0.9.

SCALEFACTOR=*number*

specifies the scaling coefficient that is used to adjust the base learning rate. The *number* must be in the range $[0, 1]$. By default, SCALEFACTOR=0.001.

WARMUP=*number*

specifies the number of warmup epochs to complete before applying layerwise learning rates in the LARS optimization algorithm. The *number* must be greater than or equal to -1 . By default, WARMUP= -1 , which means that there are no warmup epochs.

LBFGS<(*lbfgs-options*)>

specifies the L-BFGS optimization algorithm. In the *lbfgs-options*, you can specify one or more of the *common-algorithm-options*. The GAMMA=, LEARNINGRATE=, LEARNINGRATEPOLICY=, POWER=, and STEPSIZE= options do not support the L-BFGS optimization algorithm. You can also specify one or more of the following *lbfgs-options*:

BACKTRACKRATIO=*number*

specifies the backtrack ratio of line search iterations for the L-BFGS optimization algorithm. The *number* must be in the range $[0, 1)$. By default, BACKTRACKRATIO=0.5.

M=*number*

NUMCORRECTIONS=*number*

specifies the number of corrections to use in the L-BFGS update. The *number* must be greater than or equal to 0. By default, M=6.

MAXLINESEARCHITERS=*number*

specifies the maximum number of line search iterations for L-BFGS optimization algorithm. The *number* must be an integer greater than or equal to 1. By default, MAXLINESEARCHITERS=60.

MOMENTUMALG<(momentumalg-options)>

MOMENTUMSGD<(momentumalg-options)>

specifies the MOMENTUM optimization algorithm. In the *momentumalg-options*, you can specify one or more of the *common-algorithm-options*. You can also specify the following *momentumalg-option*:

MOMENTUM=*number*

specifies the momentum parameter value for stochastic gradient descent (SGD). The *number* must be between 0 and 1. By default, MOMENTUM=0.9.

TRISH<(trish-options)>

TRISHSGD<(trish-options)>

specifies the trust-region-ish (TRish) optimization algorithm. In the *trish-options*, you can specify one or more of the *common-algorithm-options*. You can also specify one or more of the following *trish-options*:

GAMMA1=*number*

specifies the Gamma1 scaling for the gradient. The *number* must be in the range [0, 10,000). By default, GAMMA1=2.

GAMMA2=*number*

specifies the Gamma2 scaling for the gradient. The *number* must be in the range [0, 10,000). By default, GAMMA2=2.

MOMENTUM=*number*

specifies the momentum parameter value for stochastic gradient descent (SGD). The *number* must be in the range [0, 1]. By default, MOMENTUM=0.9.

VANILLA<(common-algorithm-options)>

VANILLASGD<(common-algorithm-options)>

specifies the vanilla optimization algorithm.

By default, ALGORITHM=VANILLA.

COMPRESSION=(compression-options)

sparsifies the communication between workers for faster training. You can specify one or more of the following *compression-options*:

LOCALMOMENTUM=*number*

determines the strength of aggregation on the masked gradient elements when compression is used. The *number* must be in the range [0, 1]. By default, LOCALMOMENTUM=0.95.

SAMPLERATIO=*number*

determines the number of samples for gradients in each layer. The *number* must be in the range $[10^{-5}, 0.2]$. By default, SAMPLERATIO=0.05.

SPARSITYRATIO=number

determines the number of samples for gradients in each layer. The *number* must be in the range [0, 1]. By default, SPARSITYRATIO=0.75.

DROPOUT=number

specifies the probability that the output of a neuron in a fully connected layer will be set to 0 during training. The specified probability is recalculated each time an observation is processed. The *number* must be in the range [0, 1). By default, DROPOUT=0.

DROPOUTINPUT=number

specifies the probability that an input variable will be set to 0 during training. The specified probability is recalculated each time an observation is processed. The *number* must be in the range [0, 1). By default, DROPOUTINPUT=0.

DROPOUTTYPE=INVERTED | STANDARD

specifies what type of dropout to use. You can specify one of the following types:

INVERTED	specifies the inverted dropout, in which activations of some neurons are set to 0 and the remaining ones are scaled.
STANDARD	specifies the standard dropout, in which activations of some neurons are set to 0 and the remaining ones are not scaled.

By default, DROPOUTTYPE=STANDARD.

FCONV=number

specifies the relative function convergence criterion. If the relative loss error, $\text{abs}[(\text{previous_loss} - \text{current_loss})/\text{previous_loss}]$, does not result in a change in the objective function, the optimization stops. The *number* must be greater than or equal to 0. By default, FCONV=0, and the relative function convergence is not checked.

FREEZEBATCHNORMSTATS**FREEZENSTATS**

freezes statistics of all batch normalization layers.

IGNORETRAININGERROR

specifies that the model training continue without interruption by ignoring the following issue: there are training data observations that contain invalid or missing variable data. If you omit this option, training stops, and PROC DEEPCAUSAL terminates if bad input data are found.

MAXEPOCHS=number

specifies the maximum number of epochs. The *number* must be greater than or equal to 1. By default, MAXEPOCHS=1. For SGD with a single-machine server, or for a session that uses one worker on a distributed server, one epoch is reached when the optimizer passes through the data one time. For a session that uses more than one worker, one epoch is reached when all the workers exchange the weights with the controller one time. The SYNCFREQ= option specifies the number of times that each worker passes through the data before exchanging weights with the controller. For the L-BFGS optimization algorithm with a full batch, each iteration might process more than one epoch, and the final number of epochs might exceed the parameter value for the maximum number of epochs.

MINIBATCHBUFSIZE=*number*

specifies the number of observations to buffer in memory (including input data and intermediate calculations) before processing the remaining records in the minibatch. The *number* must be greater than or equal to 1 and must be smaller than the *number* that you specify for the MINIBATCHSIZE= option. The MINIBATCHBUFSIZE= option setting is ignored on GPUs.

MINIBATCHSIZE=*number*

specifies the number of observations per thread in a minibatch. The parameter controls the number of observations used

per worker in each thread to compute the gradient, prior to updating the weights. Larger values use more memory. The *number* is greater than or equal to 1. By default, MINIBATCHSIZE=1. When you use synchronous SGD (the default), the total minibatch size is calculated as $\text{miniBatchSize} * \text{number of threads} * \text{number of workers}$. When you use asynchronous SGD by specifying the ELASTICSYNCFREQ= option, each worker trains its own local model. In this case, the total minibatch size for each worker is calculated as $\text{miniBatchSize} * \text{number of threads}$.

MODE=DOWNPOUR | ELASTIC | SYNCHRONOUS

specifies the optimization mode and the corresponding options. You can specify one of the following values:

DOWNPOUR

specifies the downpour optimization mode.

ELASTIC<(elastic-options)>

specifies the elastic optimization mode. You can specify the following *elastic-options*:

ALPHA=*number***ELASTICALPHA=*number***

specifies the significance level (a value between 0 and 1) that is used for elastic SGD. By default, ALPHA=0.

ELASTICSYNCFREQ=*number***SYNCFREQ=*number***

specifies the frequency (a nonnegative value) for communication between the workers and controller for exchanging weights. You can exchange the weights more often than once each epoch by specifying a *number* that is less than the number of batches in an epoch. If the *number* is greater than the number of batches in an epoch, then the weights are exchanged once for each epoch. By default, ELASTICSYNCFREQ=0.

SYNCHRONOUS<(SYNCFREQ=*number*)>

specifies the synchronous optimization mode. The SYNCFREQ= option, which is not required, specifies the synchronization frequency for SGD in terms of epochs. By default, SYNCFREQ=1.

By default, MODE=SYNCHRONOUS.

NOBNSRCLAYERWARNINGS

suppresses the warning, if the batch normalization source layer has an atypical type, activation, or includeBias setting.

REGL1=number

specifies the weight for the L1 regularization term. The *number* must be greater than or equal to 0. By default, REGL1=0. At the default setting, PROC DEEPCAUSAL does not perform L1 regularization. Setting the L1 regularization weight to 0 disables the regularization. Initial L1 weight values should be small (such as $1E-3$). You can combine L1 regularization with L2 regularization.

REGL2=number

specifies the weight for the L2 regularization term. The *number* must be greater than or equal to 0. By default, REGL2=0. At the default setting, PROC DEEPCAUSAL does not perform L2 regularization. Setting the L2 regularization weight to 0 disables the regularization. Initial L2 weight values should be small (such as $1E-3$). You can combine L2 regularization with L1 regularization.

SEED=number

specifies the random number seed value for the random number generator in the L-BFGS optimization algorithm. Seed values less than or equal to 0 generate random number streams by using the time of day from the computer's clock. Seed values greater than 0 generate reproducible random number sequences. By default, SEED=0.

SNAPSHOTFREQ=number

specifies the frequency for generating snapshots of the neural weights and storing the weights in a weight table during the training process. When asynchronous SGD is specified, PROC DEEPCAUSAL synchronizes all the weights before writing out the weights. The *number* must be greater than or equal to 0. By default, SNAPSHOTFREQ=0.

STAGNATION=number

specifies the number of iterations to complete without improvement before stopping the optimization early. The *number* must be greater than or equal to 0. By default, STAGNATION=0; this turns off the stagnation monitoring.

THRESHOLD=number

specifies the threshold that is used to determine whether the loss error or validation scores are improving or stagnating across iterations. The iteration does not improve when the magnitude of the score change between successive iterations is less than or equal to the absolute value of `current_score * threshold value`. When an iteration does not improve, the stagnation counter increments. Otherwise, the stagnation counter is set to 0. The *number* must be greater than or equal to 0. By default, THRESHOLD= 10^{-8} .

TOTALMINIBATCHSIZE=(totalminibatchsize-options)

specifies the number of observations in a minibatch. You can specify one or more of the following *totalminibatchsize-options*:

NONOTIFY

suppresses the message that is printed if the total minibatch size is rounded up.

ROUND

rounds up the total minibatch size.

SIZE=number**N=number**

specifies the number of observations in a minibatch. The computation for the total minibatch size is $nWorkers * miniBatchSize * nThreads$. For example, a two-worker scenario with 32 threads per worker and a minibatch size of 10 has a total minibatch size of $2 * 32 * 10 = 640$ records.

You can use these options to control the number of observations that the DNN uses to compute the gradient prior to updating the weights. Larger values use more memory. If the specified size cannot be evenly divided by the number of threads (if you are using asynchronous SGD) or by the number of threads * number of workers (if you are using synchronous SGD), then PROC DEEPCAUUSAL terminates with an error unless you specify the ROUND option. In that case, the total minibatch size is rounded up so that it is evenly divided.

RECORDSEED=number

specifies the random number seed for random record selection within a worker. The default (RECORDSEED=0) disables random record selection. Records are read in the order in which they are written in memory. Seed values that are less than or equal to 0 generate random number streams by using the time of day from the computer's clock. Seed values greater than 0 generate reproducible random number sequences.

SEED=number

specifies the random number seed value for the random number generator in stochastic gradient descent (SGD). Seed values that are less than or equal to 0 generate random number streams by using the time of day from the computer's clock. Seed values greater than 0 generate reproducible random number sequences. By default, SEED=0.

TARGETMISSING=MAX | MEAN | MIN | NONE

specifies the policy to use for replacing missing outcome variables with imputed values. You can specify one of the following values:

MAX	replaces missing values with the maximum.
MEAN	replaces missing values with the mean value.
MIN	replaces missing values with the minimum.
NONE	ignores observations that have missing target variables.

By default, TARGETMISSING=MEAN. The TARGETMISSING= option is for DNN training only. In the later inference, observations that have missing outcome variables have missing values for residuals and for any estimates that need residuals.

ID Statement

ID *variable* ;

The ID statement specifies the ID variable in the data set. The *variable* must have a unique value for each row in the input data table, or PROC DEEPCAUSAL issues an error.

INFER Statement

INFER *options* ;

The INFER statement specifies the parameters for inference. You can specify one or more of the following *options*:

OUT=*libref.data-table*

OUTEST=*libref.data-table*

writes the estimation of the parameters of interest, policy evaluation, and policy comparison to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 909.

OUTDETAILS=*libref.data-table*

writes the details of the estimation, including $\alpha(\cdot)$, $\beta(\cdot)$, $p(\cdot)$, the residual, and influence functions for each unit, to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 909.

POLICY=(*policy-variable-list*)

specifies the list of policy variables to be evaluated. All symbol names in the *policy-variable-list* must correspond to the policy variables; the symbol names are separated by spaces.

POLICYCOMPARISON=(*comparison-options*)

specifies the options for policy comparison. You must specify the following *comparison-options*:

BASE=(*base-list*)

specifies a list of policy variables, each of which is used as a base policy in the policy comparison. All symbol names in the *base-list* must correspond to the policy variables; the symbol names are separated by spaces.

COMPARE=(*compare-list*)

specifies a list of policy variables, each of which is used to compare with each base policy that you specify in the BASE= option. All symbol names in the *compare-list* must correspond to the policy variables; the symbol names are separated by spaces.

MODEL Statement

MODEL *outcome-variable* <=*covariates*> </options> ;

The MODEL statement specifies options that are related to the outcome model and the DNN to fit the outcome model. The *outcome-variable* specifies the outcome variable of the outcome model. The *covariates* specify the covariates of the outcome model. If you omit the *covariates*, no DNN is trained for the outcome model. For more information about the outcome model, see the section “[Outcome Model](#)” on page 932. Covariate names must be separated by spaces. The treatment variable is automatically included in the outcome model as an independent variable.

You can specify the following *option* after a forward slash (/):

DNN=(*dnn-options*)

specifies the options of the DNN for the outcome model. If you omit this option and specify the DNN statement, the DNN for the outcome model has the options that you specify in the DNN statement. If you omit both this option and the DNN statement, the DNN for the outcome model uses the default option values. If you specify both this option and the DNN statement, the DNN statement is ignored for the outcome model. For the *dnn-options*, you can specify one or more options that are listed in the section “[DNN Statement](#)” on page 917. If no covariates are specified in the MODEL statement, the DNN= option is ignored.

PSMODEL Statement

PSMODEL *treatment-variable* <=*covariates*> </options> ;

The PSMODEL statement specifies options that are related to the propensity score model and the DNN to fit the propensity score model. The *treatment-variable* specifies the treatment variable of the propensity score model. It corresponds to one variable in the input data table; that variable must satisfy the following requirements:

- The treatment variable in the input data table must be binary; that is, its value must be either 0 or 1.
- The values of the treatment variable across all observations in the input data table must not be identical.

The *covariates* specify the covariates of the propensity score model. All covariate names are separated by spaces. If you omit the *covariates*, no DNN is trained for the propensity score model. For more information about the propensity score model, see the section “[Propensity Score Model](#)” on page 932.

You can specify the following *option* after a forward slash (/):

DNN=(*dnn-options*)

specifies the options of the DNN for the propensity score model. If you omit this option and specify the DNN statement, the DNN for the propensity score model has the options that you specify in the DNN statement. If you omit both this option and the DNN statement, the DNN for the propensity score model uses the default option values. If you specify both this option and the DNN statement, the DNN statement is ignored for the propensity score model. For the *dnn-options*, you can specify one or more options that are listed in the section “[DNN Statement](#)” on page 917. If no *covariates* are specified in the PSMODEL statement, the DNN= option is ignored.

SCORE Statement

SCORE options ;

The SCORE statement specifies options that are related to scoring data. You can specify the following options:

INA=*libref.data-table*

INALPHA=*libref.data-table*

specifies the input data table that contains information about $\alpha(\cdot)$ estimation. The data table must be an output data table that the OUTA= option produces in a previous call of the DEEPCAUSAL procedure. When you specify this option, the MODEL statement and the OUTA=, OUTB=, and OUTO= options in the SCORE statement are ignored. If this option is specified, you must also specify the INB= option. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the DATA= option and the section “Using CAS Sessions and CAS Engine Librefs” on page 909.

INB=*libref.data-table*

INBETA=*libref.data-table*

specifies the input data table that contains information about $\beta(\cdot)$ estimation. The data table must be an output data table that the OUTB= option produces in a previous call of the DEEPCAUSAL procedure. When you specify this option, the MODEL statement and the OUTA=, OUTB=, and OUTO= options in the SCORE statement are ignored. If this option is specified, you must also specify the INA= option. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the DATA= option and the section “Using CAS Sessions and CAS Engine Librefs” on page 909.

INO=*libref.data-table*

INOUTCOME=*libref.data-table*

specifies the input data table that contains information about the outcome model. The data table must be an output data table that the OUTO= option produces in a previous call of the DEEPCAUSAL procedure. When you specify this option, the MODEL statement and the INA=, INB=, OUTA=, OUTB=, and OUTO= options in the SCORE statement are ignored. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the DATA= option and the section “Using CAS Sessions and CAS Engine Librefs” on page 909.

INPS=*libref.data-table*

INPROPSITYSCORE=*libref.data-table*

specifies the input data table that contains information about the propensity score model. The data table must be an output data table that the OUTPS= option produces in a previous call of the DEEPCAUSAL procedure. When you specify this option, the PSMODEL statement and the OUTPS= option in the SCORE statement are ignored. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the DATA= option and the section “Using CAS Sessions and CAS Engine Librefs” on page 909.

OUTA=*libref.data-table*

OUTALPHA=*libref.data-table*

writes the $\alpha(\cdot)$ estimation information to the specified output data table. The output data table consists of binary large object (BLOB) columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters, because the data type of each column is binary. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 909.

OUTB=*libref.data-table*

OUTBETA=*libref.data-table*

writes the $\beta(\cdot)$ estimation information to the specified output data table. The output data table consists of binary large object (BLOB) columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters, because the data type of each column is binary. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 909.

OUTO=*libref.data-table*

OUTOUTCOME=*libref.data-table*

writes the outcome model information to the specified output data table. The output data table consists of binary large object (BLOB) columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters, because the data type of each column is binary. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 909.

OUTPS=*libref.data-table*

OUTPROPENSITYSCORE=*libref.data-table*

writes the propensity score model information to the specified output data table. The output data table consists of binary large object (BLOB) columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters, because the data type of each column is binary. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 909.

Details: The DEEPCAUSAL Procedure

Causal Inference Overview

Causal inference is the science of why. Many classical statistics models, such as linear regression, show how the outcome variable is associated with the covariates. It is known that correlation does not equal causation. However, it is often not known whether a change in the outcome is caused by the change in a treatment. Randomized experiments provide a solution, but there are many constraints that often make the experiment impossible. For example, designing and then conducting the experiment is time-consuming and expensive. Moreover, an experiment might encounter some ethical issues that prevent the experiment from being conducted. Therefore, causal inference based on observational data is indispensable to answering the causal questions.

The DEEPCAUSAL procedure is designed primarily for observational data when the subjects are not randomly assigned to the treatment conditions. However, in some situations the randomized trials need to be treated as observational studies. For example, subjects can be randomly assigned to the treatment group, or block randomization can be used when there are several confounding variables. However, after the experiment, maybe a few more confounding variables are discovered. Or worse yet, maybe the treatment and control groups do not have similar distributions across the segments of one or more new confounding variables. In these cases, instead of doing the experiment again, you need to estimate the causal effect by treating the experiment as an observational study. Moreover, selection bias can affect the treatment effect estimation. For example, suppose that there is a new version of a smartphone app, and the relevant notifications are sent to randomly selected individuals, who can be seen as the treatment group. Then the effect of the new app version on a certain outcome, such as the average time spent on the app every day, is worth investigating. The issue is that not everyone in the treatment group will download the new version. In the treatment group, those who download the new version are different from those who do not, and then selection bias arises. To avoid that bias, the control group can be compared to all subjects in the treatment group no matter whether a particular individual downloads the app. The estimated treatment effect is no doubt diluted because some individuals in the treatment group are not actually treated. Again, one solution is to treat the experiment as an observational study.

PROC DEEPCAUSAL exploits deep neural networks (DNNs) for causal inference. It applies deep learning to causal inference in a two-step semiparametric framework: the nonparametric step and the parametric step. In the nonparametric step, two DNNs are used to estimate the unknown functions in the propensity score model and outcome model. In the parametric step, parameters of interest are estimated through the corresponding influence functions.

Estimating Unknown Functions in Propensity Score and Outcome Models

There are two main models in causal inference: the propensity score model and the outcome model. Two approximate DNNs are constructed to estimate these two models. The DEEPCAUSAL procedure supports one binary treatment and one continuous outcome. The unconfoundedness is assumed; it is also called ignorability, selection on the observables, or no omitted variable bias.

Propensity Score Model

The propensity score model estimates the treatment assigning probability conditional on some covariates:

$$p(\mathbf{x}^{(1)}) = \Pr(T = 1 | \mathbf{X}^{(1)} = \mathbf{x}^{(1)})$$

where $p(\mathbf{x}^{(1)})$ denotes the propensity score, T denotes the binary treatment, and $\mathbf{x}^{(1)}$ is a vector of the observed covariates. The superscript (1) in $\mathbf{X}^{(1)}$ denotes the covariates in Set 1, which are the covariates used in the propensity score model. The $p(\cdot)$ is one unknown function to be estimated by a DNN.

The DNN for the propensity score model, a binary classification predictor, predicts the binary treatment by using the covariates in Set 1. It trains the observations in the input data set. The DNN is a fully connected multilayer perceptron (MLP). The input layer of that DNN corresponds to $\mathbf{X}^{(1)}$, and the output layer corresponds to the observed treatment variable. The activation functions for the hidden layers are all rectified linear unit (ReLU) functions, and the activation function for the output layer is a sigmoid function. The loss function is the negative log-likelihood function.

If no covariates are used to predict the binary treatment ($\mathbf{X}^{(1)} = \emptyset$), then no DNN needs to be trained for the propensity score model. A random assignment of the treatment and many other reasons might result in the empty $\mathbf{X}^{(1)}$; that is, all covariates are independent of the treatment. The propensity score is estimated by

$$p(\emptyset) = \Pr(T = 1 | \mathbf{X}^{(1)} = \emptyset) = \Pr(T = 1) = \frac{\sum_{i=1}^n \mathbb{1}\{t_i = 1\}}{n}$$

where t_i denotes the treatment value of the i th observation and n denotes the number of observations. The indicator function $\mathbb{1}\{A\} = 1$ if A is true; otherwise, it is 0.

Outcome Model

The outcome model describes how the outcome depends on the treatment and some covariates in Set 2, which are the covariates used in the propensity score model. The covariates in Set 1 and Set 2 might be different. The DEEPCAUSAL procedure supports only one continuous outcome variable, and the outcome model is as follows:

$$\mathbb{E}[Y | \mathbf{X}^{(2)} = \mathbf{x}^{(2)}, T = t] = G(\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})t)$$

where Y is the outcome, t is the treatment, and $G(\cdot)$ is a known function. For example, $G(u)$ might be the identity function; that is, $G(u) = u$. The superscript (2) in $\mathbf{X}^{(2)}$ denotes the covariates in Set 2. In PROC DEEPCAUSAL, $G(\cdot)$ is the identity function. The $\alpha(\cdot)$ and $\beta(\cdot)$ are unknown functions to be estimated by a DNN.

The DNN for the outcome model, a regression predictor, predicts the outcome by using the covariates in Set 2 and the treatment variable. It trains the observations in the input data set. The input layer of that DNN corresponds to $\mathbf{X}^{(2)}$. After the hidden layers, there is a parameter layer with two neurons that correspond to

$\alpha(\mathbf{x}^{(2)})$ and $\beta(\mathbf{x}^{(2)})$. The activation functions for this parameter layer are linear functions. Subsequently, t is included, and $G(\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})t)$ is calculated as the result of the final output layer. $G(\cdot)$ is set to the identity function in PROC DEEPCAUSAL, so $\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})t$ is output as the prediction.

If no covariates are used to predict the outcome ($\mathbf{X}^{(2)} = \emptyset$), then no DNN needs to be trained for the outcome model. The outcome model is predicted by

$$\mathbb{E}[Y|\mathbf{X}^{(2)} = \emptyset, T = t] = \mathbb{E}[Y|T = t]$$

Moreover, when $\mathbf{X}^{(2)} = \emptyset$, $\alpha(\mathbf{x}^{(2)})$ and $\beta(\mathbf{x}^{(2)})$ are constants and are computed by

$$\begin{aligned}\alpha(\emptyset) &= \mathbb{E}[Y|T = 0] = \frac{\sum_{i=1}^n y_i \mathbb{1}\{t_i = 0\}}{\sum_{i=1}^n \mathbb{1}\{t_i = 0\}} \\ \beta(\emptyset) &= \mathbb{E}[Y|T = 1] - \mathbb{E}[Y|T = 0] = \frac{\sum_{i=1}^n y_i \mathbb{1}\{t_i = 1\}}{\sum_{i=1}^n \mathbb{1}\{t_i = 1\}} - \frac{\sum_{i=1}^n y_i \mathbb{1}\{t_i = 0\}}{\sum_{i=1}^n \mathbb{1}\{t_i = 0\}}\end{aligned}$$

where y_i denotes the outcome value of the i th observation, t_i denotes the treatment value of the i th observation, and n denotes the number of observations. The indicator function $\mathbb{1}\{A\} = 1$ if A is true; otherwise, it is 0.

Estimating Parameters of Interest

A parameter of interest can be defined through the following structural model:

$$\theta_0 = \mathbb{E}[H(y, \mathbf{X}, T, \alpha(\mathbf{X}^{(2)}), \beta(\mathbf{X}^{(2)}); t^*)]$$

where θ_0 is a certain parameter of interest, $H(\cdot)$ is a known function that corresponds to θ_0 , $\mathbf{X}$ is the union of $\mathbf{X}^{(1)}$ and $\mathbf{X}^{(2)}$, and t^* is a fixed treatment value of interest. To have the expected value, a naive approach is to plug the DNN-based estimates $\hat{\alpha}(\mathbf{x}^{(2)})$ and $\hat{\beta}(\mathbf{x}^{(2)})$ into the structural model of θ_0 . This estimator, which is known as the plug-in estimator, is given by

$$\hat{\theta}_0 = \frac{1}{n} \sum_{i=1}^n H(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}); t^*)$$

where n is the sample size and the subscript i stands for the i th observation. For example, if T is binary ($T \in \{0, 1\}$), then θ_0 is the estimator of the average treatment effect (ATE) when $H(y, \mathbf{X}, T, \alpha(\mathbf{X}^{(2)}), \beta(\mathbf{X}^{(2)}); t^*) = \beta(\mathbf{X}^{(2)})$. Then the plug-in estimator of ATE is given by

$$\hat{\theta}_0 = \frac{1}{n} \sum_{i=1}^n \hat{\beta}(\mathbf{x}_i^{(2)})$$

This estimator might be highly biased, because the covariates might have both effects on the outcome and treatment assignment. One way to solve this problem is to use an influence function–based estimator. With one treatment variable, Farrell, Liang, and Misra (2020) proposed the following influence function:

$$\begin{aligned}\psi(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ = H(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) + \nabla \mathbf{H}(\mathbf{x}) \Lambda(\mathbf{x})^{-1} (1, t)' (y - G(\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})t))\end{aligned}$$

where $\nabla \mathbf{H}(\mathbf{x}) = (\frac{\partial H}{\partial \alpha}, \frac{\partial H}{\partial \beta})$, $\Lambda(\mathbf{x}) = \mathbb{E}[\dot{G}(1, T)'(1, T)|\mathbf{X} = \mathbf{x}]$, and $\dot{G} = [dG(u)/du]_{u=\alpha(\mathbf{x}^{(2)})+\beta(\mathbf{x}^{(2)})t}$.

Because PROC DEEPCAUSAL sets $G(\cdot)$ to the identity function and supports one binary treatment, $\dot{G} = 1$ and the inverse of $\Lambda(\mathbf{x})$ can be computed directly. The preceding influence function can be simplified as follows:

$$\begin{aligned} \psi(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ = H(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) \\ + \frac{\dot{H}_\alpha(\mathbf{x})(\lambda_2(\mathbf{x}) - \lambda_1(\mathbf{x})t) + \dot{H}_\beta(\mathbf{x})(\lambda_0(\mathbf{x})t - \lambda_1(\mathbf{x}))}{\lambda_2(\mathbf{x})\lambda_0(\mathbf{x}) - \lambda_1(\mathbf{x})^2} (Y - \alpha(\mathbf{x}^{(2)}) - \beta(\mathbf{x}^{(2)})t) \end{aligned}$$

where $\lambda_j(\mathbf{x}) = \mathbb{E}[T^j | \mathbf{X} = \mathbf{x}]$, $j = 0, 1, 2$; $\dot{H}_\alpha(\mathbf{x}) = \frac{\partial H}{\partial \alpha}$; and $\dot{H}_\beta(\mathbf{x}) = \frac{\partial H}{\partial \beta}$. The binary treatment ($T \in \{0, 1\}$) is supported in PROC DEEPCAUSAL so that $\lambda_0(\mathbf{x}) = 1$ and $\lambda_1(\mathbf{x}) = \lambda_2(\mathbf{x}) = p(\mathbf{x})$.

The estimator for the parameter of interest is given by

$$\hat{\theta}_0 = \frac{\sum_{i=1}^n \psi(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

This estimator is doubly robust, which means that the estimator is unbiased when either the propensity score model or the outcome model is correct. The standard error of $\hat{\theta}_0$ is

$$\sigma(\hat{\theta}_0) = \frac{\sqrt{\sum_{i=1}^n (\psi(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*) - \hat{\theta}_0)^2}}{n}$$

For ease of presentation, the missing value is not indicated in the preceding equations. In practice, if $\psi(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$ is a missing value for $i = 1, \dots, n$, then it is ignored in both the denominator and numerator of the equation of $\hat{\theta}_0$ or $\sigma(\hat{\theta}_0)$. This policy is applied to all parameters of interest described in the sections “[Full-Population Average Effect Parameters](#)” on page 934, “[Subpopulation Average Effect Parameters](#)” on page 936, and “[Policy Evaluation and Comparison](#)” on page 937.

Next, the calculation of some common parameters of interest is introduced.

Full-Population Average Effect Parameters

There are three types of full-population average effect parameters:

- $\mathbb{E}[Y(0)] = \frac{1}{n} \sum_{i=1}^n Y_i(0)$, where Y_0 denotes the population-level potential outcome without the treatment, $Y_i(0)$ denotes the potential outcome for the i th observation without the treatment, and n denotes the number of observations
- $\mathbb{E}[Y(1)] = \frac{1}{n} \sum_{i=1}^n Y_i(1)$, where Y_0 denotes the population-level potential outcome with the treatment, $Y_i(1)$ denotes the potential outcome for the i th observation with the treatment, and n denotes the number of observations
- average treatment effect (ATE); $\text{ATE} = \mathbb{E}[Y(1) - Y(0)]$

The word “potential” is used in the preceding definitions because it is often impossible for an individual who is treated to return to the original status and be untreated, and vice versa.

The three full-population average effect parameters are estimated as follows:

- average with potential outcome 0, $\mu_0 = \mathbb{E}[Y(0)]$:

The influence function, denoted by $\psi_{\mu_0}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*)$, is defined by setting $H(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) = H_{\mu_0}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) = \alpha(\mathbf{x}^{(2)})$ in the influence function. When $G(\cdot)$ is set to the identity function and the treatment is binary, the influence function is simplified as

$$\psi_{\mu_0}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) = \alpha(\mathbf{x}^{(2)}) + \frac{1-t}{1-p(\mathbf{x}^{(1)})}(y - \alpha(\mathbf{x}^{(2)}) - \beta(\mathbf{x}^{(2)})t)$$

where $p(\mathbf{x}^{(1)}) = \Pr(T = 1 | \mathbf{X}^{(1)} = \mathbf{x}^{(1)})$. Then μ_0 is estimated by

$$\mu_0 = \frac{\sum_{i=1}^n \psi_{\mu_0}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

- average with potential outcome 1, $\mu_1 = \mathbb{E}[Y(1)]$:

The influence function, denoted by $\psi_{\mu_1}(Y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*)$, is defined by setting $H(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) = H_{\mu_1}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) = \alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})$ in the influence function. When $G(\cdot)$ is set to the identity function and the treatment is binary, the influence function is simplified as

$$\psi_{\mu_1}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) = \alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)}) + \frac{t}{p(\mathbf{x}^{(1)})}(y - \alpha(\mathbf{x}^{(2)}) - \beta(\mathbf{x}^{(2)})t)$$

where $p(\mathbf{x}^{(1)}) = \Pr(T = 1 | \mathbf{X}^{(1)} = \mathbf{x}^{(1)})$. Then μ_1 is estimated by

$$\mu_1 = \frac{\sum_{i=1}^n \psi_{\mu_1}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

- average treatment effect (ATE):

The influence function, denoted by $\psi_{\text{ATE}}(Y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*)$, is defined by setting $H(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) = H_{\text{ATE}}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) = \beta(\mathbf{x}^{(2)})$ in the influence function. When $G(\cdot)$ is set to the identity function and the treatment is binary, the influence function is simplified as

$$\psi_{\text{ATE}}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) = \beta(\mathbf{x}^{(2)}) + \frac{t - p(\mathbf{x}^{(1)})}{p(\mathbf{x}^{(1)})(1 - p(\mathbf{x}^{(1)}))}(y - \alpha(\mathbf{x}^{(2)}) - \beta(\mathbf{x}^{(2)})t)$$

where $p(\mathbf{x}^{(1)}) = \Pr(T = 1 | \mathbf{X}^{(1)} = \mathbf{x}^{(1)})$. Then ATE is estimated by

$$\text{ATE} = \frac{\sum_{i=1}^n \psi_{\text{ATE}}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

Subpopulation Average Effect Parameters

The subpopulation average effect parameters are based on the conditional average with potential outcome t_1 and treatment level t_2 , ρ_{t_1, t_2} , which is defined by

$$\rho_{t_1, t_2} = \mathbb{E}[Y(t_1)|T = t_2], \quad t_1, t_2 \in \{0, 1\}$$

The subpopulation average effect parameters are estimated as follows:

- ρ_{t_1, t_2} :

The influence function is calculated by

$$\begin{aligned} & \psi_{t_1, t_2}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ &= \frac{\Pr(t = t_2 | \mathbf{X}^{(1)} = \mathbf{x}^{(1)})}{\Pr(t = t_2)} \frac{\mathbb{1}\{t = t_1\}(Y - \mathbb{E}[Y | \mathbf{X}^{(2)} = \mathbf{x}^{(2)}, t = t_1])}{\Pr(t = t_1 | \mathbf{X}^{(1)} = \mathbf{x}^{(1)})} \\ &+ \frac{\mathbb{1}\{t = t_2\}\mathbb{E}[Y | \mathbf{X}^{(2)} = \mathbf{x}^{(2)}, t = t_1]}{\Pr(t = t_2)} \end{aligned}$$

where $\Pr(t = t_i | \mathbf{X}^{(1)} = \mathbf{x}^{(1)})$ is acquired from the DNN for the propensity model and $\mathbb{E}[Y | \mathbf{X}^{(2)} = \mathbf{x}^{(2)}, t = t_1]$ is acquired from the DNN for the outcome model. For more information, see Farrell, Liang, and Misra (2021). Then ρ_{t_1, t_2} is estimated by

$$\rho_{t_1, t_2} = \frac{\sum_{i=1}^n \psi_{t_1, t_2}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

- average treatment effect for the treated (ATT), $\text{ATT} = \rho_{1,1} - \rho_{0,1}$:

For ATT, the influence function is replaced by

$$\begin{aligned} & \psi_{\text{ATT}}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ &= \psi_{1,1}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) - \psi_{0,1}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \end{aligned}$$

Then ATT is estimated by

$$\text{ATT} = \frac{\sum_{i=1}^n \psi_{\text{ATT}}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

- average treatment effect for the untreated (ATU), $\text{ATU} = \rho_{1,0} - \rho_{0,0}$:

For ATU, the influence function is replaced by

$$\begin{aligned} & \psi_{\text{ATU}}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ &= \psi_{1,0}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) - \psi_{0,0}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \end{aligned}$$

Then ATU is estimated by

$$\text{ATU} = \frac{\sum_{i=1}^n \psi_{\text{ATU}}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

- composition effect, $\Delta_X = \rho_{1,1} - \rho_{1,0}$:

For Δ_X , the influence function is replaced by

$$\begin{aligned} \psi_{\Delta_X}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ = \psi_{1,1}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) - \psi_{1,0}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \end{aligned}$$

Then Δ_X is estimated by

$$\Delta_X = \frac{\sum_{i=1}^n \psi_{\Delta_X}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

- observed difference, $\Delta = \rho_{1,1} - \rho_{0,0}$:

For Δ , the influence function is replaced by

$$\begin{aligned} \psi_{\Delta}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ = \psi_{1,1}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) - \psi_{0,0}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \end{aligned}$$

Then Δ is estimated by

$$\Delta = \frac{\sum_{i=1}^n \psi_{\Delta}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

Policy Evaluation and Comparison

First, a policy is defined to be a rule that assigns a given set of information, represented by covariates $\mathbf{X}$, to treatment status; that is, a policy is a known map function that is defined by

$$s(\mathbf{X}) : \mathbf{X} \rightarrow \{0, 1\}$$

The expected utility of a policy, denoted by $\pi(s)$, is given by

$$\pi(s) = \mathbb{E}[s(\mathbf{X})Y(1) + (1 - s(\mathbf{X}))Y(0)]$$

To estimate $\pi(s)$, the influence function is replaced by

$$\begin{aligned} \psi_{\pi(s)}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ = s(\mathbf{x})\psi_{\mu_1}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) + (1 - s(\mathbf{x}))\psi_{\mu_0}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \end{aligned}$$

where $\psi_{\mu_j}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*)$ denotes the influence function for μ_j ($j = 0$ or 1). Then $\pi(s)$ is estimated by

$$\pi(s) = \frac{\sum_{i=1}^n \psi_{\pi(s)}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

The difference in expected utility of two policies is defined by

$$\pi(s_1, s_0) = \mathbb{E}[(s_1(\mathbf{X}) - s_0(\mathbf{X}))(Y(1) - Y(0))]$$

To estimate $\pi(s_1, s_0)$, the influence function is replaced by

$$\begin{aligned} \psi_{\pi(s_1, s_0)}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ = (s_1(\mathbf{x}) - s_0(\mathbf{x}))\psi_{\text{ATE}}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \end{aligned}$$

where $\psi_{\text{ATE}}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*)$ denotes the influence function for estimating ATE. Then $\pi(s_1, s_0)$ is estimated by

$$\pi(s_1, s_0) = \frac{\sum_{i=1}^n \psi_{\pi(s_1, s_0)}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

Missing Values

Treatment Variable

The input treatment variable cannot have missing values. If the input treatment variable has missing values, PROC DEEPCAUSAL terminates with an error.

Outcome Variable

In the DNN training stage of the outcome model, the missing outcome values are replaced by imputed values. For more information, see the **TARGETMISSING=** option. In the inference stage, the observations that have missing outcome values have missing values for residuals and any estimates that need residuals.

Covariate

In the DNN training stage of the propensity score model or the outcome model, the missing covariate values are replaced by imputed values. For more information, see the **MISSING=** option. In the inference stage, the observations that have missing covariates are ignored. However, the probability mass function (PMF) of the treatment variable ($\Pr(t = 0)$ or $\Pr(t = 1)$) considers all observations. As mentioned in the section “Treatment Variable” on page 938, each observation has a nonmissing treatment variable, and that value is used for calculating the PMF of the treatment variable.

Parameter of Interest

For any parameter of interest, $\psi(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$ is assigned a missing value if any component of it is missing, except for the following two subpopulation parameters of interest:

- $\rho_{0,0}$:
If $t_i = 1$, then $\psi_{0,0}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*) = 0$ always holds no matter whether any component of it is missing for $i = 1, \dots, n$, where n is the number of observations in the input data table.
- $\rho_{1,1}$:
If $t_i = 0$, then $\psi_{1,1}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*) = 0$ always holds no matter whether any component of it is missing for $i = 1, \dots, n$, where n is the number of observations in the input data table.

Data Table Output

The DEEPCASUAL procedure can create the data tables that are specified in the OUT= and OUTDETAILS= options in the INFER statement. The information in each table is described in the following sections.

OUT= Data Table Generated from the INFER Statement

The estimate and the corresponding standard error of each parameter of interest are displayed in this table. For more information about the parameters of interest, see the sections “[Full-Population Average Effect Parameters](#)” on page 934 and “[Subpopulation Average Effect Parameters](#)” on page 936. The output data table contains the following variables:

NOBS	number of observations in the input data table
_N_MU0_	number of nonmissing μ_0
_EST_MU0_	estimate of μ_0
_STD_MU0_	standard error of μ_0
_N_MU1_	number of nonmissing μ_1
_EST_MU1_	estimate of μ_1
_STD_MU1_	standard error of μ_1
_N_ATE_	number of nonmissing ATEs
_EST_ATE_	estimate of ATE
_STD_ATE_	standard error of ATE
_N_RHO00_	number of nonmissing $\rho_{0,0}$
_EST_RHO00_	estimate of $\rho_{0,0}$
_STD_RHO00_	standard error of $\rho_{0,0}$
_N_RHO01_	number of nonmissing $\rho_{0,1}$
_EST_RHO01_	estimate of $\rho_{0,1}$
_STD_RHO01_	standard error of $\rho_{0,1}$
_N_RHO10_	number of nonmissing $\rho_{1,0}$
_EST_RHO10_	estimate of $\rho_{1,0}$
_STD_RHO10_	standard error of $\rho_{1,0}$
_N_RHO11_	number of nonmissing $\rho_{1,1}$
_EST_RHO11_	estimate of $\rho_{1,1}$
_STD_RHO11_	standard error of $\rho_{1,1}$
_N_ATT_	number of nonmissing ATTs
_EST_ATT_	estimate of ATT
_STD_ATT_	standard error of ATT
_N_DELTAX_	number of nonmissing Δ_X

<code>_EST_DELTAX_</code>	estimate of Δ_X
<code>_STD_DELTAX_</code>	standard error of Δ_X
<code>_N_ATU_</code>	number of nonmissing ATUs
<code>_EST_ATU_</code>	estimate of ATU
<code>_STD_ATU_</code>	standard error of ATU
<code>_N_DELTA_</code>	number of nonmissing Δ . NOTE: In releases through 2023.03, this variable is named <code>_N_DELTA_</code> . Because of a conflict with some reserved SAS system variables, it has been renamed <code>_N_DELTA__</code> (with two final underscores) as of release 2023.04.
<code>_EST_DELTA_</code>	estimate of Δ . NOTE: In releases through 2023.03, this variable is named <code>_EST_DELTA_</code> . Because of a conflict with some reserved SAS system variables, it has been renamed <code>_EST_DELTA__</code> (with two final underscores) as of release 2023.04.
<code>_STD_DELTA_</code>	standard error of Δ . NOTE: In releases through 2023.03, this variable is named <code>_STD_DELTA_</code> . Because of a conflict with some reserved SAS system variables, it has been renamed <code>_STD_DELTA__</code> (with two final underscores) as of release 2023.04.
<code>_N_POLICY_POLICY-VAR_</code>	number of nonmissing $\pi(s)$, where s is the value of a policy variable, <code>POLICY-VAR</code> , that you specify in the <code>POLICY=(policy-variable-list)</code> option in the <code>INFER</code> statement. The estimate is displayed for each policy variable.
<code>_EST_POLICY_POLICY-VAR_</code>	estimate of $\pi(s)$, where s is the value of a policy variable, <code>POLICY-VAR</code> , that you specify in the <code>POLICY=(policy-variable-list)</code> option in the <code>INFER</code> statement. The estimate is displayed for each policy variable.
<code>_STD_POLICY_POLICY-VAR_</code>	standard error of $\pi(s)$, where s is the value of a policy variable, <code>POLICY-VAR</code> , that you specify in the <code>POLICY=(policy-variable-list)</code> option in the <code>INFER</code> statement. The standard error is displayed for each policy variable.
<code>_N_POLICY_COMPARISON_POLICY-VAR_BASE-VAR_</code>	number of nonmissing $\pi(s_c, s_b)$, where s_c is the value of a policy variable, <code>POLICY-VAR</code> , that you specify in the <code>POLICYCOMPARISON(COMPARE=(compare-list))</code> option in the <code>INFER</code> statement and s_b is the value of a policy variable, <code>BASE-VAR</code> , that you specify in the <code>POLICYCOMPARISON(BASE=(base-list))</code> option in the <code>INFER</code> statement. The estimate is displayed for each combination of s_c and s_b .
<code>_EST_POLICY_COMPARISON_POLICY-VAR_BASE-VAR_</code>	estimate of $\pi(s_c, s_b)$, where s_c is the value of a policy variable, <code>POLICY-VAR</code> , that you specify in the <code>POLICYCOMPARISON(COMPARE=(compare-list))</code> option in the <code>INFER</code> statement and s_b is the value of a policy variable, <code>BASE-VAR</code> , that you specify in the <code>POLICYCOMPARISON(BASE=(base-list))</code> option in the <code>INFER</code> statement. The estimate is displayed for each combination of s_c and s_b .
<code>_STD_POLICY_COMPARISON_POLICY-VAR_BASE-VAR_</code>	standard error of $\pi(s_c, s_b)$, where s_c is the value of a policy variable, <code>POLICY-VAR</code> , that you specify in the <code>POLICYCOMPARISON(COMPARE=(compare-list))</code> option in the <code>INFER</code> statement and s_b is the value of a policy variable, <code>BASE-VAR</code> , that you specify in the <code>POLICYCOMPARISON(BASE=(base-list))</code> option in the <code>INFER</code> statement. The standard error is displayed for each combination of s_c and s_b .

OUTDETAILS= Data Table Generated from the INFER Statement

The output data first consists of the variables in the input data table and the details in the estimation, including $\alpha(\cdot)$, $\beta(\cdot)$, $p(\cdot)$, the residual, and the influence functions for each observation in the input data table. For more information about the influence functions for parameters of interest, the propensity score prediction model, and the outcome prediction model, see the sections “[Estimating Unknown Functions in Propensity Score and Outcome Models](#)” on page 932 and “[Estimating Parameters of Interest](#)” on page 933. In what follows, i denotes the observation index. Moreover, the output data table contains the following variables in addition to the input variables:

<code>_PSHAT_</code>	logarithm of the odds $p(\mathbf{x}_i^{(1)})/(1 - p(\mathbf{x}_i^{(1)}))$ for each observation, where $p(\mathbf{x}_i^{(1)}) = \Pr(T = 1 \mathbf{X}^{(1)} = \mathbf{x}_i^{(1)})$
<code>_YHAT_</code>	value of $\mathbb{E}[Y \mathbf{X}^{(2)} = \mathbf{x}_i^{(2)}, T = t_i] = \hat{\alpha}(\mathbf{x}_i^{(2)}) + \hat{\beta}(\mathbf{x}_i^{(2)})t_i$ for each observation
<code>_Y0_</code>	value of $\mathbb{E}[Y \mathbf{X}^{(2)} = \mathbf{x}_i^{(2)}, T = 0] = \hat{\alpha}(\mathbf{x}_i^{(2)})$ for each observation
<code>_Y1_</code>	value of $\mathbb{E}[Y \mathbf{X}^{(2)} = \mathbf{x}_i^{(2)}, T = 1] = \hat{\alpha}(\mathbf{x}_i^{(2)}) + \hat{\beta}(\mathbf{x}_i^{(2)})$ for each observation
<code>_AVGPX_</code>	value of $\Pr(T = 1) = \frac{\sum_{i=1}^N \mathbb{1}\{t_i=1\}}{n}$, where n the total number of observations. This is the unconditional probability that a treatment equals 1. The value is identical for each observation.
<code>_px_</code>	value of $p(\mathbf{x}_i^{(1)}) = \Pr(T = 1 \mathbf{X}^{(1)} = \mathbf{x}_i^{(1)})$ for each observation
<code>_alpha_</code>	value of $\hat{\alpha}(\mathbf{x}_i^{(2)})$ for each observation
<code>_beta_</code>	value of $\hat{\beta}(\mathbf{x}_i^{(2)})$ for each observation
<code>_eps_</code>	value of $y_i - \mathbb{E}[Y \mathbf{X}^{(2)} = \mathbf{x}_i^{(2)}, T = t_i] = y_i - \hat{\alpha}(\mathbf{x}_i^{(2)}) - \hat{\beta}(\mathbf{x}_i^{(2)})t_i$ for each observation
<code>_mu0_</code>	value of $\psi_{\mu_0}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$
<code>_mu1_</code>	value of $\psi_{\mu_1}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$
<code>_ATE_</code>	value of $\psi_{\text{ATE}}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$
<code>_rho00_</code>	value of $\psi_{0,0}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$
<code>_rho01_</code>	value of $\psi_{0,1}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$
<code>_rho10_</code>	value of $\psi_{1,0}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$
<code>_rho11_</code>	value of $\psi_{1,1}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$
<code>_ATT_</code>	value of $\psi_{\text{ATT}}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$
<code>_deltaX_</code>	value of $\psi_{\Delta_X}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$
<code>_ATU_</code>	value of $\psi_{\text{ATU}}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$
<code>_delta__</code>	value of $\psi_{\Delta}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$. NOTE: In releases through 2023.03, this variable is named <code>_delta_</code> . Because of a conflict with some reserved SAS system variables, it has been renamed <code>_delta__</code> (with two final underscores) as of release 2023.04.

- `_policy_policy-var_` value of $\psi_{\pi(s)}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$, where s is the value of a policy variable that you specify in the `POLICY=(policy-variable-list)` option in the `INFER` statement. The estimate is displayed for each policy variable.
- `_policy_comparison_policy-var_base-var_` value of $\psi_{\pi(s_c, s_b)}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$, where s_c is the value of a policy variable, `POLICY-VAR`, that you specify in the `POLICYCOMPARISON(COMPARE=(compare-list))` option in the `INFER` statement and s_b is the value of a policy variable, `BASE-VAR`, that you specify in the `POLICYCOMPARISON(BASE=(base-list))` option in the `INFER` statement. The estimate is displayed for each combination of s_c and s_b .

ODS Table Names

The DEEPCAUSAL procedure assigns a name to each table that it creates. You can use these names to refer to the tables when you use the Output Delivery System (ODS) to select tables and create output data tables.

These names are listed in [Table 15.2](#).

Table 15.2 ODS Tables Produced in the DEEPCAUSAL Procedure

ODS Table Name	Description	Option
NObs	Number of observations	Default
ParameterEstimates	Full-population parameter estimates	Default
PolicyEvaluation	Policy evaluation	POLICY=
PolicyComparison	Policy comparison	POLICYCOMPARISON=
SubPopulationEstimates	Subpopulation parameter estimates	Default

Examples: DEEPCAUSAL Procedure

Example 15.1: Treatment Effect of Unemployment Insurance Bonus on Unemployment Duration

This example investigates the incentive effect of unemployment insurance (UI) by analyzing the Pennsylvania Reemployment Bonus experiment that was conducted by the US Department of Labor from July 1988 to October 1989. In the experiment, each UI claimant was randomly assigned to the control group or to one of the bonus treatment groups. The UI claimants in the treatment groups were given a corresponding bonus if they found a job within the specified qualification period. The amount of the bonus and the length of the qualification period varied across different treatment groups; the fourth treatment group had the most generous bonus offer—the highest bonus amount for the longest qualification period. For the UI claimants in the control group, no bonus was offered.

The report of the experiment with raw data is provided by W. E. Upjohn Institute for Employment Research at <https://www.upjohn.org/data-tools/employment-research-data-center/pennsylvania-reemployment-bonus-demonstration>. The public-use data consist of two files. This example examines the records file that contains administrative data for individuals from the participant tracking system and data for selected ineligible claimants.

The following statements load the data set of the records file into the data set `mydata` and then delete the duplicated rows:

```
/*---load .dta data set---*/
proc import out=mydata file="/dept/app/doc/viya/en/src/casecon/deepcausal/Recsfile.dta"
  dbms=dta replace;
run;
/*---delete duplicated rows---*/
proc sort data = mydata out = mydata nodupkey;
  by _all_;
run;
```

The variables for duration of unemployment (`inuidur1`), treatment group code (`tg`), age group dummies (`agelt35` and `agegt54`), gender dummy (`female`), race dummies (`black`, `hispanic`, and `othrace`), number of dependents (`dep`), quarters of the experiment (`q1–q6`), major industry code (`sic`), and locations (`site1–site12`) are selected from the data set `mydata`. The other variables are ignored. The following statements select the corresponding variables and delete rows that have missing values:

```
/*---select variables---*/
data mydata;
  set mydata (keep = tg inuidur1 female black hispanic
    othrace dep q1-q6 agelt35 agegt54 site1-site12 sic);
run;

/*---delete rows with missing values---*/
data mydata;
  set mydata;
  if cmiss(of _all_) then delete;
run;
```

This example splits the occupations of the claimants into two categories: durable manufacturing (`durable`) and other occupations. The durable manufacturing dummy variable is created using the major industry code (see <https://www.osha.gov/data/sic-manual> and <https://www2.deloitte.com/us/en/insights/economy/spotlight/economics-insights-analysis-04-2019.html>). The location variables are split into three categories: areas that had a low unemployment rate and a short duration of unemployment (`lusrd`), areas that had a high unemployment rate and a short duration of unemployment (`husrd`), and other areas. Moreover, only the most generous treatment group 4 (`tg=4`) is incorporated. Treatment group 6 (`tg=6`) and treatment group 4 had only one difference: treatment group 4 was offered the job-search workshop, and treatment group 6 was not. Although claimants in treatment group 4 were offered the workshop, only a few of them attended it eventually. Thus, treatment groups 4 and 6 are merged into one treatment group. The following statements complete the previously mentioned data set modification and load the data into the data set `selectData`:

```
data selectData;
  set mydata;
  /*---durable occupation dummy---*/
  if sic in (24 14 33 34 35 36 37 38 39) then durable = 1;
```

```

else durable = 0;
/*---lud dummy---*/
if site1 = 1 or site4 = 1 or site12 = 1 then lud = 1;
else lud = 0;
/*---husd dummy---*/
if site5 = 1 or site10 = 1 or site11 = 1 then husd = 1;
else husd = 0;
if tg=0 or tg=4 or tg=6 then output; /*group 4 and 6 will be merged later*/
run;

```

The treatment group (tg=4 or 6) is then assigned a value of 1, and the control group is treatment group 0 (tg=0). Finally, the binary treatment variable tg is ready for PROC DEEPCAUSAL. The outcome variable, logUldur, which represents the log of duration of unemployment, is computed, and the ID variable is also created. The following statements complete those modifications of selectData:

```

data selectData;
  set selectData;
  logUldur = log(inuidur1); * outcome variable;
  if tg=4 or tg=6 then tg=1; * merge group 4 and 6, binary treatment variable;
  i = _N_; * row id, PROC DEEPCAUSAL requires an ID variable;
run;

```

It is worth investigating whether the subjects are randomly assigned to the treatment group across the segments of each category covariate. The following statements generate the category variable quarter, which denotes the quarter index:

```

data selectData;
  set selectData;
  if q1 = 1 then quarter = 1;
  if q2 = 1 then quarter = 2;
  if q3 = 1 then quarter = 3;
  if q4 = 1 then quarter = 4;
  if q5 = 1 then quarter = 5;
  if q6 = 1 then quarter = 6;
run;

```

The following statements plot the mean of tg by quarter, which is shown in [Output 15.1.1](#). The mean of tg can be seen as the proportion of the treatment group, because tg is a binary treatment (tg=0 or 1).

```

proc sgplot data=selectData;
  vbar quarter / response=tg stat=mean;
  yaxis grid;
run;

```

Output 15.1.1 Proportion of Treatment by Quarter

Output 15.1.1 shows that the proportions of the treatment group of the fifth and sixth quarters are obviously different from the proportions of the other four quarters; that is, the proportion of the fifth or sixth quarter in the treatment group is different from proportions of the other four quarters. Thus, the subjects of the experiment are not randomly assigned to the treatment group across the six quarters.

To verify this conclusion, the following statements use PROC FREQ with the CHISQ option to test whether there is an association between the two category variables, tg and quarter:

```
proc freq data=selectData;
  tables tg*quarter / chisq cellchi2;
run;
```

The results are listed in Output 15.1.2, which shows that tg is significantly associated with quarter.

Output 15.1.2 Frequency Table and Chi-Square Test Results**The FREQ Procedure**

Frequency Cell Chi-Square Percent Row Pct Col Pct	Table of tg by quarter							
	tg(treatment group)	quarter						Total
		1	2	3	4	5	6	
	0	44	722	822	779	939	246	3552
		0.6998	6.1408	9.6928	9.0052	48.099	26.367	
		0.65	10.68	12.16	11.52	13.89	3.64	52.54
		1.24	20.33	23.14	21.93	26.44	6.93	
		46.32	47.91	47.13	47.18	65.85	72.78	
	1	51	785	922	872	487	92	3209
		0.7746	6.7971	10.729	9.9677	53.241	29.186	
		0.75	11.61	13.64	12.90	7.20	1.36	47.46
		1.59	24.46	28.73	27.17	15.18	2.87	
		53.68	52.09	52.87	52.82	34.15	27.22	
	Total	95	1507	1744	1651	1426	338	6761
		1.41	22.29	25.80	24.42	21.09	5.00	100.00

Statistic	DF	Value	Prob
Chi-Square	5	210.6996	<.0001
Likelihood Ratio Chi-Square	5	215.3130	<.0001
Mantel-Haenszel Chi-Square	1	132.3424	<.0001
Phi Coefficient		0.1765	
Contingency Coefficient		0.1738	
Cramer's V		0.1765	

In the same way, you can test whether the subjects of the experiment are randomly assigned to the treatment group across segments of other category variables, such as female.

Before you investigate the causal effect of tg by using PROC DEEPCAUSAL, the following statements calculate the descriptive statistics of the outcome variables for the control and treatment groups, respectively:

```
proc means data=selectData;
  class tg;
  var logUIdur;
run;
```

The results are shown in [Output 15.1.3](#).

Output 15.1.3 Summary Statistics for the Control and Treatment Groups**The MEANS Procedure**

Analysis Variable : logUIdur						
treatment group	N Obs	N	Mean	Std Dev	Minimum	Maximum
0	3552	3552	1.9660014	1.2567128	0	3.9512437
1	3209	3209	1.8938635	1.2391991	0	3.9512437

The statistical inference can be used to test whether the association, $\mathbb{E}[\log UIdur|tg = 1] - \mathbb{E}[\log UIdur|tg = 0]$, is significantly less than 0. However, directly considering the association statistical inference result to be ATE

is biased because the experiment is not fully randomized. Thus, the experiment is seen as an observational study.

The following DATA step loads the data set `selectData` into a data table in your session that is associated with the `mylib` libref. The DATA step assumes that your libref is named `mylib`, but you can substitute any appropriately defined libref.

```
data mylib.selectData;
    set selectData;
run;
```

The following statements use PROC DEEPCAUSAL to estimate ATE and other parameters of interest of the treatment variable, `tg`:

```
proc deepcausal data=mylib.selectData;
    id i;
    psmodel tg=female black othrace dep q2 q3 q4 q5 q6 age1t35
        age1t54 durable lused husd / dnn=(nodes=(32 32 32 32)
        train=(optimizer=(miniBatchSize=125
            regL1=0.35 regL2=0.004 maxEpochs=1000
            algorithm=adam(learningRate=0.025))
            nthreads=5 seed=12345));
    model logUIdur=female black othrace dep q2 q3 q4 q5 q6 age1t35
        age1t54 durable lused husd / dnn=(nodes=(32 32 32 32)
        train=(optimizer=(miniBatchSize=120
            regL1=0.0035 regL2=0.0035 maxEpochs=1000
            algorithm=adam(learningRate=0.0005))
            nthreads=5 seed=12345));
    infer out=mylib.oest outdetails=mylib.odetails;
run;
```

The number of observations is shown in [Output 15.1.4](#).

Output 15.1.4 Number of Observations

The DEEPCAUSAL Procedure

Number of Observations	6761
Observations with Missing Covariates	0
Observations with Missing Covariates for PS Model	0
Observations with Missing Covariates for Outcome Model	0
Observations with Missing Outcome	0

The estimates of parameters of interest are shown in [Output 15.1.5](#), which shows that ATE on log unemployment duration is significantly negative at the 5% level.

Output 15.1.5 Parameters of Interest

Population Parameter Estimates								
Parameter	Potential Outcome	Estimate	Standard Error	95% Confidence Limits		Z	Pr > Z

Example 15.2: Personalized Discount Policy for an Online Media Company

This example illustrates how a music subscription service from an online media company can offer targeted discounts through a personalized pricing plan based on many features that it observes about its customers to encourage them to buy more songs or become members. The main goal is to construct a policy that raises demand enough to boost overall revenue despite decreasing the price for some customers.

The data set is provided by the Microsoft research project ALICE and is available at https://msalicedatapublic.z5.web.core.windows.net/datasets/Pricing/pricing_sample.csv. The data set has 10,000 simulated observations that represent customers’ personal characteristics, such as age and log income, and online behavior history, such as previous purchase and previous online time per week. The treatment variable, t , is a binary variable that indicates whether or not a discount is applied. This variable is generated according to the values that the variable price takes in the data set. The value of t is 0 if the value of price is 1, indicating that no discount is given, and the value of t is 1 if the value of price is less than 1, indicating that a discount is applied. The outcome variable, revenue, is calculated by multiplying the number of songs purchased during the discount season by the price paid for the songs. Table 15.3 shows the names of the variables that are used in the model, their types, and their definitions. The type can be T (treatment), Y (outcome), $x^{(1)}$ (a covariate in the propensity score model), and/or $x^{(2)}$ (a covariate in the outcome model).

Table 15.3 Model Variables

Name	Type	Details
account_age	$x^{(1)}, x^{(2)}$	User's account age
age	$x^{(1)}, x^{(2)}$	User's age
avg_hours	$x^{(1)}, x^{(2)}$	Average number of hours user was online per week in the past
days_visited	$x^{(1)}, x^{(2)}$	Average number of days user visited website per week in the past
friend_count	$x^{(1)}, x^{(2)}$	Number of friends user connected to in account
has_membership	$x^{(1)}, x^{(2)}$	Whether user has membership
is_US	$x^{(1)}, x^{(2)}$	Whether user accesses website from US
songs_purchased	$x^{(1)}, x^{(2)}$	Average number of songs user purchased per week in the past
income	$x^{(1)}, x^{(2)}$	User's income
t	T	Whether a discount is applied
revenue	Y	Number of songs purchased during discount season times price paid

Assuming that you have downloaded the data set `pricing_sample` in your session that is associated with the `mylib` libref, the following statements create an ID variable that has a unique value for each observation, the treatment variable (`t`), and the outcome variable (`revenue`) in the data table `new_pricing_sample`:

```
data mylib.new_pricing_sample;
  set mylib.pricing_sample;
  id = put(_threadid_, 8.) || '_' || Put(_n_, 8.); * ID variable;
  if price<1 then t=1; else t=0; * treatment variable;
  revenue=price*demand; * outcome variable;
run;
```

The first step in policy evaluation and policy optimization is to estimate the effect of the treatment and to save to a specified output data table the details of the estimation, including $\alpha(\cdot)$, $\beta(\cdot)$, $p(\cdot)$, the residual, and the influence functions for each unit. You can do this by using the following statements:

```
/*--- Estimate the treatment effect and save the estimation details ---*/
proc deepcausal data=mylib.new_pricing_sample;
  id id;
  psmodel t = account_age age avg_hours days_visited friends_count
    has_membership is_US songs_purchased income /
    dnn=(nodes=(32 32 32 32))
    train=(optimizer=(miniBatchSize=500 regL1=0.0001 maxEpochs=32000
    algorithm=adam) nthreads=20 seed=12345 recordseed=67890));
  model revenue = account_age age avg_hours days_visited friends_count
    has_membership is_US songs_purchased income /
    dnn=(nodes=(32 32 32 32))
    train=(optimizer=(miniBatchSize=500 regL1=0.001 maxEpochs=32000
    algorithm=adam) nthreads=20 seed=12345 recordseed=67890));
  infer out=mylib.oest outdetails=mylib.odetails;
run;
```

For this example, the same covariates are used in both the propensity score model and the outcome model. The model estimation details are saved in the output data table `odetails`.

The estimation results are shown in [Output 15.2.1](#). The estimate of the average treatment effect, ATE, is negative and statistically significant, suggesting that the discount, on average, causes revenue that is generated

by the whole population to decrease. However, the effect of the discount on the revenue among the customers who received a discount, which is measured by the parameter ATT (average treatment effect on the treated), is considerably different from the ATE estimate. It might suggest that identifying the characteristics of customers to whom the discount matters would help construct the optimum policy so that it uses the fewest resources and earns the most profit.

Output 15.2.1 Parameters of Interest

The DEEPCAUSAL Procedure

Population Parameter Estimates

Composition Effect	1		-5.304422	0.305935	-5.904044	-4.704799	-17.34 <.0001
Observed Difference			-7.081225	0.330048	-7.728108	-6.434342	-21.46 <.0001

In policy optimization, the goal is to maximize the expected utility of a policy. For the definition of the expected utility function and how it is estimated, as well as details such as the definition of a policy rule, see the section “[Policy Evaluation and Comparison](#)” on page 937. In this example, because a positive treatment effect is preferred, anyone whose $\beta(x_i)$ value is positive should be given the treatment (that is, a discount). This function is sometimes referred to as the individual treatment effect (ITE).

The variable `_beta_` in the data table `odetails` that is obtained during the previous estimation contains the estimated values for this function for each individual. You can construct an optimal policy by offering a discount to individuals whose `_beta_` value is positive. For comparison, the following DATA steps create the optimal policy, `s2`, along with the other policies: `s0`, offer no one a discount; and `s1`, offer everyone a discount.

```
data mylib.discountPolicy;
  set mylib.odetails;
  s0 = 0; * treat none;
  s1 = 1; * treat all;
  s2 = _beta_ >= 0; * treat only individuals whose ITEs are positive;
  keep id t account_age age avg_hours days_visited
        friends_count has_membership is_US songs_purchased
        income revenue s0 s1 s2;
run;
```

You can do policy evaluation by specifying the POLICY= option in the INFER statement and do policy comparison by specifying the POLICYCOMPARISON= option in the same statement. The following statements estimate the model and do policy evaluation and comparison:

```

/*--- Policy evaluation and comparison ---*/
proc deepcausal data=mylib.discountPolicy;
  id id;
  psmodel t = account_age age avg_hours days_visited friends_count
              has_membership is_US songs_purchased income /
              dnn=(nodes=(32 32 32 32))
              train=(optimizer=(miniBatchSize=500 regL1=0.0001
              maxEpochs=32000 algorithm=adam) nthreads=20
              seed=12345 recordseed=67890));
  model revenue = account_age age avg_hours days_visited friends_count
                  has_membership is_US songs_purchased income /
                  dnn=(nodes=(32 32 32 32))
                  train=(optimizer=(miniBatchSize=500 regL1=0.001
                  maxEpochs=32000 algorithm=adam) nthreads=20
                  seed=12345 recordseed=67890));
  infer policy=(t s0 s1 s2) policyComparison=(base=(t)
          compare=(s0 s1 s2))
          out=mylib.oest2 outdetails=mylib.odetails2;
run;

```

The option POLICY=(t s0 s1 s2) requests that the policy evaluation be done for the initial discount policy (t), the policy of giving no one a discount (s0), the policy of giving everyone a discount (s1), and the personalized discount policy of giving a discount only to those whose `_beta_` value is positive (s2). The suboption COMPARE=(s0 s1 s2) in the POLICYCOMPARISON= option indicates that the policies s0, s1, and s2 are to be compared to the base policy, t, which is specified by the suboption BASE=(t), also in the POLICYCOMPARISON= option.

The policy evaluation results are shown in [Output 15.2.2](#).

Output 15.2.2 Policy Evaluation

The DEEPCAUSAL Procedure

Policy Evaluation						
Policy	Estimate	Standard Error	95% Confidence Limits		Z	Pr > Z
t	14.383749	0.068443	14.249603	14.517895	210.16	<.0001
s0	14.309670	0.074717	14.163227	14.456112	191.52	<.0001
s1	13.592299	0.058081	13.478463	13.706135	234.02	<.0001
s2	14.835283	0.069198	14.699658	14.970909	214.39	<.0001

The optimal policy, s2, indeed has the highest estimate. When the discount is given to customers whose ITE is positive, the average outcome, which in this example is the revenue for each person, is higher than the average outcome that is obtained by the base policy. This is the largest revenue that is generated, and it is generated by the personalized discount policy.

[Output 15.2.3](#) shows the output for the policy comparison. Negative values indicate that the corresponding discount policy is worse than the base policy, and positive values indicate that the corresponding discount policy is better than the base policy. As expected, s2, giving the discount to the right person, produces the

best results.

Output 15.2.3 Policy Comparison

Policy Comparison							
Comparison Policy	Base Policy	Estimate	Standard Error	95% Confidence Limits		Z	Pr > Z
s0	t	-0.074079	0.017349	-0.108082	-0.040077	-4.27	<.0001
s1	t	-0.791450	0.014168	-0.819218	-0.763681	-55.86	<.0001
s2	t	0.451535	0.015455	0.421243	0.481826	29.22	<.0001

Overview: DEEPPRICE Procedure

The DEEPPRICE procedure estimates the average causal effect and performs policy evaluation and policy comparison by using deep neural networks (DNNs) when the treatment variable is continuous. DNNs overcome several technical difficulties in the big data era, including the following:

- the huge amount of discrete or continuous potential covariates
- the unknown nonlinear relationships among the covariates, the outcome, and the treatment variables

A problem in applying DNNs to causal inference is interpretability. To solve this problem, the DEEPPRICE procedure applies DNNs via a two-step semiparametric framework (see the section “[Details: The DEEPPRICE Procedure](#)” on page 982) and provides inferential results for the parameters of interest through the corresponding influence functions.

The DEEPPRICE procedure can estimate two types of causal effects (or parameters of interest): the average intercept and the average slope. For more information, see the section “[Average Intercept and Slope Parameters](#)” on page 987. The procedure can also perform policy evaluation and policy comparison. For more information, see the section “[Policy Evaluation and Comparison](#)” on page 990. PROC DEEPPRICE supports the SCORE statement, which enables you to save causal model specifications and estimation results for scoring and policy evaluation and comparison without needing to reestimate the DNNs for these models.

Tools for causal analysis of nonrandomized data are available in the following procedures:

- The CAUSALGRAPH procedure enables you to analyze graphical causal models and to construct sound statistical strategies for causal effect estimation. For more information, see Chapter 37, “The CAUSALGRAPH Procedure” (*SAS/STAT User’s Guide*).
- The PSMATCH procedure enables you to perform propensity score analyses and to assess covariate balance. For more information, see Chapter 101, “The PSMATCH Procedure” (*SAS/STAT User’s Guide*).
- The CAUSALTRT procedure enables you to estimate a causal effect. For more information, see Chapter 39, “The CAUSALTRT Procedure” (*SAS/STAT User’s Guide*).
- The CAUSALMED procedure enables you to decompose a (total) causal effect into direct and indirect effects. For more information, see Chapter 38, “The CAUSALMED Procedure” (*SAS/STAT User’s Guide*).
- The DEEPCAUSAL procedure enables you to estimate the average causal effect and perform policy evaluation and policy comparison by using deep neural networks (DNNs) when the treatment variable is binary. For more information, see Chapter 15, “[DEEPCAUSAL Procedure](#).”
- The MODEL, PANEL, QLIM, and TMODEL procedures in SAS/ETS and the CPANEL and CQLIM procedures in SAS Econometrics support endogenous variables and instrumental variables. For more information, see Chapter 24, “MODEL Procedure” (*SAS/ETS User’s Guide*), Chapter 25, “PANEL Procedure” (*SAS/ETS User’s Guide*), Chapter 27, “QLIM Procedure” (*SAS/ETS User’s Guide*), Chapter 39, “TMODEL Procedure” (*SAS/ETS User’s Guide*), Chapter 11, “CPANEL Procedure,” and Chapter 12, “CQLIM Procedure.”

- The VARMAX procedure supports Granger causality tests. For more information, see Chapter 42, “VARMAX Procedure” (*SAS/ETS User’s Guide*).

PROC DEEPPRICE requires SAS Cloud Analytic Services (CAS) in order to run, and it does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- exploits all the available cores and concurrent threads

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the `mylib` CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “[Introduction to Shared Concepts](#)” on page 54 in Chapter 4, “[Shared Concepts](#).”

Getting Started: DEEPPRICE Procedure

This section provides two examples that demonstrate some of the capabilities of the DEEPPRICE procedure.

A Demand-Price Example When the Price Is Not Endogenous

This example illustrates how the DEEPPRICE procedure enables you to estimate the parameters of interest and perform policy evaluation and policy comparison when the treatment variable is not endogenous. In this case, the instrumental variable is not needed. This example also demonstrates how you can save the model information and use it later to score other new data.

A simulated data set is generated, based on the following assumptions:

- The treatment variable, scaled flight price (denoted by p), is continuous, and its value ranges from 0.01 to 75, inclusive.
- The outcome variable, demand (denoted by y), is continuous and nonnegative.
- There are two covariates:
 - The customer type (denoted by s), is discrete, and its value ranges from 1 to 10, inclusive.
 - The time (denoted by t) is continuous, and its value ranges from 0 to 12, exclusive.
- The disturbance in the treatment model is independent of the disturbance in the outcome model; this implies that the treatment variable is not endogenous.

The treatment model is given as

$$\begin{aligned}
 p &= \eta_0(t) + \eta, \quad \eta \stackrel{\text{iid}}{\sim} N(0, 1) \\
 \eta_0(t) &= 5 + 0.3\psi(t) \\
 \psi(t) &= 2 \left(\frac{50}{3} \left(\frac{t-6}{12} \right)^4 + \exp \left(-400 \left(\frac{t-6}{12} \right)^2 \right) + \frac{t}{12} - \frac{41}{20} \right)
 \end{aligned}$$

where $\psi(\cdot)$ describes the seasonality.

The outcome model is given as

$$\begin{aligned}
 y &= \alpha(s, t) + \beta(s, t)p + \epsilon, \quad \epsilon \stackrel{\text{iid}}{\sim} N(0, 0.25) \\
 \alpha(s, t) &= 30 + 0.1s\psi(t) \\
 \beta(s, t) &= 0.1s\psi(t) - 0.2
 \end{aligned}$$

Note that ϵ and η are uncorrelated, which implies that the scaled flight price is not endogenous.

The following statements simulate 12,500 samples that are based on the treatment and outcome models that were just presented:

```

%macro deepPriceGenerateData(n,rho,seed);
  data deepPriceDGP;
    call streaminit('pcg', &seed.);
    rho = &rho.;
    do i = 1 to &n.;
      s = floor(rand('Uniform')*10+1);
      t = rand('Uniform')*12;
      z = rand('Normal',0,1);
      eta = rand('Normal',0,1);
      psi = 2*((t-6)/12*(t-6)/12*(t-6)/12*(t-6)/12*50/3
        +exp(-400*(t-6)/12*(t-6)/12)+t/12-41/20);
      eta0 = 5+0.3*psi;
      eta1 = 0.1*psi;
      if(rho ^= 0) then p = eta0 + eta1*z + eta;
      else p = eta0 + eta;
      plb = 0.01;
      pub = 75;
      if(p<plb) then p=plb;
      if(p>pub) then p=pub;

      eps = rand('Normal',rho*eta,0.25);
      alpha = 30 + 0.1*s*psi;
      beta = 0.1*s*psi - 0.2;
      if(beta>0) then beta=0;
      y0 = alpha + beta*p;
      y = y0 + eps;
      if(y<0) then y = 0;

      * the realized revenue;
      R = y * p;
      R0 = y0 * p;

      * the best price to maximize the revenue,
        which cannot be obtained without knowing DGP;
      if(beta<0) then pstar = -alpha/beta/2;
      else pstar = pub;
      ystar = alpha + beta * pstar;
      * the maximized expected revenue;
      Rstar = ystar * pstar;

      output;
    end;
  run;
%mend;

%let n=12500;
%let rho = 0;
%let seed=12346;
%deepPriceGenerateData(&n.,&rho.,&seed.);

```

The following DATA steps load the first 10,000 observations of the data set deepPriceDGP into the data table simPrice_train and the next 2,500 observations into the data table simPrice_test in your session that is associated with the mylib libref. The DATA steps assume that your libref is named mylib, but you can

substitute any appropriately defined libref.

```
data mylib.simPrice_train;
  set deepPriceDGP(obs=10000 keep=i s t p y R pstar);
run;

data mylib.simPrice_test;
  set deepPriceDGP(firstobs=10001 keep=i s t p y R pstar);
run;
```

The unknown functions $\eta_0(\cdot)$, $\alpha(\cdot)$, and $\beta(\cdot)$ are estimated through two DNNs by using the data set `simPrice_train`. The parameters of interest are then estimated, and policy evaluation and policy comparison are performed. The following statements use PROC DEEPPRICE to perform these tasks and store the model information and parameter learning results:

```
proc deepprice data=mylib.simPrice_train;
  id i;
  tmodel p=s t / dnn=(nodes=(32 32 32 32)
    train=(optimizer=(miniBatchSize=2000 regL1=0.001 maxEpochs=2000
      algorithm=adam) nthreads=5 seed=12346 recordseed=12346));
  model y=s t / dnn=(nodes=(32 32 32 32)
    train=(optimizer=(miniBatchSize=2000 regL1=0.001 maxEpochs=4000
      algorithm=adam) nthreads=5 seed=12346 recordseed=12346));
  infer policy=(pstar) policyComparison=(base=(p) compare=(pstar))
    out=mylib.oest outdetails=mylib.odetails;
  score outt=mylib.outtdata outa=mylib.outadata outb=mylib.outbdata;
run;
```

Note that specifying the `SEED=` and `RECORDSEED=` option values does not guarantee that you get identical results each time you run the DEEPPRICE procedure in single-machine or distributed computing mode. This is because the execution environment is the combination of the operating environment and the number of threads (single-machine mode) or the number of worker nodes, together with the number of threads that are used for execution on each worker node (distributed computing mode).

The `OUTT=` option writes the treatment model information to the data table `outtdata`, the `OUTA=` option writes the $\alpha(\cdot)$ estimation information to the data table `outadata`, and the `OUTB=` option writes the $\beta(\cdot)$ estimation information to the data table `outbdata`. The number of observations is shown in Figure 16.1.

Figure 16.1 Number of Observations

The DEEPPRICE Procedure

Number of Observations	10000
Observations with Missing Covariates	0
Observations with Missing Covariates for Treatment Model	0
Observations with Missing Covariates for Outcome Model	0
Observations with Missing Outcome	0
Observations with Missing Treatment	0

The estimates of parameters of interest are shown in Figure 16.2.

Figure 16.2 Parameters of Interest

Parameter Estimates						
Parameter	Estimate	Standard	95%		Z	Pr > Z
		Error	Confidence Limits			
Average Intercept	28.442737	0.032558	28.378925	28.506549	873.61	<.0001
Average Slope	-1.515271	0.011544	-1.537896	-1.492646	-131.27	<.0001

The policy evaluation estimates the expected demand of a policy. The policy evaluation results are shown in Figure 16.3.

Figure 16.3 Policy Evaluation

Policy Evaluation						
Policy	Estimate	Standard	95%		Z	Pr > Z
		Error	Confidence Limits			
pstar	14.671826	0.107646	14.460845	14.882808	136.30	<.0001

The policy comparison estimates the difference in expected demand of two policies. The policy comparison results are shown in Figure 16.4.

Figure 16.4 Policy Comparison

Policy Comparison						
Comparison Policy	Base Policy	Estimate	Standard Error	95% Confidence Limits		Z Pr > Z
pstar	p	-7.273572	0.111963	-7.493016	-7.054129	-64.96 <.0001

According to the comparison of the two policies, the policy p in the observed data generates more demand on average than the policy $pstar$; however, this does not mean that p generates more revenue than $pstar$! In fact, in the real world, although $pstar$ is theoretically the best policy to maximize revenue, it cannot be available because it requires the unknown functions $\alpha(\cdot)$ and $\beta(\cdot)$. Because of the availability of the true data generating process (DGP), the revenue that the optimized policies generate that is suggested by the plug-in estimator and influence-function estimator can be compared to that of the best-in-theory infeasible policy $pstar$. The following statements compare the actual function values in the true DGP to the estimates of $\eta_0(\cdot)$, $\alpha(\cdot)$, and $\beta(\cdot)$, which are `_that_`, `_alpha_`, and `_beta_`, respectively, in the `oDetails` data table in your session; compare the revenues that are generated through different policies; and use PROC MEANS to get the bias and variance of each estimator:

```
proc sort data=mylib.odetails out=odetails_tmp;
  by i;
run;

data odetails;
  merge odetails_tmp(in=a) deepPriceDGP(in=b where=(i<=10000));
  by i;
  diff_eta0 = _that_ - eta0;
  diff_alpha = _alpha_ - alpha;
  diff_beta = _beta_ - beta;
  * revenue difference between observed policy and best policy;
  diff_R = R0 - Rstar;
```

```

* pipstar, the optimized policy suggested by plug-in estimator;
if(_beta_<0) then pipstar = -_alpha/_beta_/2;
else pipstar = pub;
if(pipstar>pub) then pipstar = pub;
if(pipstar<plb) then pipstar = plb;
piystar = alpha + beta * pipstar;
if(piystar<0) then piystar=0;
piRstar = piystar * pipstar;
* revenue difference between plug-in optimized policy and best policy;
diff_piR = piRstar - Rstar;
* ifpstar, the optimized policy suggested by influence-function
  estimator;
if(_if_beta_<0) then ifpstar = -_if_alpha/_if_beta_/2;
else ifpstar = pub;
if(ifpstar>pub) then ifpstar = pub;
if(ifpstar<plb) then ifpstar = plb;
ifystar = alpha + beta * ifpstar;
if(ifystar<0) then ifystar=0;
ifRstar = ifystar * ifpstar;
* revenue difference between influence-function optimized policy and
  best policy;
diff_ifR = ifRstar - Rstar;
run;

proc means data=odetails;
  var diff_eta0 diff_alpha diff_beta diff_R diff_ifR diff_piR;
run;

```

The results are displayed in Figure 16.5, which shows that all three estimated functions are unbiased.

Figure 16.5 Summary Statistics of Difference between Actual Value and Estimate

The MEANS Procedure

Variable	N	Mean	Std Dev	Minimum	Maximum
diff_eta0	10000	0.0513895	0.1463623	-0.4907291	0.2826009
diff_alpha	10000	-0.1021674	0.6435525	-2.4314195	1.5739562

You can apply the previously saved treatment model, the $\alpha(\cdot)$ estimation information, and the $\beta(\cdot)$ estimation information to a new data set by specifying the INT=, INA=, and INB= options, respectively, in the SCORE statement. The following statements use the outtdata, outadata, and outbdata data tables as input data tables and then estimate the parameters of interest and perform the policy evaluation and comparison by using the simPrice_test data table:

```

proc deepprice data=mylib.simPrice_test;
  id i;
  infer policy=(pstar) policyComparison=(base=(p) compare=(pstar))
    out=mylib.oest2 outdetails=mylib.odetails2;
  score int=mylib.outtdata ina=mylib.outadata inb=mylib.outbdata;
run;

```

When you specify the INT=, INA=, and INB= options in the SCORE statement, you do not need to specify the TMODEL or MODEL statement. The estimates of the parameters of interest and the results of the policy evaluation and policy comparison are shown in [Figure 16.6](#).

Figure 16.6 Parameters of Interest, Policy Evaluation, and Policy Comparison

For more information about the estimates of parameters of interest, policy evaluation, and policy comparison, see the sections “[Average Intercept and Slope Parameters](#)” on page 987 and “[Policy Evaluation and Comparison](#)” on page 990.

A Demand-Price Example When the Price Is Endogenous

This example illustrates how the DEEPPRICE procedure estimates the parameters of interest and performs policy evaluation and policy comparison when the treatment variable is endogenous. In this case, the instrumental variable should be used. This example also demonstrates how you can save the model information and use it later to score other new data.

A simulated data set is generated, based on the following assumptions:

- The treatment variable, scaled flight price (denoted by p), is continuous, and its value ranges from 0.01 to 75, inclusive.
- The outcome variable, demand (denoted by y), is continuous and nonnegative.
- The instrumental variable, normalized oil price (denoted by z), is continuous and available.
- There are two covariates:
 - The customer type (denoted by s) is discrete, and its value ranges from 1 to 10, inclusive.
 - The time (denoted by t) is continuous, and its value ranges from 0 to 12, exclusive.

- The disturbance in the treatment model is correlated with the disturbance in the outcome model. This implies that the treatment variable is endogenous.

The treatment model is given as

$$\begin{aligned}
 p &= \eta_0(t) + \eta_1(t)z + \eta, \quad \eta \stackrel{\text{iid}}{\sim} N(0, 1) \\
 \eta_0(t) &= 5 + 0.3\psi(t) \\
 \eta_1(t) &= 0.1\psi(t) \\
 \psi(t) &= 2 \left(\frac{50}{3} \left(\frac{t-6}{12} \right)^4 + \exp \left(-400 \left(\frac{t-6}{12} \right)^2 \right) + \frac{t}{12} - \frac{41}{20} \right)
 \end{aligned}$$

where $\psi(\cdot)$ describes the seasonality.

The outcome model is given as

$$\begin{aligned}
 y &= \alpha(s, t) + \beta(s, t)p + \epsilon, \quad \epsilon \stackrel{\text{iid}}{\sim} N(2\eta, 0.25) \\
 \alpha(s, t) &= 30 + 0.1s\psi(t) \\
 \beta(s, t) &= 0.1s\psi(t) - 0.2
 \end{aligned}$$

Note that ϵ and η are correlated, which indicates that the scaled flight price is endogenous.

The following statements simulate 12,500 samples that are based on the treatment and outcome models that were just presented:

```

%let n=12500;
%let rho = 2;
%let seed=12346;
%deepPriceGenerateData(&n., &rho., &seed.);

```

The following DATA steps load the first 10,000 observations of the data set `deepPriceDGP` into the data table `simPrice_train` and the next 2,500 observations into the data table `simPrice_test` in your session that is associated with the `mylib` libref. The DATA steps assume that your libref is named `mylib`, but you can substitute any appropriately defined libref.

```

data mylib.simPrice_train;
  set deepPriceDGP(obs=10000 keep=i s t z p y R pstar);
run;

data mylib.simPrice_test;
  set deepPriceDGP(firstobs=10001 keep=i s t z p y R pstar);
run;

```

The unknown functions $\eta_0(\cdot)$, $\eta_1(\cdot)$, $\alpha(\cdot)$, and $\beta(\cdot)$ are estimated through two DNNs by using the `simPrice_train` data table. The parameters of interest are then estimated, and the policy evaluation and policy comparison are performed. The instrumental variable is introduced into the model by using the `INSTRUMENT` statement. The following statements use PROC DEEPPRICE to perform these tasks and store the model information and parameter learning results:

```

proc deepprice data=mylib.simPrice_train;
  id i;
  instrument z;
  tmodel p=s t / dnn=(nodes=(32 32 32 32)
    train=(optimizer=(miniBatchSize=2000 regL1=0.001 maxEpochs=2000
      algorithm=adam) nthreads=5 seed=12346 recordseed=12346));
  model y=s t / dnn=(nodes=(32 32 32 32)
    train=(optimizer=(miniBatchSize=2000 regL1=0.001 maxEpochs=8000
      algorithm=adam) nthreads=5 seed=12346 recordseed=12346));
  infer policy=(pstar) policyComparison=(base=(p) compare=(pstar))
    out=mylib.oest outdetails=mylib.odetails;
  score outeta0=mylib.outeta0data outeta1=mylib.outeta1data
    outa=mylib.outadata outb=mylib.outbdata;
run;

```

The OUTETA0= option writes the $\eta_0(\cdot)$ estimation information to the data table outeta0data, the OUTETA1= option writes the $\eta_1(\cdot)$ estimation information to the data table outeta1data, the OUTA= option writes the $\alpha(\cdot)$ estimation information to the data table outadata, and the OUTB= option writes the $\beta(\cdot)$ estimation information to the data table outbdata. The number of observations is shown in Figure 16.7.

Figure 16.7 Number of Observations

The DEEPPRICE Procedure

Number of Observations	10000
Observations with Missing Covariates	0
Observations with Missing Covariates for Treatment Model	0

pstar	10.807473	6.861139	-2.640113	24.255058	1.58	0.1152

The policy comparison estimates the difference in expected demand between two policies. The policy comparison results are shown in Figure 16.10.

Figure 16.10 Policy Comparison

Policy Comparison							
Comparison Policy	Base Policy	Estimate	Standard Error	95% Confidence Limits		Z	Pr > Z
pstar	p	-10.975870	6.871267	-24.443305	2.491566	-1.60	0.1102

According to the comparison of two policies, the policy p in the observed data generates more demand on average than the policy $pstar$; however, this does not mean that p generates more revenue than $pstar$! In fact, in the real world, although $pstar$ is theoretically the best policy to maximize revenue, it cannot be available because it needs the unknown functions $\alpha(\cdot)$ and $\beta(\cdot)$. Because of the availability of the true data generating process (DGP), the revenue that the optimized policies generate that is suggested by the plug-in estimator and influence-function estimator can be compared to that of the best-in-theory infeasible policy $pstar$. The following statements compare the actual function values in the true DGP to the estimates of $\eta_0(\cdot)$, $\eta_1(\cdot)$, $\alpha(\cdot)$, and $\beta(\cdot)$, which are `_eta0_`, `_eta1_`, `_alpha_`, and `_beta_`, respectively, in the `oDetails` data table in your session; compare the revenues that are generated through different policies; and use PROC MEANS to get the bias and variance of each estimator:

```
proc sort data=mylib.odetails out=odetails_tmp;
  by i;
run;

data odetails;
  merge odetails_tmp(in=a) deepPriceDGP(in=b where=(i<=10000));
  by i;
  diff_eta0 = _eta0_ - eta0;
  diff_eta1 = _eta1_ - eta1;
  diff_alpha = _alpha_ - alpha;
  diff_beta = _beta_ - beta;
  * revenue difference between observed policy and best policy;
  diff_R = R0 - Rstar;
  * ifpstar, the optimized policy suggested by influence-function
    estimator;
  if(_if_beta_ < 0) then ifpstar = -_if_alpha_/_if_beta_/2;
  else ifpstar = pub;
  if(ifpstar > pub) then ifpstar = pub;
  if(ifpstar < plb) then ifpstar = plb;
  ifystar = alpha + beta * ifpstar;
  if(ifystar < 0) then ifystar = 0;
  ifRstar = ifystar * ifpstar;
  * revenue difference between influence-function optimized policy and
    best policy;
  diff_ifR = ifRstar - Rstar;
  * pipstar, the optimized policy suggested by plug-in estimator;
  if(_beta_ < 0) then pipstar = -_alpha_/_beta_/2;
  else pipstar = pub;
  if(pipstar > pub) then pipstar = pub;
  if(pipstar < plb) then pipstar = plb;
  piystar = alpha + beta * pipstar;
```

```

    if(piystar<0) then piystar=0;
    piRstar = piystar * pipstar;
    * revenue difference between plug-in optimized policy and best policy;
    diff_piR = piRstar - Rstar;
run;

proc means data=odetails;
    var diff_eta0 diff_eta1 diff_alpha diff_beta diff_R diff_ifR diff_piR;
run;

```

The results are displayed in Figure 16.11, which shows that all four estimated functions are unbiased and also that the plug-in optimized policy is the best feasible policy.

Figure 16.11 Summary Statistics for Differences
The MEANS Procedure

Variable	N	Mean	Std Dev	Minimum	Maximum
diff_eta0	10000	-0.0054662	0.1393846	-0.5600274	0.2398572
diff_eta1	10000	-0.0101667	0.0514571	-0.2134025	0.0734339
diff_alpha	10000	-0.0288887	2.4017872	-4.2549535	8.2332300
diff_beta	10000	0.0440188	0.5654596	-1.8312735	1.3122532
diff_R	10000	-115.5029685	153.9612042	-996.3512062	-2.001858E-7
diff_ifR	10000	-132.0524553	148.7798031	-990.7514537	-2.105923E-8
diff_piR	10000	-76.3508287	133.3256657	-813.2234595	-4.053138E-8

You can apply the previously saved $\eta_0(\cdot)$ estimation information, $\eta_1(\cdot)$ estimation information, $\alpha(\cdot)$ estimation information, and $\beta(\cdot)$ estimation information to a new data set by specifying the INETA0=, INETA1=, INA=, and INB= options, respectively, in the SCORE statement. The following statements use the outeta0data, outeta1data, outadata, and outbdata data tables as input data tables and then estimate the parameters of interest and perform the policy evaluation and comparison by using the simPrice_test data table:

```

proc deepprice data=mylib.simPrice_test;
    id i;
    instrument z;
    infer policy=(pstar) policyComparison=(base=(p) compare=(pstar))
        out=mylib.oest2 outdetails=mylib.odetails2;
    score ineta0=mylib.outeta0data ineta1=mylib.outeta1data
        ina=mylib.outadata inb=mylib.outbdata;
run;

```

When you specify the INETA0=, INETA1=, INA=, and INB= options in the SCORE statement, you do not need to specify the TMODEL or MODEL statement. The estimates of parameters of interest and the results of the policy evaluation and policy comparison are shown in Figure 16.12.

Syntax: DEEPPRICE Procedure

The following statements are available in the DEEPPRICE procedure. Items within angle brackets (<>) are optional.

```

PROC DEEPPRICE options ;
  DNN options ;
  ID variable ;
  INFER <options> ;
  INSTRUMENT variable ;
  MODEL outcome-variable <=covariates> </options> ;
  SCORE options ;
  TMODEL treatment-variable <=covariates> </options> ;

```

Functional Summary

The statements and options available in the DEEPPRICE procedure are summarized in Table 16.1. The sections after the table provide a description of each statement in alphabetical order, following the PROC DEEPPRICE statement.

Table 16.1 Functional Summary

PROC DEEPPRICE Statement

PROC DEEPPRICE *options* ;

The PROC DEEPPRICE statement invokes the DEEPPRICE procedure. You must specify the following *option*:

DATA=*libref.data-table*

names the input data table for PROC DEEPPRICE to use. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

data-table specifies the name of the input data table.

NOTE: The input data table must not contain any of the reserved variables (case-insensitive): *_PSHAT_*, *_YHAT_*, *_Y0_*, *_Y1_*, *_AVGPX_*, *_px_*, *_alpha_*, *_beta_*, *_eps_*, *_mu0_*, *_mu1_*, *_ate_*, *_rho00_*, *_rho01_*, *_rho10_*, *_rho11_*, *_att_*, *_atu_*, *_deltaX_*, *_delta_*, *_that_*, *_eta0_*, *_eta1_*, *_iv_rename_*, *_DL_PRED_*, *_epst_*, *_epsy_*, *_treatment_rename_*, *_alphanatilda_*, *_betatilda_*, *_if_alpha_*, or *_if_beta_*.

DNN Statement

DNN < *options* > ;

The DNN statement specifies the parameters for the deep neural network (DNN). It includes options that are related to the DNNs for the treatment model and outcome model. You can specify the following *options*:

NODES=(*numeric-list*)

specifies the number of nodes for each hidden layer in the DNN, where each value in the *numeric-list* must be a positive number and values are separated by commas or spaces. The length of the list specifies the number of layers, and each value specifies the number of nodes for the corresponding layer. If the length of the list is denoted by n , then the i th ($1 \leq i \leq n$) value denotes the number of nodes for the i th layer. By default, NODES=(32 32 32 32), which yields four hidden layers, with 32 nodes in each layer.

TRAIN=(*train-options*)

specifies the options that you can use to train the DNN. You can specify one or more of the following *train-options*:

GPU=(< (*gpu-options*) >)

specifies that the DNN perform calculations by using graphics processing unit (GPU) hardware. You can specify the following *gpu-options*:

DEVICE=(*numeric-list*)

DEVICES=(*numeric-list*)

specifies a list of GPU devices to use.

PRECISION=FP16 | FP32

specifies the computational precision in forward-backward computations. You can specify the following values:

FP16	uses half-precision (16-bit floating-point) computations to train and score the DNN. The lower computational precision in forward-backward computations can encourage tensor-core engagements.
FP32	uses single-precision (32-bit floating-point) computations to train and score the DNN.

By default, PRECISION=FP32.

USEEXCLUSIVE

specifies that only GPU devices be used.

USETensorRT

enables the use of the TensorRT software development kit for fast inference.

MISSING=MAX | MEAN | MIN | NONE

specifies the policy to use for replacing missing input covariate values with imputed values. You can specify one of the following policies:

MAX	replaces missing values with the maximum of the corresponding covariate.
MEAN	replaces missing values with the mean of the corresponding covariate.
MIN	replaces missing values with the minimum of the corresponding covariate.
NONE	ignores observations that have missing values.

By default, MISSING=MEAN. The MISSING= option is for DNN training only. In the inference that is performed later, observations that have missing covariates are removed.

NTHREADS=number

specifies the number of threads to use for the DNN.

OPTIMIZATION=(optimizer-options)**OPTIMIZE=(optimizer-options)****OPTIMIZER=(optimizer-options)**

specifies the settings for the optimization algorithm and optimization mode, as well as other settings, such as a seed, the maximum number of epochs, and so on. You can specify the following *optimizer-options*:

ALGORITHM=algorithm-keyword<(common-algorithm-options)>

specifies the optimization algorithm and the corresponding options. First, you can specify some options common to all the optimization algorithms, *common-algorithm-options*, in the parentheses that follow the *algorithm-keyword*. They are as follows:

CLIPGRADMAX=number

specifies the maximum gradient value. All gradient values that exceed the specified maximum value are set to the specified maximum value. The *number* should be greater than or equal to 0.

CLIPGRADMIN=number

specifies the minimum gradient value. All gradient values that are less than the specified minimum value are set to the specified minimum value. The *number* should be less than or equal to 0.

FCMPEARLYSTOPPING=symbol-name**FCMPES=symbol-name**

specifies the function compiler (FCMP) early stopping function.

FCMPLEARNINGRATE=symbol-name**FCMPLR=symbol-name**

specifies the function compiler (FCMP) learning rate function.

GAMMA=number

specifies the gamma value for the learning rate policy. The *number* must be between 0 and 100, exclusive. By default, GAMMA=0.1.

LEARNINGRATE=number

specifies the learning rate (a positive value) for stochastic gradient descent (SGD). By default, LEARNINGRATE=0.001.

LEARNINGRATEPOLICY=FIXED | INV | MULTISTEP | POLY | STEP**LRPOLICY=FIXED | INV | MULTISTEP | POLY | STEP**

specifies the learning rate policy. You can specify one of the following values:

FIXED	specifies a fixed learning rate.
INV	sets the learning rate option value after each epoch, according to the initial learning rate, the value of the GAMMA= option (γ), and the value of the POWER= option. The rate is calculated as $\text{learningRate} * (1 + \gamma * \text{currentEpoch})^{-\text{power}}$.
MULTISTEP	sets the learning rate after each of the epochs that you specify in the STEPS= option. The updated learning rate is the product of the previous learning rate value and the GAMMA= option value.
POLY	sets the learning rate option value after each epoch, according to the initial learning rate, the maximum number of epochs, and the value of the POWER= option. The rate is calculated as $\text{learningRate} * (1 - \text{currentEpoch}/\text{maxEpochs})^{\text{power}}$.
STEP	sets the learning rate option by multiplying the current learning rate option value by the GAMMA= option value. The number of steps is specified in the STEPSIZE= option. The configured learning rate is recalculated for each group of epochs, according to the step size.

By default, LEARNINGRATEPOLICY=FIXED.

NOUSELOCKING

computes gradients asynchronously with multiple threads.

POWER=number

specifies the power for the learning rate policy. The *number* must be nonnegative. By default, POWER=0.75.

STEPS=(numeric-list)

specifies a list of epoch counts. When the current epoch matches one of the specified steps, the learning rate is multiplied by the value of the GAMMA= option. For example, if you specify STEPS=(5 9 13), then the learning rate is multiplied by the GAMMA= option value after the 5th, 9th, and 13th epochs.

STEPSIZE=number

specifies the step size (a value greater than or equal to 1) when the learning rate policy is set to STEP. By default, STEPSIZE=10.

For the ALGORITHM= option, you can specify one of the following *algorithm-keywords* and its associated options:

ADAM<(adam-options)>**ADAMSGD<(adam-options)>**

specifies the adaptive moment estimation (ADAM) optimization algorithm. For the *adam-options*, you can specify one or more of the *common-algorithm-options*. You can also specify the following *adam-options*:

BETA1=number

specifies the exponential decay rate for the first moment in an ADAM learning algorithm. The *number* must be in the range [0, 1). By default, BETA1=0.9.

BETA2=number

specifies the exponential decay rate for the second moment in an ADAM learning algorithm. The *number* must be in the range [0, 1). By default, BETA2=0.999.

By default, ALGORITHM=ADAM.

COMPRESSION=(compression-options)

makes communication between workers more sparse for faster training by using gradient sparsification, a distributed training technique that makes stochastic gradients more sparse to reduce communication costs. You can specify one or more of the following *compression-options*:

LOCALMOMENTUM=number

determines the strength of aggregation on the masked gradient elements when compression is used. The *number* must be in the range [0, 1]. By default, LOCALMOMENTUM=0.95.

SAMPLERATIO=number

determines the number of samples for gradients in each layer. The *number* must be in the range $[10^{-5}, 0.2]$. By default, SAMPLERATIO=0.05.

SPARSITYRATIO=number

determines the number of samples for gradients in each layer. The *number* must be in the range $[0, 1]$. By default, SPARSITYRATIO=0.75.

DROPOUT=number

specifies the probability that the output of a neuron in a fully connected layer will be set to 0 during training. This probability is recalculated each time an observation is processed. The *number* must be in the range $[0, 1)$. By default, DROPOUT=0.

DROPOUTINPUT=number

specifies the probability that an input variable will be set to 0 during training. This probability is recalculated each time an observation is processed. The *number* must be in the range $[0, 1)$. By default, DROPOUTINPUT=0.

DROPOUTTYPE=INVERTED | STANDARD

specifies what type of dropout to use. You can specify one of the following types:

INVERTED	uses the inverted dropout, in which activations of some neurons are set to 0 and the remaining activations are scaled.
STANDARD	uses the standard dropout, in which activations of some neurons are set to 0 and the remaining activations are not scaled.

By default, DROPOUTTYPE=STANDARD.

FCONV=number

specifies the relative function convergence criterion. If the relative loss error, $\text{abs}[(\text{previous_loss} - \text{current_loss})/\text{previous_loss}]$, does not result in a change in the objective function, the optimization stops. The *number* must be greater than or equal to 0. By default, FCONV=0, and the relative function convergence is not checked.

FREEZEBATCHNORMSTATS**FREEZEBNSTATS**

freezes statistics of all batch normalization layers.

IGNORETRAININGERROR

continues model training without interruption by ignoring the issue of training data observations containing invalid or missing variable data. If you omit this option, training stops and PROC DEEPPRICE terminates when bad input data are found.

MAXEPOCHS=number

specifies the maximum number of epochs. The *number* must be greater than or equal to 1. By default, MAXEPOCHS=1. For SGD with a single-machine server, or for a session that uses one worker on a distributed server, one epoch is reached when the optimizer passes through the data one time. For a session that uses more than one worker, one epoch is reached when all the workers exchange the weights with the controller one time. The SYNCFREQ= option specifies the number of times that each worker passes through the

data before exchanging weights with the controller. For the L-BFGS optimization algorithm with a full batch, each iteration might process more than one epoch, and the final number of epochs might exceed the parameter value for the maximum number of epochs.

MINIBATCHBUFSIZE=*number*

specifies the number of observations to buffer in memory (including input data and intermediate calculations) before processing the remaining records in the minibatch. The *number* must be greater than or equal to 1 and must be smaller than the *number* that you specify for the MINIBATCHSIZE= option. The MINIBATCHBUFSIZE= option setting is ignored when GPUs are used.

MINIBATCHSIZE=*number*

specifies the number of observations per thread in a minibatch. The parameter controls the number of observations that are used

per worker in each thread to compute the gradient, prior to updating the weights. Larger values use more memory. The *number* is greater than or equal to 1. By default, MINIBATCHSIZE=1. When you use synchronous SGD (the default), the total minibatch size is calculated as miniBatchSize * number of threads * number of workers. When you use asynchronous SGD by specifying the ELASTICSYNCFREQ= option, each worker trains its own local model. In this case, the total minibatch size for each worker is calculated as miniBatchSize * number of threads. You can specify values for either the MINIBATCHSIZE= or TOTALMINIBATCHSIZE= option, but not for both.

MODE=*optimization-mode*

specifies the optimization mode and the corresponding options. You can specify one of the following values:

DOWNPOUR

specifies the downpour optimization mode.

ELASTIC<(elastic-options)>

specifies the elastic optimization mode. You can specify the following *elastic-options*:

ALPHA=*number*

ELASTICALPHA=*number*

specifies the significance level (a value between 0 and 1, inclusive) that is used for elastic SGD. By default, ALPHA=0.

ELASTICSYNCFREQ=*number*

SYNCFREQ=*number*

specifies the frequency (a nonnegative value) for communication between the workers and controller for exchanging weights. You can exchange the weights more often than once each epoch by specifying a *number* that is less than the number of batches in an epoch. If the *number* is greater than the number of batches in an epoch, then the weights are exchanged once each epoch. By default, ELASTICSYNCFREQ=0.

SYNCHRONOUS<(SYNCFREQ=*number*)>

specifies the synchronous optimization mode. The SYNCFREQ= option, which is not required, specifies the synchronization frequency for SGD in terms of epochs. By default, SYNCFREQ=1.

By default, MODE=SYNCHRONOUS.

NOBNSRCLAYERWARNINGS

suppresses the warning if the batch normalization source layer has an atypical type or activation setting.

REGL1=*number*

specifies the weight for the L1 regularization term. The *number* must be greater than or equal to 0. By default, REGL1=0. At the default setting, PROC DEEPPRICE does not perform L1 regularization. Initial L1 weight values should be small (such as 1E-3). You can combine L1 regularization with L2 regularization.

REGL2=*number*

specifies the weight for the L2 regularization term. The *number* must be greater than or equal to 0. By default, REGL2=0. At the default setting, PROC DEEPPRICE does not perform L2 regularization. Initial L2 weight values should be small (such as 1E-3). You can combine L2 regularization with L1 regularization.

SEED=*number*

specifies the random number seed value for the random number generator in the L-BFGS optimization algorithm. Seed values less than or equal to 0 generate random number streams by using the time of day from the computer's clock. Seed values greater than 0 generate reproducible random number sequences. By default, SEED=0.

SNAPSHOTFREQ=*number*

specifies the frequency for generating snapshots of the neural weights and storing the weights in a weight table during the training process. When you specify asynchronous SGD by specifying the ELASTICSYNCFREQ= option, PROC DEEPPRICE synchronizes all the weights before writing out the weights. The *number* must be greater than or equal to 0. By default, SNAPSHOTFREQ=0.

STAGNATION=*number*

specifies the number of iterations to complete without improvement before stopping the optimization early. The *number* must be greater than or equal to 0. By default, STAGNATION=0; this turns off the stagnation monitoring.

THRESHOLD=*number*

specifies the threshold that is used to determine whether the loss error or validation scores are improving or stagnating across iterations. The iteration does not improve when the magnitude of the score change between successive iterations is less than or equal to the absolute value of current_score * threshold value. When an iteration does not improve, the stagnation counter increments. Otherwise, the stagnation counter is set to 0. The *number* must be greater than or equal to 0. By default, THRESHOLD=10⁻⁸.

TOTALMINIBATCHSIZE=(totalminibatchsize-options)

specifies the number of observations in a minibatch. You can specify one or more of the following *totalminibatchsize-options*:

NONOTIFY

suppresses the message that is printed if the total minibatch size is rounded up.

ROUND

rounds up the total minibatch size.

SIZE=number**N=number**

specifies the number of observations in a minibatch. The computation for the total minibatch size is $nWorkers * miniBatchSize * nThreads$. For example, a two-worker scenario with a minibatch size of 10 and 32 threads per worker has a total minibatch size of $2 * 32 * 10 = 640$ records.

You can use these options to control the number of observations that the DNN uses to compute the gradient prior to updating the weights. Larger values use more memory. If the specified size cannot be evenly divided by the number of threads (if you are using asynchronous SGD) or by the number of threads * number of workers (if you are using synchronous SGD), then PROC DEEPPRICE terminates with an error unless you specify the ROUND option. In that case, the total minibatch size is rounded up so that it is evenly divided. You can specify values for either the MINIBATCHSIZE= or TOTALMINIBATCHSIZE= option, but not for both.

RECORDSEED=number

specifies the random number seed for random record selection within a worker. Records are read in the order in which they are written in memory. Seed values that are less than or equal to 0 generate random number streams by using the time of day from the computer's clock. Seed values greater than 0 generate reproducible random number sequences. By default, RECORDSEED=0; this disables random record selection.

SEED=number

specifies the random number seed value for the random number generator in SGD. Seed values that are less than or equal to 0 generate random number streams by using the time of day from the computer's clock. Seed values greater than 0 generate reproducible random number sequences. By default, SEED=0.

TARGETMISSING=MAX | MEAN | MIN | NONE

specifies the policy to use for replacing missing outcome variables with imputed values. You can specify one of the following policies:

MAX	replaces missing values with the maximum.
MEAN	replaces missing values with the mean value.
MIN	replaces missing values with the minimum.
NONE	ignores observations that have missing target variables.

By default, TARGETMISSING=MEAN. The TARGETMISSING= option is for DNN training only. In the inference that is performed later, observations that have missing outcome variables have missing values for residuals and for any estimates that need residuals.

ID Statement

ID *variable* ;

The ID statement specifies the ID variable in the data set. The *variable* must have a unique value for each row in the input data table. If it does not, PROC DEEPPRICE issues an error.

INFER Statement

INFER *options* ;

The INFER statement specifies the parameters for inference. You can specify one or more of the following *options*:

OUT=*libref.data-table*

OUTEST=*libref.data-table*

writes the estimation of the parameters of interest and the policy evaluation and policy comparison results to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

OUTDETAILS=*libref.data-table*

writes the details of the estimation, including $\alpha(\cdot)$, $\beta(\cdot)$, $p(\cdot)$, the residual, and the influence functions for each unit, to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

POLICY=(*policy-variable-list*)

specifies the list of policy variables to be evaluated. All symbol names that the user specifies in the *policy-variable-list* must correspond to the policy variables; the symbol names are separated by spaces.

POLICYCOMPARISON=(*comparison-options*)

specifies the options for policy comparison. You must specify the following *comparison-options*:

BASE=(*base-list*)

specifies a list of policy variables, each of which is used as a base policy in the policy comparison. All symbol names that the user specifies in the *base-list* must correspond to the policy variables; the symbol names are separated by spaces.

COMPARE=(compare-list)

specifies a list of policy variables, each of which is compared to each base policy that you specify in the BASE= option. All symbol names that the user specifies in the *compare-list* must correspond to the policy variables; the symbol names are separated by spaces.

INSTRUMENT Statement

INSTRUMENT *variable* ;

The INSTRUMENT statement specifies the instrumental variable in the data table. The *variable* must be numeric in the input data table.

The instrumental variable cannot be the same as any of the following: the ID variable that you specify in the ID statement; the treatment variables or covariates that you specify in the TREATMENT statement; or the outcome variable or covariates that you specify in the MODEL statement.

When you are scoring by using the INT=, INETA0=, or INETA1= option in the SCORE statement for a treatment model that contains the instrumental variable, you must specify the INSTRUMENT statement in exactly same way (by using the same instrumental variable name) that you specify the INSTRUMENT statement used in the previous call of PROC DEEPPRICE that generates the corresponding OUTT=, OUTETA0=, or OUTETA1= table.

MODEL Statement

MODEL *outcome-variable* <=*covariates*> </*options*> ;

The MODEL statement specifies options that are related to the outcome model and the DNN to fit the outcome model. The *outcome-variable* specifies the outcome variable of the outcome model. The *covariates* specify the covariates of the outcome model. If you omit the *covariates*, no DNN is trained for the outcome model. For more information about the outcome model, see the section “[Outcome Model](#)” on page 984. Covariate names must be separated by spaces. The treatment variable is automatically included in the outcome model as an independent variable.

You can specify the following *option* after a forward slash (/):

DNN=(dnn-options)

specifies the options of the DNN for the outcome model. If you omit the DNN= option and specify the DNN statement, the DNN for the outcome model has the options that you specify in the DNN statement. If you omit both the DNN= option and the DNN statement, the DNN for the outcome model uses the default option values. If you specify both the DNN= option and the DNN statement, the DNN statement is ignored for the outcome model. For the *dnn-options*, you can specify one or more options that are listed in the section “[DNN Statement](#)” on page 969. If no covariates are specified in the MODEL statement, the DNN= option is ignored.

SCORE Statement

SCORE options ;

The SCORE statement specifies options that are related to scoring data. You can specify the following options:

INA=*libref.data-table*

INALPHA=*libref.data-table*

specifies the input data table that contains information about $\alpha(\cdot)$ estimation. The data table must be an output data table that the OUTA= option produces in a previous call of PROC DEEPPRICE. When you specify the INA= option, you must also specify the INB= option, and the MODEL statement and the OUTA=, OUTB=, and OUTO= options in the SCORE statement are ignored. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

INB=*libref.data-table*

INBETA=*libref.data-table*

specifies the input data table that contains information about $\beta(\cdot)$ estimation. The data table must be an output data table that the OUTB= option produces in a previous call of PROC DEEPPRICE. When you specify the INB= option, you must also specify the INA= option, and the MODEL statement and the OUTA=, OUTB=, and OUTO= options in the SCORE statement are ignored. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

INETA0=*libref.data-table*

specifies the input data table that contains information about $\eta_0(\cdot)$ estimation. If you omit the INSTRUMENT statement, this option is ignored. The data table must be an output data table that the OUTETA0= option produces in a previous call of PROC DEEPPRICE. When you specify the INETA0= option, you must also specify the INETA1= option, and the TMODEL statement and the OUTETA0=, OUTETA1=, and OUTT= options in the SCORE statement are ignored. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

INETA1=*libref.data-table*

specifies the input data table that contains information about $\eta_1(\cdot)$ estimation. If you omit the INSTRUMENT statement, this option is ignored. The data table must be an output data table that the OUTETA1= option produces in a previous call of PROC DEEPPRICE. When you specify the INETA1= option, you must also specify the INETA0= option, and the TMODEL statement and the OUTETA0=, OUTETA1=, and OUTT= options in the SCORE statement are ignored. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

INO=libref.data-table**INOUTCOME=libref.data-table**

specifies the input data table that contains information about the outcome model. The data table must be an output data table that the OUTO= option produces in a previous call of PROC DEEPPRICE. When you specify the INO= option, the MODEL statement and the INA=, INB=, OUTA=, OUTB=, and OUTO= options in the SCORE statement are ignored. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

INT=libref.data-table**INPROPNESITYSCORE=libref.data-table**

specifies the input data table that contains information about the treatment model. The data table must be an output data table that the OUTT= option produces in a previous call of PROC DEEPPRICE. When you specify the INT= option, the TMODEL statement and the OUTT= option in the SCORE statement are ignored. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

OUTA=libref.data-table**OUTALPHA=libref.data-table**

writes the $\alpha(\cdot)$ estimation information to the specified output data table. The output data table consists of binary large object (BLOB) columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters, because the data type of each column is binary. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

OUTB=libref.data-table**OUTBETA=libref.data-table**

writes the $\beta(\cdot)$ estimation information to the specified output data table. The output data table consists of binary large object (BLOB) columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters, because the data type of each column is binary. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

OUTETA0=libref.data-table

writes the $\eta_0(\cdot)$ estimation information to the specified output data table. The output data table consists of binary large object (BLOB) columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters, because the data type of each column is binary. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

OUTETA1=libref.data-table

writes the $\eta_1(\cdot)$ estimation information to the specified output data table. The output data table consists of binary large object (BLOB) columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters, because the data type of each column is binary. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

OUTO=libref.data-table**OUTOUTCOME=libref.data-table**

writes the outcome model information to the specified output data table. The output data table consists of binary large object (BLOB) columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters, because the data type of each column is binary. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

OUTT=libref.data-table**OUTPROPENSITYSCORE=libref.data-table**

writes the treatment model information to the specified output data table. The output data table consists of binary large object (BLOB) columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters, because the data type of each column is binary. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 955.

TMODEL Statement

TMODEL *treatment-variable* <=*covariates*> </options> ;

The TMODEL statement specifies options that are related to the treatment model and the DNN that is used to fit the treatment model. The *treatment-variable* specifies the treatment variable of the treatment model. It corresponds to one numeric variable in the input data table. The *covariates* specify the covariates of the treatment model. All covariate names are separated by spaces. If you omit the *covariates* and also omit the INSTRUMENT statement, no DNN is trained for the treatment model. For more information about the treatment model, see the section “Treatment Model” on page 983.

You can specify the following *option* after a forward slash (/):

DNN=(dnn-options)

specifies the options of the DNN that is used to fit the treatment model. If you omit the DNN= option and specify the DNN statement, the DNN for the treatment model has the options that you specify in the DNN statement. If you omit both the DNN= option and the DNN statement, the DNN for the treatment model uses the default option values. If you specify both the DNN= option and the DNN statement, the DNN statement is ignored for the treatment model. For the *dnn-options*, you can specify

one or more options that are listed in the section “DNN Statement” on page 969. If no *covariates* are specified in the TMODEL statement, the DNN= option is ignored.

Details: The DEEPPRICE Procedure

Causal Inference Overview

Causal inference is the science of why. Many classical statistics models, such as linear regression, show how the outcome variable is associated with the covariates. It is well known that correlation does not equal causation. However, it is often not known whether a change in the outcome is caused by a change in the treatment. Randomized experiments provide a solution, but there are many constraints that often make the experiment impossible. For example, designing and then conducting the experiment is time-consuming and expensive. Moreover, an experiment might encounter some ethical issues that prevent the experiment from being conducted. Therefore, causal inference based on observational data is indispensable to answering the causal questions.

The DEEPPRICE procedure is designed primarily for observational data when the subjects are not randomly assigned to the treatment conditions. But in some situations the randomized trials need to be treated as observational studies. For example, you can randomly assign subjects to the treatment group, or you can use block randomization when there are several confounding variables. However, after the experiment, what if you discover a few more confounding variables? Or worse yet, what if the treatment and control groups do not have similar distributions across the segments of one or more new confounding variables? In these cases, instead of doing the experiment again, you need to estimate the causal effect by treating the experiment as an observational study. Moreover, selection bias can affect the estimation of the treatment effect. For example, suppose that there is a new version of a smartphone app, and the relevant notifications are sent to randomly selected individuals, who can be seen as the treatment group. In that case, the effect of the new app version on a certain outcome, such as the average time spent on the app every day, is worth investigating. The issue is that not everyone in the treatment group will download the new version. In the treatment group, those who download the new version are different from those who do not, and then selection bias arises. To avoid that bias, the control group can be compared to all subjects in the treatment group, no matter whether a particular individual downloads the app. The estimated treatment effect is no doubt diluted because some individuals in the treatment group are not actually treated. Again, one solution is to treat the experiment as an observational study.

PROC DEEPPRICE exploits deep neural networks (DNNs) for causal inference. It applies deep learning to causal inference in a two-step semiparametric framework: the nonparametric step and the parametric step. In the nonparametric step, two DNNs are used to estimate the unknown functions in the treatment model and outcome model. In the parametric step, parameters of interest are estimated through the corresponding influence functions.

For more information about using DNNs, see *SAS Viya: Deep Learning Programming Guide*.

Estimating Unknown Functions in Treatment and Outcome Models

There are two main models in causal inference: the treatment model and the outcome model. Two approximate DNNs are constructed to estimate these two models. The DEEPPRICE procedure supports one continuous treatment and one continuous outcome.

Treatment Model

Without an Instrumental Variable

The treatment model estimates the treatment value conditional on some covariates:

$$\mathbb{E}[T|\mathbf{X}^{(1)} = \mathbf{x}^{(1)}] = \eta(\mathbf{x}^{(1)})$$

where T denotes the continuous treatment and $\mathbf{x}^{(1)}$ is a vector of the observed covariates. The superscript (1) in $\mathbf{X}^{(1)}$ denotes the covariates in Set 1, which are the covariates used in the treatment model. The function $\eta(\cdot)$ is one unknown function to be estimated by a DNN.

The DNN for the treatment model, which is a regression predictor, predicts the continuous treatment by using the covariates in Set 1. It trains the observations in the input data set. The DNN is a fully connected multilayer perceptron (MLP). The input layer of that DNN corresponds to $\mathbf{X}^{(1)}$, and the output layer corresponds to the observed treatment variable. The activation functions for the hidden layers are all rectified linear unit (ReLU) functions, and the activation function for the output layer is an identity function. The loss function is the sum of squared error function.

If no covariates are used to predict the treatment ($\mathbf{X}^{(1)} = \emptyset$), then no DNN needs to be trained for the treatment model. The treatment model is predicted by

$$\mathbb{E}[T|\mathbf{X}^{(1)} = \emptyset] = \mathbb{E}[T] = \eta(\emptyset)$$

The parameter $\eta(\emptyset)$ is estimated through the sample mean of the treatment variable, $\frac{1}{n} \sum_{i=1}^n t_i$, where t_i denotes the treatment value of the i th observation and n denotes the number of observations.

With an Instrumental Variable

The treatment model estimates the treatment value conditional on some covariates and the instrumental variable:

$$\mathbb{E}[T|\mathbf{X}^{(1)} = \mathbf{x}^{(1)}, Z = z] = \eta_0(\mathbf{x}^{(1)}) + \eta_1(\mathbf{x}^{(1)})z$$

where T denotes the continuous treatment, Z denotes the instrumental variable, and $\mathbf{x}^{(1)}$ is a vector of the observed covariates. The superscript (1) in $\mathbf{X}^{(1)}$ denotes the covariates in Set 1, which are the covariates used in the treatment model. The functions $\eta_0(\cdot)$ and $\eta_1(\cdot)$ are two unknown functions to be estimated by a DNN.

The DNN for the treatment model, which is a regression predictor, predicts the continuous treatment by using the covariates in Set 1 and the instrumental variable. It trains the observations in the input data set. The DNN is a fully connected multilayer perceptron (MLP). The input layer of that DNN corresponds to $\mathbf{X}^{(1)}$. The activation functions for those hidden layers are rectified linear unit (ReLU) functions. After those hidden layers, there is a parameter layer with two neurons that correspond to $\eta_0(\mathbf{x}^{(1)})$ and $\eta_1(\mathbf{x}^{(1)})$. The activation functions for this parameter layer are linear functions. Subsequently, z is included, and $\eta_0(\mathbf{x}^{(1)}) + \eta_1(\mathbf{x}^{(1)})z$ is calculated as the result of the final output layer, which corresponds to the observed treatment variable. The activation function for the output layer is an identity function. The loss function is the sum of squared error function.

If no covariates are used to predict the treatment ($\mathbf{X}^{(1)} = \emptyset$), then no DNN needs to be trained for the treatment model. The treatment model is predicted by

$$\mathbb{E}[T|\mathbf{X}^{(1)} = \emptyset, Z = z] = \mathbb{E}[T|Z = z] = \eta_0(\emptyset) + \eta_1(\emptyset)z$$

The parameters $\eta_0(\emptyset)$ and $\eta_1(\emptyset)$ are the intercept and slope coefficients, respectively, in the linear projection of the treatment T on the instrumental variable Z , and they are estimated through ordinary least squares (OLS) regression; that is,

$$\eta_1(\emptyset) = \frac{\sum_{i=1}^n z_i t_i}{\sum_{i=1}^n z_i^2}$$

$$\eta_0(\emptyset) = \frac{1}{n} \sum_{i=1}^n t_i - \frac{\eta_1(\emptyset)}{n} \sum_{i=1}^n z_i$$

where t_i denotes the treatment value of the i th observation, z_i denotes the instrumental variable value of the i th observation, and n denotes the number of observations.

Outcome Model

Without an Instrumental Variable

The outcome model describes how the outcome depends on the treatment and some covariates in Set 2, which are the covariates used in the outcome model. The covariates in Set 1 might differ from those in Set 2. The DEEPPRICE procedure supports only one continuous outcome variable, and the outcome model is as follows:

$$\mathbb{E}[Y|\mathbf{X}^{(2)} = \mathbf{x}^{(2)}, T = t] = G(\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})t)$$

where Y is the outcome, t is the treatment, and $G(\cdot)$ is a known function. For example, $G(u)$ might be the identity function; that is, $G(u) = u$. The superscript (2) in $\mathbf{X}^{(2)}$ denotes the covariates in Set 2. In PROC DEEPPRICE, $G(\cdot)$ is the identity function. The functions $\alpha(\cdot)$ and $\beta(\cdot)$ are unknown functions to be estimated by a DNN.

The DNN for the outcome model, which is a regression predictor, predicts the outcome by using the covariates in Set 2 and the treatment variable. It trains the observations in the input data set. The input layer of that DNN corresponds to $\mathbf{X}^{(2)}$. After the hidden layers, there is a parameter layer with two neurons that correspond to $\alpha(\mathbf{x}^{(2)})$ and $\beta(\mathbf{x}^{(2)})$. The activation functions for this parameter layer are linear functions. Subsequently, t is included, and $G(\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})t)$ is calculated as the result of the final output layer. $G(\cdot)$ is set to the identity function in PROC DEEPPRICE, so $\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})t$ is output as the prediction.

If no covariates are used to predict the outcome ($\mathbf{X}^{(2)} = \emptyset$), then no DNN needs to be trained for the outcome model. The outcome model is predicted by

$$\mathbb{E}[Y|\mathbf{X}^{(2)} = \emptyset, T = t] = \mathbb{E}[Y|T = t]$$

Moreover, when $\mathbf{X}^{(2)} = \emptyset$, the functions $\alpha(\mathbf{x}^{(2)})$ and $\beta(\mathbf{x}^{(2)})$ are constants and are computed by

$$\beta(\emptyset) = \frac{\sum_{i=1}^n t_i y_i}{\sum_{i=1}^n t_i^2}$$

$$\alpha(\emptyset) = \frac{1}{n} \sum_{i=1}^n y_i - \frac{\beta(\emptyset)}{n} \sum_{i=1}^n t_i$$

where y_i denotes the outcome value of the i th observation, t_i denotes the treatment value of the i th observation, and n denotes the number of observations.

With an Instrumental Variable

The outcome model describes how the outcome depends on the treatment and some covariates in Set 2, which are the covariates used in the outcome model. The covariates in Set 1 might differ from those in Set 2. The DEEPPRICE procedure supports only one continuous outcome variable, and the outcome model is as follows:

$$\mathbb{E}[Y | \mathbf{X}^{(2)} = \mathbf{x}^{(2)}, T = t] = G(\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})t)$$

where Y is the outcome, t is the treatment, and $G(\cdot)$ is a known function. For example, $G(u)$ might be the identity function; that is, $G(u) = u$. The superscript (2) in $\mathbf{X}^{(2)}$ denotes the covariates in Set 2. In PROC DEEPPRICE, $G(\cdot)$ is the identity function. The functions $\alpha(\cdot)$ and $\beta(\cdot)$ are unknown functions to be estimated by a DNN. However, because the treatment variable is endogenous and the instrumental variable is required, the two-stage regression is applied: first, the treatment variable is predicted by using the covariates in Set 1 and the instrumental variable (see the section “With an Instrumental Variable” on page 983); then the treatment variable t is replaced by its prediction $\hat{t}$. That is,

$$\mathbb{E}[Y | \mathbf{X}^{(2)} = \mathbf{x}^{(2)}, T = \hat{t}] = G(\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})\hat{t})$$

The DNN for the outcome model, which is a regression predictor, predicts the outcome by using the covariates in Set 2 and the treatment variable. It trains the observations in the input data set. The input layer of that DNN corresponds to $\mathbf{X}^{(2)}$. After the hidden layers, there is a parameter layer with two neurons that correspond to $\alpha(\mathbf{x}^{(2)})$ and $\beta(\mathbf{x}^{(2)})$. The activation functions for this parameter layer are linear functions. Subsequently, t is included, and $G(\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})\hat{t})$ is calculated as the result of the final output layer. $G(\cdot)$ is set to the identity function in PROC DEEPPRICE, so $\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})\hat{t}$ is output as the prediction.

If no covariates are used to predict the outcome ($\mathbf{X}^{(2)} = \emptyset$), then no DNN needs to be trained for the outcome model. The outcome model is predicted by

$$\mathbb{E}[Y | \mathbf{X}^{(2)} = \emptyset, T = \hat{t}] = \mathbb{E}[Y | T = \hat{t}]$$

Moreover, when $\mathbf{X}^{(2)} = \emptyset$, the functions $\alpha(\mathbf{x}^{(2)})$ and $\beta(\mathbf{x}^{(2)})$ are constants and are computed by

$$\begin{aligned}\beta(\emptyset) &= \frac{\sum_{i=1}^n \hat{t}_i y_i}{\sum_{i=1}^n \hat{t}_i^2} \\ \alpha(\emptyset) &= \frac{1}{n} \sum_{i=1}^n y_i - \frac{\beta(\emptyset)}{n} \sum_{i=1}^n \hat{t}_i\end{aligned}$$

where y_i denotes the outcome value of the i th observation, $\hat{t}_i$ denotes the predicted treatment value of the i th observation, and n denotes the number of observations.

Estimating Parameters of Interest

A parameter of interest can be defined through the following structural model:

$$\theta_0 = \mathbb{E}[H(y, \mathbf{X}, T, \alpha(\mathbf{X}^{(2)}), \beta(\mathbf{X}^{(2)}); t^*)]$$

where θ_0 is a certain parameter of interest, $H(\cdot)$ is a known function that corresponds to θ_0 , $\mathbf{X}$ is the union of $\mathbf{X}^{(1)}$ and $\mathbf{X}^{(2)}$, and t^* is a fixed treatment value of interest. To obtain the expected value, a naive approach is to plug the DNN-based estimates $\hat{\alpha}(\mathbf{x}^{(2)})$ and $\hat{\beta}(\mathbf{x}^{(2)})$ into the structural model of θ_0 . This estimator, which is known as the plug-in estimator, is given by

$$\hat{\theta}_0 = \frac{1}{n} \sum_{i=1}^n H(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}); t^*)$$

where n is the sample size and the subscript i stands for the i th observation. For example, if T is continuous, then θ_0 is the estimator of the average slope when $H(y, \mathbf{X}, T, \alpha(\mathbf{X}^{(2)}), \beta(\mathbf{X}^{(2)}); t^*) = \beta(\mathbf{X}^{(2)})$. Then the plug-in estimator of the average slope is given by

$$\hat{\theta}_0 = \frac{1}{n} \sum_{i=1}^n \hat{\beta}(\mathbf{x}_i^{(2)})$$

This estimator might be highly biased, because the covariates might have both effects on the outcome and treatment assignment. One way to solve this problem is to use an estimator based on the influence function. With one treatment variable, Farrell, Liang, and Misra (2020) propose the following influence function for the case in which there is no instrumental variable:

$$\begin{aligned} \psi(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ = H(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) + \nabla \mathbf{H}(\mathbf{x}) \Lambda(\mathbf{x})^{-1} (1, t)' (y - G(\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})t)) \end{aligned}$$

where $\nabla \mathbf{H}(\mathbf{x}) = (\frac{\partial H}{\partial \alpha}, \frac{\partial H}{\partial \beta})$, $\Lambda(\mathbf{x}) = \mathbb{E}[\dot{G}(1, T)'(1, T) | \mathbf{X} = \mathbf{x}]$, and $\dot{G} = [dG(u)/du]_{u=\alpha(\mathbf{x}^{(2)})+\beta(\mathbf{x}^{(2)})t}$.

Because PROC DEEPPRICE sets $G(\cdot)$ to the identity function and supports one continuous treatment, $\dot{G} = 1$ and the inverse of $\Lambda(\mathbf{x})$ can be computed directly. The preceding influence function can be simplified as follows:

$$\begin{aligned} \psi(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ = H(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) \\ + \frac{\dot{H}_\alpha(\mathbf{x})(\lambda_2(\mathbf{x}) - \lambda_1(\mathbf{x})t) + \dot{H}_\beta(\mathbf{x})(\lambda_0(\mathbf{x})t - \lambda_1(\mathbf{x}))}{\lambda_2(\mathbf{x})\lambda_0(\mathbf{x}) - \lambda_1(\mathbf{x})^2} (y - \alpha(\mathbf{x}^{(2)}) - \beta(\mathbf{x}^{(2)})t) \end{aligned}$$

where $\lambda_j(\mathbf{x}) = \mathbb{E}[T^j | \mathbf{X} = \mathbf{x}]$, $j = 0, 1, 2$; $\dot{H}_\alpha(\mathbf{x}) = \frac{\partial H}{\partial \alpha}$; and $\dot{H}_\beta(\mathbf{x}) = \frac{\partial H}{\partial \beta}$. When the treatment variable is continuous,

$$\begin{aligned} \lambda_0(\mathbf{x}) &= \mathbb{E}[T^0 | \mathbf{X} = \mathbf{x}] = 1 \\ \lambda_1(\mathbf{x}) &= \mathbb{E}[T^1 | \mathbf{X} = \mathbf{x}] = \eta_0(\mathbf{x}) \\ \lambda_2(\mathbf{x}) &= \mathbb{E}[T^2 | \mathbf{X} = \mathbf{x}] = \sigma_t^2 + \eta_0^2(\mathbf{x}) \end{aligned}$$

where σ_t^2 is the variance of the treatment (regression) model and is used to approximate the conditional variance.

The estimator for the parameter of interest is given by

$$\hat{\theta}_0 = \frac{\sum_{i=1}^n \psi(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

This estimator is doubly robust, which means that the estimator is unbiased when either the treatment model or the outcome model is correct. The standard error of $\hat{\theta}_0$ is

$$\sigma(\hat{\theta}_0) = \frac{\sqrt{\sum_{i=1}^n (\psi(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*) - \hat{\theta}_0)^2}}{n}$$

For the case in which there is an instrumental variable, the influence function becomes

$$\begin{aligned} & \psi(y, \mathbf{x}, t, z, \tilde{\alpha}(\mathbf{x}), \tilde{\beta}(\mathbf{x}), \eta_0(\mathbf{x}^{(1)}), \eta_1(\mathbf{x}^{(1)}), \Lambda_Z, t^*) \\ &= H(y, \mathbf{x}, t, z, \tilde{\alpha}(\mathbf{x}), \tilde{\beta}(\mathbf{x}), \eta_0(\mathbf{x}^{(1)}), \eta_1(\mathbf{x}^{(1)}), \Lambda_Z, t^*) \\ &+ \nabla \mathbf{H}(\mathbf{x}) \begin{pmatrix} \Lambda_Z^{-1}(1, z)'(y - (\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})\hat{t})) \\ \Lambda_Z^{-1}(1, z)'(t - (\eta_0(\mathbf{x}^{(1)}) + \eta_1(\mathbf{x}^{(1)})z)) \end{pmatrix} \end{aligned}$$

where $\nabla \mathbf{H}(\mathbf{x}) = (\frac{\partial H}{\partial \tilde{\alpha}}, \frac{\partial H}{\partial \tilde{\beta}}, \frac{\partial H}{\partial \eta_0}, \frac{\partial H}{\partial \eta_1})$; $\Lambda_Z = \begin{pmatrix} 1 & \mu_z \\ \mu_z & \sigma_z^2 + \mu_z^2 \end{pmatrix}$ if you assume that z is independent of all covariates in $\mathbf{x}$; and μ_z and σ_z^2 are the sample mean and variance of z , respectively. Also, $\tilde{\alpha}(\mathbf{x}) = \alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})\eta_0(\mathbf{x}^{(1)})$ and $\tilde{\beta}(\mathbf{x}) = \beta(\mathbf{x}^{(2)})\eta_1(\mathbf{x}^{(1)})$; and $\hat{t} = \eta_0(\mathbf{x}^{(1)}) + \eta_1(\mathbf{x}^{(1)})z$.

For ease of presentation, the missing value is not indicated in the preceding equations. In practice, if $\psi(\cdot)$ is a missing value for $i = 1, \dots, n$, then it is ignored in both the denominator and numerator of the equation of $\hat{\theta}_0$ or $\sigma(\hat{\theta}_0)$. This policy is applied to all parameters of interest that are described in the sections “[Average Intercept and Slope Parameters](#)” on page 987 and “[Policy Evaluation and Comparison](#)” on page 990.

Next, the calculation of some common parameters of interest is introduced.

Average Intercept and Slope Parameters

There are two types of average parameters:

- $\mathbb{E}[\alpha(X)]$, the average intercept
- $\mathbb{E}[\beta(X)]$, the average slope

The two average parameters are estimated as follows:

- Average intercept, $\mathbb{E}[\alpha(X)]$

- Without an instrumental variable:

The influence function, denoted by $\psi_\alpha(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*)$, is defined by setting $H(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) = H_\alpha(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) = \alpha(\mathbf{x}^{(2)})$ in the influence

function. When $G(\cdot)$ is set to the identity function and the treatment is continuous, the influence function is simplified as

$$\begin{aligned}\psi_\alpha(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ &= \alpha(\mathbf{x}^{(2)}) + \frac{\lambda_2(\mathbf{x}) - \lambda_1(\mathbf{x})t}{\lambda_2(\mathbf{x})\lambda_0(\mathbf{x}) - \lambda_1(\mathbf{x})^2} (y - \alpha(\mathbf{x}^{(2)}) - \beta(\mathbf{x}^{(2)})t) \\ &= \alpha(\mathbf{x}^{(2)}) + \frac{\sigma_t^2 - \eta_0(\mathbf{x}^{(1)})(t - \eta_0(\mathbf{x}^{(1)}))}{\sigma_t^2} (y - \alpha(\mathbf{x}^{(2)}) - \beta(\mathbf{x}^{(2)})t)\end{aligned}$$

Then $\mathbb{E}[\alpha(X)]$ is estimated by

$$\mathbb{E}[\alpha(X)] = \frac{\sum_{i=1}^n \psi_\alpha(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

– With an instrumental variable:

The influence function, denoted by $\psi_\alpha(y, \mathbf{x}, t, z, \tilde{\alpha}(\mathbf{x}), \tilde{\beta}(\mathbf{x}), \eta_0(\mathbf{x}^{(1)}), \eta_1(\mathbf{x}^{(1)}), \Lambda_Z, t^*)$, is defined by setting

$$\begin{aligned}H(y, \mathbf{x}, t, z, \tilde{\alpha}(\mathbf{x}), \tilde{\beta}(\mathbf{x}), \eta_0(\mathbf{x}^{(1)}), \eta_1(\mathbf{x}^{(1)}), \Lambda_Z; t^*) \\ &= H_\alpha(y, \mathbf{x}, t, z, \tilde{\alpha}(\mathbf{x}), \tilde{\beta}(\mathbf{x}), \eta_0(\mathbf{x}^{(1)}), \eta_1(\mathbf{x}^{(1)}), \Lambda_Z; t^*) \\ &= \alpha(\mathbf{x}^{(2)}) = \tilde{\alpha}(\mathbf{x}) - \frac{\tilde{\beta}(\mathbf{x})}{\eta_1(\mathbf{x}^{(1)})} \eta_0(\mathbf{x}^{(1)})\end{aligned}$$

in the influence function. When $G(\cdot)$ is set to the identity function and the treatment is continuous, the influence function is simplified as

$$\begin{aligned}\psi_\alpha(y, \mathbf{x}, t, z, \tilde{\alpha}(\mathbf{x}), \tilde{\beta}(\mathbf{x}), \eta_0(\mathbf{x}^{(1)}), \eta_1(\mathbf{x}^{(1)}), \Lambda_Z, t^*) \\ &= \tilde{\alpha}(\mathbf{x}) - \frac{\tilde{\beta}(\mathbf{x})}{\eta_1(\mathbf{x}^{(1)})} \eta_0(\mathbf{x}^{(1)}) + \nabla \mathbf{H}_\alpha(\mathbf{x}) \begin{pmatrix} \Lambda_Z^{-1}(1, z)'(y - (\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})\hat{t})) \\ \Lambda_Z^{-1}(1, z)'(t - (\eta_0(\mathbf{x}^{(1)}) + \eta_1(\mathbf{x}^{(1)})z)) \end{pmatrix} \\ &= \tilde{\alpha}(\mathbf{x}) - \frac{\tilde{\beta}(\mathbf{x})}{\eta_1(\mathbf{x}^{(1)})} \eta_0(\mathbf{x}^{(1)}) \\ &\quad + (1)(\sigma_z^{-2}(\sigma_z^2 + \mu_z^2 - \mu_z z))(y - (\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})\hat{t})) \\ &\quad + (-\frac{\eta_0(\mathbf{x}^{(1)})}{\eta_1(\mathbf{x}^{(1)})})(-\mu_z + z)(y - (\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})\hat{t})) \\ &\quad + (-\frac{\tilde{\beta}(\mathbf{x})}{\eta_1(\mathbf{x}^{(1)})})(\sigma_z^{-2}(\sigma_z^2 + \mu_z^2 - \mu_z z))(t - (\eta_0(\mathbf{x}^{(1)}) + \eta_1(\mathbf{x}^{(1)})z)) \\ &\quad + (-\frac{\tilde{\beta}(\mathbf{x})}{\eta_1^2(\mathbf{x}^{(1)})} \eta_0(\mathbf{x}^{(1)}))(-\mu_z + z)(t - (\eta_0(\mathbf{x}^{(1)}) + \eta_1(\mathbf{x}^{(1)})z))\end{aligned}$$

where $\nabla \mathbf{H}_\alpha(\mathbf{x}) = (1, -\frac{\eta_0(\mathbf{x}^{(1)})}{\eta_1(\mathbf{x}^{(1)})}, -\frac{\tilde{\beta}(\mathbf{x})}{\eta_1(\mathbf{x}^{(1)})}, \frac{\tilde{\beta}(\mathbf{x})}{\eta_1^2(\mathbf{x}^{(1)})} \eta_0(\mathbf{x}^{(1)}))$ and $\mu_z = \frac{\sum_{i=1}^n z_i}{n}$. Then $\mathbb{E}[\alpha(X)]$ is estimated by

$$\mathbb{E}[\alpha(X)] = \frac{\sum_{i=1}^n \psi_\alpha(y_i, \mathbf{x}_i, t_i, z_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \hat{\eta}_0(\mathbf{x}^{(1)}), \hat{\eta}_1(\mathbf{x}^{(1)}), \Lambda_Z, t^*)}{n}$$

where $\hat{\alpha}(\mathbf{x}_i^{(2)}) = \hat{\alpha}(\mathbf{x}^{(2)}) + \hat{\beta}(\mathbf{x}^{(2)})\hat{\eta}_0(\mathbf{x}^{(1)})$ and $\hat{\beta}(\mathbf{x}_i^{(2)}) = \hat{\beta}(\mathbf{x}^{(2)})\hat{\eta}_1(\mathbf{x}^{(1)})$.

• Average slope, $\mathbb{E}[\beta(X)]$

– Without an instrumental variable:

The influence function, denoted by $\psi_\beta(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*)$, is defined by setting $H(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) = H_\beta(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}); t^*) = \beta(\mathbf{x}^{(2)})$ in the influence function. When $G(\cdot)$ is set to the identity function and the treatment is continuous, the influence function is simplified as

$$\begin{aligned} \psi_\beta(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ &= \beta(\mathbf{x}^{(2)}) + \frac{\lambda_0(\mathbf{x})t - \lambda_1(\mathbf{x})}{\lambda_2(\mathbf{x})\lambda_0(\mathbf{x}) - \lambda_1(\mathbf{x})^2} (y - \alpha(\mathbf{x}^{(2)}) - \beta(\mathbf{x}^{(2)})t) \\ &= \beta(\mathbf{x}^{(2)}) + \frac{t - \eta_0(\mathbf{x}^{(1)})}{\sigma_t^2} (y - \alpha(\mathbf{x}^{(2)}) - \beta(\mathbf{x}^{(2)})t) \end{aligned}$$

Then $\mathbb{E}[\beta(X)]$ is estimated by

$$\mathbb{E}[\beta(X)] = \frac{\sum_{i=1}^n \psi_\beta(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

– With an instrumental variable:

The influence function, denoted by $\psi_\beta(y, \mathbf{x}, t, z, \tilde{\alpha}(\mathbf{x}), \tilde{\beta}(\mathbf{x}), \eta_0(\mathbf{x}^{(1)}), \eta_1(\mathbf{x}^{(1)}), \Lambda_Z, t^*)$, is defined by setting

$$\begin{aligned} H(y, \mathbf{x}, t, z, \tilde{\alpha}(\mathbf{x}), \tilde{\beta}(\mathbf{x}), \eta_0(\mathbf{x}^{(1)}), \eta_1(\mathbf{x}^{(1)}), \Lambda_Z; t^*) \\ &= H_\beta(y, \mathbf{x}, t, z, \tilde{\alpha}(\mathbf{x}), \tilde{\beta}(\mathbf{x}), \eta_0(\mathbf{x}^{(1)}), \eta_1(\mathbf{x}^{(1)}), \Lambda_Z; t^*) \\ &= \beta(\mathbf{x}^{(2)}) = \frac{\tilde{\beta}(\mathbf{x})}{\eta_1(\mathbf{x}^{(1)})} \end{aligned}$$

in the influence function. When $G(\cdot)$ is set to the identity function and the treatment is continuous, the influence function is simplified as

$$\begin{aligned} \psi_\beta(y, \mathbf{x}, t, z, \tilde{\alpha}(\mathbf{x}), \tilde{\beta}(\mathbf{x}), \eta_0(\mathbf{x}^{(1)}), \eta_1(\mathbf{x}^{(1)}), \Lambda_Z, t^*) \\ &= \frac{\tilde{\beta}(\mathbf{x})}{\eta_1(\mathbf{x}^{(1)})} + \nabla \mathbf{H}_\beta(\mathbf{x}) \begin{pmatrix} \Lambda_Z^{-1}(1, z)'(y - (\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})\hat{t})) \\ \Lambda_Z^{-1}(1, z)'(t - (\eta_0(\mathbf{x}^{(1)}) + \eta_1(\mathbf{x}^{(1)})z)) \end{pmatrix} \\ &= \frac{\tilde{\beta}(\mathbf{x})}{\eta_1(\mathbf{x}^{(1)})} \\ &\quad + (0)(\sigma_z^{-2}(\sigma_z^2 + \mu_z^2 - \mu_z z))(y - (\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})\hat{t})) \\ &\quad + \left(\frac{1}{\eta_1(\mathbf{x}^{(1)})}\right)(-\mu_z + z)(y - (\alpha(\mathbf{x}^{(2)}) + \beta(\mathbf{x}^{(2)})\hat{t})) \\ &\quad + (0)(\sigma_z^{-2}(\sigma_z^2 + \mu_z^2 - \mu_z z))(t - (\eta_0(\mathbf{x}^{(1)}) + \eta_1(\mathbf{x}^{(1)})z)) \\ &\quad + \left(-\frac{\tilde{\beta}(\mathbf{x})}{\eta_1^2(\mathbf{x}^{(1)})}\right)(-\mu_z + z)(t - (\eta_0(\mathbf{x}^{(1)}) + \eta_1(\mathbf{x}^{(1)})z)) \end{aligned}$$

where $\nabla \mathbf{H}_\beta(\mathbf{x}) = (0, \frac{1}{\eta_1(\mathbf{x}^{(1)})}, 0, -\frac{\tilde{\beta}(\mathbf{x})}{\eta_1^2(\mathbf{x}^{(1)})})$ and $\mu_z = \frac{\sum_{i=1}^n z_i}{n}$. Then $\mathbb{E}[\beta(X)]$ is estimated by

$$\mathbb{E}[\beta(X)] = \frac{\sum_{i=1}^n \psi_\beta(y_i, \mathbf{x}_i, t_i, z_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \hat{\eta}_0(\mathbf{x}^{(1)}), \hat{\eta}_1(\mathbf{x}^{(1)}), \Lambda_Z, t^*)}{n}$$

where $\hat{\alpha}(\mathbf{x}_i^{(2)}) = \hat{\alpha}(\mathbf{x}^{(2)}) + \hat{\beta}(\mathbf{x}^{(2)})\hat{\eta}_0(\mathbf{x}^{(1)})$ and $\hat{\beta}(\mathbf{x}_i^{(2)}) = \hat{\beta}(\mathbf{x}^{(2)})\hat{\eta}_1(\mathbf{x}^{(1)})$.

Policy Evaluation and Comparison

First, a policy is defined to be a rule that assigns a given set of information, represented by the covariates $\mathbf{X}$, to a treatment value; that is, a policy is a known map function that is defined by

$$s(\mathbf{X}) : \mathbf{X} \rightarrow \mathbb{R}$$

The expected utility of a policy, denoted by $\pi(s)$, is given by

$$\pi(s) = \mathbb{E}[\alpha(\mathbf{X}) + \beta(\mathbf{X})s(\mathbf{X})]$$

To estimate $\pi(s)$, the influence function is replaced by

$$\begin{aligned} \psi_{\pi(s)}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ = s(\mathbf{x})\psi_{\beta}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) + \psi_{\alpha}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \end{aligned}$$

Then $\pi(s)$ is estimated by

$$\pi(s) = \frac{\sum_{i=1}^n \psi_{\pi(s)}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

The difference in expected utility of two policies is defined by

$$\pi(s_1, s_0) = \mathbb{E}[(s_1(\mathbf{X}) - s_0(\mathbf{X}))\beta(\mathbf{X})]$$

To estimate $\pi(s_1, s_0)$, the influence function is replaced by

$$\begin{aligned} \psi_{\pi(s_1, s_0)}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \\ = (s_1(\mathbf{x}) - s_0(\mathbf{x}))\psi_{\beta}(y, \mathbf{x}, t, \alpha(\mathbf{x}^{(2)}), \beta(\mathbf{x}^{(2)}), \Lambda(\mathbf{x}), t^*) \end{aligned}$$

Then $\pi(s_1, s_0)$ is estimated by

$$\pi(s_1, s_0) = \frac{\sum_{i=1}^n \psi_{\pi(s_1, s_0)}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)}{n}$$

Missing Values

Treatment Variable

In the DNN training stage of the treatment model, the missing treatment values are replaced by imputed values. (For more information, see the [TARGETMISSING=](#) option.) In the inference stage, the observations that have missing treatment values have missing values for residuals of the treatment model and for any estimates that need such residuals.

Outcome Variable

In the DNN training stage of the outcome model, the missing outcome values are replaced by imputed values. (For more information, see the [TARGETMISSING=](#) option.) In the inference stage, the observations that have missing outcome values have missing values for residuals of the outcome model and for any estimates that need such residuals.

Covariate

In the DNN training stage of the treatment model or the outcome model, the missing covariate values are replaced by imputed values. (For more information, see the [MISSING=](#) option.) In the inference stage, the observations that have missing covariates are ignored.

Data Table Output

The DEEPPRICE procedure can create the data tables that you specify in the [OUT=](#) and [OUTDETAILS=](#) options in the [INFER](#) statement. The information in each table is described in the following sections.

OUT= Data Table Generated by the INFER Statement

The estimate and the corresponding standard error of each parameter of interest are displayed in this table. For more information about the parameters of interest, see the section “[Average Intercept and Slope Parameters](#)” on page 987. The output data table contains the following variables:

NOBS	number of observations in the input data table
_N_AVERAGE_INTERCEPT_	number of observations in the estimation of $\mathbb{E}[\alpha(X)]$
_EST_AVERAGE_INTERCEPT_	estimate of $\mathbb{E}[\alpha(X)]$
_STD_AVERAGE_INTERCEPT_	standard error of $\mathbb{E}[\alpha(X)]$
_N_AVERAGE_SLOPE_	number of observations in the estimation of $\mathbb{E}[\beta(X)]$
_EST_AVERAGE_SLOPE_	estimate of $\mathbb{E}[\beta(X)]$
_STD_AVERAGE_SLOPE_	standard error of $\mathbb{E}[\beta(X)]$
_N_POLICY_POLICY-VAR_	number of observations in the estimation of $\pi(s)$, where s is the value of a policy variable, POLICY-VAR , that you specify in the POLICY= option in the INFER statement. The estimate is displayed for each policy variable.

<code>_EST_POLICY_POLICY-VAR_</code>	estimate of $\pi(s)$, where s is the value of a policy variable, <code>POLICY-VAR</code> , that you specify in the <code>POLICY=</code> option in the <code>INFER</code> statement. The estimate is displayed for each policy variable.
<code>_STD_POLICY_POLICY-VAR_</code>	standard error of $\pi(s)$, where s is the value of a policy variable, <code>POLICY-VAR</code> , that you specify in the <code>POLICY=</code> option in the <code>INFER</code> statement. The standard error is displayed for each policy variable.
<code>_N_POLICY_COMPARISON_POLICY-VAR_BASE-VAR_</code>	number of observations in the estimation of $\pi(s_c, s_b)$, where s_c is the value of a policy variable, <code>POLICY-VAR</code> , that you specify in the <code>COMPARE=</code> suboption of the <code>POLICYCOMPARISON=</code> option in the <code>INFER</code> statement and s_b is the value of a policy variable, <code>BASE-VAR</code> , that you specify in the <code>BASE=</code> suboption of the <code>POLICYCOMPARISON=</code> option in the <code>INFER</code> statement. The estimate is displayed for each combination of s_c and s_b .
<code>_EST_POLICY_COMPARISON_POLICY-VAR_BASE-VAR_</code>	estimate of $\pi(s_c, s_b)$, where s_c is the value of a policy variable, <code>POLICY-VAR</code> , that you specify in the <code>COMPARE=</code> suboption of the <code>POLICYCOMPARISON=</code> option in the <code>INFER</code> statement and s_b is the value of a policy variable, <code>BASE-VAR</code> , that you specify in the <code>BASE=</code> suboption of the <code>POLICYCOMPARISON=</code> option in the <code>INFER</code> statement. The estimate is displayed for each combination of s_c and s_b .
<code>_STD_POLICY_COMPARISON_POLICY-VAR_BASE-VAR_</code>	standard error of $\pi(s_c, s_b)$, where s_c is the value of a policy variable, <code>POLICY-VAR</code> , that you specify in the <code>COMPARE=</code> suboption of the <code>POLICYCOMPARISON=</code> option in the <code>INFER</code> statement and s_b is the value of a policy variable, <code>BASE-VAR</code> , that you specify in the <code>BASE=</code> suboption of the <code>POLICYCOMPARISON=</code> option in the <code>INFER</code> statement. The standard error is displayed for each combination of s_c and s_b .

OUTDETAILS= Data Table Generated by the INFER Statement

The output data first consist of the variables in the input data table and the details in the estimation, including $\alpha(\cdot)$, $\beta(\cdot)$, $p(\cdot)$, the residual, and the influence functions for each observation in the input data table. For more information about the influence functions for parameters of interest, the treatment prediction model, and the outcome prediction model, see the sections “[Estimating Unknown Functions in Treatment and Outcome Models](#)” on page 983 and “[Estimating Parameters of Interest](#)” on page 986. In the following list, i denotes the observation index. Moreover, the output data table contains the following variables in addition to the input variables:

<code>_THAT_</code>	value of $\mathbb{E}[T \mathbf{X}^{(1)} = \mathbf{x}_i^{(1)}] = \hat{\eta}_0(\mathbf{x}_i^{(1)})$ for each observation when there is no instrumental variable, and value of $\mathbb{E}[T \mathbf{X}^{(1)} = \mathbf{x}_i^{(1)}, Z = z_i] = \hat{\eta}_0(\mathbf{x}_i^{(1)}) + \hat{\eta}_1(\mathbf{x}_i^{(1)})z_i$ for each observation when there is the instrumental variable Z
<code>_YHAT_</code>	value of $\mathbb{E}[Y \mathbf{X}^{(2)} = \mathbf{x}_i^{(2)}, T = t_i] = \hat{\alpha}(\mathbf{x}_i^{(2)}) + \hat{\beta}(\mathbf{x}_i^{(2)})t_i$ for each observation when there is no instrumental variable, and value of $\mathbb{E}[Y \mathbf{X}^{(2)} = \mathbf{x}_i^{(2)}, T = \hat{t}_i] = \hat{\alpha}(\mathbf{x}_i^{(2)}) + \hat{\beta}(\mathbf{x}_i^{(2)})\hat{t}_i$ for each observation, where $\hat{t}_i = \hat{\eta}_0(\mathbf{x}_i^{(1)}) + \hat{\eta}_1(\mathbf{x}_i^{(1)})z_i$, when there is the instrumental variable Z

<code>_SIGMAT_</code>	standard error of the residuals in the treatment model, $\sigma_t = \sqrt{\frac{\sum_{i=1}^N (t_i - \hat{\eta}_0(\mathbf{x}_i^{(1)}))^2}{n}}$ when there is no instrumental variable or $\sigma_t = \sqrt{\frac{\sum_{i=1}^N (t_i - (\hat{\eta}_0(\mathbf{x}_i^{(1)}) + \hat{\eta}_1(\mathbf{x}_i^{(1)})z_i))^2}{n}}$ when there is the instrumental variable Z , where n the total number of observations. The value is identical for all observations.
<code>_epst_</code>	value of the residual in the treatment model for each observation, $\eta_i = t_i - \hat{\eta}_0(\mathbf{x}_i^{(1)})$ when there is no instrumental variable, and $\eta_i = t_i - (\hat{\eta}_0(\mathbf{x}_i^{(1)}) + \hat{\eta}_1(\mathbf{x}_i^{(1)})z_i)$ when there is the instrumental variable Z
<code>_epsy_</code>	value of the residual in the outcome model, $\varepsilon_i = y_i - (\hat{\alpha}(\mathbf{x}_i^{(2)}) + \hat{\beta}(\mathbf{x}_i^{(2)})t_i)$ when there is no instrumental variable, and $\varepsilon_i = y_i - (\hat{\alpha}(\mathbf{x}_i^{(2)}) + \hat{\beta}(\mathbf{x}_i^{(2)})\hat{t}_i)$ when there is the instrumental variable Z , where $\hat{t}_i = \hat{\eta}_0(\mathbf{x}_i^{(1)}) + \hat{\eta}_1(\mathbf{x}_i^{(1)})z_i$
<code>_eta0_</code>	value of $\hat{\eta}_0(\mathbf{x}_i^{(1)})$ for each observation. This variable is available only when there is the instrumental variable Z .
<code>_eta1_</code>	value of $\hat{\eta}_1(\mathbf{x}_i^{(1)})$ for each observation. This variable is available only when there is the instrumental variable Z .
<code>_alpha_</code>	value of $\hat{\alpha}(\mathbf{x}_i^{(2)})$ for each observation
<code>_beta_</code>	value of $\hat{\beta}(\mathbf{x}_i^{(2)})$ for each observation
<code>_alphatilde_</code>	value of $\hat{\tilde{\alpha}}(\mathbf{x})$ for each observation. This variable is available only when there is the instrumental variable Z .
<code>_betatilde_</code>	value of $\hat{\tilde{\beta}}(\mathbf{x})$ for each observation. This variable is available only when there is the instrumental variable Z .
<code>_if_alpha_</code>	value of $\psi_\alpha(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$ for each observation when there is no instrumental variable, and value of $\psi_\alpha(y_i, \mathbf{x}_i, t_i, z_i, \hat{\tilde{\alpha}}_i(\mathbf{x}_i), \hat{\tilde{\beta}}_i(\mathbf{x}_i), \hat{\eta}_0(\mathbf{x}_i^{(1)}), \hat{\eta}_1(\mathbf{x}_i^{(1)}), \Lambda_Z, t^*)$ for each observation when there is the instrumental variable Z
<code>_if_beta_</code>	value of $\psi_\beta(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$ for each observation when there is no instrumental variable, and value of $\psi_\beta(y_i, \mathbf{x}_i, t_i, z_i, \hat{\tilde{\alpha}}_i(\mathbf{x}_i), \hat{\tilde{\beta}}_i(\mathbf{x}_i), \hat{\eta}_0(\mathbf{x}_i^{(1)}), \hat{\eta}_1(\mathbf{x}_i^{(1)}), \Lambda_Z, t^*)$ for each observation when there is the instrumental variable Z
<code>_policy_policy-var_</code>	value of $\psi_{\pi(s)}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$, where s is the value of a policy variable that you specify in the POLICY= option in the INFER statement. The estimate is displayed for each policy variable.
<code>_policy_comparison_policy-var_base-var_</code>	value of $\psi_{\pi(s_c, s_b)}(y_i, \mathbf{x}_i, t_i, \hat{\alpha}(\mathbf{x}_i^{(2)}), \hat{\beta}(\mathbf{x}_i^{(2)}), \Lambda(\mathbf{x}_i), t^*)$, where s_c is the value of a policy variable, POLICY-VAR, that you specify in the COMPARE= suboption of the POLICYCOMPARISON= option in the INFER statement and s_b is the value of a policy variable, BASE-VAR, that you specify in the BASE= suboption of the POLICYCOMPARISON= option in the INFER statement. The estimate is displayed for each combination of s_c and s_b .

ODS Table Names

The DEEPPRICE procedure assigns a name to each table that it creates. You can use these names to refer to the tables when you use the Output Delivery System (ODS) to select tables and create output data tables.

These names are listed in Table 16.2.

Table 16.2 ODS Tables Produced in the DEEPPRICE Procedure

ODS Table Name	Description	Option
NObs	Number of observations	Default
ParameterEstimates	Parameter estimates	Default
PolicyComparison	Policy comparison	POLICYCOMPARISON=
PolicyEvaluation	Policy evaluation	POLICY=

Examples: DEEPPRICE Procedure

Example 16.1: Personalized Customer Segmentation for an Online Media Company

This example illustrates how a music subscription service from an online media company can offer targeted discounts through a personalized pricing plan based on many features that the company observes about its customers to encourage them to buy more songs.

The data set is provided by the Microsoft research project ALICE and is available at https://econmldata.azurewebsites.net/datasets/Pricing/pricing_sample.csv. The data set has 10,000 simulated observations that represent users' personal characteristics, such as age, log income, and account age, as well as users' online behavior history, including previous purchases and previous online time per week. The treatment variable, price, is the price that the customer was exposed to during the discount season. A value of 1 indicates that no discount is given, and a value less than 1 indicates that a discount is applied. The outcome variable, demand, is the number of songs that the customer purchased during the discount season. Table 16.3 shows the names of the variables that are used in the model, their types, and their definitions. The type can be T (treatment), Y (outcome), $x^{(1)}$ (a covariate in the treatment model), and/or $x^{(2)}$ (a covariate in the outcome model).

Table 16.3 Model Variables

Name	Type	Details
account_age	$x^{(1)}$, $x^{(2)}$	User's account age
age	$x^{(1)}$, $x^{(2)}$	User's age
avg_hours	$x^{(1)}$, $x^{(2)}$	Average number of hours per week user was online in the past
days_visited	$x^{(1)}$, $x^{(2)}$	Average number of days per week user visited website in the past
friend_count	$x^{(1)}$, $x^{(2)}$	Number of friends user connected to in account
has_membership	$x^{(1)}$, $x^{(2)}$	Whether user has membership

Table 16.3 *continued*

Name	Type	Details
is_US	$x^{(1)}, x^{(2)}$	Whether user accesses website from the United States
songs_purchased	$x^{(1)}, x^{(2)}$	Average number of songs user purchased per week in the past
income	$x^{(1)}, x^{(2)}$	User's income
price	T	Price that user was exposed to during the discount season (baseline price * small discount)
demand	Y	Number of songs user purchased during the discount season

This example has three goals:

1. Estimate the parameters of interest, such as average partial effect of price on demand.
2. Estimate the price elasticity of demand for songs, and assess its variation with users' characteristics.
3. Conduct a policy analysis that aims at increasing revenue despite decreasing the price for some users.

Assuming that you have downloaded the data set `pricing_sample` in your session that is associated with the `mylib` libref, the following statements create an ID variable that has a unique value for each observation in the data table `new_pricing_sample`:

```
data mylib.new_pricing_sample;
  set mylib.pricing_sample;
  id = put(_threadid_,8.) || '_' || Put(_n_,8.); * ID variable;
run;
```

The first step in policy evaluation and policy optimization is to estimate the effect of the treatment and to save to a specified output data table the details of the estimation, including $\alpha(\cdot)$ and $\beta(\cdot)$, the residual, and the influence functions for each unit. You can do this by using the following statements, which also store the estimated treatment model information, $\alpha(\cdot)$ information, and $\beta(\cdot)$ information in the data tables `outtdata`, `outadata`, and `outbdata`, respectively, to be used later for policy evaluation:

```
/*--- Estimate the treatment effect and save the estimation details ---*/
proc deepprice data=mylib.new_pricing_sample;
  id id;
  tmodel price = account_age age avg_hours days_visited friends_count
    has_membership is_US songs_purchased income /
    dnn=(nodes=(32 32 32 32)
    train=(optimizer=(miniBatchSize=500 regL1=0.0001 maxEpochs=32000
    algorithm=adam) nthreads=20 seed=12345 recordseed=67890));
  model demand = account_age age avg_hours days_visited friends_count
    has_membership is_US songs_purchased income /
    dnn=(nodes=(32 32 32 32)
    train=(optimizer=(miniBatchSize=500 regL1=0.001 maxEpochs=32000
    algorithm=adam) nthreads=20 seed=12345 recordseed=67890));
  infer out=mylib.oest outdetails=mylib.odetails;
  score outt=mylib.outtdata outa=mylib.outadata outb=mylib.outbdata;
run;
```

For this example, the same covariates are used in both the treatment model and the outcome model. The model estimation details are saved in the output data table `odetails`.

The estimation results are shown in [Output 16.1.1](#). The estimate of the average partial effect of price on demand is negative, as expected, and statistically significant.

Output 16.1.1 Parameters of Interest
The DEEPPRICE Procedure

Parameter	Parameter Estimates					Z	Pr > Z
	Estimate	Standard Error	95% Confidence Limits				
Average Intercept	23.629698	0.215064	23.208180	24.051217	109.87	<.0001	
Average Slope	-9.235895	0.244447	-9.715001	-8.756788	-37.78	<.0001	

Another parameter of interest is the price elasticity of demand, which measures the degree of sensitivity of demand to price. In general, demand decreases when price increases for most products, but the amount by which demand decreases is greater for some products than for others. Price elasticity measures the percentage change in demand when there is a 1% increase in price. In this example, a price elasticity of -3 means that a 1% increase in price will lead to a 3% decrease in the number of songs purchased.

Heterogeneity in price sensitivity is introduced among users by allowing the price elasticity to depend on users' characteristics x_i , so that the heterogeneous elasticity function is defined for the i th user as

$$\text{elasticity}(x_i) = \beta(x_i) \frac{\text{price}_i}{\text{demand}_i}$$

It is of particular interest to assess how price elasticity varies among users with respect to their income and other personal characteristics. The variable `_beta_` in the data table `odetails` that is obtained during the previous estimation contains the estimated values for this function for each user. Price elasticity is computed for each user by using the following statements:

```
data odetails;
  set mylib.odetails;
  elasticity = _beta_ *price/demand;
run;
```

The estimated price elasticities can then be plotted against various characteristics of users. The following statements plot the relationship between elasticity and income, which is shown in [Output 16.1.2](#):

```
proc sort data=odetails ;
  by income;
run;
proc sgplot data=odetails ;
  series x=income y=elasticity /legendlabel='Sales elasticity prediction';
  xaxis label='Income' values=(0 to 6 by 1);
  yaxis label='Song sales elasticity';
run;
```

Output 16.1.2 Song Sales Price Elasticity vs. Income

Output 16.1.2 shows a remarkable heterogeneity among users with respect to income for their response to a price increase. Users whose income is less than 1 (51% of all users) are more sensitive to a price increase; if price goes up by 1%, their number of songs purchased falls by 1% to 5%, compared to around 0.15% for higher-income users.

The following statements plot the relationship between elasticity, income, and days_visited, which is shown in Output 16.1.3:

```
proc sort data=odetails ;
  by days_visited income;
run;
proc sgpanel data=odetails;
  panelby days_visited/layout=panel columns=4 rows=2 uniscale=column;
  series x=income y=elasticity;
  colaxis label='Income' valueshint values=(0 1 2 3 4 5 6);
  rowaxis label='Song sales elasticity' grid;
run;
```

Output 16.1.3 Song Sales Price Elasticity vs. Income and Days Visited

Output 16.1.3 further shows that low-income users who visited the website less often in the past (less than five days a week) are even more price-sensitive than low-income users who visited the website more often. The discussion next turns to policy evaluation and comparison.

In policy optimization, the goal is to maximize the expected utility of a policy. For the definition of the expected utility function and how it is estimated, as well as details such as the definition of a policy rule, see the section “Policy Evaluation and Comparison” on page 990. In this example, the policy decisions are to choose user-specific prices (price_i) in order to maximize the revenue, which is defined as

$$\text{Revenue}(\text{price}_i, \mathbf{x}_i) = (\alpha(\mathbf{x}_i) + \beta(\mathbf{x}_i) * \text{price}_i) * \text{price}_i$$

The optimal price for each user is therefore derived as $\text{price}_i^* = -\frac{\alpha(\mathbf{x}_i)}{2\beta(\mathbf{x}_i)}$. Let $\mathbf{s}1$ be the optimal policy that sets each user’s price as price_i^* . This optimal policy is highly personalized, because it sets user-specific prices during the discount season, but those prices can exceed the original prices. It is therefore more meaningful to consider an optimized discount personalized policy, $\mathbf{s}1d$, that is equal to $\mathbf{s}1$ if $\mathbf{s}1$ does not exceed the original price, and equal to 1 otherwise.

Although the optimal pricing policy $\mathbf{s}1$ guarantees the maximum revenue and is highly personalized, the online media company might want to consider a price discount that targets a group of users or all users. Whether the company’s revenue will rise or fall depends on the price elasticity of songs’ demand. Microeconomic theory

predicts that lowering prices will increase revenue if demand is price-elastic (elasticity < -1) and decrease revenue if demand is price-inelastic (elasticity > -1).

Output 16.1.2 and **Output 16.1.3** show that price elasticity is heterogeneous among users; the most price-sensitive users are those whose income is less than 1 and who spend on average less than five days a week on the website. This suggests a policy that offers this type of user a price discount. Let **s2** be this policy. For comparison, also consider policies **s3** (offer everyone a discount) and **s0** (offer no one a discount).

To select the discount rates, revenues were computed for policies **s2** and **s3** and for each of the six discount values 5%, 10%, 15%, 20%, 25%, and 30%. For policy **s2**, a 5% discount did not improve the base policy price, and although a 10%, 15%, 20%, 25%, or 30% discount generated more revenue than the base policy, there was no significant difference among the five discount rates. A 10% discount was therefore selected for policy **s2**. Using a similar analysis, a 5% discount was selected for policy **s3**.

Policies **s2** and **s3** offer the same discount to all users or groups of users. Versions of these policies (**s4** and **s5**) that randomly select with equal probability a discount rate from the set (5%, 10%, 15%, 20%, 25%, and 30%) are also considered.

The following DATA step creates policies **s0**, **s1**, **s1d**, **s2**, **s3**, **s4**, and **s5** in the data table **odetails**, which also contains the variable **elasticity** that was previously computed:

```
data mylib.discountPolicy;
  array prob[6] _temporary_ (6*0.1666667);
  call streaminit(54321);
  set odetails;
  s0 = 1;
  s1 = -_alpha_/(2*_beta_);
  if s1 > 1 then s1d = 1;
  else s1d = s1;
  if (income < 1 and days_visited < 5) then s2 = 0.9;
  else s2 = 1;
  s3 = 0.95;
  if (income < 1 and days_visited < 5) then s4c = rand("Table", of prob[*]);
  else s4c = 0;
  s4=. ;
  do k = 1 to 7;
    if (s4c = k-1) then s4 = 1 - 0.05*(k-1);
  end;
  s5c = rand("Table", of prob[*]);
  s5=. ;
  do k = 1 to 7;
    if (s5c = k-1) then s5 = 1 - 0.05*(k-1);
  end;
  keep id price account_age age avg_hours days_visited
      friends_count has_membership is_US songs_purchased
      income demand s0 s1 s1d s2 s3 s4 s5 elasticity;
run;
```

Before policy evaluation and comparison are conducted, the variation of the optimal prices with respect to users' price sensitivity and income is assessed.

In the following code, the DATA step defines the variables **elasticity_type** and **price_discount**, and the PROC steps plot the relationship between **price_discount**, **elasticity_type**, and **income**, which

is shown in **Output 16.1.4**:

```

data discountPolicy2;
  set mylib.discountPolicy;
  if elasticity > -1 then elasticity_type = 'Inelastic';
  else if elasticity < -1 then elasticity_type = 'Elastic';
  else if elasticity = -1 then elasticity_type = 'Unit Elastic';
  price_discount = ((1-s1)/1)*100;
run;
proc sort data=discountPolicy2 ;
  by elasticity_type income;
run;
proc sgpanel data=discountPolicy2;
  panelby elasticity_type / layout=panel columns=2 rows=1 uniscale=column;
  series x=income y=price_discount;
  colaxis label='Income' valueshint values=(0 1 2 3 4 5 6);
  rowaxis label='Price discount (%)' grid max=200 min=-1000;
run;

```

Output 16.1.4 Price Discount Distribution by Elasticity and Income

Output 16.1.4 shows that the optimal policy offers a positive discount to users whose income is less than 1 and to nearly all price-sensitive users (elastic group).

You can do policy evaluation by specifying the POLICY= option in the INFER statement, and you can do policy comparison by specifying the POLICYCOMPARISON= option in the INFER statement. The previously estimated treatment model, $\alpha(\cdot)$ information, and $\beta(\cdot)$ information are applied to the new data set by specifying the INT=, INA=, and INB= options, respectively, in the SCORE statement. The following statements estimate the model and do policy evaluation and comparison:

```
/*--- Policy evaluation and comparison ---*/
proc deepprice data=mylib.discountPolicy;
  id id;
  infer out=mylib.oest2 outdetails=mylib.odetails2
    policy=(price s0 s1 s1d s2 s3 s4 s5)
    policyComparison=(base=(price)
      compare=(s0 s1 s1d s2 s3 s4 s5));
  score int=mylib.outtdata ina=mylib.outadata inb=mylib.outbdata ;
run;
```

The POLICY= option performs the policy evaluation for the initial price policy (price) and policies s0, s1, s1d, s2, s3, s4, and s5. The COMPARE= suboption of the POLICYCOMPARISON= option compares policies s0, s1, s1d, s2, s3, s4, and s5 to the base policy, price, which is specified by the BASE= suboption of the POLICYCOMPARISON= option.

The policy evaluation results are shown in [Output 16.1.5](#).

Output 16.1.5 Policy Evaluation

The DEEPPRICE Procedure

Policy Evaluation						
Policy	Estimate	Standard Error	95% Confidence Limits		Z	Pr > Z
price	14.648911	0.073155	14.505529	14.792293	200.24	<.0001
s0	14.393804	0.077702	14.241511	14.546096	185.24	<.0001
s1	12.017483	0.659866	10.724169	13.310798	18.21	<.0001
s1d	16.271219	0.059482	16.154637	16.387800	273.55	<.0001
s2	14.869897	0.069841	14.733011	15.006784	212.91	<.0001
s3	14.855598	0.072180	14.714128	14.997069	205.81	<.0001
s4	15.220208	0.069391	15.084205	15.356211	219.34	<.0001
s5	15.985290	0.070627	15.846863	16.123717	226.33	<.0001

The optimal policy s1 has the lowest expected demand, whereas the optimized discount policy s1d and the policy s5, which offer each user a randomly selected discount, generate the most demand. Policies s2, s3, and s4 generate slightly more demand than s0 (no user gets a discount).

[Output 16.1.6](#) shows the output for the policy comparison. Policies s1d and s5 are better than the current price policy with respect to demand.

Output 16.1.6 Policy Comparison

Policy Comparison						
Comparison Policy	Base Policy	Estimate	Standard Error	95% Confidence Limits		Z Pr > Z
s0	price	-0.255108	0.035676	-0.325032	-0.185183	-7.15 <.0001
s1	price	-2.631428	0.671764	-3.948062	-1.314794	-3.92 <.0001

s2	price	0.220986	0.029949	0.162287	0.279685	7.38 <.0001
s3	price	0.206687	0.027870	0.152063	0.261311	7.42 <.0001
s4	price	0.571296	0.037946	0.496924	0.645669	15.06 <.0001
s5	price	1.336379	0.035783	1.266245	1.406512	37.35 <.0001

Output 16.1.5 and Output 16.1.6 evaluate and compare the different policies on the basis of demand. However, it would be better for the comparison of the policies to be based on revenue.

The following statements evaluate and compare the different policies by computing the average revenue per user and the associated confidence interval for each policy in the data table odetails2:

```
data odetails2;
  set mylib.odetails2;
  if (_alpha+_beta*price>0) then revenue_price = price*(_alpha+_beta*price);
  else revenue_price = 0;
  if (_alpha+_beta*s0>0) then revenue_s0 = s0*(_alpha+_beta*s0);
  else revenue_s0 = 0;
  if (_alpha+_beta*s1>0 and s1>0) then revenue_s1 = s1*(_alpha+_beta*s1);
  else revenue_s1 = 0;
  if (_alpha+_beta*s1d>0 and s1d>0) then revenue_s1d = s1d*(_alpha+_beta*s1d);
  else revenue_s1d = 0;
  if (_alpha+_beta*s2>0) then revenue_s2 = s2*(_alpha+_beta*s2);
  else revenue_s2 = 0;
  if (_alpha+_beta*s3>0) then revenue_s3 = s3*(_alpha+_beta*s3);
  else revenue_s3 = 0;
  if (_alpha+_beta*s4>0) then revenue_s4 = s4*(_alpha+_beta*s4);
  else revenue_s4 = 0;
  if (_alpha+_beta*s5>0) then revenue_s5 = s5*(_alpha+_beta*s5);

    UpperCL = Estimate + StdErr*quantile('NORMAL',.975);
    ProbZ = 2*(1-cdf('NORMAL',abs(Z)));

run;

```

The table that shows policy evaluation based on revenue is printed by the following statements and shown in [Output 16.1.7](#). As expected, the optimal personalized policy s1 generates the most revenue. The optimized personalized discount policy s1d and the personalized policies s2 and s4 generate comparable revenue, which is also the second-highest revenue.

```
proc print data=odetails2_stats2 noobs;
  var Policy Estimate StdErr LowerCL UpperCL ProbZ;
  where Policy ~= '';
run;
```

Output 16.1.7 Policy Evaluation Based on Revenue

	Policy	Estimate	StdErr	LowerCL	UpperCL	ProbZ
price		15.0378	0.06639	14.9077	15.1679	<.0001
s0		15.1765	0.07319	15.0331	15.3200	<.0001
s1		34.4007	0.33318	33.7477	35.0537	<.0001

s5		13.7614	0.05384	13.6558	13.8669	<.0001

Output 16.1.8 shows the output for the policy comparison based on revenue. The personalized policies s1, s1d, s2, and s4 generate more average revenue per user than the base policy price. The policy s0 (offer no user a discount) is equivalent to price, and policies that offer every user a discount (s3 and s5) are worse than price, with s5 being the worst. The following statements print the policy comparison results, as shown in Output 16.1.8:

```
proc print data=odetails2_stats2 noobs;
  var ComparisonPolicy BasePolicy Estimate StdErr LowerCL UpperCL ProbZ;
  where Policy = '';
run;
```

Output 16.1.8 Policy Comparison Based on Revenue

	ComparisonPolicy	BasePolicy	Estimate	StdErr	LowerCL	UpperCL	ProbZ

In fact, the data generating process (DGP) behind the observed demand in the pricing_sample data set is known, and the objectives of this final section are to assess how well the estimated intercept and slope functions approximate the truth and to compare the different policies by using true DGP revenues.

The true DGP is defined as follows:

$$\alpha(\mathbf{x}) = 20 + 0.5 * \text{avg_hours} + 5 * (\text{days_visited} > 4)$$

$$\beta(\mathbf{x}) = -3 - 14 * (\text{income} < 1)$$

$$\text{demand} = \alpha(\mathbf{x}) + \beta(\mathbf{x}) * \text{price}$$

The following statements compute the true intercept and slope functions, as well as the revenue that is generated per user by the different price policies and by the true DGP demand. The optimal policies $s1star$ and $s1dstar$ are the true DGP counterparts of the estimated policies $s1$ and $s1d$. The $s1star$ policy is the best revenue-maximizing policy in theory, but it is not available in practice because it depends on the unknown functions $\alpha(\cdot)$ and $\beta(\cdot)$.

```
data odetails2_DGP;
  set mylib.odetails2;
  alpha_dgp = 20 + 0.5*avg_hours + 5*(days_visited > 4);
  beta_dgp = -3 -14*(income < 1);

  s1star = -alpha_dgp/(2*beta_dgp);
  if s1star>1 then s1dstar = 1; else s1dstar = s1star;

  if (alpha_dgp+beta_dgp*price>0) then
    revenue_price = price*(alpha_dgp+beta_dgp*price);
  else revenue_price = 0;
  if (alpha_dgp+beta_dgp*s0>0) then
    revenue_s0 = s0*(alpha_dgp+beta_dgp*s0);
  else revenue_s0 = 0;
  if (alpha_dgp+beta_dgp*s1>0 and s1>0) then
    revenue_s1 = s1*(alpha_dgp+beta_dgp*s1);
  else revenue_s1 = 0;
  if (alpha_dgp+beta_dgp*s1d>0 and s1d>0) then
    revenue_s1d = s1d*(alpha_dgp+beta_dgp*s1d);
  else revenue_s1d = 0;
  if (alpha_dgp+beta_dgp*s1star>0 and s1star>0) then
    revenue_s1star = s1star*(alpha_dgp+beta_dgp*s1star);
  else revenue_s1star = 0;
  if (alpha_dgp+beta_dgp*s1dstar>0 and s1dstar>0) then
    revenue_s1dstar = s1dstar*(alpha_dgp+beta_dgp*s1dstar);
  else revenue_s1dstar = 0;
  if (alpha_dgp+beta_dgp*s2>0) then revenue_s2 = s2*(alpha_dgp+beta_dgp*s2);
  else revenue_s2 = 0;
  if (alpha_dgp+beta_dgp*s3>0) then revenue_s3 = s3*(alpha_dgp+beta_dgp*s3);
  else revenue_s3 = 0;
  if (alpha_dgp+beta_dgp*s4>0) then revenue_s4 = s4*(alpha_dgp+beta_dgp*s4);
  else revenue_s4 = 0;
  if (alpha_dgp+beta_dgp*s5>0) then revenue_s5 = s5*(alpha_dgp+beta_dgp*s5);
  else revenue_s5 = 0;
run;
```

The true and estimated intercept functions are then plotted using the code that follows. The results are shown in [Output 16.1.9](#). The estimated and true intercepts are highly positively correlated, and the estimated slope function reasonably approximates the true slope except in the case of high-income users. It should be noted that the estimated intercept and slope are functions of

all nine users' characteristics, whereas the true intercept and slope are functions of only income, avg_hours, and days_visited. Despite this difference, the DEEPPRICE procedure is able to accurately estimate the patterns in these functions.

```

proc sort data=odetails2_DGP ;
  by alpha_dgp;
run;
proc sgplot data=odetails2_DGP noautolegend;
  lineparm x=0 y=0 slope=1/lineattrs=(color=red) ;
  series x=_alpha_ y=alpha_dgp ;
  xaxis min=15 max=35;
  yaxis min=15 max=35;
run;

```

Output 16.1.9 Estimated vs. True Intercept Function $\alpha(\cdot)$

The following statements plot the true and estimated slope functions, as shown in [Output 16.1.10](#):

```

proc sort data=odetails2_DGP ;
  by income;
run;
proc sgplot data=odetails2_DGP ;
  series x=income y=beta_dgp /legendlabel='True slope';
  series x=income y=_beta_ /legendlabel='Estimated slope';
  xaxis label='Income' values=(0 to 6 by 1);

```

```
yaxis label='Slope';
run;
```

Output 16.1.10 Estimated and True Slope Function $\beta(\cdot)$ vs. Income

As with the non-DGP revenues, the following statements compute the average revenue per user for each price policy in the data table `odetails2_DGP`:

```
proc means data=odetails2_DGP noprint;
  var revenue_price revenue_s0 revenue_s1 revenue_s1star revenue_s1d
      revenue_s1dstar revenue_s2 revenue_s3 revenue_s4 revenue_s5;
  output out=odetails2_DGP_stats(drop=_type_ _freq_) mean= STD= N=/autoname;
run;
data odetails2_DGP_stats;
  set odetails2_DGP_stats;
  s0_price_Estimate = revenue_s0_mean - revenue_price_mean;

Output 16.1.11 shows that the average revenue per user that is generated by the estimated optimal policy s1 is less than but close to that obtained using its true DGP counterpart and best policy, s1star. Without knowing the true DGP, the DEEPPRICE procedure can accurately estimate the average optimal revenue per user. The optimized discount policies s1d and s1dstar generate comparable but substantially less revenue than s1 and s1star.

In terms of policy comparison, Output 16.1.12 shows that the s1 and s1star policies generate much more revenue per user than the base policy price. The optimized discount personalized policies (s1d and s1dstar) and the personalized policies that offer only price-sensitive users a discount (s2 and s4) are better than price, whereas the policies that offer every user a discount (s3 and s5) are worse than price.

In summary, this example shows how, by taking advantage of the flexibility of PROC DEEPPRICE in specifying heterogeneous price effects as a function of users' characteristics, the online media company can set user-specified prices to achieve maximum revenue and discount policies that target a specified group of users.

Example 16.2: Functional Forms and Analyzing Price and Demand

This example demonstrates the effect of functional form misspecification on the estimated demand curve and shows how to compare demand curves across customer characteristics and purchasing time.

The data set has 10,000 simulated observations, which include customer type, customer purchase time, price, and demand. The treatment variable, price, is the selling price of a product. The outcome variable, demand, is the sales quantity of the product. Table 16.4 describes the variables that are used in the model. The type can be T (treatment), Y (outcome), $x^{(1)}$ (a covariate in the treatment model), and/or $x^{(2)}$ (a covariate in the outcome model).

Table 16.4 Variables in Model

Name	Type	Details
customertype	$x^{(1)}, x^{(2)}$	Customer type
time	$x^{(1)}, x^{(2)}$	Time of purchase of goods
demand	Y	Quantity of purchased goods
price	T	Selling price of a product

The following statements create the data set and load the data into your session:

```
data deepPriceData;
  input i customertype time price demand ;
  datalines;
1      10 3.2517  0.82502 0.59985
2       8 9.6777  1.47760 0.35881
3       1 6.4239  1.82441 2.24215
4       4 10.0217 1.56411 1.18040
5       3 11.2567 2.13610 1.39896

... more lines ...

9995   8 3.4223  1.04572 0.38379
9996   6 11.1666 1.65613 1.29208
9997   3 2.9016  1.11613 1.97467
9998   6 3.8167  0.97021 1.05249
9999   7 3.7612  1.17288 0.35869

;

data mylib.deeppricedata;
  set deeppricedata;
run;
```

It is first assumed that the demand curve is linear. The following statements use PROC DEEPPRICE to estimate the intercept and slope functions and then to save the estimation details:

```
proc deepprice data=mylib.deeppricedata;
  id i;
  tmodel price = customerType time /
    dnn=(nodes=(32 32 32 32)
    train=(optimizer=(miniBatchSize=500 regL1=0.0001 maxEpochs=32000
    algorithm=adam) nthreads=20 seed=12345 recordseed=67890));
  model demand = customerType time /
    dnn=(nodes=(32 32 32 32)
    train=(optimizer=(miniBatchSize=500 regL1=0.001 maxEpochs=32000
    algorithm=adam) nthreads=20 seed=12345 recordseed=67890));
  infer out=mylib.oest outdetails=mylib.outtabdetails;
  score outt=mylib.outtdata outa=mylib.outadata outb=mylib.outbdata;
run;
```

For this example, the same covariates are used in both the treatment model and the outcome model. The model estimation details are saved in the output data table outtabdetails.

The estimation results are shown in [Output 16.2.1](#).

Output 16.2.1 Parameter Estimates

Parameter Estimates						
Parameter	Estimate	Standard Error	95% Confidence Limits		Z	Pr > Z
Average Intercept	23.629698	0.215064	23.208180	24.051217	109.87	<.0001
Average Slope	-9.235895	0.244447	-9.715001	-8.756788	-37.78	<.0001

This predicted demand might not be accurate, because the covariates might affect both price and demand. The following statements show how you can construct the grid of price and calculate the predicted demand by using the influence functions `_if_alpha_` and `_if_beta_` that you saved in the `outtabdetails` data set in the initial call to PROC DEEPPRICE and then how you can plot the demand curve:

```
data myGrid_if;
  array gridPrice[100];
  array gridY[100];
  set mylib.outtabdetails;
  do j = 1 to 100;
    gridPrice[j] = 0.7 + 2.8*j / 101;
    gridY[j] = _if_alpha_ + _if_beta_*gridPrice[j] ;
  end;
run;
```

The following statements compute the average demand, its standard error, and its 95% confidence interval at each of the 100 price values and then plot the results:

```
proc univariate data=mygrid_if;
  var gridPrice1-gridPrice100 gridy1-gridy100;
  output out= estCurve_if
  mean=gridPrice1-gridPrice100 gridym1-gridym100
  std=gridPrices1-gridPrices100 gridys1-gridys100;
run;

data estCurve_if_ci;
  set estCurve_if;
  array prices[100] gridPrice1-gridPrice100;
  array demands[100] gridym1-gridym100;
  array stds[100] gridys1-gridys100;
  do i = 1 to 100;
    price=prices[i];
    estDemand=demands[i];
    estDemandLb = estDemand - 1.96*stds[i]/sqrt(10000);
    estDemandUb = estDemand + 1.96*stds[i]/sqrt(10000);
    output;
  end;
  keep price estDemand estDemandLb estDemandUb;
run;

proc sgplot data= estCurve_if_ci;
  title 'Demand Curve';
  band x=price lower=estDemandLb upper=estDemandUb /
  legendlabel="95% Confidence Band " name="band";
  scatter x=price y=estDemand / markerattrs=(color=blue size=3 symbol=circle)
  legendlabel="Estimated Demand" name="estDemand";
  refline 0;
  xaxis label='Price';
  yaxis label='Demand' ;
run;
```

The generated demand curve and 95% pointwise confidence band are shown in [Output 16.2.2](#).

Output 16.2.2 Estimated Demand Curve

The curve looks unrealistic, especially given that a large portion of the curve is below zero. This indicates that the linear demand curve assumption might be incorrect. There is another way to model price and demand: by using log transformation.

The following DATA step computes the logarithm of price and demand data:

```
data mylib.deeppricedata_log;
  set deepPriceData;
  logy=log(demand);
  logp=log(price);
run;
```

The following statements use PROC DEEPPRICE to estimate the price effect and save the estimation details to the output table outtabdetails_log:

```
proc deepprice data=mylib.deeppricedata_log;
  id i;
  tmodel logp = customerType time /
    dnn=(nodes=(32 32 32 32)
    train=(optimizer=(miniBatchSize=500 regL1=0.0001 maxEpochs=32000
    algorithm=adam) nthreads=20 seed=12345 recordseed=67890));
  model logy = customerType time /
    dnn=(nodes=(32 32 32 32)
    train=(optimizer=(miniBatchSize=500 regL1=0.001 maxEpochs=32000
```

```

        algorithm=adam) nthreads=20 seed=12345 recordseed=67890));
infer out=mylib.oest_log outdetails=mylib.outtabdetails_log;
score outt=mylib.outtdata_log outa=mylib.outadata_log outb=mylib.outbdata_log;
run;

```

The estimation results are shown in [Output 16.2.3](#). The average slope is negative, indicating that the impact of price on demand is negative. This is consistent with expectations.

Output 16.2.3 Parameter Estimates

Demand Curve

The DEEPPRICE Procedure

Parameter Estimates						
Parameter	Estimate	Standard Error	95% Confidence Limits		Z	Pr > Z
Average Intercept	0.628116	0.009709	0.609087	0.647145	64.69	<.0001
Average Slope	-2.859250	0.011297	-2.881392	-2.837109	-253.10	<.0001

The following DATA step constructs a grid of price values and calculates the corresponding expected demand, whose influence function is given by

$$\psi(\cdot) = \exp(\alpha(x) + \beta(x) \log(t)) \{1 + (\psi_{\alpha}(\cdot) - \alpha(x)) + \log(t)(\psi_{\beta}(\cdot) - \beta(x))\}$$

```

data myGrid_log_if;
    array gridPrice[100];
    array gridY[100];
    set mylib.outtabdetails_log;
    do j = 1 to 100;
        gridPrice[j] = 0.7 + 2.8*j / 101 ;
        gridY[j] = exp(_alpha_ + _beta_ * log(gridPrice[j]))*(1+(_if_alpha_-_alpha_)
            +log(gridPrice[j])*(_if_beta_-_beta_));
    end;
run;

```

The following PROC UNIVARIATE and DATA steps compute the average demand, its standard error, and its 95% confidence interval at each of the 100 price values:

```

proc univariate data=myGrid_log_if noprint;
    var gridPrice1-gridPrice100 gridy1-gridy100;
    output out=estCurve_log_if mean=gridPrice1-gridPrice100 gridy1-gridy100
        std=gridPrice1-gridPrice100 gridys1-gridys100;
run;

data estCurve_log_if_ic;
    set estCurve_log_if;
    array prices[100] gridPrice1-gridPrice100;
    array demands[100] gridy1-gridy100;
    array stds[100] gridys1-gridys100;
    do i = 1 to 100;
        price=prices[i];
        estDemand=demands[i];
    end;
run;

```

```

    estDemandLb = estDemand - 1.96*stds[i]/sqrt(10000);
    estDemandUb = estDemand + 1.96*stds[i]/sqrt(10000);
    output;
end;
keep price estDemand estDemandLb estDemandUb;
run;

```

Then the demand curve and 95% pointwise confidence intervals are displayed as shown in [Output 16.2.4](#), using the following statements:

```

proc sgplot data=estCurve_log_if_ic;
  title 'Demand Curve';
  band x=price lower=estDemandLb upper=estDemandUb /
  legendlabel="95% Confidence Band " name="band";
  scatter x=price y=estDemand / markerattrs=(color=blue size=3 symbol=circle)
  legendlabel="Estimated Demand" name="estDemand";
  xaxis label='Price';
  yaxis label='Demand';
run;

```

Output 16.2.4 Estimated Demand Curve

The curve looks considerably better. As expected, the demand curve slopes downward. In fact, the data generating process (DGP) is available, and the objective of this section of the example is to assess how well the estimated demand curves approximate the truth.

The true DGP is defined as follows:

- η has a normal distribution with mean $\mu = 0$ and standard deviation $\sigma = 0.1$.
- The time (t) is continuous and has a uniform distribution from 0 to 12, exclusive.
- The customer type (s) is discrete and has an integer uniform distribution from 1 to 10, inclusive.
- The price (p) is continuous, and its value ranges from 0.7 to 3.5, inclusive.
- The demand (y) is continuous and nonnegative.

The treatment model is given as

$$p = \exp(1 + 0.3 * \zeta(t) + \eta)$$

$$\zeta(t) = 2 \left(\frac{50}{3} \left(\frac{t-6}{12} \right)^4 + \exp \left(-400 \left(\frac{t-6}{12} \right)^2 \right) + \frac{t}{12} - \frac{41}{20} \right)$$

where $\zeta(\cdot)$ describes the seasonality.

The outcome model is given as

$$y = \alpha(s, t) \exp(\log(p) \beta(s, t))$$

$$\alpha(s, t) = \exp(2 + 0.1 * s * \zeta(t))$$

$$\beta(s, t) = 0.1 * s * \zeta(t) - 1.5$$

The following DATA steps generate the data by using the true DGP:

```
data deepPriceDGP;
  array gridPrice[100] gridPrice1-gridPrice100;
  array gridY[100] gridY1-gridY100;
  call streaminit('pcg', 12440);
  do i = 1 to 10000;
    customertype = floor(rand('Uniform')*10+1);
    time = rand('Uniform')*12;
    eta = 0.1*rand('Normal',0,1);
    * z: seasonality;
    z = 2*(50/3*((time-6)/12)**4
      +exp(-400*((time-6)/12)**2)+time/12-41/20);
    price = exp(1+0.3*z + eta);
    a = exp(2 + 0.1*customertype*z);
    b = 0.1*customertype*z - 1.5;
    demand = a * exp(log(price) * b);
    do j = 1 to 100;
      gridPrice[j] = 0.7 + 2.8*j / 101;
      gridY[j] = a * exp( log(gridPrice[j]) * b);
    end;
  output;
```

```

    end;
run;

data mylib.deepPriceDataFull;
    set deepPriceDGP;
run;

```

Then, using the code segments that follow, you can plot the true and estimated demand curves.

First, the following code calculates the mean of the true price and demand:

```

proc univariate data=mylib.deepPriceDataFull noprint;
    var gridPrice1-gridPrice100 gridy1-gridy100;
    output out=trueCurve mean=gridPrice1-gridPrice100 gridym1-gridym100;
run;

data trueCurve2;
    set trueCurve;
    array prices[100] gridPrice1-gridPrice100;
    array demands[100] gridym1-gridym100;
    do i = 1 to 100;
        price=prices[i];
        demand=demands[i];
        output;
    end;
    keep price demand;
run;

```

The following code calculates the mean of estimated price and demand, and then the true and estimated demand curves and 95% pointwise confidence intervals are displayed in [Output 16.2.5](#) and [Output 16.2.6](#):

```

%macro createcurve(infile,outfile,bothfile);
    proc univariate data=&infile noprint;
        var gridPrice1-gridPrice100 gridy1-gridy100;
        output out=&outfile mean=gridPrice1-gridPrice100
            gridym1-gridym100 std=gridPrices1-gridPrices100 gridys1-gridys100;
    run;

    data &outfile%str(_mean);
        set &outfile;
        array prices[100] gridPrice1-gridPrice100;
        array demands[100] gridym1-gridym100;
        array stds[100] gridys1-gridys100;
        do i = 1 to 100;
            price=prices[i];
            estDemand=demands[i];
            estDemandLb = estDemand - 1.96*stds[i]/100;
            estDemandUb = estDemand + 1.96*stds[i]/100;
            output;
        end;
        keep price estDemand estDemandLb estDemandUb;
    run;

    data &bothfile;
        set trueCurve2;

```

```

    set &outfile%str(_mean);
run;

proc sgplot data=&bothfile;
    title 'True and Estimated Demand Curves';
    scatter x=price y=demand / markerattrs=(color=red size=5 symbol=trianglefilled)
    legendlabel="True Demand" name="demand";
    band x=price lower=estDemandLb upper=estDemandUb /
    legendlabel="95% Confidence Band " name="band";
    scatter x=price y=estDemand / markerattrs=(color=blue size=3 symbol=circle)
    legendlabel="Estimated Demand" name="estDemand";
    refline 0;
    xaxis label='Price';
    yaxis label='Demand';
run;
%mend;

```

The results of using a linear demand curve assumption as follows are shown in [Output 16.2.5](#):

```

%let infile=mygrid_if;
%let outfile=estCurve_if;
%let bothfile=bothCurves_if;
%createcurve(&infile.,&outfile.,&bothfile.);

```

Output 16.2.5 True and Estimated Demand Curves

The results of using a log-log model as follows are shown in [Output 16.2.6](#):

```
%let infile=mygrid_log_if;
%let outfile=estCurve_log_if;
%let bothfile=bothCurves_log_if;
%createcurve(&infile.,&outfile.,&bothfile.);
```

Output 16.2.6 True and Estimated Demand Curves

The coverage rate of the 95% confidence interval for the linear curve is 0%, whereas that for the log-log curve is 93%. The linear demand curve assumption is clearly wrong for this example. However, in the real world, when there is no true demand curve or it is too expensive to get such a curve through randomized controlled trials (RCTs), how can you know what is the correct model specification? You can use the nonparametric framework, but that is beyond the scope of this example.

Considering that different types of customers and different purchase times can have an impact on the estimated results, the following code segments show how to produce the conditional demand curve. There are two situations: the first is the demand curve for different types of customers, and the second is the demand curve in different time periods. The following statements generate subsets of DGP based on various conditions:

```
%macro createtrue(n,where);
  %do j=1 %to &n;
    %let l=%eval(&j-1);
    proc univariate data=mylib.deepPriceDataFull(where=(&where)) noprint;
      var gridPrice1-gridPrice100 gridy1-gridy100;
```

```

        output out=trueCurve_&j mean=gridPrice1-gridPrice100
        gridym1-gridym100;
run;

data trueCurve2_&j;
  set trueCurve_&j;
  array prices[100] gridPrice1-gridPrice100;
  array demands[100] gridym1-gridym100;
  do i = 1 to 100;
    price=prices[i];
    demand=demands[i];
    output;
  end;
  keep price demand;
run;
%end;
%mend;

```

The following statements generate subsets of estimated price and demand data sets under various conditions:

```

%macro createdata(infile,outfile,bothfile,k);
  proc univariate data=&infile noprint;
    var gridPrice1-gridPrice100 gridy1-gridy100;
    output out=&outfile mean=gridPrice1-gridPrice100
    gridym1-gridym100
    std=gridPrices1-gridPrices100 gridys1-gridys100;
  run;

  data "&outfile%scan(_2,-1, ' ') "n;
    set &outfile;
    array prices[100] gridPrice1-gridPrice100;
    array demands[100] gridym1-gridym100;
    array stds[100] gridys1-gridys100;
    do i = 1 to 100;
      price=prices[i];
      estDemand=demands[i];
      estDemandLb = estDemand - 1.96*stds[i]/sqrt(10000);
      estDemandUb = estDemand + 1.96*stds[i]/sqrt(10000);
      output;
    end;
    keep price estDemand estDemandLb estDemandUb;
  run;

  data &bothfile;
    set trueCurve2_&k;
    set "&outfile%scan(_2,-1, ' ') "n;
  run;
%mend;

```

The following statements merge the data sets and plot the demand curves under various conditions:

```

%macro createcurve(n,where,title,cols,rows,type);
  %do k=1 %to &n;
    %let l=%eval(&k-1);
    data mygrid_log_if_&k;
      set mygrid_log_if(where=(&where));
    run;
    %let infile=mygrid_log_if_&k;
    %let outfile=estCurve_log_if_&k;
    %let bothfile=bothCurves_log_if_&k;
    %createdata(&infile.,&outfile.,&bothfile.,&k);

    data bothCurves_log_if_&k;
      set bothCurves_log_if_&k;
      &type=&k;
    run;
    %if &k=1 %then %do;
      data bothCurves_log_if_all;
        set bothCurves_log_if_&k;
      run;
    %end;
    %if &k>1 %then %do;
      data bothCurves_log_if_all;
        merge bothCurves_log_if_all bothCurves_log_if_&k;
        by &type;
      run;
    %end;
  %end;

  %let varname=;

  %if &type=time %then %do;
    data bothCurves_log_if_all;
      set bothCurves_log_if_all;
      month=put(time,NLSTRMON3.1);
    run;
    %let type=time month;
    %let varname=novarname;
  %end;

  proc sgpanel data=bothCurves_log_if_all;
    title "&title";
    panelby &type /layout=panel columns=&cols rows=&rows uniscale=column &varname;
    scatter x=price y=demand / markerattrs=(color=red size=5 symbol=trianglefilled)
    legendlabel="True Demand" name="demand";
    band x=price lower=estDemandLb upper=estDemandUb /
    legendlabel="95% Confidence Band " name="band";
    scatter x=price y=estDemand / markerattrs=(color=blue size=3 symbol=circle)
    legendlabel="Estimated Demand" name="estDemand";
    refline 1.5 /AXIS=X lineattrs=( color=green thickness=1);
    refline 1 /AXIS=Y lineattrs=( color=green thickness=1);
    colaxis label='Price';
    rowaxis label='Demand' values=(0 to 10 by 1) ;
  run;

```

```
%mend;
```

The following statements pass parameters to the macro, select criteria for classification, add a title, and format the display:

```
%let n=10;
%let where= customertype %quote(=)%str(&j);
%createtrue(&n,&where);
%let where= customertype %quote(=)%str(&k);
%let title=Demand Curves for Different Types of Customers;
%let cols=2;
%let rows=5;
%let type=customertype;
%createcurve(&n,&where,&title,&cols,&rows,&type);
```

The results are shown in [Output 16.2.7](#)

Output 16.2.7 True and Estimated Condition Price vs. Demand Curves

Different types of customers have varying degrees of sensitivity to prices. Customers of customertype1 and customertype2 are the most price-sensitive, especially when price < 1.5. Customers of customertype4 and customertype5 are somewhat price-sensitive, whereas customers of customertype7, customertype8, customertype9, and customertype10 are relatively price-insensitive.

The following statements pass parameters to the macro, select criteria for purchasing time, add a title, and format the display:

```

%let n=12;
%let where=time%quote(>=)%str(&)1 and time%quote(<=)%str(&)j;
%createtrue(&n, &where)
%let where=time%quote(>=)%str(&)1 and time%quote(<=)%str(&)k;
%let title=Demand Curves for Each Month;
%let type=time;
%let cols=3;
%let rows=4;
%createcurve(&n, &where, &title, &cols, &rows, &type);

```

The results are shown in [Output 16.2.8](#):

Output 16.2.8 True and Estimated Condition Demand Curves

The price sensitivity varies in different months. In February, March, April, and May, customers are not very sensitive to price changes, but in November and December, customers are very sensitive to price changes. The closer to the end of the year, the higher the price sensitivity. At the beginning of the year, the price sensitivity is relatively low.

In summary, only by specifying the correct functional form in PROC DEEPPRICE can you correctly estimate the demand curve. The shape of the estimated demand curves varies across customer types and over time.

Overview: DYNAMICLINEAR Procedure

Dynamic linear models (DLMs) are a cornerstone in the analysis of time series data. Their versatility has led to their widespread application in diverse fields such as economics, finance, science, and engineering. One of the primary SAS tools for working with DLMs is the DYNAMICLINEAR procedure, which focuses on simultaneous graphical dynamic linear models (SGDLMs) in particular.

PROC DYNAMICLINEAR offers a number of features, including the following:

- the ability to specify the model structure, enabling users to define the relationship between variables
- a provision for setting initial values for prior distributions, which is pivotal in Bayesian time series analysis
- detailed output options, which include filtering results. These help you refine and adjusting the model for better predictions.
- comprehensive forecasting tools, which deliver the mean, standard error, covariance matrix, median, and confidence intervals for forecasts of variables. Such in-depth statistics provide a holistic view of potential future scenarios.
- support for multistep forecasts after each observation, which enhance the granularity and flexibility of prediction

Because PROC DYNAMICLINEAR runs on SAS Cloud Analytic Services (CAS), it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- exploits all the available cores and concurrent threads

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);  
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “[Introduction to Shared Concepts](#)” on page 54 in Chapter 4, “[Shared Concepts](#).”

Overview of Dynamic Linear Models

Dynamic linear models (DLMs) emerged in the early 1960s and are intricately linked with state space models (SSMs). Petris, Petrone, and Campagnoli (2009) stated that DLMs held an advantage over the then-popular ARMA models by providing more flexibility in handling nonstationary data, modeling structural changes, and offering increased interoperability.

At the core of DLMs is the idea of considering the outputs of a dynamic system as functions of unobservable or latent state processes that are influenced by random disturbances. By conditioning on these latent variables, DLMs can effectively capture the dependencies within data. A standout feature of DLMs is their Bayesian structure, which facilitates recursive computation. This capability ensures that conditional distributions can be seamlessly updated to incorporate fresh data. Significantly, this can be achieved without the need to retain past data, making DLMs especially well suited for sequential data analysis, online learning, and handling voluminous data sets.

General one-dimension DLMs have the following format:

$$y_t = \mathbf{F}_t' \boldsymbol{\theta}_t + v_t$$

$$\boldsymbol{\theta}_t = \mathbf{G}_t \boldsymbol{\theta}_{t-1} + \mathbf{w}_t$$

where

- y_t is the observation at time t .
- $\mathbf{F}_t$ is the known $p \times 1$ constant or regressor matrix at time t .
- $\boldsymbol{\theta}_t$ is the $p \times 1$ state variable.
- v_t is the observation noise, where $v_t \sim N(0, v_t)$.
- $\mathbf{w}_t$ is the $p \times 1$ state evolution noise, or innovation, where $\mathbf{w}_t \sim N(0, \mathbf{W}_t)$.
- v_t and $\mathbf{w}_t$ are mutually independent.
- $\mathbf{G}_t$ is the known $p \times p$ state evolution matrix at time t .
- $\boldsymbol{\theta}_t \sim N(\mathbf{m}_t, \mathbf{C}_t)$, where $\boldsymbol{\theta}_t$ is independent of v_t and $\mathbf{w}_t$ for all t .

Getting Started: DYNAMICLINEAR Procedure

This section provides a basic example of using the DYNAMICLINEAR procedure.

Simultaneous Graphical Dynamic Linear Models

This example is designed to demonstrate the process of defining a simultaneous graphical dynamic linear model (SGDLM) within PROC DYNAMICLINEAR. SGDLMs, known for their advanced approach in handling dynamic, multivariate time series data, offer a robust framework for modeling complex interactions over time. For a deeper dive into the mechanics and applications of SGDLMs, including their unique strengths and how they can be effectively used in various scenarios, see the section “[Simultaneous Graphical Dynamic Linear Models](#)” on page 1053.

The following DATA step loads the sample data:

```

;
```

Parental sets play a pivotal role in the structure and effectiveness of SGDLMs. According to Gruber and West (2016) and Gruber and West (2017), SGDLMs are adept at extracting correlations among time series, largely because of their sophisticated structural design that involves parental sets. For a more comprehensive understanding of parental sets, including their definition and importance in SGDLMs, see the sections “[PARENTALSET Statement](#)” on page 1052 and “[Parental Sets of Simultaneous Graphical Dynamic Linear Models](#)” on page 1059. The following code produces the parental sets for the provided sample data, illustrating their configuration within the model:

```
data mylib.adj_table;
  input ChildID ParentID;
datalines;
2          1
3          1
3          2
4          2
2          3
4          3
2          4
```

```

3           4
3           5
4           5
1           5
;

```

In SGDLMS, it is assumed that the observations adhere to a normal-gamma distribution, and their progression is tracked using the Kalman filter. PROC DYNAMICLINEAR offers multiple methods of defining the initial posterior distribution of these models. The following SAS code shows how to create input data tables that determine the initial means and covariances for SGDLMS. These tables are subsequently used in the INITIALDISTRIBUTION statement to set up the model's initial state.

```

data mylib.init_mean;
  input varname $1-4   varid parmname $24-40   parmid parmvalue;

```

This initial setup is crucial, because it forms the foundation on which the model builds its subsequent forecasts and analyses. For a thorough understanding of how to configure the initial distribution in SGDLMs, see the section “[INITIALDISTRIBUTION Statement](#)” on page 1049.

The INITIALDISTRIBUTION statement enables you to continue analyzing a previously saved SGDLM. This is particularly effective when you use it along with the OUTFILTERINFO= option in the [FILTER statement](#). Together, these features allow for a seamless continuation of model analysis from a saved state, ensuring the integrity and consistency of the SGDLM’s progression over time.

DLMs use discount factors to regulate the proportion of state evolution error variance that is considered during the model’s evolution. For more information, see the section “[Discount Factors in Dynamic Linear Models](#)” on page 1057. The following code shows how to use PROC DYNAMICLINEAR to fit an SGDLM to a given data set. In this example, the discount factors are defined using the [DISCOUNTFACTOR statement](#).

```
proc dynamicLinear data=mylib.test_data;
  id t;
  model y1-y5;
  parentalSet inAdjacency=mylib.adj_table;
  filter out(percentiles=(2.5 50 97.5))=mylib.out_filter back=0;
  forecast out(percentiles=(2.5 50 97.5))=mylib.out_forecast lead=3;
  initialDistribution inMean=mylib.init_mean inCovariance=mylib.init_cov
    shape=(positions=(1 2 5) values=(20 30 40));
  discountFactor deltaGamma=(positions=(3 5) values=(0.997 0.998));
run;
```

Upon successful execution of the preceding code, you can review the model’s summary tables in [Figure 17.1](#), which provides insight into the fit and performance of the SGDLM.

Figure 17.1 Model Summary
The DYNAMICLINEAR Procedure

The following SAS code is designed to create a visual representation of the empirical confidence interval for the variable y_1 . An empirical confidence interval offers an estimate of the range within which you expect to find the true value of y_1 a certain percentage of the time, according to the sample data. This code produces a plot that showcases the variability of y_1 , with the empirical confidence interval demarcated, thus providing a visual assessment of the precision of y_1 's estimated values within the model. The results are shown in Figure 17.4.

        markers markerattrs=(color=red size=5 symbol=circlefilled)
        lineattrs=(color=red pattern=shortdash);
    series x=t y=Mean_y1 / legendlabel='Mean_y1'
        markers markerattrs=(color=blue size=5 symbol=triangle)
        lineattrs=(color=blue pattern=solid);
    series x=t y=P50_y1 / legendlabel='Median_y1'
        markers markerattrs=(color=cyan size=5 symbol=circle)
        lineattrs=(color=cyan pattern=solid);
    label t="Date" y1="Values";
run;
```

Figure 17.4 Empirical Confidence Intervals of Variable y1

The prior example demonstrates how to specify parental sets, initial distributions, and discount factors in PROC DYNAMICLINEAR. It is important to note that these statements are optional, offering flexibility according to the user's needs and expertise. Additionally, for generating plots of confidence intervals, the data that are specified in the OUT= option of the FILTER statement are essential.

PROC DYNAMICLINEAR is designed with a high degree of flexibility to cater to a wide range of users. This includes those who are primarily interested in forecasting outcomes but might not have extensive knowledge of model configuration. For such users, a simpler and more concise code setup can be just as effective. The following code is an example of such a streamlined configuration, which is aimed at maximizing ease of use and accessibility:

```
proc dynamicLinear data=mylib.test_data;
  id t;
  model y1-y5;
  parentalSet inAdjacency=mylib.adj_table;
  forecast out=mylib.out_forecast lead=3;
run;
```

This simplified approach enables users to take advantage of the powerful forecasting capabilities of PROC DYNAMICLINEAR without the need to delve into more complex configuration details.

Syntax: DYNAMICLINEAR Procedure

The following statements are available in the DYNAMICLINEAR procedure. Items within angle brackets (<>) are optional.

```
PROC DYNAMICLINEAR DATA=libref.data-table < options > ;
  DISCOUNTFACTOR < options > ;
  FILTER < options > ;
  FORECAST < options > ;
  GPU < options > ;
  ID variable ;
  INITIALDISTRIBUTION < options > ;
  MODEL variable-list ;
  PARENTALSET < options > ;
```

Functional Summary

The statements and options available in the DYNAMICLINEAR procedure are summarized in [Table 17.1](#).

Table 17.1 Functional Summary

Description	Statement	Option
Input Data Table Options		
Specifies the input data table	PROC DYNAMICLINEAR	DATA=
Specifies the initial values for all discount factors	DISCOUNTFACTOR	INDISCOUNTFACTOR=
Specifies the initial covariance values by using a row-oriented table	INITIALDISTRIBUTION	INCOVARIANCE=
Specifies the initial variance values (diagonal) for the initial distribution's covariances	INITIALDISTRIBUTION	INCOVARIANCE(DIAGONAL)=
Specifies the initial values for the shape and rate parameters of the normal-gamma distribution	INITIALDISTRIBUTION	INGAMMA=
Specifies the initial values of means by using a column-oriented table	INITIALDISTRIBUTION	INMEAN=
Specifies the adjacency matrix of the parental sets	PARENTALSET	INADJACENCY=
Output Data Table Options		
Specifies the table to use for validating the input discount factors	DISCOUNTFACTOR	OUTVERIFICATION=
Specifies the output table for the covariances of prior/naive posterior/posterior normal-gamma distributions	FILTER	COVARIANCE=
Specifies the output table for the shape and rate parameters of prior/naive posterior/posterior normal-gamma distributions	FILTER	GAMMA=

Table 17.1 *continued*

Description	Statement	Option
Specifies the output table for Kullback-Leibler divergence information in the decoupling step of updating the distribution from naive posterior to posterior	<code>FILTER</code>	<code>KLDIVERGENCE=</code>
Specifies the output table for raw random samples of precisions during forecasting/importance sampling	<code>FILTER</code>	<code>LAMBDA=</code>
Specifies the output table for the means of prior/naive posterior/posterior normal-gamma distributions	<code>FILTER</code>	<code>MEAN=</code>
Specifies the output table for raw random samples of observation errors during forecasting	<code>FILTER</code>	<code>NU=</code>
Writes in-sample forecasting results and statistics to an output table	<code>FILTER</code>	<code>OUT=</code>
Writes the covariances of samples of in-sample forecasting observations to an output table	<code>FILTER</code>	<code>OUTCOVARIANCE=</code>
Writes samples of in-sample forecasting observations to an output table	<code>FILTER</code>	<code>OUTSIM=</code>
Specifies the output table for raw random samples of state vectors during forecasting/importance sampling	<code>FILTER</code>	<code>THETA=</code>
Writes out-of-sample forecasting results and statistics to an output table	<code>FORECAST</code>	<code>OUT=</code>
Writes the covariances of samples of out-of-sample forecasting observations to an output table	<code>FORECAST</code>	<code>OUTCOVARIANCE=</code>
Writes samples of out-of-sample forecasting observations to an output table	<code>FORECAST</code>	<code>OUTSIM=</code>
Specifies the output table for the covariances of the initial distribution	<code>INITIALDISTRIBUTION</code>	<code>COVARIANCE=</code>
Specifies the output table for the shape and rate parameters of the initial distribution	<code>INITIALDISTRIBUTION</code>	<code>GAMMA=</code>
Specifies the output table for the means of the initial distribution	<code>INITIALDISTRIBUTION</code>	<code>MEAN=</code>
Specifies the output table to use for verifying the input adjacency matrices	<code>PARENTALSET</code>	<code>OUTVERIFICATION=</code>
Common Options		
Specifies the number of simulations in filtering and forecasting	<code>PROC DYNAMICLINEAR</code>	<code>NSIMULATIONS=</code>
Specifies a nonnegative integer to use as the seed for generating random number sequences	<code>PROC DYNAMICLINEAR</code>	<code>SEED=</code>

Table 17.1 *continued*

Description	Statement	Option
ID Variable		
Identifies observations in the input data table by specifying a variable for the time series data	ID	
Variable and Parameter Declaration Options		
Specifies the model's stochastic volatility discount factors	DISCOUNTFACTOR	BETA=
Specifies the model's discount factors for regressors in the parental sets	DISCOUNTFACTOR	DELTAGAMMA=
Specifies the model's discount factors for regressors not in the parental sets	DISCOUNTFACTOR	DELTAPHI=
Specifies the starting covariance settings for the initial distribution	INITIALDISTRIBUTION	COVARIANCE=
Specifies the default initial value for all means	INITIALDISTRIBUTION	MEAN=
Specifies the starting setting for the initial distribution's rate parameter	INITIALDISTRIBUTION	RATE=
Specifies the starting setting for the initial distribution's shape parameter	INITIALDISTRIBUTION	SHAPE=
Specifies the variables to use for the model	MODEL	
Inference Options		
Specifies the number of observations before the end of the data at which the forecasts begin	FILTER	BACK=
Specifies the number of the multistep forecast values to compute during filtering	FILTER	LEAD=
Specifies which parameters of the naive posterior distribution to output	FILTER	NAIVEPOSTERIOR=
Specifies which filtering information to write to output tables	FILTER	OUTFILTERINFO=
Specifies which parameters of the posterior distribution to output	FILTER	POSTERIOR=
Specifies which raw random samples to output during forecasting	FILTER	PREDICTIONSAMPLE=
Specifies which parameters of the prior distribution to output	FILTER	PRIOR=
Specifies which raw random samples to output during the recoupling of importance sampling	FILTER	RECOUPLINGSAMPLE=
Specifies the number of the multistep forecast values to compute during forecasting	FORECAST	LEAD=
GPU Options		
Specifies that the model perform calculations by using GPU hardware	GPU	

Table 17.1 *continued*

Description	Statement	Option
Specifies the computation precision that the model uses for calculations on GPU hardware	GPU	PRECISION=

PROC DYNAMICLINEAR Statement

PROC DYNAMICLINEAR DATA=*libref.data-table* < options > ;

The PROC DYNAMICLINEAR statement invokes the DYNAMICLINEAR procedure. You must specify the following option:

DATA=*libref.data-table*

TABLE=*libref.data-table*

names the input data table for PROC DYNAMICLINEAR to use. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

data-table specifies the name of the input data table.

For the sample data, see the section “Simultaneous Graphical Dynamic Linear Models” on page 1030.

NOTE: No missing data are allowed in the input data table. If missing data are detected, the procedure stops and returns an error message.

You can also specify the following *options*:

NSIMULATIONS=*number*

NSIM=*number*

specifies the number of simulations during both forecasting and the subsequent posterior update phase. The *number* must be a positive integer. By default, NSIMULATIONS=10000.

SEED=*number*

specifies a nonnegative integer as the seed for generating random number sequences. When the seed value is set to 0, random number streams are generated by using the time of day from the computer’s clock. A seed value greater than 0 ensures a consistent and reproducible random number sequence. By default, SEED=0.

DISCOUNTFACTOR Statement

DISCOUNTFACTOR <options> ;

The DISCOUNTFACTOR statement specifies parameters of discount factors. For more information, see the section “Discount Factors in Dynamic Linear Models” on page 1057.

You can use one of the following methods to specify the discount factors:

1. Default value: If you do not specify a value, a system-defined default value is applied to all variables.
2. Position-value number-list pair: You can provide a list in which each pair consists of a variable's position in the *variables*, followed by the desired discount factor.
3. INDISCOUNTFACTOR= option: You can assign parameters directly through an input data table that you specify in the INDISCOUNTFACTOR= option.

When you use multiple methods to specify the discount factors, they are applied in the preceding sequence: first, the default value is applied; then, any specified position-value number-list pairs override the default; and finally, any values that are provided in the input table supersede previous specifications.

You can specify the following *options*:

BETA=(suboptions)

specifies the volatility discount factor, which is applicable to all variables (series) that you specify in the MODEL statement. The values of discount factors must be between 0 and 1, exclusive.

You can specify the following *suboptions*:

DEFAULT=number

DEF=number

specifies the default BETA= option value for all variables in the MODEL statement. By default, DEFAULT=0.95.

POSITIONS=(number-list)

POS=(number-list)

designates the positions of the variables for which values differ from the default. Every number in the *number-list* must be a positive integer.

VALUES=(number-list)

VAL=(number-list)

specifies values that correspond to the POSITIONS= option list values. Every number in the *number-list* must be between 0 and 1, exclusive.

DELTAGAMMA=(suboptions)

specifies the discount factor for regressors (the independent or exogenous variables) that are in the parental sets.

You can specify the following *suboptions*:

DEFAULT=*number*

DEF=*number*

specifies the default DELTAGAMMA= option value for all variables in the MODEL statement. By default, DEFAULT=0.995.

POSITIONS=(*number-list*)

POS=(*number-list*)

designates the positions of the variables for which values differ from the default. Every number in the *number-list* must be a positive integer.

VALUES=(*number-list*)

VAL=(*number-list*)

specifies values that correspond to the POSITIONS= option list values. Every number in the *number-list* must be between 0 and 1, exclusive.

DELTAPHI=(*suboptions*)

specifies the model's discount factors for regressors (the independent or exogenous variables) that are not in the parental sets.

You can specify the following *suboptions*:

DEFAULT=*number*

DEF=*number*

specifies the default DELTAPHI= option value for all variables in the MODEL statement. By default, DEFAULT=0.995.

POSITIONS=(*number-list*)

POS=(*number-list*)

designates the positions of the variables for which values differ from the default. Every number in the *number-list* must be a positive integer.

VALUES=(*number-list*)

VAL=(*number-list*)

specifies values that correspond to the POSITIONS= option list values. Every number in the *number-list* must be between 0 and 1, exclusive.

INDISCOUNTFACTOR=*libref.data-table*

INDF=*libref.data-table*

specifies the input data table for discount factors. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

When you use this option to specify discount factors, the input data table must adhere to specific format requirements. For more information, see the section “[INDISCOUNTFACTOR= Data Table in the DISCOUNTFACTOR Statement](#)” on page 1060.

OUTVERIFICATION=*libref.data-table*

OUTVERIFY=*libref.data-table*

specifies the table to use for validating input discount factors. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

FILTER Statement

FILTER <options> ;

The FILTER statement specifies the outputs and parameters of filtering. You can specify the following options:

BACK=*number*

specifies the number of steps from the end of the data set at which to begin generating output for the **OUT=**, **OUTSIM=**, and **OUTFILTERINFO=** options. The *number* should be less than or equal to the total number of observations minus one and must be greater than zero. When **BACK=0**, the output starts from the beginning of the data set. By default, **BACK=1**, which initiates the output one step before the end of the data set.

LEAD=*number*

specifies the quantity of multistep forecast values to be calculated during the filtering process. The *number* must be a nonnegative integer. By default, **LEAD=1**, which executes a one-step-ahead forecast.

OUT<(**PERCENT=***numeric-list*)>=*libref.data-table*

OUT<(**PCT=***numeric-list*)>=*libref.data-table*

writes the sample means of predictions, the sample variances, and the associated percentiles during the filtering process to a designated output data table. **PERCENT=***numeric-list* is an optional component that denotes the desired percentile points. Every value in the *numeric-list* should be between 0 and 100, inclusive, with values separated by either commas or spaces. Notably, the values of 0 and 100 equate to the minimum and maximum values, respectively. By default, **PERCENT=2.5** and **97.5**, which represent the 2.5th and 97.5th percentile points, respectively. For more information, see the section “[OUT= Data Table Generated by the Statements](#)” on page 1065. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

Consistency in the results of percentiles aligns with the **PCTLDEF=4** criteria, as discussed in the section “Calculating Percentiles” (Chapter 3, *Base SAS Procedures Guide: Statistical Procedures*) in the UNIVARIATE procedure.

OUTCOVARIANCE=*libref.data-table*

OUTCOV=*libref.data-table*

writes the covariances of samples of in-sample forecasting observations to an output table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

NOTE: This table consumes memory resources, particularly in scenarios that involve multistep forecasting where the LEAD= option value is greater than 1 and the number of variables in the MODEL statement is large. The requirement for memory also increases when multiple steps at the end of the data are included for output, which occurs when the BACK= option value is 0 or greater than 1.

OUTFILTERINFO=(suboptions)

specifies the scope of filtering information to be exported to output tables. It includes the distribution parameters such as the prior, the naive posterior, and the posterior. Additionally, it encompasses the Kullback-Leibler divergence of posteriors, raw samples obtained during the prediction generation, and the recoupling of importance sampling. **NOTE:** Exercise caution when using the following *suboptions*, because they are memory-intensive.

You can specify the following *suboptions*:

KLDIVERGENCE=libref.data-table

KLDIV=libref.data-table

specifies the output table for Kullback-Leibler (KL) divergence information in the decoupling step of updating the distribution from naive posterior to posterior. The KL divergence is the indication of the closeness between the revised variational-Bayes-based posterior estimation and the true posterior. The larger the value, the closer the two distributions are. The range of the KL divergence is between 0 and 1, inclusive. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

NAIVEPOSTERIOR=(naiveposterior-options)

NAIVEPOST=(naiveposterior-options)

specifies which parameters of the naive posterior distribution to output.

You can specify the following *naiveposterior-options*:

COVARIANCE=libref.data-table

COV=libref.data-table

specifies the output table for the covariances of naive posterior normal-gamma distributions. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

GAMMA=libref.data-table

specifies the output table for the shape and rate parameters of naive posterior normal-gamma distributions. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

MEAN=*libref.data-table*

specifies the output table for the means of naive posterior normal-gamma distributions. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

POSTERIOR=(*posterior-options*)**POST=**(*posterior-options*)

specifies which parameters of the posterior distribution to output.

You can specify the following *posterior-options*:

COVARIANCE=*libref.data-table***COV=***libref.data-table*

specifies the output table for the covariances of posterior normal-gamma distributions. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

GAMMA=*libref.data-table*

specifies the output table for the shape and rate parameters of posterior normal-gamma distributions. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

MEAN=*libref.data-table*

specifies the output table for the means of posterior normal-gamma distributions. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

PREDICTIONSAMPLE=(*predictionsample-options*)**PREDSMPL=**(*predictionsample-options*)

specifies which raw random samples to output during forecasting. **NOTE:** 1. These tables require significant memory resources, particularly the table that stores samples of state vectors (a table that you specify in the *THETA= predictionsample-option*). 2. The *PREDSMPL=* option is not supported when you run the procedure and enable GPUs.

You can specify the following *predictionsample-options*:

LAMBDA=*libref.data-table*

specifies the output table for raw random samples of precisions during forecasting. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

NU=libref.data-table

specifies the output table for raw random samples of observation errors during forecasting. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

THETA=libref.data-table

specifies the output table for raw random samples of state vectors during forecasting. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

PRIOR=(prior-options)

specifies which parameters of the prior distribution to output.

You can specify the following *prior-options*:

COVARIANCE=libref.data-table**COV=libref.data-table**

specifies the output table for the covariances of prior normal-gamma distributions. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

GAMMA=libref.data-table

specifies the output table for the shape and rate parameters of prior normal-gamma distributions. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

MEAN=libref.data-table

specifies the output table for the means of prior normal-gamma distributions. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

RECOUPLINGSAMPLE=(recouplingsample-options)**RECSMPL=(recouplingsample-options)**

specifies which raw random samples to output during the recoupling of importance sampling. **NOTE:** 1. These tables require significant memory resources, particularly the table that stores samples of state vectors (a table that you specify in the *THETA= prediction-sample-option*). 2. The RECSMPL= option is not supported when you run the procedure and enable GPUs.

You can specify the following *recouplingsample-options*:

LAMBDA=libref.data-table

specifies the output table for raw random samples of precisions during the recoupling of importance sampling. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

THETA=libref.data-table

specifies the output table for raw random samples of state vectors during the recoupling of importance sampling. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

OUTSIM=libref.data-table

writes samples of in-sample forecasting observations to an output table. These samples are generated according to the prior distribution and are used to compute the statistics in the [OUT=](#) output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

NOTE: This table requires substantial memory resources, particularly in scenarios that involve multi-step forecasting where the [LEAD=](#) option value is greater than 1. The requirement for memory also increases when multiple steps at the end of the data are included for output, which occurs when the [BACK=](#) option value is greater than 1 or when [BACK=0](#).

FORECAST Statement

FORECAST < options> ;

The FORECAST statement specifies the outputs and parameters of forecasting.

You can specify the following *options*:

LEAD=number

specifies the number of the multistep forecast values to compute, where *number* is a nonnegative integer. By default, [LEAD=1](#), which means that a one-step-ahead forecast is performed at the end of the available data.

OUT<(PERCENT=numeric-list)>=libref.data-table**OUT<(PCT=numeric-list)>=libref.data-table**

writes the sample means of predictions, the sample variances, and the associated percentiles during the forecasting process to a designated output data table. [PERCENT=numeric-list](#) is an optional component that denotes the desired percentile points. Every value in the *numeric-list* should be between 0 and 100, inclusive, with values separated by either commas or spaces. Notably, the values of 0 and 100 equate to the minimum and maximum values, respectively. By default, [PERCENT=2.5](#) and [97.5](#), which represent the 2.5th and 97.5th percentile points, respectively. For more information, see the section “[OUT= Data Table Generated by the Statements](#)” on page 1065. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more

information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

Consistency in the results of percentiles aligns with the PCTLDEF=4 criteria, as discussed in the section “Calculating Percentiles” (Chapter 3, *Base SAS Procedures Guide: Statistical Procedures*) in the UNIVARIATE procedure.

OUTCOVARIANCE=*libref.data-table*

OUTCOV=*libref.data-table*

writes the covariances of samples of out-of-sample forecasting observations to an output table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

NOTE: This table consumes memory resources, particularly in scenarios that involve multistep forecasting where the **LEAD=** option value is greater than 1 and the number of variables in the **MODEL** statement is large.

OUTSIM=*libref.data-table*

writes samples of out-of-sample forecasting observations to an output table. These samples are generated according to the prior distribution and are used to compute the statistics in the **OUT=** output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

NOTE: This table requires substantial memory resources, particularly in scenarios that involve multi-step forecasting where the **LEAD=** option value is greater than 1.

GPU Statement

GPU <option> ;

USEGPU <option> ;

The GPU statement specifies that the model perform calculations by using graphics processing units (GPUs).

NOTE: The model reverts to CPU processing for efficiency when the value of the **NSIMULATIONS=** option in the **DYNAMICLINEAR** statement is less than 100.

You can specify the following *option*:

PRECISION=FP32 | TF32 | FP64

specifies the computation precision that the model uses for calculations on GPU hardware. The value must be FP32, TF32, or FP64. For more information, see the section “Precision of GPU Computation in PROC DYNAMICLINEAR” on page 1059. By default, **PRECISION=FP32**.

ID Statement

ID *variable* ;

The ID statement identifies observations in the input data table by specifying a variable for the time series data. The *variable* cannot have missing or duplicated values.

INITIALDISTRIBUTION Statement

INITIALDISTRIBUTION < *options* > ;

The INITIALDISTRIBUTION statement defines the initial parameters of the posterior normal-gamma distribution, which sets the starting point for the filtering process in the model. This involves specifying the mean vector, variance-covariance matrix, and other hyperparameters that are associated with the normal-gamma distribution to establish the prior beliefs about the state vector before any data are processed.

You can use one of the following methods to specify the parameters for the initial gamma distribution:

1. Default value: If you do not specify a value, a system-defined default value is applied to all variables.
2. Position-value number-list pair: You can provide a list in which each pair consists of a variable's position in the *variables*, followed by the desired gamma distribution parameter.
3. INGAMMA= option: You can assign parameters directly through an input data table that you specify in the INGAMMA= option.

When you use multiple methods to specify the gamma distribution parameters, they are applied in the preceding sequence: first, the default value is applied; then, any specified position-value number-list pairs override the default; and finally, any values that are provided in the input table supersede previous specifications.

You can specify the following *options*:

INCOVARIANCE=*libref.data-table*

INCOV=*libref.data-table*

specifies the covariance matrices for the state variables by inputting full matrices. **NOTE:** For the covariance matrices, you need to provide only the lower-triangular part of each full matrix. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

You can find an example input table for the INCOVARIANCE= option in the section “[Simultaneous Graphical Dynamic Linear Models](#)” on page 1030 and the format requirements in the section “[INCOVARIANCE= Data Table in the INITIALDISTRIBUTION Statement](#)” on page 1061.

INCOVARIANCE(DIAGONAL)=libref.data-table**INCOVARIANCE(DIAG)=libref.data-table**

specifies the diagonal elements of the covariance matrices, following the same structural guidelines as those for the INMEAN= option (see the section “[INMEAN= Data Table in the INITIALDISTRIBUTION Statement](#)” on page 1062). *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1028.

It is crucial to ensure that the inputs for the diagonal elements in the table are nonzero values. This is because zero values on the diagonal of a covariance matrix imply no variance, which is invalid in the context of defining a distribution. Variance must be greater than zero to reflect the inherent uncertainty and variability of the state variables.

You can find example inputs in the section “[INCOVARIANCE\(DIAGONAL\)= Data Table in the INITIALDISTRIBUTION Statement](#)” on page 1061.

INGAMMA=libref.data-table

specifies initial values for the shape and rate parameters of the normal-gamma distribution. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1028.

The input data table must adhere to specific format requirements. These are provided in the section “[INGAMMA= Data Table in the INITIALDISTRIBUTION Statement](#)” on page 1062.

INMEAN=libref.data-table

specifies initial values for means by using a column-oriented table. You can find an example input table for this option in the section “[Simultaneous Graphical Dynamic Linear Models](#)” on page 1030. The inclusion of varname and parmname in the table is optional, because they primarily serve to clarify the table. There are certain requirements for specifying the INMEAN= option. The requirements are provided in the section “[INMEAN= Data Table in the INITIALDISTRIBUTION Statement](#)” on page 1062. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1028.

MEAN=number

specifies the default initial value for all means within the normal-gamma distribution framework. By default, MEAN=0.

OUTVERIFICATION=(suboptions)**OUTVERIFY=(suboptions)**

outputs the initial distribution to tables for validation.

You can specify the following *suboptions*:

COVARIANCE=*libref.data-table*

COV=*libref.data-table*

specifies the output table for the covariances of the initial distribution. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

GAMMA=*libref.data-table*

specifies the output table for the shape and rate parameters of the initial distribution. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

MEAN=*libref.data-table*

specifies the output table for the means of the initial distribution. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

RATE=(*suboptions*)

specifies the initial values for the rate parameters of gamma priors that are associated with all variables (series) in the MODEL statement. For the rate parameters, you must specify positive numbers greater than 0.

You can specify the following *suboptions*:

DEFAULT=*number*

DEF=*number*

specifies the default rate parameter for all variables. By default, DEFAULT=5.

POSITIONS=(*number-list*)

POS=(*number-list*)

designates the positions of the variables for which values differ from the default. Every number in the *number-list* must be a positive integer.

VALUES=(*number-list*)

VAL=(*number-list*)

specifies values that correspond to the POSITIONS= option list values. Every number in the *number-list* must be greater than 0.

SHAPE=(*suboptions*)

specifies the initial values for the shape parameters of gamma priors that are associated with all variables (series) in the MODEL statement. For the rate parameters, specified values must be positive numbers greater than 1. These parameters are crucial, because they influence the skewness and variability of the prior distribution, thereby affecting the posterior estimates in Bayesian analysis.

You can specify the following *suboptions*:

DEFAULT=*number*

DEF=*number*

specifies the default shape parameter for all variables. By default, DEFAULT=10.

POSITIONS=(*number-list*)

POS=(*number-list*)

designates the positions of the variables for which values differ from the default. Every number in the *number-list* must be a positive integer.

VALUES=(*number-list*)

VAL=(*number-list*)

specifies values that correspond to the POSITIONS= option list values. Every number in the *number-list* must be greater than 1.

MODEL Statement

MODEL *variable-list* ;

The MODEL statement specifies the variables to use in the model. You can specify variables in a space-separated *variable-list*, and the order does not matter. The variables must be selected from the input data table (see the **DATA=** option in the **PROC DYNAMICLINEAR** statement).

PARENTALSET Statement

PARENTALSET < *options* > ;

The PARENTALSET statement specifies the parental set of the model. For more information, see the section “Parental Sets of Simultaneous Graphical Dynamic Linear Models” on page 1059.

You can specify the following *options*:

INADJACENCY=*libref.data-table*

INADJ=*libref.data-table*

specifies the input data table for the adjacency matrix, which delineates the relationships within parental sets. This option supports multiple ways to specify the adjacency matrix. For more information, see the section “Multiple Representations of the Adjacency Matrix” on page 1055. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

OUTVERIFICATION=*libref.data-table*

OUTVERIFY=*libref.data-table*

specifies the output table to use for verifying the input adjacency matrices. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1028.

Details: The DYNAMICLINEAR Procedure

Simultaneous Graphical Dynamic Linear Models

The classical dynamic linear model (DLM) often falters when confronted with high-dimensional time series that are characterized by intricate correlations. Recognizing this limitation, Gruber and West (2016) and Gruber and West (2017) introduced an enhanced version known as a simultaneous graphical dynamic linear model (SGDLM). This advanced model is adept at efficiently managing large-scale, correlated time series.

Consider an m -dimensional time series that is denoted by $\mathbf{y}_t = (y_{1t}, y_{2t}, \dots, y_{mt})'$. The SGDLM can be expressed as

$$\begin{aligned} y_{jt} &= \mathbf{F}'_{jt} \boldsymbol{\theta}_{jt} + v_{jt} = \mathbf{x}'_{jt} \boldsymbol{\phi}_{jt} + \mathbf{y}'_{\text{sp}(j),t} \boldsymbol{\gamma}_{jt} + v_{jt} \\ \boldsymbol{\theta}_{jt} &= \mathbf{G}_{jt} \boldsymbol{\theta}_{j,t-1} + \mathbf{w}_{jt} \end{aligned}$$

In this representation, $v_{jt} \sim N(0, \lambda_{jt}^{-1})$ and $\mathbf{w}_{jt} \sim N(\mathbf{0}, \mathbf{W}_{jt})$. The expression $\mathbf{y}_{\text{sp}(j),t}$ denotes a vector that represents values of other series indexed by $\text{sp}(j) \subseteq 1 : m \setminus j$, where $\text{sp}(j)$ denotes the simultaneous parental set of series j . The vector $\mathbf{x}_{jt} = (x_{j,1,t}, x_{j,2,t}, \dots)'$ denotes the vector of external predictors for series j at time t ; it is important to note that $\mathbf{x}_{jt}$ might vary in dimensions across the m variables.

First, here are the definitions of certain matrices and vectors that are related to SGDLMs:

- Let $\boldsymbol{\Theta}_t$ represent the collection of $\boldsymbol{\theta}_{jt}$ values for every j , formally written as

$$\boldsymbol{\Theta}_t = \{\boldsymbol{\theta}_{1t}, \boldsymbol{\theta}_{2t}, \dots, \boldsymbol{\theta}_{mt}\}$$

- Define $\boldsymbol{\Lambda}_t$ as a diagonal matrix that contains λ_{jt} values:

$$\boldsymbol{\Lambda}_t = \text{diag}\{\lambda_{1t}, \lambda_{2t}, \dots, \lambda_{mt}\}$$

- $\boldsymbol{\mu}_t$ is the vector given by

$$\boldsymbol{\mu}_t = (\mu_{1t}, \mu_{2t}, \dots, \mu_{mt})'$$

where the individual components are defined as $\mu_{jt} = \mathbf{x}'_{jt} \boldsymbol{\phi}_{jt}$.

The matrix $\boldsymbol{\Gamma}_t$ captures the relationships between various time series. It is defined as

$$\boldsymbol{\Gamma}_t = \begin{bmatrix} \boldsymbol{\gamma}'_{1t} \\ \boldsymbol{\gamma}'_{2t} \\ \vdots \\ \boldsymbol{\gamma}'_{mt} \end{bmatrix} = \begin{bmatrix} 0 & \gamma_{1,2,t} & \gamma_{1,3,t} & \cdots & \gamma_{1,m,t} \\ \gamma_{2,1,t} & 0 & \gamma_{2,3,t} & \cdots & \gamma_{2,m,t} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ \gamma_{m,1,t} & \gamma_{m,2,t} & \cdots & \gamma_{m,m-1,t} & 0 \end{bmatrix}$$

where $\gamma_{j,h,t} = 0$ for each $h \notin \text{sp}(j)$, $j = 1 : m$.

Use these definitions to represent the distribution of $\mathbf{y}_t$ as

$$\mathbf{y}_t \sim N(\boldsymbol{\Lambda}_t \boldsymbol{\mu}_t, \boldsymbol{\Sigma}_t)$$

where the matrices $\mathbf{A}_t$ and $\mathbf{\Sigma}_t$ are given by

$$\mathbf{A}_t = (\mathbf{I} - \mathbf{\Gamma}_t)^{-1}, \quad \mathbf{\Omega}_t \equiv \mathbf{\Sigma}_t^{-1} = (\mathbf{I} - \mathbf{\Gamma}_t)' \mathbf{A}_t (\mathbf{I} - \mathbf{\Gamma}_t)$$

and where $\mathbf{\Omega}_t$ is the precision matrix.

Finally, PROC DYNAMICLINEAR integrates the local-level dynamic linear model with the simultaneous graphical feature, as follows:

$$\begin{aligned} y_{jt} &= \mathbf{F}'_{jt} \boldsymbol{\theta}_{jt} + v_{jt} = 1 \cdot \phi_{jt} + \mathbf{y}'_{\text{sp}(j),t} \boldsymbol{\gamma}_{jt} + v_{jt} \\ \boldsymbol{\theta}_{jt} &= \mathbf{I} \cdot \boldsymbol{\theta}_{j,t-1} + \mathbf{w}_{jt} \end{aligned}$$

where $\mathbf{F}_{jt} = (1, \mathbf{y}_{\text{sp}(j),t})'$ for all j , and $\mathbf{G}_{jt} = \mathbf{I}$ for all j and t .

Forward Filtering in SGDLMS

To understand the forward filtering process in an SGDLMS, you need to understand the distributions at play. Here are the key distributions that this process uses. For more information about these distributions, see Gruber and West (2016) and Gruber and West (2017).

- The prior at time t is given by

$$p(\boldsymbol{\Theta}_t, \mathbf{A}_t | \mathcal{I}_t, \mathcal{D}_{t-1}) = \prod_{j=1:m} p_{jt}(\boldsymbol{\theta}_{jt}, \lambda_{jt} | \mathcal{I}_t, \mathcal{D}_{t-1})$$

where $\mathcal{I}_t$ denotes the information set at time t ; $\mathcal{D}_{t-1}$ denotes the data set up to time $t - 1$; and $p(\cdot | \cdot)$ denotes the density function of

$$(\boldsymbol{\theta}_{jt}, \lambda_{jt} | \mathcal{I}_t, \mathcal{D}_{t-1}) \sim \text{NG}(\mathbf{a}_{jt}, \mathbf{R}_{jt}, r_{jt}, c_{jt})$$

and

$$\begin{aligned} (\boldsymbol{\theta}_{jt} | \lambda_{jt}, \mathcal{I}_t, \mathcal{D}_{t-1}) &\sim \text{N}(\mathbf{a}_{jt}, \mathbf{R}_{jt} / (c_{jt} \lambda_{jt})) \\ (\lambda_{jt} | \mathcal{I}_t, \mathcal{D}_{t-1}) &\sim \text{Gamma}(r_{jt}/2, r_{jt} c_{jt} / 2) \end{aligned}$$

where $\text{N}(\mathbf{a}, \mathbf{A})$ is a multivariate normal distribution that has the mean $\mathbf{a}$ and the covariance matrix $\mathbf{A}$, and $\text{Gamma}(\alpha, \beta)$ is a gamma distribution that has the shape parameter α and the rate parameter β .

- The naive posterior approximation at time t to the true posterior $p(\boldsymbol{\Theta}_t, \mathbf{A}_t | \mathcal{D}_t)$ is given by

$$\tilde{p}(\boldsymbol{\Theta}_t, \mathbf{A}_t | \mathcal{D}_t) = \prod_{j=1:m} \tilde{p}_{jt}(\boldsymbol{\theta}_{jt}, \lambda_{jt} | \mathcal{D}_t)$$

where

$$(\boldsymbol{\theta}_{jt}, \lambda_{jt} | \mathcal{D}_t) \sim \text{NG}(\tilde{\mathbf{m}}_{jt}, \tilde{\mathbf{C}}_{jt}, \tilde{n}_{jt}, \tilde{s}_{jt})$$

- The true posterior at time t is

$$p(\boldsymbol{\Theta}_t, \mathbf{A}_t | \mathcal{D}_t) \propto |\mathbf{I} - \mathbf{\Gamma}_t| \prod_{j=1:m} \tilde{p}_{jt}(\boldsymbol{\theta}_{jt}, \lambda_{jt} | \mathcal{D}_t) \propto \prod_{j=1:m} p_{jt}(\boldsymbol{\theta}_{jt}, \lambda_{jt} | \mathcal{D}_t)$$

with the components

$$(\boldsymbol{\theta}_{jt}, \lambda_{jt} | \mathcal{D}_t) \sim \text{NG}(\mathbf{m}_{jt}, \mathbf{C}_{jt}, n_{jt}, s_{jt})$$

Multiple Representations of the Adjacency Matrix

For the adjacency matrix Γ , the matrix entries $\Gamma(i, j)$ indicate whether variable j belongs to the parental set of variable i . These entries must be binary (0 or 1), and all diagonal elements must be set to zero; that is, $\Gamma(i, j)$ takes the value of 0 or 1, and for all i , $\Gamma(i, i) = 0$. Here, i and j range from 1 to n , where n is the total number of variables in the data set. The adjacency matrix is not required to be symmetric, implying that $\Gamma(i, j)$ does not necessarily equal $\Gamma(j, i)$.

The Γ matrix might be formatted in one of two ways:

- A single or multiple full adjacency matrices can be provided. For a single matrix, the data table should include all variables in the MODEL statement along with an additional variable VarID, which indexes the variables according to their order in the statement. When multiple matrices are present, the data table must also include the variable RowID for the purpose of ordering. If there are n matrices in the data table and m observations for which $m > n$, then each of the first $n - 1$ matrices correlates with the $n - 1$ observations, and the last matrix applies to the subsequent $m - n + 1$ observations. **NOTE:** For different adjacency matrices that correspond to distinct time points, it is imperative to maintain a consistent number of candidates within each variable's parental set across all time points. For example, if the variable y1 has two candidates in its parental set at the initial time point, it must retain a parental set of two throughout all subsequent time points. This consistency must be followed for all variables.
- A compact form of the adjacency matrix is also available for use when suitable. In this approach, the data table that you specify in the INADJACENCY= option in the PARENTALSET statement should have as many observations as there are nonzero entries in the adjacency matrix. This data table has precisely two columns, which record the row and column indices of the nonzero elements. You can find an example of the compact form input in the section “[Simultaneous Graphical Dynamic Linear Models](#)” on page 1030.

Compact Representation of the Adjacency Matrix

PROC DYNAMICLINEAR facilitates a more streamlined input process by allowing a compact representation of Γ . To use this compact form, specify a data table that contains just two variables via the INADJACENCY= option. In this efficient format, the number of rows in the data table, each of which corresponds to an observation, should match the total count of nonzero elements in Γ .

When you use this compact representation, the data table must include these two columns:

- ParentID: Identifies the variable that is considered the “parent” in the relationship.
- ChildID: Denotes variables that are “children,” meaning that they are part of the parent variable's parental set.

The values in ParentID and ChildID are not arbitrary but should directly correspond to the order of variables as they are listed in the MODEL statement.

As an illustration, consider a compact representation for an adjacency matrix Γ_1 ,

$$\Gamma_1 = \begin{pmatrix} 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \end{pmatrix}$$

Here is the code for how such a table would be structured:

```
data Gamma_1;
  input ParentID ChildID;
datalines;
1 2
1 4
2 1
3 4
4 1
4 3
;
```

In instances where a variable's parental set is empty, meaning that it has no members, two methods are available to denote this in the compact form of an adjacency matrix. For illustration, consider that the parental sets for the second and third variables (ParentID = 2 and ParentID = 3, respectively) are empty. You can take the following approaches:

1. Assign ChildID = 0 to the variable that has an empty parental set, which in this example would apply to ParentID = 2.
2. Omit the entire row that corresponds to the variable that has the empty set, as would be the case for ParentID = 3.

A compact code representation of the adjacency matrix Γ_2 ,

$$\Gamma_2 = \begin{pmatrix} 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 0 \end{pmatrix}$$

is as follows:

```
data Gamma_2;
  input ParentID ChildID;
datalines;
1 2
1 4
2 0
4 1
4 3
;
```

Full Representation of the Adjacency Matrix

The following code is an example of a full adjacency matrix. In this matrix, the presence of a 1 indicates that the column variable is in the parental set of the row variable. For example, the variables y_2 and y_3 are in the parental set of the variable y_1 , the variables y_3 and y_4 are in the parental set of the variable y_2 , and the pattern continues accordingly.

```
data mylib.adjacency;
  input VarID y1 y2 y3 y4 y5;
datalines;
1 0 1 1 0 0
2 0 0 1 1 0
3 0 1 0 1 0
4 0 1 1 0 0
5 0 0 1 1 0
;
```

In scenarios where multiple adjacency matrices are required—such as for two distinct adjacency matrices—you can code the specification as follows:

```
data mylib.multi_adjacency;
  input VarID y1 y2 y3 y4 y5 RowID;
datalines;
1 0 1 1 0 0 1
2 0 0 1 1 0 2
3 0 1 0 1 0 3
4 0 1 1 0 0 4
5 0 0 1 1 0 5
1 0 1 0 1 0 6
2 0 0 1 0 1 7
3 1 0 0 1 0 8
4 1 0 1 0 0 9
5 0 1 1 1 0 10
;
```

Discount Factors in Dynamic Linear Models

In accordance with the exposition of Petris, Petrone, and Campagnoli (2009), the discount factor δ signifies the proportion of the state evolution error variance to be accounted for during the transition from the posterior to the prior distribution. The state evolution is mathematically represented as

$$\theta_t = \mathbf{G}_t \theta_{t-1} + \mathbf{w}_t \implies \mathbf{R}_t = \mathbf{G}_t' \mathbf{C}_{t-1} \mathbf{G}_t + \mathbf{W}_t$$

where θ_t is the state at time t , $\mathbf{G}_t$ is the state transition matrix, $\mathbf{w}_t$ is the process noise, $\mathbf{R}_t$ is the covariance of the prior normal-gamma distribution at time t , and $\mathbf{C}_{t-1}$ is the covariance of the posterior at time $t - 1$. This leads to an interpretation of $\mathbf{W}_t$ as a fraction of the term $\mathbf{G}_t' \mathbf{C}_{t-1} \mathbf{G}_t$:

$$\mathbf{W}_t = \frac{1 - \delta}{\delta} \mathbf{G}_t' \mathbf{R}_{t-1} \mathbf{G}_t \implies \mathbf{R}_t = \frac{1}{\delta} \mathbf{G}_t' \mathbf{C}_{t-1} \mathbf{G}_t$$

which suggests that $\mathbf{W}_t$ adjusts the covariance of the state evolution error to reflect the selected proportion of variance.

Petris, Petrone, and Campagnoli (2009) further note that, in practical settings, the discount factor is typically selected within the range of 0.9 to 0.99. A value closer to 1 indicates a higher confidence in the model's stability over time, whereas a value closer to 0.9 suggests greater variability and less certainty in the persistence of the state's dynamics.

The stochastic volatility discount factor, which is denoted by β , plays a critical role in the evolution of the model by updating the precision λ_{t-1} of the observation error v as you transition from the posterior to the prior distribution. To illustrate, if the gamma distribution of the posterior normal-gamma distribution at time $t - 1$ is characterized by a shape parameter n_{t-1} and a rate parameter s_{t-1} , then the transition that is influenced by β yields the parameters of the prior gamma distribution at time t as $n_t = \beta \times n_{t-1}$ for the shape and $s_t = s_{t-1}$ for the rate. This reflects how β modulates the degree of belief that is carried over from one time step to the next in the sequence of observations.

Memory Considerations in Simultaneous Graphical Dynamic Linear Models

When you work with SGDLMs, it is crucial to understand and plan for memory requirements, because these requirements scale with the size of the problem. For example, consider modeling a system that contains 400 variables. The adjacency matrix $\mathbf{\Gamma}_t$ and the precision matrix $\mathbf{\Omega}_t$, which are pivotal for importance sampling and prediction generation, would each have dimensions of 400×400 , totaling 160,000 elements per matrix. Storing each element in double precision, which is standard practice and requires 8 bytes per element, means that a single matrix consumes approximately 1.28 MB of memory, calculated by $160,000 \times 8$ bytes.

In Monte Carlo simulations that encompass 10,000 iterations, storing all adjacency and precision matrices would require approximately 25.6 GB of memory, which is twice the product of 1.28 MB per matrix and 10,000 iterations, or 12.8 GB multiplied by 2. This figure does not account for the memory consumption during other steps. Adequate memory resources are paramount. If you have insufficient memory, PROC DYNAMICLINEAR cannot run.

If memory constraints present an issue, you might need to reduce the number of variables being modeled, shorten the length of time series, or decrease the number of simulations. Each of these adjustments comes with trade-offs: reducing the number of variables and shortening series length might oversimplify the model, whereas fewer simulations could compromise the statistical robustness of the forecast results. Therefore, it is essential to find an optimal point that meets the memory limitations without significantly compromising the model's integrity and results.

Generating detailed output from the filtering and forecasting process demands significant memory resources, because these data must be retained in memory prior to being recorded in tables upon completion of the program's execution. Exercise caution when enabling such output options. For more information, see the document of the [FILTER statement](#) and the [FORECAST statement](#).

Currently, an SGDLM that contains approximately 350 variables is estimated to require about 50 GB of memory for processing on CPUs. Through careful design and optimized implementation, the GPU workflow of PROC DYNAMICLINEAR uses memory more efficiently than the CPU workflow. Using single-precision floating-point arithmetic (FP32) for GPU computations further reduces memory consumption while maintaining sufficient accuracy for the SGDLM. For instance, “[Example 17.2: Comparing CPU and GPU Workflows in Simultaneous Graphical Dynamic Linear Models](#)” on page 1077 has 300 time series ($m = 300$) and 300 observations ($T = 300$), where each variable has 10 elements in its parental set. In that case, FP32

precision requires approximately 7.6 GB of GPU memory, whereas FP64 precision requires approximately 15.04 GB.

Parental Sets of Simultaneous Graphical Dynamic Linear Models

Gruber and West (2016) posit that in practical scenarios, models are likely to have small parental sets, denoted as $\text{sp}(j)$, leading to a sparse $\mathbf{\Gamma}_t$ matrix. This sparsity in $\mathbf{\Gamma}_t$ often suggests a correspondingly sparse structure in the precision matrices $\mathbf{\Omega}_t$. The connection between zero entries in $\mathbf{\Omega}_t$ and conditional independencies within the Gaussian graphical models is discussed by Carvalho and West (2007). This foundational concept informs the nomenclature of this model class as simultaneous graphical dynamic linear models. In cases where the number of variables m is even moderate, the parental sets tend to be relatively limited in scope. If k represents the maximum size of any parental set, there would be mk nonzero entries in $\mathbf{\Gamma}_t$. Therefore, a condition where $k < (m - 1)/2$ ensures that $\mathbf{\Omega}_t$ avoids overparameterization.

The SGDLM, as implemented in PROC DYNAMICLINEAR, is specifically designed for adaptability and flexibility. Unlike fixed models, it allows the parental sets to vary over time, a feature that is crucial for evolving in response to data. This means that candidates of parental sets can differ across various time points and even for different variables. Such flexibility enables the model to effectively adapt to data, capturing the dynamics of the system under study.

Gruber and West (2017) provide an extensive discussion on the adaptability of SGDLMs. They find that smaller parental sets are generally preferable, provided that they are supported by data and predictive performance, thereby favoring increased sparsity. In larger-scale problems, a set of, for example, 20 parents for one series over a short time period might be practically indistinguishable from other candidate sets in which some parents are replaced by strongly collinear alternatives. The objective is to identify compact parental sets and adaptively revise them over time. This approach is essential for capturing and characterizing the structure and dynamics of resulting volatility matrices in terms of precision and variance. For example, in the study by Gruber and West (2017), a portfolio optimization problem that involves 401 assets is analyzed, using 20 parents for each series.

Precision of GPU Computation in PROC DYNAMICLINEAR

By default, the GPU workflow in PROC DYNAMICLINEAR uses single-precision floating-point arithmetic. This can lead to differences in the results compared to the CPU workflow, which uses double-precision arithmetic. The precision of GPU computation can affect the accuracy of the predictions and the convergence of the model, especially in cases where the data has a large range or the model is complex. It is important to understand these differences and consider them when you interpret the results from PROC DYNAMICLINEAR.

The GPU workflow supports three different precisions: TF32, FP32, and FP64.

- TF32 uses 19 bits for the significand and 8 bits for the exponent, allowing it to represent a wide range of values while maintaining a reasonable level of precision.
- FP32, or single-precision floating-point format, uses 23 bits for the significand and 8 bits for the exponent, providing higher precision than TF32 but with increased computational requirements.

- FP64, or double-precision floating-point format, uses 52 bits for the significand and 11 bits for the exponent, offering even higher precision but with significantly increased computational requirements.

The default precision is FP32, which provides a good balance between performance and accuracy for many applications. However, you can use FP64 for higher precision at the cost of slower computations. The choice of precision can depend on the specific requirements of the analysis and the characteristics of the data that you are analyzing. In general, it is recommended that you start with the default FP32 precision and evaluate the results before considering other precision options.

TF32 is not a C++ data type; it is purely a compute mode for NVIDIA Tensor Cores on Ampere+ GPUs. Within cuBLAS GEMM (general matrix multiplication) operations, the Tensor Core internally truncates the mantissa from 23 to 10 bits, performs multiplication in that reduced precision, and accumulates the result in FP32. The output is then written back as a regular single-precision float. Because GPU architectures are optimized around GEMM operations, TF32 can deliver substantial throughput gains (measured in tera floating-point operations per second, or TFLOPS) over FP32 and FP64, as illustrated by the following A100 Tensor Core peak throughput figures:

Precision	GEMM TFLOPS
FP64	19.5
FP32	19.5
TF32	156
FP16	312

Because PROC DYNAMICLINEAR is currently more GEMV (general matrix-vector multiplication)-intensive than GEMM-intensive, TF32 provides less benefit than it would for a workload that is dominated by GEMM operations. However, as the implementation of PROC DYNAMICLINEAR continues to evolve, future versions might use more GEMM operations, which could make TF32 a more attractive option for users who want to maximize performance on compatible GPUs.

Data Table Input

PROC DYNAMICLINEAR takes multiple input data tables. All input data tables are listed in [Table 17.1](#). The following sections provide an example of each table.

INDISCOUNTFACTOR= Data Table in the DISCOUNTFACTOR Statement

The input data table should be row-oriented, adhering to the following format specifications:

- The identifiers FactorID for discount factors are outlined in the following table:

Factor Name	Factor ID
beta	1
deltaphi	2
deltagamma	3

- You must include the IDs of discount factors, labeled as FactorID, in the data table.

- In the input of the TABLE= option, the number 0 can serve as a placeholder for any variables for which you choose not to assign specific values. This placeholder is ignored by the program, preserving the previously specified values from the DEFAULT= option or from the lists in the POSITIONS= and VALUES= options.

The following code demonstrates how to set the discount factors for a subset of variables—namely, y1, y2, y3, and y5—within your model for the BETA= and DELTAGAMMA= options:

```
data mylib.init_discfactors;
    input factorid y1 y2 y3 y5;
datalines;
1    0.91  0.92  0.93  0.94
3    0.85  0.86  0.87  0.89
;
```

INCOVARIANCE= Data Table in the INITIALDISTRIBUTION Statement

When you specify the INCOVARIANCE= option, use the following format requirements:

- An index column labeled RowID must be included in the INCOVARIANCE= data table. This column is essential for sorting the entries in the correct order, ensuring the proper structure of the covariance matrix.
- The table should be free of redundant columns. Because all columns in the table are processed, extraneous columns could introduce errors or distort the intended covariance specifications.
- The table must not have any missing values. In the context of a covariance matrix, missing entries are not permissible, because they could imply undefined relationships between variables. If gaps are present, they must be filled with zeros. However, care should be taken, because zero entries in a covariance matrix suggest no correlation, which might not always be the intended implication. Therefore, filling with zeros should be done with consideration of the matrix's interpretive context.

INCOVARIANCE(DIAGONAL)= Data Table in the INITIALDISTRIBUTION Statement

Here is example input for the diagonal covariance input. Including varname and parmname in the table is optional, because they primarily serve to make the table easier to understand.

```
data mylib.init_diag;
    input varname $1-4  varid parmname $24-40 parmvalue;
datalines;
y1          1    Const          1      0.008596271
y1          1    ParSet_1       2      0.041964947
y1          1    ParSet_2       3      0.367778311
y2          2    Const          1      0.004223895
y2          2    ParSet_1       2      0.002395241
y2          2    ParSet_2       3      0.022385176
y3          3    Const          1      0.003904836
y3          3    ParSet_1       2      0.047429031
y3          3    ParSet_2       3      0.489922549
y4          4    Const          1      0.05762658
y4          4    ParSet_1       2      0.075128833
```

```

y4          4    ParSet_2          3    0.22400379
y5          5    Const             1    0.104497114
y5          5    ParSet_1          2    2.129695978
y5          5    ParSet_2          3    0.047091226
;

```

INGAMMA= Data Table in the INITIALDISTRIBUTION Statement

The input data table should use a row-oriented format. The specifications for the gamma distribution factors are as follows:

- Assign FactorID to the gamma distribution parameters as outlined in the following table:

Factor Name	Factor ID
rate	2
shape	1

- You must include the FactorID column in the data table to reference these parameters.
- In the input of the GAMMA= option, the number 0 can be used as a placeholder for any variables for which values are not being specified. This placeholder is ignored by the program, and the program uses existing values that you specify in the DEFAULT= option or in the lists in the POSITIONS= and VALUES= options.

Here is an example of the input gamma. The following code specifies the shape parameter for y1 as 2, y2 as 5, y5 as 8, and the rate parameter for y3 as 4, respectively:

```

data mylib.init_gamma;
  input factorid y1 y2 y3 y5;
datalines;
1  2  5  0  8
2  0  0  4  0
;

```

INMEAN= Data Table in the INITIALDISTRIBUTION Statement

To correctly format the input data table of the INMEAN= option, use the following requirements:

- The table must include three specific columns: VarID, ParmID, and ParmValue.
- VarID values should correspond to the order of the variables as they appear in the MODEL statement.
- ParmID values represent distinct parameters that are associated with the means of state variables within the initial normal-gamma distribution framework:
 - A ParmID value of 1 designates the constant level (intercept) for the state variable's mean.
 - Subsequent integers (2, 3, and so on) in ParmID relate to the sequential elements of the variable's parental set, in the order in which they are defined.
- ParmValue values represent the actual values of the means for the state variables.

Data Table Output

PROC DYNAMICLINEAR can create multiple output data tables. All output data tables are listed in Table 17.1. The information in these tables is described in the following sections.

DISCOUNTFACTOR Statement

OUTVERIFICATION= Data Table Generated by the Statement

The OUTVERIFICATION= output data table contains the following variables:

RowID	index of the rows.
Variable_ i	value of the discount factors for the i th variable, $i = 1, \dots, m$, where m is the number of variables in the MODEL statement.
VarName	name of the parameter. The values are beta, deltaphi, and deltagamma.
VarID	FactorID value of the parameter.

FILTER Statement

COVARIANCE= Data Table Generated by the PRIOR=/NAIVEPOSTERIOR=/POSTERIOR= Suboption of the OUTFILTERINFO= Option

The COVARIANCE= output data table contains the following variables:

ID Variable	value of the variable in the ID statement.
LeadStep	value of h in the h -step-ahead forecast.
ParmValue_ k	parameter value for the covariances of the normal-gamma distributions at the time given by the sum of the ID Variable value and the LeadStep value. The parameters correspond to those in the local-level simultaneous graphical dynamic linear model in the section “ Simultaneous Graphical Dynamic Linear Models ” on page 1053. The dimension p of the variable is the sum of the number of the variables in the i th variable parental set and 1, and $k = 1, \dots, p$.
RowID	index of the rows.
VarName	name of the variable that corresponds to the variable in the MODEL statement.
VarID	order of the variables as they appear in the MODEL statement.
ParmName	name of the parameter.
ParmID	order of the parameters as they appear in the local-level SGDLM.

GAMMA= Data Table Generated by the PRIOR=/NAIVEPOSTERIOR=/POSTERIOR= Suboption of the OUTFILTERINFO= Option

The GAMMA= output data table contains the following variables:

ID Variable	value of the variable in the ID statement.
LeadStep	value of h in the h -step-ahead forecast.

Variable_ i	value of the shape and rate parameters for the normal-gamma distributions at a given time step for the i th variable, $i = 1, \dots, m$, where m is the number of variables in the MODEL statement. These parameters correspond to the time given by the sum of the ID Variable value and the LeadStep value.
RowID	index of the rows.
VarName	name of the parameter. The possible values are shape and rate.
VarID	FactorID value of the parameter. The possible values are 1 and 2.

KLDIVERGENCE= Data Table Generated by the OUTFILTERINFO= Option

The KLDIVERGENCE= output data table contains the following variables:

ID Variable	value of the variable in the ID statement.
LeadStep	value of h in the h -step-ahead forecast.
Effective Sample Size	value of the effective sample size at a given time step. The value is calculated on the basis of the KL divergence during the importance sampling of posterior updating. For more information about the calculation, see Gruber and West (2016).
KL Divergence	value of KL divergence at the time given by the sum of the ID Variable value and the LeadStep value.

LAMBDA= Data Table Generated by the PREDICTIONSAMPLE=/RECOUPLINGSAMPLE= Suboption of the OUTFILTERINFO= Option

The LAMBDA= output data table contains the following variables:

ID Variable	value of the variable in the ID statement.
LeadStep	value of h in the h -step-ahead forecast.
Variable_ i	samples of the precision parameter for observation errors at a given time step for the i th variable, $i = 1, \dots, m$, where m is the number of variables in the MODEL statement. The given time step is the sum of the ID Variable value and the LeadStep value.
RowID	index of the rows.

MEAN= Data Table Generated by the PRIOR=/NAIVEPOSTERIOR=/POSTERIOR= Suboption of the OUTFILTERINFO= Option

The MEAN= output data table contains the following variables:

ID Variable	value of the variable in the ID statement.
LeadStep	value of h in the h -step-ahead forecast.
ParmValue	parameter value of the means for the normal-gamma distributions at the time given by the sum of the ID Variable value and the LeadStep value.
RowID	index of the rows.
VarName	name of the variable that corresponds to the variable in the MODEL statement.
VarID	order of the variables as they appear in the MODEL statement.

ParmName	name of the parameter.
ParmID	order of the parameters as they appear in the local-level simultaneous graphical dynamic linear model in the section “ Simultaneous Graphical Dynamic Linear Models ” on page 1053.

NU= Data Table Generated by the RECOUPLINGSAMPLE= Suboption of the OUTFILTERINFO= Option

The NU= output data table contains the following variables:

ID Variable	value of the variable in the ID statement.
LeadStep	value of h in the h -step-ahead forecast.
Variable_ i	samples of the observation errors at a given time step for the i th variable, $i = 1, \dots, m$, where m is the number of variables in the MODEL statement. The given time step is the sum of the ID Variable value and the LeadStep value.
RowID	index of the rows.

THETA= Data Table Generated by the PREDICTIONSAMPLE=/RECOUPLINGSAMPLE= Suboption of the OUTFILTERINFO= Option

The THETA= output data table contains the following variables:

ID Variable	value of the variable in the ID statement.
LeadStep	value of h in the h -step-ahead forecast.
ParmValue_ k	samples of the state vectors at the time given by the sum of the ID Variable value and the LeadStep value. The dimension p of the variable is the sum of the number of the variables in the i th variable parental set and 1, and $k = 1, \dots, p$.
RowID	index of the rows.
VarName	name of the variable that corresponds to the variable in the MODEL statement.
VarID	order of the variables as they appear in the MODEL statement.

FILTER and FORECAST Statements

OUT= Data Table Generated by the Statements

NOTE: The variable names display a maximum of four decimal places. Any percentile values lower than 0.0001 are replaced by 0.0001 for representation.

In the output table, you might encounter instances where variance values of all variables are listed as 0. This situation typically arises when the NSIMULATIONS= option in the PROC DYNAMICLINEAR statement is set too low; the result is that each CPU thread handles only one job or none at all. Such a scenario can lead to an insufficient number of simulations for accurately estimating variance. To solve this problem, consider increasing the NSIMULATIONS= option value, ensuring that each thread processes a sufficient number of jobs to produce more reliable variance estimates.

The OUT= output data table contains the following variables:

ID Variable	value of the variable in the ID statement.
LeadStep	value of h in the h -step-ahead forecast.
Mean_ i	sample mean at a given time step for the i th variable, $i = 1, \dots, m$, where m is the number of variables in the MODEL statement. These sample means are derived from the prior normal-gamma distributions that correspond to the time given by the sum of the ID Variable value and the LeadStep value.
Variance_ i	sample variance at a given time step for the i th variable, $i = 1, \dots, m$, where m is the number of variables in the MODEL statement. Like the sample mean, this variable is calculated using the prior normal-gamma distributions that correspond to the time given by the sum of the ID Variable value and the LeadStep value.
P_ ij	j th ($j = 1, \dots, J$) percentile points at a given time step for the i th variable, $i = 1, \dots, m$, where m is the number of variables in the MODEL statement. The percentile points are specified by the PERCENT= <i>number-list</i> suboption of the OUT= option, and J is the number of elements in the <i>number-list</i> .

OUTCOVARIANCE= Data Table Generated by the Statements

The OUTCOVARIANCE= output data table contains the following variables:

ID Variable	value of the variable in the ID statement.
LeadStep	value of h in the h -step-ahead forecast.
Variable_ i	the covariance value at a given time step between the i th and j th variables, $i, j = 1, \dots, m$, where m is the number of variables in the MODEL statement. The sample covariance is calculated using the samples in the OUTSIM= output data table.
RowID	index of the rows.
VarName	name of the variable that corresponds to the variable in the MODEL statement.
VarID	order of the variables as they appear in the MODEL statement.

OUTSIM= Data Table Generated by the Statements

The OUTSIM= output data table contains the following variables:

ID Variable	value of the variable in the ID statement.
LeadStep	value of h in the h -step-ahead forecast.
Variable_ i	samples of forecasting observations at a given time step for the i th variable, $i = 1, \dots, m$, where m is the number of variables in the MODEL statement. These sample means are derived from the prior normal-gamma distributions that correspond to the time given by the sum of the ID Variable value and the LeadStep value.
RowID	index of the rows.

INITIALDISTRIBUTION Statement***COVARIANCE= Data Table Generated by the OUTVERIFICATION= Option***

The COVARIANCE= output data table contains the following variables:

RowID	index of the rows.
ParmValue_ k	parameter value for the covariances of the initial normal-gamma distributions. The parameters correspond to those in the local-level simultaneous graphical dynamic linear model in the section “ Simultaneous Graphical Dynamic Linear Models ” on page 1053. The dimension p of the variable is the sum of the number of the variables in the i th variable parental set and 1, and $k = 1, \dots, p$.
VarName	name of the variable that corresponds to the variable in the MODEL statement.
VarID	order of the variables as they appear in the MODEL statement.
ParmName	name of the parameter.
ParmID	order of the parameters as they appear in the local-level SGDLM.

GAMMA= Data Table Generated by the OUTVERIFICATION= Option

The GAMMA= output data table contains the following variables:

RowID	index of the rows.
Variable_ i	value of the shape and rate parameters for the initial normal-gamma distributions for the i th variable, $i = 1, \dots, m$, where m is the number of variables in the MODEL statement.
VarName	name of the parameter.
VarID	FactorID value of the parameter.

MEAN= Data Table Generated by the OUTVERIFICATION= Option

The MEAN= output data table contains the following variables:

RowID	index of the rows.
ParmValue	parameter value of the means for the initial normal-gamma distributions.
VarName	name of the variable that corresponds to the variable in the MODEL statement.
VarID	order of the variables as they appear in the MODEL statement.
ParmName	name of the parameter.
ParmID	order of the parameters as they appear in the local-level simultaneous graphical dynamic linear model in the section “ Simultaneous Graphical Dynamic Linear Models ” on page 1053.

PARENTALSET Statement**OUTVERIFICATION= Data Table Generated by the Statement**

The OUTVERIFICATION= output data table contains the following variables:

RowID	index of the rows.
Variable_ <i>i</i>	value of the adjacency matrices for the <i>i</i> th variable, $i = 1, \dots, m$, where m is the number of variables in the MODEL statement.
VarName	name of the variable that corresponds to the variable in the MODEL statement.
VarID	order of the variables as they appear in the MODEL statement.

Examples: DYNAMICLINEAR Procedure**Example 17.1: Tracking Volatility with Simultaneous Graphical Dynamic Linear Models**

This example shows how the DYNAMICLINEAR procedure enables you to track volatility by using the simultaneous graphical dynamic linear model (SGDLM) and how the parental set of the SGDLM can help you predict volatility more accurately.

Using the same notation as in the section “[Simultaneous Graphical Dynamic Linear Models](#)” on page 1053, consider generating m -dimensional time series $\mathbf{y}_t = (y_{1t}, y_{2t}, \dots, y_{mt})'$ that follow the SGDLM by using the following steps:

1. Define the adjacency matrix representation of the parental sets in the SGDLM and generate the matrix $\mathbf{\Gamma}_t$ that corresponds to the adjacency matrix for each time step, where $\mathbf{y}_{it} \sim N(0, \sigma_\gamma \mathbf{I})$ for $i = 1, \dots, m$ in the $\mathbf{\Gamma}_t$, and σ_γ is the factor that controls the volatility of the state vectors that correspond to the parental sets.
2. Generate the precision matrix $\mathbf{\Lambda}_t$ for each time step, where λ_{it} follows the gamma distribution with a shape parameter value of 1 and a rate parameter value of 1 for all $i = 1, \dots, m$ in $\mathbf{\Lambda}_t$.
3. Generate the vector $\boldsymbol{\mu}_t$ for each time step, where $\boldsymbol{\mu}_t \sim N(0, \sigma_\phi \mathbf{I})$, and where σ_ϕ is a factor to control the volatility of the state vectors that correspond to the external predictors.
4. Calculate the matrices $\mathbf{A}_t$ and $\boldsymbol{\Sigma}_t$ according to the equations $\mathbf{A}_t = (\mathbf{I} - \mathbf{\Gamma}_t)^{-1}$ and $\boldsymbol{\Sigma}_t^{-1} = (\mathbf{I} - \mathbf{\Gamma}_t)' \mathbf{\Lambda}_t (\mathbf{I} - \mathbf{\Gamma}_t)$.
5. Calculate the Cholesky decomposition of $\boldsymbol{\Sigma}_t$ to generate the lower-triangular matrix $\mathbf{L}_t$.
6. Simulate a vector $\tilde{\mathbf{y}}_t$, where $\tilde{\mathbf{y}}_t \sim N(0, \mathbf{I})$. Then generate $\mathbf{y}_t$, where $\mathbf{y}_t = \mathbf{A}_t \boldsymbol{\mu}_t + \mathbf{L}_t \tilde{\mathbf{y}}_t$.

This example assumes that each variable has five elements in its parental set. The following statements simulate 300 observations ($T = 300$) for 11 time series ($m = 11$) with the volatility factors $\sigma_\phi = 0.0001$ and $\sigma_\gamma = 0.01$:

```

*macro variables;
%let seed = 12345;
%let m = 11;
%let T = 300;
%let nparent = 5;
%let sigma_phi = 0.0001;
%let sigma_gamma = 0.01;

proc iml;
  call randseed(&seed.);
  *define the parental sets;
  nparent_j = j(&m,1,0);
  do h=1 to &m.;
    nparent_j[h] = &nparent.;
  end;

  parents=j(&m.,&m.,0);
  all_ind = 1:&m.;
  do h=1 to &m.;
    p_gam=nparent_j[h];
    if p_gam >0 then do;
      all_ind_j = all_ind[loc(all_ind ^= h)];
      parent_ju = sample(all_ind_j, p_gam, "NoReplace");
      parent_ju_c = parent_ju`;
      call sort(parent_ju_c);
      parent_j = parent_ju_c`;
      *print p_gam parent_j;
      parents[h,parent_j]=1;
    end;
  end;

  parentsc= {};
  all_ind = 1:&m.;
  do h=1 to &m.;
    parents_h = loc(parents[h,]=1);
    npar_h = ncol(parents_h);
    if npar_h >0 then do;
      do k=1 to npar_h;
        pjk = h||parents_h[k];
        parentsc = parentsc//pjk;
      end;
    end;
  end;

  *generate data;
  y=j(&T,&m.+1);
  do t=1 to &T;
    gamma_t = j(&m, &m, 0);
    all_ind = 1:&m.;
    do h=1 to &m.;
      p_gam=nparent_j[h];
      if p_gam >0 then do;
        parent_j = all_ind[loc(parents[h,] = 1)];

```

```

        gamj = j(p_gam,1);
        call randgen(gamj,"normal");
        gamma_t[h,parent_j`]=&sigma_gamma.*gamj`;
    end;
end;

*generate mu_t;
mu_ts = j(&m, 1);
call randgen(mu_ts, "Normal");
mu_t = &sigma_phi.*mu_ts;

*generate Lambdat;
lambda_t = j(&m, 1);
call randgen(lambda_t, "Gamma",1);
lambda_t = inv(diag(lambda_t));

*compute A_t, Sigma_t;
A_t = inv(I(&m)-gamma_t);
mean_t = A_t*mu_t;
Sigma_t = A_t*inv(lambda_t)*A_t`;
/* the Cholesky root of the full covariance matrix */
L_t = root(Sigma_t);
z_t = j(&m,1);
call randgen(z_t, "Normal"); /* z is MVN(0,I(&m)) */
y_t = mean_t + L_t`*z_t;
y[t,1:&m.]=y_t`;
y[t,&m.+1]=t;
end;

yr = y[loc(y[,&m.+1] <= &T-1),];

yvarNames = "y1":"y&m.";
varNames =yvarNames||"t";
create data_correlated from y [colname=varNames];
append from y;
close data_correlated;

create data_correlatedr from yr [colname=varNames];
append from yr;
close data_correlatedr;

create parents from parents [colname=yvarNames];
append from parents;
close parents;

varNamesc = {'ParentID', 'ChildID'};
create adj_table from parentsc [colname=varNamesc];
append from parentsc;
close adj_table;
run;

proc sort data=data_correlatedr;
    by t;
run;

```

The following statements load the generated data set `data_correlatedr` and the defined adjacency matrix data set `adj_table` into data tables in your session that is associated with the `mylib` libref. The DATA step assumes that your libref is named `mylib`, but you can substitute any appropriately defined libref.

```
data mylib.test_data;
    set data_correlatedr;
run;

data mylib.adj_table;
    set adj_table;
run;
```

Initialization settings are very important in SGDLMs. PROC DYNAMICLINEAR uses the identity matrix as the default initialization covariance. However, the identity matrix does not work well in this example. Following Gruber and West (2016), the covariance matrix $\mathbf{R}_{i0} = \text{diag}\{0.0001, 0.01, 0.01, 0.01, 0.01, 0.01\}$ is chosen as the initialization covariance matrix for all variables in the SGDLM. The following DATA step inputs the covariance matrices into the data set `initial_cov_with_adj` and then loads it into a data table in your session that is associated with the `mylib` libref:

```
data initial_cov_with_adj;
    input VarID ParmID ParmValue;
datalines;
1 1 0.0001
1 2 0.01
1 3 0.01

... more lines ...

11 3 0.01
11 4 0.01
11 5 0.01
11 6 0.01
;

data mylib.initial_cov_with_adj;
    set initial_cov_with_adj;
run;
```

The following statements use PROC DYNAMICLINEAR to define the preceding SGDLM and then generate predictions for the simulated data set:

```
proc dynamicLinear data=mylib.test_data nSimulations=10000 seed=12345;
    id t;
    model y1-y11;
    parentalSet inAdjacency=mylib.adj_table;
    filter out(percentiles=(0.5 2.5 50 97.5 99.5))=mylib.out_filter_with_adj
        outFilterInfo=(klDivergence=mylib.kldiv)
        back=0;
    forecast out(percentiles=(0.5 2.5 50 97.5 99.5))=mylib.out_forecast_with_adj;
    initialDistribution inCovariance(diagonal)=mylib.initial_cov_with_adj
        shape=(default=5) rate=(default=1.5);
    discountFactor beta=(default=0.98) deltaPhi=(default=0.98)
```

```
deltaGamma=(default=0.99);
run;
```

The summary tables of the model are shown in [Output 17.1.1](#).

Output 17.1.1 Model Summary
The DYNAMICLINEAR Procedure

Model Information			
Number of Variables Used		11	
Simulation Size		10000	
Random Number Seed		12345	
Forecast Lead		1	
Filter Back		0	
Filter Lead		1	
Number of Observations		299	
Number of Observations Used		299	
Input Tables			
Name	Contents	Number of Rows	Number of Columns
TEST_DATA	Data	299	12
ADJ_TABLE	Adjacency Matrices	55	2
INITIAL_COV_WITH_ADJ	Covariances (Diagonal)	66	3
Output CAS Tables			
CAS Library	Name	Number of Rows	Number of Columns
CASUSER(chuaxu)	OUT_FORECAST_WITH_ADJ	1	80
CASUSER(chuaxu)	OUT_FILTER_WITH_ADJ	298	80
CASUSER(chuaxu)	KLDIV	298	4

SGDLMs use the Kullback-Leibler (KL) divergence to measure the difference between the estimated and true posterior distributions. The KL divergence is calculated during the importance sampling of posterior updating. PROC DYNAMICLINEAR provides the KLDIVERGENCE= suboption of the OUTFILTERINFO= option in the [FILTER statement](#) to output the values of the KL divergence and the effective sample size at each step. The following statements create a plot of the two values at each step. The plot is shown in [Output 17.1.2](#).

```
data kldiv;
    set mylib.kldiv;
run;

proc sort data=kldiv;
    by t;
run;

proc sgplot data=kldiv;
    series x=t y=KLDivergence / legendlabel='KL Divergence Values'
```

```

lineattrs=(color=blue pattern=solid);
series x=t y=EffectiveSampleSize / legendlabel='Effective Sample Size Values'
lineattrs=(color=red pattern=shortdash) Y2Axis;
label t="Step" KLDivergence="KL Divergence"
EffectiveSampleSize="Effective Sample Size";
run;

```

Output 17.1.2 Values of the KL Divergence and the Effective Sample Size

Output 17.1.2 shows that PROC DYNAMICLINEAR creates a good estimation of the posterior distribution in this example: first, the effective sample size converges to the number of simulations (10,000); then the KL divergence converges to 0. For more information about the quality of the posterior estimation in SGDLMs, see Gruber and West (2016).

The following statements run the same SGDLM *without the parental sets* to compare the results to the previous ones. The purpose of this comparison is to demonstrate the effect of the parental sets. The statements first define the initial covariance matrices and then run PROC DYNAMICLINEAR. All other settings are the same as those in the preceding statements.

```

data mylib.initial_cov_wo_adj;
    input VarID ParmID ParmValue;
datalines;
1 1 0.0001
2 1 0.0001
3 1 0.0001
4 1 0.0001
5 1 0.0001
6 1 0.0001
7 1 0.0001
8 1 0.0001
9 1 0.0001
10 1 0.0001

run;

```

The following statements create a plot of the 60-step moving average values, which are the mean predictions with and without the parental sets of the variable y_1 at each step, starting from $t = 60$. The moving average values of the variable y_1 are calculated by the EXPAND procedure and recorded in the data table `test_data_ma`. Then the data are merged and recorded in the data table `y1_mean_comb`. The plot is shown in [Output 17.1.3](#).

```

proc expand data=data_correlatedr out=test_data_ma method=none;
    id t;
    convert y1 = y1_ma / transout=(movave 60);
run;

data y1_mean_comb;
    format t y1_ma y1_adj y1_wo_adj Best12.;
    set test_data_ma(keep=t y1_ma where=(t>=60));
    set mylib.out_filter_with_adj(keep=t Mean_y1 where=(t>=59)
        rename=(Mean_y1=y1_adj));
    set mylib.out_filter_wo_adj(keep=t Mean_y1 where=(t>=59)
        rename=(Mean_y1=y1_wo_adj));
    t = t+1;
run;

proc sort data=y1_mean_comb;
    by t;
run;

```

```

proc sgplot data=y1_mean_comb;
  series x=t y=y1_ma / legendlabel='Moving Average Values of y1'
    markers markerattrs=(color=red size=5 symbol=circlefilled)
    lineattrs=(color=red pattern=shortdash);
  series x=t y=y1_adj / legendlabel='Mean_y1 with the Parental Sets'
    markers markerattrs=(color=blue size=5 symbol=triangle)
    lineattrs=(color=blue pattern=solid);
  series x=t y=y1_wo_adj / legendlabel='Mean_y1 without the Parental Sets'
    markers markerattrs=(color=cyan size=5 symbol=circle)
    lineattrs=(color=cyan pattern=solid);
  label t="Step" y1_ma="Values of the Means";
run;

```

Output 17.1.3 Comparison of the Mean Predictions

Output 17.1.3 shows that in this example, the SGDLM with the parental sets and the SGDLM without the parental sets provide similar mean predictions.

The following statements create a plot of the 60-step moving average variances, which are the variance predictions with and without the parental sets of the variable y_1 at each step, starting from $t = 60$. The moving average variances of the variable y_1 are calculated by the EXPAND procedure and recorded in the data table `test_data_ma_var`. Then the data are merged and recorded in the data table `y1_var_comb`. The plot is shown in [Output 17.1.4](#).

```
/*calculate 60-step moving average variances of the variable y1*/
proc expand data=data_correlatedr out=test_data_ma_var method=none;
  id t;
  convert y1 = y1_ma_var / transout=(MOVVAR 60);
run;

data y1_var_comb;
  format t y1_ma_var y1_adj y1_wo_adj Best12.;
  set test_data_ma_var(keep=t y1_ma_var where=(t>=60));
  set mylib.out_filter_with_adj(keep=t Variance_y1 where=(t>=59)
    rename=(Variance_y1=y1_adj));
  set mylib.out_filter_wo_adj(keep=t Variance_y1 where=(t>=59)
    rename=(Variance_y1=y1_wo_adj));
  t = t+1;
run;

proc sort data=y1_var_comb;

  label t="Step" y1_ma_var="Values of the Variances";
run;
```

Output 17.1.4 Comparison of the Variance Predictions

Output 17.1.4 shows that the SGDLM with the parental sets provides better volatility tracking than the SGDLM without the parental sets. The results are consistent with the conclusions of Gruber and West (2016).

Example 17.2: Comparing CPU and GPU Workflows in Simultaneous Graphical Dynamic Linear Models

This example demonstrates how to use the GPU statement in PROC DYNAMICLINEAR to accelerate the filtering and forecasting of a large-scale simultaneous graphical dynamic linear model (SGDLM). It compares the Kullback-Leibler (KL) divergence and effective sample size of the CPU and graphics processing unit (GPU) workflows, as well as the mean, median, and variance predictions for one of the variables of an SGDLM that has 300 time series ($m = 300$) and 300 observations ($T = 300$), where each variable has 10 elements in its parental set. The example is similar to “[Example 17.1: Tracking Volatility with Simultaneous Graphical Dynamic Linear Models](#)” on page 1068. **NOTE:** Because of the difference in implementation, the GPU workflow can generate results that differ from the CPU workflow results, even when using the same random seed.

Using a data generation process similar to the one in [Example 17.1](#), the following statements simulate 300 observations for 300 time series. As in [Example 17.1](#), the covariance matrix $\mathbf{R}_{i0} = \text{diag}\{0.0001, 0.01, 0.01, \dots, 0.01, 0.01, 0.01\}$ is selected as the initialization covariance matrix for all variables in the SGDLN:

```
*macro variables;
%let seed = 12345;
%let m = 300;
%let T = 300;
%let nparent = 10;
%let sigma_phi = 0.0001;
%let sigma_gamma = 0.01;
%let nSim = 10000;
%let lead = 1;

proc iml;
  call randseed(&seed.);
  *define the parental sets;
  nparent_j = j(&m, 1, 0);
  do h = 1 to &m.;
    nparent_j[h] = &nparent.;
  end;

  parents = j(&m., &m., 0);
  all_ind = 1:&m.;
  do h = 1 to &m.;
    p_gam = nparent_j[h];
    if p_gam > 0 then do;
      all_ind_j = all_ind[loc(all_ind ^= h)];
      parent_ju = sample(all_ind_j, p_gam, "NoReplace");
      parent_ju_c = parent_ju`;
      call sort(parent_ju_c);
      parent_j = parent_ju_c`;
      parents[h, parent_j] = 1;
    end;
  end;

  parentsc = {};
  all_ind = 1:&m.;
  do h = 1 to &m.;
    parents_h = loc(parents[h,] = 1);
    npar_h = ncol(parents_h);
    if npar_h > 0 then do;
      do k = 1 to npar_h;
        pjk = h || parents_h[k];
        parentsc = parentsc // pjk;
      end;
    end;
  end;

  *generate data;
  y = j(&T, &m. + 1);
  do t = 1 to &T;
```

```

gamma_t = j(&m, &m, 0);
all_ind = 1:&m.;
do h = 1 to &m.;
    p_gam = nparent_j[h];
    if p_gam > 0 then do;
        parent_j = all_ind[loc(parents[h,] = 1)];
        gamj = j(p_gam, 1);
        call randgen(gamj, "normal");
        gamma_t[h, parent_j`] = &sigma_gamma. * gamj`;
    end;
end;

*generate mut;
mu_ts = j(&m, 1);
call randgen(mu_ts, "Normal");
mu_t = &sigma_phi. * mu_ts;

*generate Lambdat;
lambda_t = j(&m, 1);
call randgen(lambda_t, "Gamma", 1);
lambda_t = inv(diag(lambda_t));

*compute A_t, Sigma_t;
A_t = inv(I(&m) - gamma_t);
mean_t = A_t * mu_t;
Sigma_t = A_t * inv(lambda_t) * A_t`;
/* the Cholesky root of the full covariance matrix */
L_t = root(Sigma_t);
z_t = j(&m, 1);
call randgen(z_t, "Normal"); /* z is MVN(0,I(&m)) */
y_t = mean_t + L_t` * z_t;
y[t, 1:&m.] = y_t`;
y[t, &m. + 1] = t;
end;

yr = y[loc(y[, &m. + 1] <= &T - 1), ];

yvarNames = "y1":"y&m.";
varNames = yvarNames || "t";
create data_correlated from y [colname=varNames];
append from y;
close data_correlated;

create data_correlatedr from yr [colname=varNames];
append from yr;
close data_correlatedr;

create parents from parents [colname=yvarNames];
append from parents;
close parents;

varNamesc = {'ParentID', 'ChildID'};
create adj_table from parentsc [colname=varNamesc];
append from parentsc;

```

```

close adj_table;

*generate initial covariance data programmatically;
nParmPerVar = 1 + &nparent.;
nRows = &m. * nParmPerVar;
init_cov = j(nRows, 3, 0);
row = 0;
do v = 1 to &m.;
  do p = 1 to nParmPerVar;
    row = row + 1;
    init_cov[row, 1] = v;
    init_cov[row, 2] = p;
    if p = 1 then
      init_cov[row, 3] = 0.0001;
    else
      init_cov[row, 3] = 0.01;
    end;
  end;
end;

covNames = {'VarID', 'ParmID', 'ParmValue'};
create initial_cov_with_adj from init_cov [colname=covNames];
append from init_cov;
close initial_cov_with_adj;
run;

proc sort data=data_correlatedr;
  by t;
run;

```

The following statements load the generated data set `data_correlatedr`, the defined adjacency matrix data set `adj_table`, and the initial covariance data set `initial_cov_with_adj` into data tables in your session that is associated with the `mylib` libref. The DATA step assumes that your libref is named `mylib`, but you can substitute any appropriately defined libref.

```

data mylib.test_data;
  set data_correlatedr;
run;

data mylib.adj_table;
  set adj_table;
run;

data mylib.initial_cov_with_adj;
  set initial_cov_with_adj;
run;

```

The following statements run the CPU workflow of PROC DYNAMICLINEAR on the simulated data set:

```

proc dynamicLinear data=mylib.test_data nSimulations=10000 seed=12345;
  id t;
  model y1 - y300;
  parentalSet inAdjacency=mylib.adj_table;
  filter out(percentiles=(2.5, 25, 50, 75, 97.5))=mylib.out_filter_cpu
    outFilterInfo=(klDivergence=mylib.kldiv_cpu)

```

```

    back=0;
    forecast out(percentiles=(2.5, 25, 50, 75, 97.5))=mylib.out_forecast_cpu;
    initialDistribution inCovariance(diagonal)=mylib.initial_cov_with_adj
        shape=(default=5) rate=(default=1.5);
    discountFactor beta=(default=0.98) deltaPhi=(default=0.98)
        deltaGamma=(default=0.99);
run;

```

The following statements run the GPU workflow. The only difference from the CPU workflow is the addition of the **GPU statement**, which directs PROC DYNAMICLINEAR to perform the computations on GPU hardware. By default, the GPU calculations use single-precision floating-point arithmetic, which typically increases the speed significantly while maintaining sufficient accuracy for the SGDLM:

```

proc dynamicLinear data=mylib.test_data nSimulations=10000 seed=12345;
    id t;
    model y1 - y300;
    parentalSet inAdjacency=mylib.adj_table;
    filter out(percentiles=(2.5, 25, 50, 75, 97.5))=mylib.out_filter_gpu
        outFilterInfo=(klDivergence=mylib.kldiv_gpu)
        lead=1 back=0;
    forecast out(percentiles=(2.5, 25, 50, 75, 97.5))=mylib.out_forecast_gpu
        lead=1;
    initialDistribution inCovariance(diagonal)=mylib.initial_cov_with_adj
        shape=(default=5) rate=(default=1.5);
    discountFactor beta=(default=0.98) deltaPhi=(default=0.98)
        deltaGamma=(default=0.99);
    gpu;
run;

```

Comparing KL Divergence

The following statements compare the KL divergence and effective sample size of the CPU and GPU workflows. The plot is shown in [Output 17.2.1](#).

```

data kldiv_cpu;
    set mylib.kldiv_cpu;
run;
data kldiv_gpu;
    set mylib.kldiv_gpu;
run;

proc sort data=kldiv_cpu; by t; run;
proc sort data=kldiv_gpu; by t; run;

data kldiv_comb;
    merge kldiv_cpu(rename=(KLDivergence=KLDiv_CPU
                          EffectiveSampleSize=ESS_CPU))
          kldiv_gpu(rename=(KLDivergence=KLDiv_GPU
                          EffectiveSampleSize=ESS_GPU));
    by t;
run;

proc sgplot data=kldiv_comb;
    series x=t y=KLDiv_CPU / legendlabel='KL Divergence (CPU) '

```

```

lineattrs=(color=blue pattern=solid thickness=2);
series x=t y=KLDiv_GPU / legendlabel='KL Divergence (GPU) '
lineattrs=(color=red pattern=shortdash thickness=2);
series x=t y=ESS_CPU / legendlabel='Effective Sample Size (CPU) '
lineattrs=(color=cyan pattern=solid) Y2Axis;
series x=t y=ESS_GPU / legendlabel='Effective Sample Size (GPU) '
lineattrs=(color=orange pattern=shortdash) Y2Axis;
yaxis label="KL Divergence";
xaxis label="Step";
run;

```

Output 17.2.1 KL Divergence and Effective Sample Size: CPU vs. GPU

Output 17.2.1 shows that the GPU workflow produces better results than the CPU workflow in terms of KL divergence and effective sample size for the problem that has the specified parameters. The KL divergence for the GPU workflow is consistently lower than that of the CPU workflow, indicating that the GPU-accelerated computations are providing a closer approximation to the true posterior distribution. Additionally, the effective sample size of the GPU workflow is higher than that of the CPU workflow, suggesting that the GPU computations yield more efficient sampling and better convergence properties than the CPU computations.

Comparing Mean and Median Predictions

The following statements compare the 60-step moving average of the actual values of `y1` to the mean and median predictions from the CPU and GPU workflows. The plots are shown in [Output 17.2.2](#) and [Output 17.2.3](#).

```
%let maWindow = 60;
%let varName = y1;

data out_filter_cpu;
    set mylib.out_filter_cpu;
run;

data out_filter_gpu;
    set mylib.out_filter_gpu;
run;

proc expand data=data_correlatedr out=test_data_ma method=none;
    id t;
    convert &varName. = var_ma / transout=(movave &maWindow.);
run;

data mean_comb;
    format t var_ma var_cpu var_gpu Best12.;
    set test_data_ma(keep=t var_ma where=(t >= &maWindow.));
    set out_filter_cpu(keep=t Mean_&varName. where=(t >= %eval(&maWindow. - 1))
        rename=(Mean_&varName.=var_cpu));
    set out_filter_gpu(keep=t Mean_&varName. where=(t >= %eval(&maWindow. - 1))
        rename=(Mean_&varName.=var_gpu));
    t = t + 1;
run;

proc sort data=mean_comb;
    by t;
run;

proc sgplot data=mean_comb;
    series x=t y=var_ma / legendlabel="Moving Average Values of &varName."
        markers markerattrs=(color=red size=5 symbol=circlefilled)
        lineattrs=(color=red pattern=shortdash);
    series x=t y=var_cpu / legendlabel="Mean_&varName. (CPU)"
        markers markerattrs=(color=blue size=5 symbol=triangle)
        lineattrs=(color=blue pattern=solid);
    series x=t y=var_gpu / legendlabel="Mean_&varName. (GPU)"
        markers markerattrs=(color=green size=5 symbol=diamond)
        lineattrs=(color=green pattern=longdash);
    label t="Step" var_ma="Values of the Means";
run;
```

Output 17.2.2 Comparison of the Mean Predictions: CPU vs. GPU

```
proc expand data=data_correlatedr out=test_data_med method=none;
  id t;
  convert &varName. = var_med / transout=(MOV MED &maWindow.);
run;

data median_comb;
  format t var_med var_cpu var_gpu Best12.;
  set test_data_med(keep=t var_med where=(t >= &maWindow.));
  set out_filter_cpu(keep=t P50_&varName. where=(t >= %eval(&maWindow. - 1))
    rename=(P50_&varName.=var_cpu));
  set out_filter_gpu(keep=t P50_&varName. where=(t >= %eval(&maWindow. - 1))
    rename=(P50_&varName.=var_gpu));
  t = t + 1;
run;

proc sort data=median_comb;
  by t;
run;

proc sgplot data=median_comb;
  series x=t y=var_med / legendlabel="Moving Median of &varName."
```

```

markers markerattrs=(color=red size=5 symbol=circlefilled)
lineattrs=(color=red pattern=shortdash);
series x=t y=var_cpu / legendlabel="Median_&varName. (CPU)"
markers markerattrs=(color=blue size=5 symbol=triangle)
lineattrs=(color=blue pattern=solid);
series x=t y=var_gpu / legendlabel="Median_&varName. (GPU)"
markers markerattrs=(color=green size=5 symbol=diamond)
lineattrs=(color=green pattern=longdash);
label t="Step" var_med="Values of the Medians";
run;

```

Output 17.2.3 Comparison of the Median Predictions (y1): CPU vs. GPU

Output 17.2.2 and Output 17.2.3 show that the CPU and GPU workflows produce mean and median predictions that share similar patterns for the variable y1. Both workflows track the moving average and moving median trends of the actual data. However, the CPU workflow has a longer burn-in period, which is reflected by the larger deviations from the moving average and moving median values in the early steps than those of the GPU workflow. The GPU workflow converges more quickly to the underlying trends, demonstrating that the GPU-accelerated computations provide more efficient sampling and better convergence properties than the CPU computations.

Comparing Variance Predictions

The following statements compare the 60-step moving average variance of the actual values of *y1* to the variance predictions from the CPU and GPU workflows. The plot is shown in [Output 17.2.4](#).

```
proc expand data=data_correlatedr out=test_data_ma_var method=none;
  id t;
  convert &varName. = var_ma_var / transout=(MOVVAR &maWindow.);
run;

data var_comb;
  format t var_ma_var var_cpu var_gpu Best12.;
  set test_data_ma_var(keep=t var_ma_var where=(t >= &maWindow.));
  set out_filter_cpu(keep=t Variance_&varName. where=(t >= %eval(&maWindow. - 1))
    rename=(Variance_&varName.=var_cpu));
  set out_filter_gpu(keep=t Variance_&varName. where=(t >= %eval(&maWindow. - 1))
    rename=(Variance_&varName.=var_gpu));
  t = t + 1;
run;

proc sort data=var_comb;
  by t;
run;

proc sgplot data=var_comb;
  series x=t y=var_ma_var / legendlabel="Moving Average Variances of &varName."
    markers markerattrs=(color=red size=5 symbol=circlefilled)
    lineattrs=(color=red pattern=shortdash);
  series x=t y=var_cpu / legendlabel="Variance_&varName. (CPU)"
    markers markerattrs=(color=blue size=5 symbol=triangle)
    lineattrs=(color=blue pattern=solid);
  series x=t y=var_gpu / legendlabel="Variance_&varName. (GPU)"
    markers markerattrs=(color=green size=5 symbol=diamond)
    lineattrs=(color=green pattern=longdash);
  label t="Step" var_ma_var="Values of the Variances";
run;
```

Output 17.2.4 Comparison of the Variance Predictions (y1): CPU vs. GPU

Output 17.2.4 shows that the GPU workflow provides variance predictions that closely agree with those of the CPU workflow. Both workflows track the underlying moving variance of y1. However, the results of the CPU workflow are slightly more volatile than those of the GPU workflow, especially in the early steps. This is consistent with the observations in Output 17.2.2 and Output 17.2.3 that the CPU workflow has a longer burn-in period than the GPU workflow.

Comparing Performance

In addition to providing greater accuracy, the GPU workflow also provides significantly better performance than the CPU workflow. In this example, the GPU workflow reduces the computation time from about four hours to about five minutes, demonstrating the substantial efficiency gains (more than 40 times faster) that can be achieved by GPU acceleration for large-scale SGDLMs. The example ran on a machine with an NVIDIA L40 48 GB VRAM GPU and a machine with an Intel Xeon Platinum 8358 CPU at 2.60 GHz.

Output 17.2.5 Total Run Time: CPU vs. GPU (Speedup: 42.1x)

If you take a closer look at the step-by-step run time comparison of the CPU and GPU workflows, you can see that the GPU workflow provides a significant increase in speed for each step of the computations, especially the prediction generation step, which is typically the most computationally intensive step of the SGDLM algorithm. The GPU workflow runs more than 60 times faster for the posterior updating step than the CPU workflow, substantially contributing to the overall performance improvement.

Output 17.2.6 Step-by-Step Run Time Comparison: CPU vs. GPU

Step	CPU		GPU
	Avg (s)	Avg (s)	Speedup
computePrior	0.0044	0.00012	38.1
computeForecast	41.2756	0.64029	64.5
computePosterior	0.0017	0.00052	3.2
computeVBPosterior	4.2127	0.17667	23.8
Total	46.1055	1.09045	42.3

Comparing Precisions: FP64 vs. FP32

You can run the following statements to execute the GPU workflow with FP64 precision. The only difference from the previous GPU workflow is the addition of the PRECISION=FP64 option in the GPU statement, which directs PROC DYNAMICLINEAR to use double-precision floating-point arithmetic for the computations on GPUs.

```
proc dynamicLinear data=mylib.test_data nSimulations=10000 seed=12345;
  id t;
  model y1 - y300;
  parentalSet inAdjacency=mylib.adj_table;
  filter out(percentiles=(2.5, 25, 50, 75, 97.5))=mylib.out_filter_gpu2
    outFilterInfo=(klDivergence=mylib.kldiv_gpu2)
    lead=1 back=0;
  forecast out(percentiles=(2.5, 25, 50, 75, 97.5))=mylib.out_forecast_gpu2
    lead=1;
  initialDistribution inCovariance(diagonal)=mylib.initial_cov_with_adj
    shape=(default=5) rate=(default=1.5);
  discountFactor beta=(default=0.98) deltaPhi=(default=0.98)
    deltaGamma=(default=0.99);
  gpu precision=FP64;
run;
```

Along with the memory savings, FP32 precision can deliver significantly greater speed than FP64 precision on the NVIDIA L40S with 48 GB VRAM.

Output 17.2.7 Total Run Time: GPU FP32 vs. GPU FP64 (Speedup: 1.6x)

Meanwhile, FP32 precision provides accuracy comparable to FP64 precision for the SGDLM in this example. The following statements produce plots that compare the KL divergence and effective sample size (Output 17.2.8), means (Output 17.2.9), and variances (Output 17.2.10) of the GPU workflow predictions for each precision setting:

```
data kldiv_gpu1;
  set mylib.kldiv_gpu;
run;

proc sort data=kldiv_gpu1; by t; run;
proc sort data=kldiv_gpu2; by t; run;

data kldiv_comb;
  merge kldiv_gpu1(rename=(KLDivergence=KLDiv_GPU1
                          EffectiveSampleSize=ESS_GPU1))
        kldiv_gpu2(rename=(KLDivergence=KLDiv_GPU2
                          EffectiveSampleSize=ESS_GPU2));
  by t;
run;
```

```

proc sgplot data=kldiv_comb;
  series x=t y=KLDiv_GPU1 / legendlabel="KL Divergence (GPU FP32)"
    lineattrs=(color=blue pattern=solid thickness=2);
  series x=t y=KLDiv_GPU2 / legendlabel="KL Divergence (GPU FP64)"
    lineattrs=(color=red pattern=shortdash thickness=2);

Output 17.2.10 Comparison of Variance Predictions: GPU FP32 vs. GPU FP64

Summary

Overall, this example demonstrates that the GPU workflow in PROC DYNAMICLINEAR can provide accuracy comparable to that of the CPU workflow while significantly reducing computation time for large SGDLMs. The GPU-accelerated computations yield better KL divergence and effective sample size than the CPU computations, as well as more efficient sampling and better convergence properties. The performance improvements from GPU acceleration make it a powerful option for analyzing large-scale problems with SGDLMs.

Overview: ECM Procedure

The ECM procedure develops an economic capital model. A financial enterprise that incurs losses that are inherent to the nature of its business needs to estimate the extent of those losses across multiple business lines. Developing a model for the enterprise-wide losses enables such an enterprise not only to estimate the minimum capital it must set aside to cover the worst-case losses and meet regulatory requirements but also to assess the economic viability and improve the risk management abilities of the enterprise.

Although there is no one precise definition of economic capital, it is generally agreed that economic capital depends on the worst-case losses you expect to cover across your enterprise's business lines or risk categories. The statistical approach that is described and illustrated in this chapter can be a component of an internal model that is allowed by a regulatory framework. Contrast the approach in this chapter to the standard model, which makes some fixed assumptions and is relatively easier to compute. However, the capital requirements that stem from using the standard model often overestimate the risks and result in higher capital requirements. So, it might be prudent to invest time and resources in developing an internal model to arrive at more accurate estimates of risk, which often result in lower capital requirements and enable you to free up some capital for developing your business and increasing shareholder value. The regulatory agency should be willing to accept your internal model as long as it is statistically sound and has reasonable assumptions.

For the purposes of the ECM procedure, a model for the total loss an enterprise can incur as a result of losses across its multiple lines of business is called an economic capital model (ECM). The process of estimating an ECM is called economic capital modeling. A particularly powerful method of developing an economic capital model consists of the following steps:

1. Collect the loss event data from all business lines that incur financial losses. The loss event data consist of frequency (count) of losses that a business line incurs in a particular time period and the severity (magnitude) of each loss.
2. Estimate separate loss distribution models for the frequency and severity for each business line. Usually, the frequency model is a parametric model that consists of a discrete probability distribution, and the severity model is a parametric model that consists of a continuous probability distribution. Each model can contain regression parameters that measure the impact of external factors on the location or shape of the probability distribution.
3. Create a compound distribution model (CDM) of the aggregate loss that a business line can incur in the particular time period. This step requires combining the frequency and severity models. Because of the possibly complex nature of the frequency and severity distributions, the CDM often cannot be encoded in a concise parametric form. Hence, it is usually estimated by simulating a large empirical sample of the aggregate loss.

At this step in the process, the worst-case losses for an individual business line can be estimated by computing the value-at-risk (VaR) or tail value-at-risk (TVaR) from the large empirical sample of the CDM.

4. Estimate a loss dependency structure of the losses across all business lines. This dependency structure essentially estimates how a loss in one business line is correlated with the losses in other business lines. A typical method of estimating the dependency is to fit a copula model to the aggregate losses in each business line, where losses are matched by the time period of interest.

5. Use the estimated dependency structure to simulate a large sample of probabilities of loss in all business lines. Each observation in the sample essentially records the probability of seeing a loss in each of the business lines in the time period of interest. In other words, each observation records one possible scenario where all business lines simultaneously incur losses, the extent of which varies according to the simulated probabilities. The simulated probabilities account for the dependency among the business lines. Simulating a large number of such scenarios provides a comprehensive picture of enterprise-wide losses. However, these simulation data are on the probability scale, which creates the need for the next step of the process.
6. For each observation in the copula simulation sample, invert the probability estimate of each business line by using that line's aggregate loss sample, which the CDM simulation creates in the third step. This produces an estimate of the loss for each business line. Aggregating the losses across all business lines produces an estimate the total loss for that observation. Repeating this process for all the observations in the copula simulation table results in a large sample of the total loss, which essentially encodes the probability distribution model of the enterprise-wide losses.
7. Compute VaR and TVaR estimates for the total loss by using the large sample that the preceding step generates. These VaR and TVaR estimates help you decide the economic capital needs of your enterprise to cover worst-case losses and meet regulatory requirements.

SAS Econometrics offers various procedures to help you implement each modeling and simulation step of this process. The CNTSELECT and SEVSELECT procedures help you estimate a wide range of frequency and severity models, respectively. The CCDM procedure helps you estimate the compound distribution model (CDM) by simulating a large, distributed sample of the aggregate loss for each business line. The CCOPULA procedure helps you fit and simulate various types of copula models.

The ECM procedure helps you implement the last two critical steps of the economic capital modeling process. It uses the large, distributed CDM samples to estimate the empirical distribution function (EDF) of each business line's aggregate loss, and uses those EDF estimates to efficiently invert the probabilities in the large, distributed copula simulation sample.

The losses in each business line often depend on the economic and social environment in which the business operates. It is important to estimate the frequency and severity models that account for such external factors. The dependence of frequency and severity on external factors implies that the CDM and the economic capital model (ECM) also depend on those factors. Hence, it is not sufficient to estimate the ECM for just one set of values of the external factors, where each set of values is called an external scenario. You should estimate the ECM for multiple external scenarios, each representing a different possible state of the world. Because the CDM and ECM modeling steps need to be repeated for each external scenario, it is important that those steps run as efficiently as possible. Not only should each step use all available computational resources, but it should also be able to efficiently consume the data that the previous step generates. In particular, when the data are large and distributed across a cluster of computing and storage nodes, the modeling steps should consume the data in their distributed format instead of bringing them to one central node purely for modeling purposes.

The SAS Econometrics procedures are designed to help you achieve computational efficiency, minimal data movement, and modeling convenience. The procedures other than PROC ECM are described in their respective chapters. This chapter describes the syntax and features of PROC ECM.

PROC ECM requires SAS Cloud Analytic Services (CAS) in order to run. Because PROC ECM runs on CAS, it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- exploits all the available cores and concurrent threads

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);  
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;  
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “[Introduction to Shared Concepts](#)” on page 54 in Chapter 4, “[Shared Concepts](#).”

Getting Started: ECM Procedure

This section outlines the use of the ECM procedure to estimate the distribution of the total loss across two dependent lines of business. The example is intended as a gentle introduction to the key functionality of PROC ECM.

The losses that a particular line of business (LoB) incurs often have a compound probability distribution that cannot be expressed in a closed form, so you need to approximate the distribution by simulating a large, empirical sample from that distribution. A common way to do that is to fit probability distribution models for the frequency and severity of losses (which can usually be expressed in parametric forms) and use those models to simulate a large sample of the aggregate loss. You would typically use the CNTSELECT procedure to estimate the frequency model, the SEVSELECT procedure to estimate the severity model, and the CCDM procedure to combine those frequency and severity models to simulate an aggregate loss sample from the compound distribution. However, for the purpose of this example, let the following two DATA steps perform the aggregate loss simulations by assuming that the losses in one LoB follow a negative binomial frequency distribution and a gamma severity distribution, whereas the losses in the second LoB follow a Poisson frequency distribution and a lognormal severity distribution. This example assumes that the CAS engine libref is named mylib, as defined in the section “Using CAS Sessions and CAS Engine Librefs” on page 1100, but you can substitute any appropriately named CAS engine libref.

```
/* Simulate a sample from the compound distribution of
   negative binomial frequency and gamma severity. */
data mylib.loss1sample(keep=loss1) / sessref=mysess;
  call streaminit(12);
  theta = 3.0; p = 0.5; * negative binomial parameters;
  gTheta = 1000; gAlpha = 2.5; * gamma parameters;
  do n = 1 to 10000;
    count = rand('NEGB',p,theta);
    loss1 = 0;
    do c=1 to count;
      loss1 = loss1 + rand('Gamma', gAlpha, gTheta);
    end;
    output;
  end;
run;

/* Simulate a sample from the compound distribution of
   Poisson frequency and lognormal severity. */
data mylib.loss2sample(keep=loss2) / sessref=mysess;
  call streaminit(135);
  lambda = 2; * Poisson parameters;
  mu = log(2500); sigma = 0.85; * lognormal parameters;
  do n = 1 to 10000;
    count = rand('POISSON',lambda);
    loss2 = 0;
    do c=1 to count;
      loss2 = loss2 + exp(mu) * rand('LOGNORMAL')**sigma;
    end;
    output;
  end;
run;
```

The preceding two DATA steps produce two large sample tables, `mylib.Loss1Sample` and `mylib.Loss2Sample`, for the two LoBs. Each data table represents an empirical sample for the aggregate loss distribution of the respective LoB. The use of the `SESSREF=` option ensures that each DATA step runs on the CAS server in parallel by using multiple threads of execution on all the worker nodes in order to create large samples quickly. When each of these DATA steps is run in a CAS session that has three worker nodes, such that each worker node uses 32 threads of execution, the sample size of each LoB is 960,000, because the loop inside the DATA step runs 10,000 times independently in each thread on each worker node.

The losses in the two LoBs are usually correlated, and you can estimate their dependency structure by fitting a copula model. In the context of copula modeling, loss in each LoB constitutes a marginal random variable, referred to simply as a marginal. For this example, assume that the dependency is captured by a Gaussian copula with a correlation matrix that is recorded in the data table `mylib.CorrTab`:

```
data mylib.corrTab;
    loss1 = 1.0; loss2 = 0.35; output;
    loss1 = 0.35; loss2 = 1.0; output;
run;
```

To simulate the total loss across both LoBs that takes the dependency structure into account, you need to first simulate the probabilities of a loss value that each LoB incurs in the same time period. The following PROC CCOPULA step simulates 500,000 such loss probability combinations and stores them in the data table `mylib.LossProb`:

```
proc ccopula;
    var loss1 loss2;
    define cop normal (corr=mylib.corrTab);
    simulate cop / ndraws=500000 seed=234
        outuniform=mylib.lossprob;
run;
```

Now, you need to perform the following steps to estimate the distribution of the total loss:

1. For each observation in the copula simulation table, you need to convert the loss probability of each LoB to its loss estimate by computing the quantile function for that LoB's probability distribution. When the cumulative distribution function (CDF) or the quantile function of a marginal distribution is not available in a closed form, you need to estimate the quantile by the corresponding percentile from an empirical sample of that marginal's distribution. For this example, you need to use the empirical samples for the two LoBs that are available in the data tables `mylib.Loss1Sample` and `mylib.Loss2Sample`. After computing each LoB's loss estimate as a percentile, you need to add those loss estimates to estimate the total loss for the current observation of the copula simulation table.
2. You need to perform the preceding step for all observations of the copula simulation table. This results in a sample of the total loss, which represents an empirical estimate of the probability distribution of the total loss. You need to analyze this sample to compute the estimates of various quantities of interest, especially the risk measures such as the value-at-risk (VaR) and tail value-at-risk (TVaR).

The ECM procedure is created precisely to help you implement the preceding steps by submitting a few simple statements and executing them efficiently by using all the computational resources of a CAS server. The following PROC ECM step implements the preceding steps by using the data table `mylib.LossProb` (which contains the copula simulations) and the data tables `mylib.Loss1Sample` and `mylib.Loss2Sample` (which contain the empirical samples of the two LoBs):

```
proc ecm data=mylib.lossprob seed=57;
  marginal loss1: data=mylib.loss1sample;
  marginal loss2: data=mylib.loss2sample;
  outsum pctlpts=default tvarpts=90 95 97.5 to 99.5 by 1;
  output out=mylib.tlossSample var=tloss;
run;
```

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections “Using CAS Sessions and CAS Engine Librefs” on page 54 and “Loading a SAS Data Set onto a CAS Server” on page 55 in Chapter 4, “Shared Concepts.”

The DATA= data table must contain the loss probabilities. Use of the OUTUNIFORM= option in the preceding PROC CCOPULA step ensures that the data table mylib.LossProb contains copula simulations on a uniform probability scale.

The SEED= option in the PROC ECM statement ensures that results are similar across multiple runs of the procedure for identical inputs and identical session configuration. This is required because, by default, the algorithm that PROC ECM uses samples the body region of the distribution to reduce the data movement among the worker nodes and to speed up the computations.

The two MARGINAL statements specify the two marginal variables, one for each LoB. The name of the marginal variable, which you must specify first in each MARGINAL statement followed by a colon (:), must match the name of the corresponding variable in the copula simulation table. The DATA= option in each MARGINAL statement specifies the data table that contains the empirical sample of that marginal.

The OUTSUM statement specifies the statistics that you want to estimate for the distribution of the total loss. The PCTLPTS=DEFAULT option requests that the percentiles be computed for the default percentile levels, which are {1, 5, 10, 25, 50, 75, 90, 95, 99, 99.5}. Each percentile is an estimate of the value-at-risk (VaR). The TVARPTS= option requests that the estimates of the tail value-at-risk (TVaR) be computed for 90th, 95th, 97.5th, 98.5th, and 99.5th percentile levels.

The OUTPUT statement requests that the total loss sample be written in the tloss variable in the output data table mylib.TlossSample. You can use this output table especially to compute a risk measure that is different from the two popular risk measures, VaR and TVaR, which PROC ECM computes for you.

Figure 18.1 shows some of the results that the preceding ECM step prepares. The “Summary Statistics” table displays various summary statistics. The “Percentiles” table displays the percentiles. The P th percentile is essentially an estimate of the VaR at level $\alpha = P/100$, because for a random loss variable L , the VaR at level α is defined as the smallest number l such that the probability that the loss exceeds l is no larger than $1 - \alpha$. Formally,

$$\begin{aligned}\text{VaR}_\alpha(L) &= \inf\{l \in \mathbb{R} : \Pr[L > l] \leq 1 - \alpha\} \\ &= \inf\{l \in \mathbb{R} : F_L(l) \geq \alpha\} \\ &= F_L^{-1}(\alpha)\end{aligned}$$

where F_L and F_L^{-1} denote the CDF and the quantile function of L , respectively. A percentile is essentially an empirical estimate of the quantile function, and hence an estimate of the VaR.

Figure 18.1 Summary Statistics and Percentile Estimates for the Total Loss

99.5	58023.0
Percentile Method = 5	

The “Tail Value-at-Risk Estimates” table in [Figure 18.2](#) displays the VaR and TVaR estimates for the percentile levels that are specified in the TVARPTS= option. The $\Pr > \text{VaR}$ column indicates the probability that a loss exceeds the VaR value. For a level α , the TVaR_α is defined as the expected value of the loss given that the loss exceeds VaR_α . Formally, $\text{TVaR}_\alpha = E[L | L > \text{VaR}_\alpha]$. Because of this definition, TVaR is also sometimes called a conditional tail expectation (CTE). Computationally, it is the average of the loss values that exceed the P th percentile. As the “Tail Value-at-Risk Estimates” table shows, the TVaR value is always greater than the VaR value, which is expected because it is the mean of the losses that exceed the VaR value. In fact, TVaR is a better risk measure than the VaR, because TVaR accounts for the shape of the tail of the distribution. To capture the tail more accurately, you need to simulate not only large samples of the loss probabilities (copula simulation) but also large samples of each of the marginals. PROC ECM is specifically designed to handle very large copula simulation and marginal samples. It uses all the computational resources of a CAS server, and it uses a novel parallel and distributed algorithm to approximate the empirical distribution function (EDF) for computing the percentiles of the marginals. Together, these uses enable PROC ECM to perform the necessary computations significantly faster.

Figure 18.2 Tail Value-at-Risk (TVaR) Estimates for the Total Loss

Tail Value-at-Risk Estimates			
Percentile	Pr > VaR	Value at Risk (VaR)	Tail Value at Risk
90	0.1	29723.3	39197.5

PROC ECM Statement

PROC ECM *options* ;

The PROC ECM statement invokes the procedure. You can specify the following *options*, which are listed in alphabetical order.

DATA=*libref.data-table*

COPULASIM=*libref.data-table*

names the input data table for PROC ECM to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section “Using CAS Sessions and CAS Engine Librefs” on page 1100.

data-table specifies the name of the input data table.

The DATA= data table specifies a copula sample on a uniform scale that is generated by using the OUTUNIFORM= option in the SIMULATE statement in the CCOPULA procedure.

Each observation in this data table is expected to contain the probability of the loss for each of the marginal variables. That probability is determined by accounting for the dependence structure among the marginal variables.

DRAWID=*sample-identifier*

SAMPLEID=*sample-identifier*

identifies the sample to use when the marginal data tables contain multiple samples of the marginal variable, where *sample-identifier* is an integer. A marginal data table can contain multiple samples when it is a result of the perturbation analysis that the CCDM procedure conducts. Each sample is identified by the value of the `_DRAWID_` variable. If you specify a *sample-identifier* value of *k*, then PROC ECM uses the observations in the marginal data tables whose `_DRAWID_ = k`.

The *sample-identifier* applies to all the marginal data tables that you specify in one or more MARGINAL statements. You can override the *sample-identifier* for a specific marginal table by specifying the DRAWID= option in the MARGINAL statement that you specify for the respective marginal variable.

If you omit this option or the DRAWID= option in the MARGINAL statement, then PROC ECM uses a default value of 0 for the marginal tables that contain the `_DRAWID_` variable.

EDFACCURACY=*number*

ACC=*number*

specifies the accuracy to be achieved when estimating the empirical distribution function (EDF) in the body region of the distribution, where the body region is defined as the region that contains values whose EDF estimate is less than the value that you specify in the TAILSTARTEDF= option. The *number* you specify represents the desired proportion of observations that each bin in the body region should contain. The *number* must be between 0 and 1.

PROC ECM uses *number* for estimating the EDF of each marginal variable. If you specify percentiles in the OUTSUM statement, PROC ECM also uses *number* when estimating the EDF of the total loss.

By default, EDFACCURACY=1.0E-5.

EXACTFINALCOUNT

computes the empirical distribution function (EDF) by making an additional pass over the data to count the final set of bins when the data are sampled and shuffled by the binning algorithm. This results in better EDF estimates, but at the cost of an additional data pass.

If you omit this option, then the final bin counts are approximated by inflating the counts by the sampling fraction. When the sampling fraction is less than 1, this count approximation happens only for the bins in the body region of the distribution.

If you specify a value of 1 for the **SAMPLEFRACTION=** option or if you specify the **NOSHUFFLE** option, then this option is not relevant and PROC ECM ignores it.

MAXITER=*number*

specifies the maximum number of iterations for the equal-proportions binning algorithm.

By default, MAXITER=50.

NOPRINT

suppresses all displayed output. If you specify this option, then PROC ECM ignores any value that you specify for the PRINT= option.

NOSHUFFLE

suppresses the use of shuffling in the EDF estimation process.

If you omit this option, then PROC ECM shuffles each marginal variable's data to different worker nodes so that it can perform in parallel the binning for different ranges of the marginal data. However, this additional parallelism comes at the cost of moving data across workers. When the majority of the data are in the body region of the distribution, you can reduce the amount of data that are being moved by using the **SAMPLEFRACTION=** option. However, if a marginal variable's data are very large or the **SAMPLEFRACTION=** option value is closer to 1, then the amount of data movement can make the algorithm slow.

If you specify this option, the binning algorithm does not shuffle the marginal data. Instead, it estimates the boundaries for a global set of bins in each of the regions (body and tail) of the distribution. This estimation increases the number of parameters that the algorithm needs to optimize while reducing the parallelism in the binning algorithm. Also, the algorithm needs to share the bin boundaries with all the worker nodes after every iteration; so if the values of the **EDFACCURACY=** and **TAILEDFACTURACY=** options are very small (resulting in a large number of bins), you might not save much in data movement cost. The cost of shuffling the data, which the algorithm incurs only once, might be lower than the cost of sharing the large number of bin boundaries with all worker nodes after each iteration.

If you specify this option, the **SAMPLEFRACTION=** and **SEED=** options are irrelevant and PROC ECM ignores them.

PCTLDEF=1 | 2 | 3 | 4 | 5

specifies the method of computing the percentiles. This option applies to the computation of percentiles of the total loss sample. It also applies to each marginal variable for which you do not specify a percentile method in the corresponding **MARGINAL** statement.

You can specify the following values:

- 1** uses the weighted average.
- 2** uses the value closest to the sample size times the percentile.
- 3** uses the empirical distribution function.
- 4** uses the weighted average (identical to **PCTLDEF=1**).
- 5** uses the empirical distribution function with averaging.

For more information about each method, see the section “[Percentile Computation Methods](#)” on page 1121. By default, **PCTLDEF=5**.

PRINT <(global-display-option)> =display-option

PRINT <(global-display-option)> =(display-option ... display-option)

specifies the desired displayed output. If you specify more than one *display-option*, then separate them with spaces and enclose them in parentheses. For more information about the displayed output, see the section “[Displayed Output](#)” on page 1124.

You can specify the following *global-display-option*:

ONLY

displays only the output that is requested by the *display-options*.

You can specify the following *display-options*:

ALL

displays all the output.

DATASUMMARY**DSUM**

displays a summary of the sample that is analyzed for each variable, marginal variable, or total loss variable for which PROC ECM prepares an empirical distribution function (EDF) estimate.

EDFINIT**EINIT**

displays the summary of the first initialization stage of the EDF estimation process.

EDFOPTDETAILS**EOPT**

displays the details for the data ranges for which the EDF estimation process runs an iterative binning algorithm.

EDFSUMMARY**ESUM**

displays the summary of the data ranges that the EDF estimation process analyzes.

NONE

displays no output. If you specify this option, then it overrides all other display options. The default displayed output is also suppressed.

PERCENTILES**PCTL**

displays the percentiles of the total loss sample. This includes all the predefined percentiles and percentiles that you request in the OUTSUM statement.

SUMMARYSTATISTICS**SUMSTAT**

displays the summary statistics of the total loss sample.

TVAR

displays the tail value-at-risk (TVaR) estimates of the total loss sample.

Not specifying the PRINT= option or the ONLY *global-display-option* is equivalent to specifying the PRINT=(SUMMARYSTATISTICS) option if you do not specify any percentiles in the OUTSUM statement, or is equivalent to specifying the PRINT=(PERCENTILES SUMMARYSTATISTICS) option if you specify percentiles in the OUTSUM statement.

SAMPLEFRACTION=*number***BODYSAMPLEFRACTION=***number*

specifies the fraction of observations to sample from the body region of the distribution during the EDF estimation process, where *number* must be between 0 and 1.

Sampling helps reduce the amount of data that need to be communicated across the worker nodes of the CAS server. It can reduce the accuracy of the EDF and percentile estimates, but if your marginal samples have large numbers of observations, then the loss in accuracy is not as significant as the reduction in communication cost that the sampling provides.

By default, SAMPLEFRACTION=0.5.

SEED=*number*

specifies an integer to use as the seed in generating the pseudorandom numbers that are used for sampling the body region of the distribution.

If you omit this option or if you specify a *number* that is negative or 0, then PROC ECM uses as the seed a number that depends on the time of day from the computer's clock.

TAILEDFAccURACY=*number***TAILACC=***number*

specifies the accuracy to be achieved when estimating the empirical distribution function (EDF) in the tail region of the distribution, where *number* (which must be between 0 and 1) is the desired fraction of observations that each bin in the tail region should contain. The tail region is defined as the region that contains values whose EDF estimate is larger than or equal to the value that you specify in the TAILSTARTEDF= option.

PROC ECM uses *number* when it estimates the EDF of each marginal variable. If you specify percentiles in the OUTSUM statement, PROC ECM also uses *number* when it estimates the EDF of the total loss.

By default, TAILEDFAccURACY=1.0E-6.

TAILSTARTEDF=*number***TAILSTART=***number*

specifies the empirical distribution function (EDF) value that marks the beginning of the tail region of the distribution, where *number* must be between 0 and 1. The first stage of the EDF estimation algorithm finds an approximate value y_t whose EDF is close to *number*. The part of the sample whose values are less than y_t defines the body region of the distribution, and the remaining values define the tail region of the distribution.

By default, TAILSTARTEDF=0.8.

TOLERANCE= ϵ **TOL=** ϵ

specifies the tolerance value that determines when the equal-proportion binning algorithm has converged, where ϵ must be a number between 0 and 1. The algorithm converges when the difference in the fractions of observations in the largest and smallest bins is less than or equal to $\delta\epsilon$, where δ is the accuracy of the body or tail region that is being analyzed.

By default, TOLERANCE=0.5.

VARDEF=divisor

specifies the divisor to use in calculating the variance, standard deviation, kurtosis, and skewness of the total loss sample. You can specify one of the following values for the *divisor*, where N is the sample size:

DF

sets the divisor for variance to $N - 1$. This also changes the definitions of skewness and kurtosis.

N

sets the divisor to N .

By default, VARDEF=DF.

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > ;

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section “[Displayed Output](#)” on page 1124. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying “/tions/” selects all pathnames that contain the substring “tions”; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying “!/tions/” selects all pathnames that do not contain the substring “tions”; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE

performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetting for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE

displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL

suppresses display of all tables. This option takes precedence over the other options.

TRACE

displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > ;

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see [SAS Output Delivery System: Procedures Guide](#).

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key=value* format or a *key* format:

key=value specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.

key specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section “[Displayed Output](#)” on page 1124. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the [DISPLAY](#) statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL

creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE

does not replace any existing output table of the same name.

REPEATED

replicates all output tables on all nodes.

MARGINAL Statement

MARGINAL *marginal-variable*: **DATA=***libref.data-table* < *marginal-options* > ;

MGL *marginal-variable*: **DATA=***libref.data-table* < *marginal-options* > ;

The MARGINAL statement enables you to specify information about one *marginal-variable*. Specify one MARGINAL statement for each marginal variable that you want to analyze.

You must specify the name of the *marginal-variable* followed by a colon (':') as the first item in the MARGINAL statement. This *marginal-variable* must appear in the copula simulation data table that you specify in the **DATA=** option in the PROC ECM statement.

Next, you must specify the data table by using the following option:

DATA=*libref.data-table*

specifies the data table that contains an empirical sample of the *marginal-variable*. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1100. The *libref* must be identical to the *libref* that you specify in the **DATA=** option in the PROC ECM statement.

Typically, you specify a data table that was generated by the CCDM procedure in order to simulate a compound distribution sample from the underlying frequency and severity models that the CNTSELECT and SEVSELECT procedures create.

You can specify the following *marginal-options* to specify the variable and observations that contain the marginal variable sample:

SAMPLEVAR=*sample-variable*

SVAR=*sample-variable*

specifies the variable that contains the marginal sample in the marginal data table.

If the name of the *sample-variable* is the same as the *marginal-variable*, then you do not need to specify this option. If PROC ECM cannot find a variable named *marginal-variable* in the marginal table and if you do not specify this option, then the sample variable name is assumed to be `_AGGSEV_`, which must be present in the marginal data table.

DRAWID=*sample-identifier*

SAMPLEID=*sample-identifier*

identifies the sample to use when the marginal data table contains multiple samples of the marginal variable, where *sample-identifier* is an integer.

The data table can contain multiple samples when it is a result of the perturbation analysis that the CCDM procedure conducts. Each sample is identified by the value of the `_DRAWID_` variable. If you specify a *sample-identifier* value of *k*, then PROC ECM uses the observations from the marginal data table whose `_DRAWID_=k`.

If you do not specify either this option or the DRAWID= option in the PROC ECM statement, then PROC ECM uses a default value of 0 when the marginal table contains the `_DRAWID_` variable.

The value that you specify for this option overrides the value that you specify for the DRAWID= option in the PROC ECM statement.

PCTLDEF=1 | 2 | 3 | 4 | 5

specifies the method of computing the percentiles. The value that you specify for this option overrides the value that you specify for the PCTLDEF= option in the PROC ECM statement.

You can specify the following values:

- 1** uses the weighted average.
- 2** uses the value closest to the sample size times the percentile.
- 3** uses the empirical distribution function.
- 4** uses the weighted average (identical to PCTLDEF=1).
- 5** uses the empirical distribution function with averaging.

For more information about each method, see the section “[Percentile Computation Methods](#)” on page 1121.

By default, PCTLDEF=5.

OUTPUT Statement

OUTPUT **OUT=***libref.data-table* < *output-options* > ;

The OUTPUT statement specifies the data table in which PROC ECM outputs the estimated total loss sample.

If you specify more than one OUTPUT statement, only the first one is used.

You must specify the output data table by using the following option:

OUT=*libref.data-table*

OUTSAMPLE=*libref.data-table*

specifies the name of the output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the **DATA=** option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1100. The *libref* must be identical to the *libref* that you specify in the **DATA=** option.

You can specify the following *output-options* to control the contents of the OUT= data table:

MARGINALSOUT

WRITEMARGINALS

writes the marginal probability and estimated percentile information to the OUT= data table. The marginal probability is copied from the copula simulation data table.

TOTALLOSSVAR=*variable-name*

VAR=*variable-name*

specifies the name of the variable to contain the total loss value in the OUT= data table. If you omit this option, then the variable is named `_TOTALLOSS_` by default.

For more information about the variables in the OUTSAMPLE= data table, see the section “[OUTSAMPLE= Data Table](#)” on page 1123.

OUTSUM Statement

OUTSUM < *outsum-options* > < *statistic-keyword* < =*variable-name* > ... *statistic-keyword* < =*variable-name* > > ;

The OUTSUM statement specifies the data table in which PROC ECM writes the summary statistics of the total loss sample.

If you specify more than one OUTSUM statement, only the first one is used.

You can specify the following *outsum-options*:

OUT=*libref.data-table*

OUTSUM=*libref.data-table*

specifies the output data table that contains the summary statistics of the total loss sample. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1100. The *libref* must be identical to the *libref* that you specify in the DATA= option.

You can control the statistics that appear in this data table by specifying the PCTLPTS= option, the TVARPTS= option, and different *statistic-keyword* values.

PCTLNDEC=*integer-value*

specifies the maximum number of decimal places to use when creating the names of the variables for the percentile values in the PCTLPTS= or TVARPTS= options. For example, for a percentile value of 99.9995, if you specify PCTLNDEC=4, then the suffix of the variable is 99_9995. Specifying a small number might result in duplicate variable names. If that happens, PROC ECM writes an error message and exits.

By default, PROC ECM computes the required number of decimal places by using the precision of the percentiles that you specify in the PCTLPTS= option or the TVARPTS= option.

PCTLPRE=*prefix*

specifies the prefix to use for creating the names of the variables that contain the percentile estimates. The percentile estimate for a value *p* is written to a variable that has the name of the form *prefixt*, where *t* is the text representation of *p* that is formed by replacing the decimal point with an underscore (_). For example, if PCTLPRE=P, then the estimate of the 97.5th percentile is written to a variable whose name is P97_5. By default, PCTLPRE=P.

PCTLPTS=*percentile-option*

specifies the percentiles of the total loss that you want PROC ECM to compute. The *percentile-option* can have one of the following two forms:

DEFAULT**DEF**

computes only the default list of percentile values, which is {1, 5, 10, 25, 50, 75, 90, 95, 99, 99.5}.

percentile-list

adds the percentiles that you specify in the *percentile-list* to the default list of percentiles, where *percentile-list* is a comma-separated list of percentile values, each of which must belong to the (0,100) open interval. You can also use a list notation of the following form: *< number1 > to < number2 > by < increment >*. For example, the following two options are equivalent:

```
pctlpts=10, 20, 99.6, 99.7, 99.8, 99.9
pctlpts=10, 20, 99.6 to 99.9 by 0.1
```

TVARPRE=*prefix*

specifies the prefix to use for creating the names of the variables that contain the tail value-at-risk (TVaR) estimates. The TVaR estimate for a percentile value *p* is written to a variable that has the name of the form *prefixt*, where *t* is the text representation of *p* that is formed by replacing the decimal point with an underscore (_). For example, if TVARPRE=TVaR, then the tail value-at-risk estimate for the 97.5th percentile is written to a variable whose name is TVaR97_5. By default, TVARPRE=TVaR.

TVARPTS=*tvar-percentile-list*

specifies the percentile values for which you want PROC ECM to compute the tail value-at-risk (TVaR) of the total loss, where *tvar-percentile-list* is a comma-separated list of percentile values, each of which must belong to the (0,100) open interval. You can also use a list notation of the form “*< number1 > to < number2 > by < increment >*”. For example, the following two options are equivalent:

```
tvarpts=90, 95, 96.25, 97.5, 98.75, 99.5
tvarpts=90, 95 to 99 by 1.25, 99.5
```

For each value in the *tvar-percentile-list*, PROC ECM also reports the percentile estimates, which are the estimates of the value-at-risk (VaR) for the corresponding TVaR estimate.

If you specify a data table in the OUTSUM= option, PROC ECM adds the TVaR estimates to that table. You can control the name of each TVaR estimate's variable by specifying the TVARPRE= option.

You can also specify one or more predefined statistics of the total loss sample to be written to the OUTSUM= table in the following form:

*statistic-keyword***< =variable-name >**

writes the statistic that corresponds to the *statistic-keyword* to a variable named *variable-name*. For the predefined statistics that correspond to percentiles, the *variable-name* takes precedence over the default name that PROC ECM forms by using the PCTLPRE= option. All variable names in the OUTSUM= data table have a limit of 32 characters.

If you do not specify the *variable-name*, then PROC ECM writes the statistic to a variable named *statistic-keyword*.

You can specify the following *statistic-keywords*, which result in the specified statistic being written to the OUTSUM= table:

KURTOSIS KURT	writes the kurtosis of the total loss sample.
MEAN	writes the mean of the total loss sample.
P01	writes the first percentile of the total loss sample.
P05	writes the fifth percentile of the total loss sample.
P10	writes the 10th percentile of the total loss sample.
P25 Q1	writes the first quartile (the 25th percentile) of the total loss sample.
P50 MEDIAN Q2	writes the median (the 50th percentile) of the total loss sample.
P75 Q3	writes the third quartile (the 75th percentile) of the total loss sample.
P90	writes the 90th percentile of the total loss sample.
P95	writes the 95th percentile of the total loss sample.
P99	writes the 99th percentile of the total loss sample.
P99_5 P995	writes the 99.5th percentile of the total loss sample.
QRANGE	writes the interquartile range (Q3–Q1) of the total loss sample.
SKEWNESS SKEW	writes the skewness of the total loss sample.
STDDEV STD	writes the standard deviation of the total loss sample.
VARIANCE	writes the variance of the total loss sample.

VAR Statement

VAR *marginal-variables* ;

The VAR statement specifies a subset of marginal variables to analyze.

You must specify a MARGINAL statement for each of the *marginal-variables* that you specify, and each variable in the list of *marginal-variables* must appear in the copula simulation data table.

Details: ECM Procedure

Overview of the Algorithm

The ECM procedure accepts as input two types of data tables. The first is a copula simulation table that contains the probability of a loss that is incurred in the time period of interest for each line of business (LoB) that you include in the copula model. These probabilities account for the dependency among the losses in different LoBs. You typically generate this table by using the CCOPULA procedure. The second type of table is an aggregate loss sample table for each LoB, which essentially encodes an empirical estimate of the probability distribution of the losses for that LoB. You typically generate this table by using the CCDM procedure. In the context of copula modeling, loss in each LoB constitutes a marginal random variable, which is simply called a marginal for brevity. You can specify multiple marginals in a PROC ECM step as long as you have used each specified marginal in the copula model and you provide a loss sample for each marginal.

The main mandate of PROC ECM is to convert the copula simulation table to a sample of the total loss that you expect to incur across all marginals. Let the copula simulation table contain N observations, and let each i th observation contain the probability p_{ik} for the k th marginal out of K marginals. Let $F_k(l)$ and $F_k^{-1}(p)$ denote the cumulative distribution function (CDF) and the quantile function, respectively, for the k th marginal. With this notation, conceptually, PROC ECM needs to execute the following steps:

1. For each i th observation in the copula simulation table:
 - a) Compute L_{ik} (the loss estimate for each k th marginal) as $L_{ik} = F_k^{-1}(p_{ik})$.
 - b) Compute L_i (the estimate of the total loss) by adding the loss estimates of all marginals as $L_i = \sum_{k=1}^K L_{ik}$.
2. Analyze the set of all $\{L_i\}$ values (which together constitute the final sample of the total loss) to compute summary statistics, value-at-risk (VaR) estimates, and tail value-at-risk (TVaR) estimates of the total loss distribution.

The key part in these steps is the computation of the quantile function for each marginal in step 1a. Because the quantile function is not available in a closed-form equation, PROC ECM has to compute it by using the empirical sample of the loss distribution of each marginal. An empirical estimate of a quantile is the percentile. So for each probability value p_{ik} , PROC ECM needs to compute the $100p_{ik}$ th percentile from the sample of the k th marginal. This seems simple at first, but it gets complicated when the marginal's sample is large and distributed across multiple nodes of the CAS server. Moreover, the copula simulation table is also large and distributed across multiple nodes, which means that a large number of percentile computations need to be done on multiple nodes for each marginal. One straightforward solution is to assemble the entire sample of each marginal in the memory of one of the worker nodes, sort that sample, and compute the percentile. However, if a percentile of a marginal is computed and available only on one worker node, then the copula simulation table also must reside in its entirety on that same worker node. So essentially, tables of all the marginals and the copula simulation table need to be moved in their entirety to a single worker node. Not only is this time-consuming because of all the data movement among nodes, but it is also a very inefficient use of the available computational power and memory resources. Moreover, depending on the sizes of all tables, this simplistic solution might not even be feasible if the main memory of any one worker node is not large enough to hold all the tables.

To overcome these challenges, PROC ECM implements a novel algorithm to compute each marginal's percentile. The key component of the algorithm is the parallel and distributed estimation of the empirical distribution function (EDF). PROC ECM computes the EDF estimates in the form of a set of bin boundaries, such that the fraction of observations in each bin is approximately equal. By keeping approximately the same fraction in each bin, the algorithm essentially offers you control over the precision of the EDF estimates. The smaller the fraction of observations in each bin, the greater the precision and the higher the accuracy of the EDF estimates. The bin boundaries together represent a compressed version of the original empirical sample. As long as the desired accuracy is not too high to cause each bin to have very few observations, the algorithm can achieve a good degree of data compression and thereby save on the memory that it needs in order to store the bin boundaries. PROC ECM runs an iterative algorithm to adjust the bin boundaries to make the distribution of observation counts in the bins as close to a uniform distribution as possible. After an acceptable set of bin boundaries is found, PROC ECM computes the EDF estimate at the beginning of each bin. To compute a percentile, it uses these EDF estimates to do a quick search for the specified cumulative probability. The boundaries of the bins whose EDF estimates are closest to the specified cumulative probability are used to estimate the percentile. The section “[Percentile Computation Methods](#)” on page 1121 describes the different percentile computation methods.

The EDF estimation algorithm is driven by the following main tuning parameters that you can control:

- **Start of the tail region:** This is expressed as the cumulative probability, p_t , at the start of the tail. The first stage of the algorithm performs an initial EDF-axis binning to estimate l_t , which is the $100p_t$ th percentile. PROC ECM uses that percentile to demarcate the body and tail regions of the distribution. All loss values that are larger than l_t are assigned to the tail region, and the rest of the values are assigned to the body region.

You can provide a guidance for the value of p_t by specifying the `TAILSTARTEDF=` option. PROC ECM uses your specified value to decide the number of bins that the first stage uses. In fact, it also uses the initial set of bins that the first stage finds to further demarcate multiple subregions within the body and tail regions, and it assigns those subregions to different worker nodes to process in parallel. The number of bins in the first stage depends not only on p_t but also on the number of worker nodes that are available to PROC ECM and the sampling fraction for the body region, because PROC ECM attempts to distribute the required binning computations equitably among all the available worker nodes. The actual EDF value at the start of the tail might be different than p_t .

- **Desired EDF accuracy:** This is expressed as the desired width of each bin along the EDF axis, which in turn is the fraction of observations that each bin should have. The second stage of the algorithm uses this value to estimate the number of bins it needs to create. The smaller the bin width, the larger the accuracy, the larger the number of bins, and possibly the slower the estimation process. If your specified bin width is so small—that is, your desired EDF accuracy is so high—that the target number of observations in each bin is smaller than five, then PROC ECM does not use the iterative binning algorithm in the second stage. Instead, it uses the sorted set of all the loss values in the region as bin boundaries.

You can specify different accuracy values for the body and tail regions of the distribution by using the `EDFACCURACY=` and `TAILEDFACTURACY=` options, respectively. If you are interested primarily in the tail region of the distribution, which is typically the case for financial losses, you can specify a relatively lower accuracy (larger bin width) for the body region to help speed up the algorithm.

- **Acceptable tolerance in the EDF accuracy:** This is expressed as a fractional multiplier, ϵ ($0 < \epsilon < 1$), of the accuracy. The algorithm attempts to make the difference in the fractions of observations in the

largest and smallest bins less than or equal to $\delta\epsilon$, where δ is the EDF accuracy of the body or tail region that is being analyzed. You can specify ϵ by using the **TOLERANCE=** option.

As the first test of convergence of the binning algorithm, PROC ECM uses Pearson's chi-squared test to test the null hypothesis that the distribution of counts in all the bins is same as the uniform distribution. However, in practice, even after the chi-squared test fails to reject the null hypothesis—that is, the p -value is larger than the usual thresholds of 0.05 or 0.1—the bin boundaries can often be adjusted further to reduce the difference in the fractions of the largest and smallest bins. PROC ECM enables you to control for this difference so that you can further improve the accuracy of the EDF and consequently the percentile estimates.

- **Sampling fraction for the body region:** The bin boundaries that are computed in the first stage of the algorithm demarcate multiple subregions of the body and tail regions. PROC ECM shuffles all values in the sample to these subregions so that they can be processed in parallel on all available worker nodes. When the sample is large and distributed, shuffling can be expensive. So sampling the body region (which typically contains a large fraction of the total observations) helps reduce the amount of data that need to be processed and communicated among different nodes. Of course, sampling reduces the accuracy in the body region. But for large samples, the loss of accuracy is not as significant as the gains that are produced by reducing the amount of data to process. You can control the sampling fraction by specifying the **SAMPLEFRACTION=** option. Because the sampling process is driven by an internal pseudorandom number generator, you can specify the **SEED=** option to obtain similar results across multiple runs of PROC ECM for identical inputs and identical grid configuration. **NOTE:** The CAS server does not guarantee row-order consistency for the same data table that is created or loaded in different CAS sessions, so the results might vary slightly even if you specify the same seed.

The algorithm never samples the tail region in order to acknowledge the fact that most interesting financial losses fall in the tail region.

In addition to the preceding set of main tuning parameters, you can also use the **EXACTFINALCOUNT** and **NOSHUFFLE** options to control the EDF estimation process.

Percentile Computation Methods

The ECM procedure computes a percentile by using the bins that it estimates for each random variable's sample. It uses the counts in each bin to estimate the value of the empirical distribution function (EDF) at the beginning of each bin. Let $\hat{F}_i$ denote the EDF at the beginning of the i th bin. The algorithm estimates B bins from a sample of size N . Assume $\hat{F}_i = 1$ for $i > B$. For the t th percentile, let $p = \frac{t}{100}$. PROC ECM first finds the i th bin that satisfies $\hat{F}_i < p \leq \hat{F}_{i+1}$. Then it computes a ratio g as

$$g = \frac{p - \hat{F}_i}{\hat{F}_{i+1} - \hat{F}_i}$$

Let b_i denote the value at which the i th bin begins. Assume $b_i = x_{\max}$ for $i > B$, where $x_{\max}$ is the maximum value in the sample. Let j denote the integer part of Np . Then the **PCTLDEF=** option defines the t th percentile, y , as described in Table 18.2.

Table 18.2 Percentile Definitions

PCTLDEF=	Description	Formula
1	Weighted average	$y = (1 - g)b_i + gb_{i+1}$
2	Value closest to Np	$y = b_i$ if $g < \frac{1}{2}$ $y = b_i$ if $g = \frac{1}{2}$ and j is even $y = b_{i+1}$ if $g = \frac{1}{2}$ and j is odd $y = b_{i+1}$ if $g > \frac{1}{2}$
3	Empirical distribution function	$y = b_i$ if $g = 0$ $y = b_{i+1}$ if $g > 0$
4	Weighted average (identical to PCTLDEF=1)	$y = (1 - g)b_i + gb_{i+1}$
5	Empirical distribution function with averaging	$y = \frac{1}{2}(b_i + b_{i+1})$ if $g = 0$ $y = b_{i+1}$ if $g > 0$

Note that each PCTLDEF= method is similar to the corresponding method that is used by the UNIVARIATE procedure in Base SAS. For more information, see *Base SAS Procedures Guide: Statistical Procedures*. The main differences are in the definition of g and in the use of the bin boundaries instead of the ordered sample values.

Input Specification

PROC ECM accepts as input the copula simulation data table (which you specify in the DATA= option in the PROC ECM statement) and marginal data tables (which you specify in the DATA= option in the MARGINAL statements). This section describes the information that these tables are expected to contain.

Copula Simulation Data Table

The copula simulation data table is expected to contain the output of the copula simulation at a uniform scale. It must contain all the marginal variables that you want to analyze. Each observation contains the probability of a loss value for each of the marginal variables; this probability is expected to be generated by accounting for the dependence structure between the marginal variables.

This is a required data table; you must specify it in the DATA= option in the PROC ECM statement.

The copula table is usually generated by specifying the OUTUNIFORM= option in the SIMULATE statement in the CCOPULA procedure for a dependency structure that is either defined by you (in the DEFINE statement in PROC CCOPULA) or estimated by PROC CCOPULA (according to the FIT statement in PROC CCOPULA).

Marginal Data Tables

The marginal data tables that you specify in the MARGINAL statements are expected to contain an empirical sample of the corresponding marginal variable. This is a required data table; you must specify it for each marginal that you want to analyze.

The empirical sample must appear in a variable that has one of the following names:

- the name of the marginal variable
- the name that you specify in the **SAMPLEVAR=** option in the MARGINAL statement
- **_AGGSEV_**

If a marginal table contains a variable named **_DRAWID_**, then the table is assumed to contain multiple empirical samples of the marginal variable. The value of the **DRAWID=** option in the MARGINAL statement or the value of the **DRAWID=** option in the PROC ECM statement determines which sample to use for the analysis.

Output Data Tables

PROC ECM writes the output data tables that you specify in the **OUT=** option of the **OUTPUT** and **OUTSUM** statements. The contents of these output data tables are described in the following sections.

OUTSAMPLE= Data Table

The OUTSAMPLE= data table records the sample of the total loss. It contains as many observations as the number of valid observations in the copula simulation data table. The OUTSAMPLE= data table contains the following variables:

Total-loss-variable

indicates the value of the total loss. The name of this variable is the value of the **TOTALLOSSVAR=** option in the OUTPUT statement. If you do not specify the **TOTALLOSSVAR=** option, then this variable is named **_TOTALLOSS_**.

The total loss for each observation is computed as the sum of the loss estimates of individual marginals. The loss estimate of each marginal is computed by inverting the estimated EDF at the probability of that marginal.

If you specify the **MARGINALSOUT** option in the OUTPUT statement, then the table also contains the following variables:

Probability-of-marginal-variable-1 ... Probability-of-marginal-variable-D

indicates the probability values of the *D* marginal variables, where *D* is the number of marginal variables that PROC ECM analyzes. The names of these variables are the *marginal-variable* values that you specify in the respective MARGINAL statements. The value of each variable is identical to the value of the respective variable in the copula simulation data table.

Loss-for-marginal-variable-1 ... Loss-for-marginal-variable-D

indicates the estimates of the losses of the D marginal variables, where D is the number of marginal variables that PROC ECM analyzes. The names of these variables are formed by adding a suffix of `_Loss` to the name of the corresponding marginal variable. The loss for a marginal variable is the percentile estimate for the probability value of that marginal.

OUTSUM= Data Table

The OUTSUM= data table records the estimates of summary statistics, percentiles, and tail values-at-risk (TVaR) of the estimated total loss. You can control the statistics that appear in this data table by specifying the PCTLPTS= option, the TVARPTS= option, and keywords for different statistics in the OUTSUM statement.

If you specify the PCTLPTS= or TVARPTS= option in the OUTSUM statement, then the OUTSUM= data table contains percentile estimates for all the default percentile levels (1, 5, 10, 25, 50, 75, 90, 95, 99, and 99.5) in addition to the percentile levels that you specifically request.

For more information about the method of naming the variables that correspond to the summary statistics, percentiles, and TVaR estimates, see the description of the OUTSUM statement.

Displayed Output

The ECM procedure optionally produces displayed output by using the Output Delivery System (ODS). You control all output by using the PRINT= option in the PROC ECM statement or by using the DISPLAY statement. Table 18.3 relates the PRINT= options to ODS tables.

Table 18.3 ODS Tables Produced by PROC ECM

ODS Table Name	Description	Option
DataSummary	Summary of the marginal or total loss sample	PRINT=DATASUMMARY
EDFInit	Initialization summary of the EDF estimation process	PRINT=EDFINIT
EDFInitOptDetails	Optimization details of the initialization of the EDF estimation process	PRINT=EDFINIT
EDFOptDetails	Optimization details of the EDF estimation process	PRINT=EDFOPTDETAILS
EDFSummary	Summary of the EDF estimation process	PRINT=EDFSUMMARY
Percentiles	Percentiles of the total loss sample	PRINT=PERCENTILES in the PROC ECM statement and PCTLPTS= in the OUTSUM statement

Table 18.3 *continued*

ODS Table Name	Description	Option
SummaryStatistics	Summary statistics of the total loss sample	PRINT=SUMMARYSTATISTICS
TVaR	Tail value-at-risk (TVaR) estimates of the total loss sample	PRINT=TVAR in the PROC ECM statement and TVARPTS= in the OUTSUM statement
Timing	Timing information for various computational stages of the procedure	PRINT=ALL

If you do not specify the PRINT= option and if you do not specify the NOPRINT, PRINT=NONE, or PRINT=ONLY options, then by default PROC ECM produces the SummaryStatistics ODS table. If you specify the PCTLPTS= option in the OUTSUM statement, then the default displayed output also includes the Percentiles ODS table. If you specify the TVARPTS= option in the OUTSUM statement, then the default displayed output also includes the Percentiles and TVaR ODS tables.

ODS Table Details

Table 18.4 provides detailed descriptions of the tables that different PRINT= options display.

Table 18.4 Description of ODS Tables

ODS Table Name	Detailed Description
DataSummary	The “Data Summary” table contains the summary of each sample for which PROC ECM estimates the EDF.
EDFInit	The “EDF Binning Initialization” table contains, for each marginal variable, the summary of the first (initialization) stage of the EDF estimation process. This summary includes the number of bins that the first stage uses and the convergence status of the optimization process of the first stage. It also reports the estimated empirical distribution function (EDF) at the start of the tail region and the tail start value. Finally, it reports whether the second stage of the binning algorithm processes different regions of the data range in parallel by distributing the bins among worker nodes. If you specify the PCTLPTS= or TVARPTS= option in the OUTSUM statement, PROC ECM displays this table also for the total loss variable’s sample.

Table 18.4 *continued*

ODS Table Name	Detailed Description
EDFInitOptDetails	The “EDF Binning Initialization Details” table contains, for each marginal variable, the details of the optimization process of the first page. The table reports the desired proportion of counts in each initial bin, the number of iterations, and the final value of the optimization criterion (which is the difference in proportions of the bins that have the largest and the smallest counts at the end of the first stage). The table also reports the chi-square test statistic (along with its degrees of freedom) and the p-value (which indicates how close the final distribution of counts in the bins is to the desired uniform distribution). Typically, a p-value that is larger than 0.05 indicates that the final distribution of bin counts is not statistically significantly different from a uniform distribution. If you specify the PCTLPTS= or TVARPTS= option in the OUTSUM statement, PROC ECM displays this table also for the total loss variable’s sample.
EDFOptDetails	The “EDF Binning Optimization Details” table contains, for each marginal variable, the details of the optimization process that PROC ECM runs in each region that does not use data points to form bins. For each region, the table reports the desired proportion, the number of iterations, and the final value of the optimization criterion, which is the difference in proportions of the bins that have the largest and the smallest counts at the end of the optimization. The table also reports the chi-square test statistic along with its degrees of freedom and the p-value. Typically, a p-value that is larger than 0.05 indicates that the final distribution of bin counts in that region is not statistically significantly different from the desired uniform distribution. If you specify the PCTLPTS= or TVARPTS= option in the OUTSUM statement, PROC ECM displays this table also for the total loss variable’s sample.
EDFSummary	The “EDF Binning Summary” table contains, for each marginal variable, the summary of the regions for which PROC ECM processes the bins independently. For each region, it reports the range and location (body, tail, or body-tail), the number of observations in that region, and the number of bins that are formed in that region. If the status for a region indicates that PROC ECM has used the data points to form bin boundaries, then PROC ECM does not run the optimization process for that region and that region’s information does not appear in the “EDF Binning Optimization Details” table. For all other regions, PROC ECM runs the optimization process, reports the convergence status of the optimization process in this table, and reports the details of the optimization process in the “EDF Binning Optimization Details” table. If you specify the PCTLPTS= or TVARPTS= option in the OUTSUM statement, PROC ECM displays this table also for the total loss variable’s sample.

Table 18.4 *continued*

ODS Table Name	Detailed Description
Percentiles	The “Percentiles” table contains estimates of the percentiles of the total loss sample. This table includes the default set of percentiles and the percentiles that you request in the OUTSUM statement.
SummaryStatistics	The “Summary Statistics” table contains estimates of the following summary statistics of the total loss sample: number of observations, maximum value, minimum value, mean, standard deviation, variance, skewness, and kurtosis. If you specify the PCTLPTS= or TVARPTS= option in the OUTSUM statement, the table also contains the estimates of median and interquartile range.
TVaR	The “Tail Value-at-Risk Estimates” table contains the tail value-at-risk (TVaR) estimates for the percentile levels that you specify in the TVARPTS= option. The table also reports the value-at-risk (VaR) estimate for each percentile level. It also includes the probability that a loss value exceeds the VaR estimate, which is equal to $1 - p/100$ for a percentile level p .

Examples: ECM Procedure

Example 18.1: Developing an Economic Capital Model

This example illustrates all the steps of developing an economic capital model by using SAS Econometrics procedures, including the ECM procedure. The section “[Overview: ECM Procedure](#)” on page 1098 describes the process in detail. Following is a quick summary of all the steps in the process:

1. Collect and prepare data.
2. For each line of business (LoB), do the following:
 - a) Fit and select the best frequency model for the number of loss events in a particular time period.
 - b) Fit and select the best severity model for the magnitude of each loss.
 - c) Estimate a compound distribution model (CDM) by combining the best frequency and severity models to create a large sample of the aggregate loss.
3. Estimate a dependency structure among the losses of the LoBs by fitting and selecting the best copula model.
4. Use the best copula model to simulate a large sample of probabilities of loss values that are observed in all LoBs in the same time period.

5. Estimate an economic capital model by combining the copula simulation sample with the aggregate loss samples of all LoBs.

The following subsections illustrate in detail each of these steps by developing a simple ECM for a bank's operational risk.

Data Preparation

Consider that you are a bank and, as part of creating an economic capital model for your operational risk, you want to analyze losses in two LoBs: retail banking and commercial banking. In addition to collecting the loss frequency and loss severity data for each LoB, you should also collect data about the key risk indicators (KRIs), which are the external factors that you believe might affect the frequency and severity of losses in at least one LOB. Let CorpKRI1, CorpKRI2, CbKRI1, CbKRI2, CbKRI3, RbKRI1, RbKRI2, and RbKRI3 be the available KRIs, where the prefix Corp indicates corporate-level KRIs, the prefix Cb indicates KRIs specific to commercial banking, and the prefix Rb indicates KRIs specific to retail banking. Some examples of corporate-level KRIs are the ratio of temporary employees to permanent employees and the number of security breaches that are reported during a year. Some examples of commercial banking KRIs are the number of credit defaults, the proportion of financed assets that are movable, and the penalty claims against your bank that can result from processing delays. Some examples of retail banking KRIs are the number of credit cards that are reported stolen, the fraction of employees who have not undergone fraud detection training, and the number of forged drafts and checks that are presented in a year. To mimic the real-world applications, let different yet overlapping sets of KRIs be used for the frequency and severity models. Let the analysis period be one month, and let the data preparation process result in the following data tables:

- The Work.OpRiskLossCounts data table contains the frequency regressors and the variable NumLoss, which records the number of losses that an LoB incurs in a month. The LoBs are identified by the BY variable Line.
- The Work.OpRiskLosses data table contains the severity regressors and the variable LossValue, which records the severity of each loss. The LoBs are identified by the BY variable Line.
- The Work.OpRiskMatchedLosses data table contains the aggregate losses of all LoBs, where the losses in each LoB are aggregated by month. These matched losses are needed for copula modeling.

The following DATA steps prepare the preceding three data tables:

```

/*** Simulate loss counts data ***/
data OpRiskLossCounts(keep=line corpKRI1 corpKRI2
                      cbKRI1 cbKRI2 cbKRI3 rbKRI1 rbKRI2 numloss);
  call streaminit(12345);
  array cx{8} corpKRI1 corpKRI2 cbKRI1 cbKRI2 cbKRI3 rbKRI1 rbKRI2 cb23;
  array cbetaR{9} _TEMPORARY_ (0.1 1 -0.5 0 0 0 0.5 0.75 0);
  array cbetaC{9} _TEMPORARY_ (0.5 0.75 0.3 -0.25 0.25 0.5 0 0 0.3);

  alpha = 0.35; theta = 1/alpha;
  call streaminit(12345);
  do obs=1 to 1000;
    do i=1 to dim(cx)-1;
      cx(i) = rand('NORMAL');
    end;

```

```

cb23 = cx(4) * cx(5);

line = 'CommercialBanking';
xbeta = cbetaC(1);
do i=1 to dim(cx);
    xbeta = xbeta + cx(i) * cbetaC(i+1);
end;
Mu = exp(xbeta); p = theta/(Mu+theta);
numloss = rand('NEGB',p,theta);
output;

line = 'RetailBanking';
xbeta = cbetaR(1);
do i=1 to dim(cx);
    xbeta = xbeta + cx(i) * cbetaR(i+1);
end;
lambda = exp(xbeta);
numloss = rand('POISSON', lambda);
output;
end;
run;

/** Simulate severity of losses and matched loss data */
data OpRiskLosses(keep=line corpKRI1 corpKRI2 cbKRI2 rbKRI1 rbKRI3 lossValue)
    OpRiskMatchedLosses(keep=CB RB);
    array sx{6} corpKRI1 corpKRI2 cbKRI2 rbKRI1 rbKRI3 corplrb3;
    array sbetaC{7} _TEMPORARY_ (5 1 0 0.3 0 0 0);
    array sbetaR{7} _TEMPORARY_ (3.5 0 0.5 0 -0.8 0.6 0.2);
    retain CB RB sigma alpha;
    if (_n_=1) then do;
        call streaminit(67890);
        sigma = 1.0; /* for lognormal */
        alpha = 3.0; /* for gamma */
    end;
    set OpRiskLossCounts(keep=line numloss corpKRI1 corpKRI2 cbKRI2 rbKRI1);
    sx(5) = rand('NORMAL'); /* simulate rbKRI3 value */
    corplrb3 = sx(1) * sx(5);

    if (line='CommercialBanking') then do;
        CB = 0;
        do il=1 to numloss;
            /* lognormal */
            Mu = sbetaC(1);
            do i=1 to dim(sx);
                Mu = Mu + sx(i) * sbetaC(i+1);
            end;
            lossValue = exp(Mu) * rand('LOGNORMAL')**Sigma;
            CB = CB + lossValue;
            output OpRiskLosses;
        end;
    end;
    else do; /* line='RetailBanking' */
        RB = 0;
        do il=1 to numloss;

```

```

        /* gamma */
        Mu = sbetaR(1);
        do i=1 to dim(sx);
            Mu = Mu + sx(i) * sbetaR(i+1);
        end;
        lossValue = rand('Gamma', Alpha, exp(Mu));
        RB = RB + lossValue;
        output OpRiskLosses;
    end;
    output OpRiskMatchedLosses;
end;
run;

```

The following DATA steps load the data tables in your session that is associated with the mylib libref. This example assumes that your libref is named mylib, but you can substitute any appropriately defined libref.

```

/** Load data tables into the session */
data mylib.OpRiskLossCounts;
    set OpRiskLossCounts;
run;
data mylib.OpRiskLosses;
    set OpRiskLosses;
run;
data mylib.OpRiskMatchedLosses;
    set OpRiskMatchedLosses(where=(CB > 0 and RB > 0));
run;

```

When your frequency or severity models contain regressors, you must also create an external scenario data table to contain values that you expect to observe for each regressor in some future state. The final CDM and ECM estimates depend on this scenario data table. For this example, the scenario data table is named Work.MultiConditionScenario, and it contains observations for 12 months of a future year. The following DATA steps simulate it and load it into your session:

```

/** Generate a scenario data table for multiple operating conditions */
data multiConditionScenario (keep=line opEnvId corpKRI1 corpKRI2
    cbKRI1 cbKRI2 cbKRI3 rbKRI1 rbKRI2 rbKRI3);
    array x{8} corpKRI1 corpKRI2 cbKRI1 cbKRI2 cbKRI3 rbKRI1 rbKRI2 rbKRI3;
    call streaminit(5151);
    do opEnvId=1 to 12;
        do i=1 to dim(x);
            x(i) = rand('NORMAL');
        end;
        line = 'CommercialBanking';
        output;
        line = 'RetailBanking';
        output;
    end;
run;
proc print; run;

/** Load the scenario data table into the session */
data mylib.multiConditionScenario;
    set multiConditionScenario;
run;

```

After this critical step of collecting and preparing the data, you are ready for the subsequent modeling and simulation steps.

Frequency (Count) Modeling

The CNTSELECT procedure in SAS Econometrics estimates frequency models. It fits a count regression model, where the dependent variable is a count variable that, conditional on the regressors, has one of the following discrete probability distributions: Poisson, negative binomial with linear or quadratic variance, or Conway-Maxwell-Poisson (CMP). It can also fit a zero-inflated version of each distribution, enabling you to account for the large number of zeros that are often present in real-life loss count data. For detailed information about all the features of PROC CNTSELECT, see Chapter 10, “[CNTSELECT Procedure](#).”

The following statements use the CNTSELECT procedure to fit Poisson and negative binomial distribution models to the example data:

```

/** Fit Poisson count models */
proc cntselect data=mylib.OpRiskLossCounts store=mylib.opriskStorePoisson
  method=CONGRA;
  by line;
  model numloss=corpKRI1 corpKRI2 cbKRI1 cbKRI2 cbKRI3 cbKRI2*cbKRI3
    rbKRI1 rbKRI2/dist=poisson;
  selection;
  ods output SelectedModel.FitModelSummary=fitPoisson;
run;

/** Fit negative binomial count models */
proc cntselect data=mylib.OpRiskLossCounts store=mylib.opriskStoreNegbin
  method=CONGRA;
  by line;
  model numloss=corpKRI1 corpKRI2 cbKRI1 cbKRI2 cbKRI3 cbKRI2*cbKRI3
    rbKRI1 rbKRI2/dist=negbin(p=2);
  selection;
  ods output SelectedModel.FitModelSummary=fitNegbin
    SelectedModel.ParameterEstimates=estNegbin;
run;

```

In the PROC CNTSELECT step, the BY statement ensures that the specified model is analyzed for both LoBs. The MODEL statements specify all the possible regression effects that you believe can affect the number of losses in all LoBs. The SELECTION statements perform model (variable) selection independently for each BY group. The default settings of the SELECTION statement choose the best subset of regression effects to maximize the Schwarz Bayesian criterion (SBC). The ODS OUTPUT statements store the fit summary of the selected model in the Work.FitPoisson and Work.FitNegbin data sets. The following DATA step reads those two data sets to prepare a comparative fit summary:

```

/** Summarize count modeling results */
data countFitSummary;
  set fitPoisson (keep=line Property PropertyValue where=(Property='SBC'));
  Model='Poisson';
  output;
  set fitNegbin (keep=line Property PropertyValue where=(Property='SBC'));
  Model='NegBin(p=2)';
  output;
run;

```

[Output 18.1.1](#) shows the comparison of the fit summary of the final count models of both business lines. It indicates that the negative binomial model is the best model for the commercial banking LoB, because it has a smaller SBC value than the Poisson model. For the retail banking LoB, the Poisson model is

the best model. Occasionally, both the Poisson and negative binomial models might have identical SBC values. This usually implies that the negative binomial model is equivalent to the Poisson model, because the overdispersion parameter α is close to 0. Formally, the conditional variance of the negative binomial distribution is $V(y|x) = \mu + \alpha\mu^2$, where μ denotes the mean. As α becomes closer 0, the variance becomes closer to the mean, making it equivalent to a Poisson distribution. The estimate of the `_Alpha` parameter in [Output 18.1.2](#) confirms this.

Output 18.1.1 Comparing Fit Statistics of Count Models

line	Model	Property	PropertyValue
CommercialBanking	Poisson	SBC	4010.42
CommercialBanking	NegBin(p=2)	SBC	3608.513
RetailBanking	Poisson	SBC	2940.835
RetailBanking	NegBin(p=2)	SBC	2940.835

Output 18.1.2 Parameter Estimates of Negative Binomial Count Model (Retail Banking)

The CNTSELECT Procedure

Selected Model

line=RetailBanking

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	0.124733	0.032401	3.85	0.0001
corpKRI1	1	0.989701	0.019687	50.27	<.0001
corpKRI2	1	-0.504275	0.019627	-25.69	<.0001
rbKRI1	1	0.522683	0.019862	26.32	<.0001
rbKRI2	1	0.712896	0.020307	35.11	<.0001
_Alpha	1	1.0536712E-8	.	.	.
Restrict 1	-1	6273.095945	.	.	.

The `STORE=` options in each PROC CNTSELECT step create item-store data tables that store all the model fit information, including the selected model's parameter estimates, which are used to estimate the compound distribution model in a later step.

Severity Modeling

The SEVSELECT procedure in SAS Econometrics estimates severity models. In the simplest form, it fits multiple continuous probability distributions to the input loss severity data (which are possibly censored or truncated), and prepares a comparative summary of the fit statistics of all candidate distributions to help you choose the best candidate. PROC SEVSELECT includes a default set of 10 distributions: Burr, exponential, gamma, generalized Pareto (GPD), inverse Gaussian (Wald), lognormal, Pareto, scaled Tweedie, Tweedie, and Weibull. However, you can define and fit your own distributions, such as mixture distributions. PROC SEVSELECT models the effect of regressors on the scale parameter or the log-scale parameter of the distribution, and it supports automatic model (variable) selection. For detailed information about all the features of PROC SEVSELECT, see Chapter 26, “[SEVSELECT Procedure](#).”

The following PROC SEVSELECT step fits severity models for three candidate distributions—gamma, lognormal, and Weibull—to the example data:

```

/** Fit severity models */
proc sevselect data=mylib.OpRiskLosses store=mylib.opriskSevstore(promote=yes)
            covout print=(allfitstats);

    by line;
    loss lossValue;
    dist gamma logn weibull;
    scalemodel corpKRI1 corpKRI2 cbKRI2 rbKRI1 rbKRI3 corpKRI1*rbKRI3;
    selection method=forward(select=aicc);

run;

```

The LOSS statement specifies the severity loss variable. The DIST statement specifies the list of candidate distributions. The STORE= option names an item store to hold the final model specifications and their parameter estimates. The COVOUT option requests that the parameter covariance estimates be kept in the item store for use in a later step. The SCALEMODEL statement lists all candidate regression effects. The SELECTION statement requests that the best subset of regression effects be chosen according to the forward selection method, where candidate subsets are compared using the corrected Akaike's information criterion (AICC). Within each BY group, PROC SEVSELECT runs the regression effect selection process independently for each candidate distribution.

After the selection process completes for all distributions, PROC SEVSELECT prepares a comparative summary of the fit statistics of the final selected scale regression models of all candidate distributions, as shown in [Output 18.1.3](#). There are two classes of fit statistics: likelihood-based (AIC, AICC, and SBC) and EDF-based (KS, AD, CvM). Akaike’s information criterion (AIC) is an asymptotic version of AICC. The Kolmogorov-Smirnov (KS), Anderson-Darling (AD), and Cramér–von Mises (CvM) statistics are the EDF-based statistics, which measure the distance between the CDF and the EDF. For scale regression models, the CDF depends on the values of the regressors, which can vary from one observation to another, making it difficult to interpret the EDF-based fit statistics. So you should use the likelihood-based statistics to compare the scale regression models. For the example data, the lognormal distribution is the best for the commercial banking line, and the gamma distribution is the best for the retail banking line, according to all the likelihood-based fit statistics.

Output 18.1.3 Comparison of Statistics of Fit for the Final Selected Severity Models

Compound Distribution Modeling

The CCDM procedure in SAS Econometrics estimates a compound distribution model (CDM) for the aggregate loss by combining the best frequency and severity models. Before illustrating the use of PROC CCDM, it is useful to define the CDM. If N and X represent the frequency and severity random variables, respectively, then the aggregate loss S is defined as $S = \sum_{j=1}^N X_j$. If $F_X(x)$ denotes the cumulative distribution function (CDF) of X and if $\Pr(N = n)$ denotes the probability of seeing n losses as per the frequency distribution, then the CDF of S is theoretically computable as $F_S(s) = \sum_{n=0}^{\infty} \Pr(N = n) \cdot F_X^{*n}(x)$, where $F_X^{*n}(x)$ denotes the n -fold convolution of the CDF of X . The probability distribution model for S , characterized by $F_S(s)$, is called a CDM. Direct computation of F_S is usually a difficult task because the n -fold convolution needs to be computed. Some methods exist for certain combinations of severity and frequency distributions (for example, Klugman, Panjer, and Willmot 1998, Ch. 4), but even those methods do not offer closed-form or easily computable expressions for F_S . Further, when the distributions of X and N are conditional on external factors (regressors), as is usually the case, each set of regressor values results in a different distribution for N and X . For all these reasons, PROC CCDM estimates the CDM by using a Monte Carlo simulation method. For detailed information about all the features of PROC CCDM, see Chapter 7, “CCDM Procedure.” An important feature that this example uses is PROC CCDM’s ability to generate multiple perturbed aggregate loss samples, each of which corresponds to a random perturbation of the frequency and severity parameters from their mean values according to the covariance structure that the CNTSELECT and SEVSELECT procedures estimate. This feature helps assess the uncertainty (variability) in the estimates of the CDM.

The following PROC CCDM steps estimate the CDM for each LoB. Because the best count model for each LoB is different for this example, you need two separate steps, each of which uses an appropriate count model item-store table in the COUNTSTORE= option.

```

/** Simulate CDM for commercial banking LoB */
proc ccdm data=mylib.multiConditionScenario
    countstore=mylib.opriskStoreNegbin severitystore=mylib.opriskSevstore
    seed=13579 nreplicates=10000 nperturb=50 print=all;
    by line;
    severitymodel logn;
    output out=mylib.aggregateLossCB samplevar=agglossCB / perturbOut;
run;

/** Simulate CDM for retail banking LoB */
proc ccdm data=mylib.multiConditionScenario
    countstore=mylib.opriskStorePoisson severitystore=mylib.opriskSevstore
    seed=13579 nreplicates=10000 nperturb=50 print=all;

```

```

by line;
severitymodel gamma;
output out=mylib.aggregateLossRB samplevar=agglossRB / perturbOut;
run;

```

When the frequency and severity models contain regression effects, you need to use the DATA= option to specify a data table that contains an external scenario that you want to analyze. This example uses a simulated scenario in the mylib.MultiConditionScenario data table. The NPERTURB= option requests that parameter perturbation analysis be conducted to generate 50 perturbed samples. The NREPLICATES= option specifies the size of each unperturbed and perturbed aggregate loss sample. The OUTPUT statement and its PERTURBOUT option request that all 51 samples be stored in a data table. PROC CCDM creates the output data table by using parallel computations and stores it in a distributed manner across all worker nodes. These samples are useful for estimating the uncertainty in the final ECM estimates in a later stage of the ECM process.

Output 18.1.4 shows one of the tables that the perturbation analysis produces for the commercial banking LoB. You can use this table to estimate the VaR for an individual LoB. The perturbation analysis gives you an estimate of the variability in each statistic of interest, which is more informative than just the estimate of the mean.

Output 18.1.4 Perturbation Analysis of Aggregate Losses (Commercial Banking LoB)

The CCDM Procedure

Severity Model: Logn
Count Model: NegBin(p=2)

line=CommercialBanking

Sample Percentile Perturbation Analysis		
Percentile	Estimate	Standard Error

Number of Perturbed Samples = 50		
Size of Each Sample = 10000		

Copula Modeling

The CCOPULA procedure in SAS Econometrics helps you analyze the dependency among losses of multiple LoBs. It supports the dependency structures that are expressed in terms of an elliptical copula (normal and t copulas) or an Archimedean copula (Clayton, Frank, and Gumbel copulas). A copula is especially useful for modeling the dependency structure in the ECM process, because it decouples the marginal distributions—that is, the probability distributions of individual random variables—from their joint probability distribution. This decoupling is based on an important theorem by Sklar (1959), which shows that a copula can be derived from

any joint distribution function and that any copula can be combined with any set of marginal distributions to result in a multivariate distribution function. PROC CCOPULA can both fit a copula model and simulate samples from a fitted copula model. For detailed information about all the features of PROC CCOPULA, see Chapter 8, “[CCOPULA Procedure](#).”

The following PROC CCOPULA steps fit four different types of copulas to the matched loss data in the data table mylib.OpRiskMatchedLosses:

```

/** Fit different copula models */
proc ccopula data=mylib.OpRiskMatchedLosses;
  var CB RB;
  fit Gumbel / store=mylib.copStoreG;
  ods output fitmodelsummary=fitsummG;
run;
proc ccopula data=mylib.OpRiskMatchedLosses;
  var CB RB;
  fit T / store=mylib.copStoreT;
  ods output fitmodelsummary=fitsummT;
run;
proc ccopula data=mylib.OpRiskMatchedLosses;
  var CB RB;
  fit Frank / store=mylib.copStoreF;
  ods output fitmodelsummary=fitsummF;
run;
proc ccopula data=mylib.OpRiskMatchedLosses;
  var CB RB;
  fit Clayton / store=mylib.copStoreC;
  ods output fitmodelsummary=fitsummC;
run;

```

In each PROC CCOPULA step, the VAR statement specifies the marginal variables, which are CB and RB for losses in the commercial and retail banking LoBs, respectively. The FIT statement specifies the type of the copula and names the item-store data table in which to store the specification and estimates of the copula parameters. The ODS OUTPUT statement stores the fit summary of the copula, which you can analyze to produce a comparative table of the SBC fit statistics of all copulas as shown in [Output 18.1.5](#). The table shows that the Gumbel copula has the best fit for the example data by virtue of having the smallest SBC value.

Output 18.1.5 Fit Statistics for Copula Models

Copula	SBC
Gumbel	-69.6587
T	-61.4826
Frank	-48.3310
Clayton	-25.3843

Copula Simulation

The next step in the ECM process is to simulate multiple future scenarios of loss values that might be observed in all LoBs in the same time period. Each scenario is represented by the probabilities of loss values in all LoBs while taking into account the dependency structure among their losses. The use of the OUTUNIFORM= option in the OUTPUT statement of the CCOPULA procedure helps you create a large number of such simulated scenarios. The following PROC CCOPULA step illustrates that for the best-fitting Gumbel copula for this example's data:

```

/** Simulate marginal probabilities on the uniform scale from the Gumbel copula */
proc ccopula;
    simulate cop / restore=mylib.copStoreG
                ndraws=10000 seed=234
                outuniform=mylib.CbRbProbs;
run;

proc print data=mylib.CbRbProbs(obs=5) noobs; run;

```

The SIMULATE statement specifies the mylib.copStoreG item store to read the estimates of the Gumbel copula's parameter. The NDRAWS= option simulates 10,000 observations from this copula. The OUTUNIFORM= option requests that the observations be generated in the uniform scale and stored in the mylib.CbRbProbs data table. PROC CCOPULA uses the multiple nodes of a CAS session to simulate and store the data in a distributed manner. The first few simulated observations in the data table are shown in [Output 18.1.6](#). Each observation contains the probability of a loss in each LoB.

Output 18.1.6 Example of Simulated Copula Observations

CB	RB
0.0585445576	0.317802304
0.9579833083	0.9688330154
0.2114479224	0.3521376759
0.3857146159	0.9856645119
0.7071269566	0.7585000789

Economic Capital Modeling: Combining Copula Simulation with CDM Samples

The final step of the ECM process is to estimate the distribution of the total loss across all LoBs. This requires transforming each observation in the copula simulation table (which contains the probability of a loss value in each LoB) to an observation that contains an estimate of the actual loss for each LoB. For a conceptual overview of this process, see the section “[Overview of the Algorithm](#)” on page 1119.

The ECM procedure is designed specifically to help you implement this step. The following PROC ECM step converts the loss probabilities in the data table mylib.CbRbProbs to a sample of the total loss across two marginals, CB and RB, for the commercial and retail banking LoBs, respectively:

```

/* Estimate an empirical model for the total loss */
proc ecm data=mylib.CbRbProbs tailstart=0.85 edfaccuracy=1.0e-2
    samplefraction=0.7 seed=789 print=all;
    marginal CB: data=mylib.aggregateLossCB samplevar=agglossCB;
    marginal RB: data=mylib.aggregateLossRB samplevar=agglossRB;
    outsum out=mylib.tlSummary mean stddev skew kurtosis qrange=iqr
    pctlpts=50, 90, 95, 97.5, 99, 99.5 pctlpre=VaR

```

```

    tvarspts=90, 95, 97.5, 99, 99.5 pctlpre=TVaR;
run;

```

The two MARGINAL statements specify the data tables that contain the aggregate loss samples of each LoB as created by the CCDM steps. The identifying name of the marginal that you specify in the MARGINAL statement must match the corresponding name that you use in the VAR statement of the CCOPULA procedure. Because the name of the variable that contains the sample is different from the name of the marginal, you need to specify the SAMPLEVAR= option in each MARGINAL statement.

PROC ECM uses the loss sample in each marginal's data table to estimate the empirical distribution function (EDF) of that marginal. The EDF estimation process works in two stages. The first stage divides the sample values into body and tail regions. For this example, the TAILSTART= option requests that the tail region start at a value whose EDF is approximately 0.85. The actual EDF value at the start of the tail region also depends on the number of worker nodes and the sampling fraction for the body region. The second stage estimates the EDF in each region independently by using the desired accuracy of EDF estimates in each region. By default, PROC ECM attempts to achieve higher accuracy in the tail region. So for this example, you should expect more accurate loss estimates for probability values that are larger than approximately 0.85. The body region can afford to have a relatively lower EDF accuracy. For this example, the EDFACCURACCY= option specifies it to be 0.01, which means that the width of the bins along the EDF axis is approximately 0.01 in the body region. In particular, when PROC ECM processes an interval $[p_1, p_2]$ of the EDF axis, it attempts to bin the data into approximately B bins, where $B \approx (p_2 - p_1)/0.01$. The SAMPLEFRACTION= option requests that only about 70% of the observations in the body region be used for estimating the EDF in that region. This helps reduce the amount of data movement among worker nodes. The SEED= option ensures that the results are similar across multiple runs of the procedure with identical inputs.

For each observation in the DATA= data table, PROC ECM computes the percentile for the probability value of each marginal by using the estimated EDF of that marginal. Adding these percentiles across all marginals results in the estimate of the total loss for that observation. Repeating this process for all observations results in the sample of the total loss, which encodes the probability distribution of the total loss, which in turn is an empirical estimate of the economic capital model (ECM). The OUTSUM statement specifies the summary statistics and various percentile levels of risk measures, VaR and TVaR, that you want to compute for the estimated ECM. The OUT= option requests that the computed statistics and risk measures be stored in the data table mylib.tlSummary.

The PRINT=ALL option in the PROC ECM statement displays all the result tables that PROC ECM produces. For each marginal, up to five result tables are displayed, as illustrated in [Output 18.1.7](#), [Output 18.1.8](#), and [Output 18.1.9](#) for the commercial banking marginal CB.

[Output 18.1.7](#) shows the “Data Summary” table, which summarizes the data sample that PROC ECM reads for CB. It displays the data table name; the number of total, valid, and zero-valued observations; and the range of the data. When the input data table is a result of the parameter perturbation analysis that PROC CCDM conducts (as in this example), it contains multiple samples, each identified by a unique value of the _DRAWID_ variable. The “Data Summary” table displays the draw identifier, which is the value of the _DRAWID_ variable it uses to read the marginal sample. You can control this value by specifying a global value in the DRAWID= option in the PROC ECM statement or a marginal-specific value in the DRAWID= option in a MARGINAL statement. Similarly, the input data table can contain samples for multiple severity distributions when you specify multiple distributions in the SEVERITYMODEL statement of PROC CCDM. PROC ECM chooses the first severity distribution that it finds and displays its name in the “Data Summary” table.

Output 18.1.7 Data Summary (Commercial Banking)**The ECM Procedure****Marginal Variable CB**

Data Summary	
Data Table	AGGREGATELOSSCB
Severity Model	Logn
Draw Identifier	0
Observations	20000
Valid Observations	20000
Zero-valued Observations	0
Minimum	233.557351
Maximum	135451

Output 18.1.8 shows the tables that provide an insight into the first stage of the EDF estimation algorithm for the commercial banking marginal CB.

Output 18.1.8 Summary of the First Stage of EDF Estimation (Commercial Banking)

EDF Binning Initialization					
Number of Bins	7				
Convergence Status	Converged				
Tail Start EDF	0.857650				
Tail Start	23510				
Bins Distributed Among Workers	No				

EDF Binning Initialization Details					
Target	Proportion	Iterations	Criterion	DF	Chi-Square
					Pr > ChiSq
0.142857	5	0.0033000	6	1.4458	0.9630

Following is a description of the contents of each table in Output 18.1.8:

- “EDF Binning Initialization”: This table summarizes the result of the first-stage binning by displaying the number of bins and the status of the iterative bin boundary optimization algorithm. It also shows the EDF value and the actual loss value at the start of the tail region. Finally, it shows whether the bins are distributed among worker nodes at the end of the first stage.
- “EDF Binning Initialization Details”: This table displays the details of the iterative bin boundary optimization algorithm of the first stage. For B number of bins (which is 7 for this marginal), the algorithm attempts to achieve a target proportion of $1/B$ observations in each bin. After several iterations, the maximum difference in fractions of observations in the largest and smallest bins is the value of Criterion. The chi-square test for uniformity of counts in the bins uses $B - 1$ degrees of freedom. The value of the test statistic and its corresponding p -value show that the final distribution of counts in bins is close to the uniform distribution.

Output 18.1.9 shows the tables that provide an insight into the second stage of the EDF estimation process for the commercial banking marginal CB.

Output 18.1.9 Summary of the Second Stage of EDF Estimation (Commercial Banking)

EDF Binning Summary						
Region	Begin	End	Location	N	Bins	Status
1	233.55735	23509.7	Body	17153	86	Converged
2	23509.7	135451.4	Tail	2847	2848	Data points used as bins

EDF Binning Optimization Details						
Target						
Region	Proportion	Iterations	Criterion	DF	Chi-Square	Pr > ChiSq
1	0.011628	1	0.0044890	85	53.1719	0.9973

Following is a description of the contents of each table in [Output 18.1.9](#):

- “EDF Binning Summary”: This table displays the different subregions of values that the second stage processes in parallel. Typically, the number of rows in this table is proportional to the number of worker nodes. For each subregion, the table displays whether the subregion is located in the body or tail region of the distribution. You might also occasionally see the ‘Body-Tail’ location value, which indicates that a subregion straddles the body and tail regions. Next, the table displays the number of observations that are processed and the number of bins that are used. The number of observations in the body subregions reflect the sampling fraction. The number of bins reflects the specified EDF accuracy. Finally, the last column displays the status of the binning process for that subregion. If the number of bins is small enough to hold at least five observations in each bin, an iterative binning algorithm is used and its convergence status is displayed. If the desired accuracy of the region is too high, the number of bins is large and the algorithm uses data points as bin boundaries, as the table shows for the tail region.
- “EDF Binning Optimization Details”: This table displays the details of the iterative bin boundary optimization algorithm for each subregion that does not use data as bin boundaries. The Region column identifies the region, and the remaining columns are similar to the columns of the “EDF Binning Initialization Details” table. For this example, the binning algorithm needs very few iterations in both subregions to achieve a nearly uniform distribution of counts.

If the algorithm decides to use data points as bin boundaries in all the subregions, then this table is not displayed.

PROC ECM also executes the same EDF estimation algorithm for the retail banking marginal RB, and the PRINT=ALL option displays up to five similar result tables for that marginal. Further, because the OUTSUM statement requests ECM statistics that require percentile-based estimates, PROC ECM also executes the same algorithm to estimate the EDF of the generated total loss sample and then uses that EDF estimate to compute the required percentiles and percentile-based risk measures. The PRINT=ALL option displays up to five similar result tables, which contain the summary of the total loss sample and information about the first and second stages of the EDF estimation algorithm for that sample.

After displaying the results of the EDF estimation algorithms for all marginals and the total loss sample, PROC ECM displays the summary statistics and requested risk measures for the total loss sample. [Output 18.1.10](#) shows the “Summary Statistics” and “Tail Value-at-Risk Estimates” tables for this example.

Output 18.1.10 Summary Statistics and Estimates of Risk Measures (VaR and TVaR) of the ECM

Summary Statistics			
Sample Size	10000		
Minimum	1921.8		
Maximum	122147.2		
Mean	23061.3		
Standard Deviation	15640.3		
Variance	244617483		
Skewness	0.90913		
Kurtosis	0.77211		
Median	20658.4		
Interquartile Range	23487.3		

Tail Value-at-Risk Estimates			
Percentile	Pr > VaR	Value at Risk (VaR)	Tail Value at Risk
90	0.1	44943.4	54976.4
95	0.05	52019.3	61880.9
97.5	0.025	59023.3	68705.4
99	0.01	68500.6	77100.1
99.5	0.005	74608.9	82843.7

The “Summary Statistics” table displays the size of the sample, the range of the total loss values in the sample, and various moments of the sample. It also displays median and interquartile range, the robust statistics of location and scale, respectively. The “Tail Value-at-Risk Estimates” table displays the VaR and TVaR estimates for the percentile levels in the TVARPTS= option in the OUTSUM statement. These result tables together provide you a comprehensive statistical picture of the distribution of the total loss. You can especially use the VaR and TVaR estimates to decide the capital requirements for your enterprise. But, you can take this analysis one step further.

The preceding estimates are for a specific set of marginal samples. However, the perturbation analysis that PROC CCDM conducts to capture the uncertainty in the parameter estimates of the severity and frequency models results in multiple samples for each marginal. Similar to how PROC CCDM uses those multiple perturbed samples to estimate the location and dispersion (variability) of various summary statistics and percentiles of a marginal’s CDM, you can use different combinations of the perturbed samples of all the marginals to generate multiple samples of the total loss, compute the risk measures for each such total loss sample, and summarize those estimates to estimate the location and dispersion of all risk measures.

Each perturbed sample is identified by a draw identifier that PROC CCDM writes in the variable `_DRAWID_` when you use the NPerturb= option in the PROC CCDM statement and the PERTURBOUT option in the OUTPUT statement. PROC ECM enables you to specify a value of the draw identifier to use for each marginal by using the DRAWID= option in the MARGINAL statement. The following programming statements use this feature to define a SAS macro that generates multiple combinations of the perturbed samples of both the marginals of this example and invokes PROC ECM for each combination:

```

/*** Macro to generate multiple ECM samples by using multiple perturbed CDM samples,
    and to estimate mean, standard deviation, median, and interquartile range
    of various risk measures of the total loss. ***/
%macro EstimateECMvariability(maxDrawId1=10, maxDrawId2=10);

```

```

%do draw1=0 %to &maxDrawId1;
  %do draw2=0 %to &maxDrawId2;
    %put draw1=&draw1 draw2=&draw2;

You have now completed the process of developing an economic capital model. You should be able to use

this template to analyze multiple dependent lines of business or risk categories of your enterprise and get a statistically sound estimate of the economic capital model to decide the minimum capital that you need to set aside for covering the worst-case losses across the parts of the enterprise that you include in the ECM.

Overview: FRONTIER Procedure

The FRONTIER procedure analyzes stochastic frontier production or cost models. These are linear models with an error term that includes two components: a symmetrically distributed component that allows for random shocks of the production or cost, and a systematic positive component that adjusts for technical or cost inefficiency. The inefficiency component of the error term can be from a half-normal, exponential, or truncated-normal distribution.

Stochastic frontier production models were first introduced by Aigner, Lovell, and Schmidt (1977) and Meeusen and van den Broeck (1977). Kumbhakar and Lovell (2000) provide a good introduction to stochastic frontier analysis. Sickles and Zelenyuk (2019) provide detailed information about this topic.

For a detailed introduction to the stochastic frontier models that PROC FRONTIER supports, see the section “[Details: FRONTIER Procedure](#)” on page 1166.

PROC FRONTIER Features

The FRONTIER procedure can fit stochastic frontier production or cost models. On the basis of the parameterization of the inefficiency term, it supports three stochastic frontier models:

- the half-normal model, where the inefficiency term is half-normally distributed
- the exponential model, where the inefficiency term is exponentially distributed
- the truncated-normal model, where the inefficiency term has a truncated-normal distribution with a truncation point at μ

The inefficiency term is assumed to be independently distributed among the observations.

The following list summarizes some of the basic features of PROC FRONTIER:

- uses model-building syntax that includes **CLASS** and effect-based **MODEL** statements that are familiar from other SAS Econometrics analytic procedures
- fits the stochastic frontier models by using maximum likelihood techniques
- provides a **TEST** statement for performing linear tests of hypotheses
- provides **RESTRICT** and **BOUNDS** statements for imposing linear parameter constraints
- provides an **OUTPUT** statement for producing a data table that contains predictions, residuals, and technical efficiency terms
- uses the **WEIGHT** statement for weighted analysis
- uses the **FREQ** statement for grouped analysis

Because PROC FRONTIER runs on SAS Cloud Analytic Services (CAS), it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- enables you to run in single-machine mode
- exploits all the available cores and concurrent threads. For information about how PROC FRONTIER uses threads, see the section “[Multithreading](#)” on page 108 in Chapter 4, “[Shared Concepts](#).”

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “[Introduction to Shared Concepts](#)” on page 54 in Chapter 4, “[Shared Concepts](#).”

Getting Started: FRONTIER Procedure

This section illustrates how to estimate stochastic frontier production models. The following statements fit a half-normal model:

```
proc frontier data=mylib.mydata;
    model y = x1 x2 / type=half;
run;
```

The output variable *y* and the input variables *x1* and *x2* are contained in the data table *mylib.mydata*. These statements assume that your CAS engine libref is named *mylib*, but you can substitute any appropriately defined CAS engine libref. The relationship between input and output is specified in the MODEL statement. The distribution of the inefficiency term is specified using the TYPE= option in the MODEL statement. In this example, it is the half-normal distribution. TYPE=EXPONENTIAL specifies an exponential distribution, and TYPE=TRUNCATED specifies a truncated-normal distribution. By default, PROC FRONTIER fits a production model. You can specify the COST option in the MODEL statement to fit a stochastic frontier cost model.

The following example fits the stochastic frontier production model to 1957 state data for the US transportation equipment manufacturing industry. The data were originally published in Zellner and Revankar (1969). The data include observations on aggregate value added (*valueadded*), aggregate capital service flow (*capital*), aggregate hours worked (*labor*), and number of establishments (*nfirm*) for 25 US states. A Cobb-Douglas production function is estimated for the output variable, log of value added (*LNV*), using the input variables log of capital (*LNK*) and log of labor (*LNL*).

The following statements create the data set:

```

```

The following statements estimate a stochastic frontier half-normal production model that uses the transportation equipment manufacturing industry data:

```

/*-- Stochastic Frontier Production Model: Half-Normal --*/
proc frontier data=mylib.transpEqp;
  model LNV = LNK LNL / type=half;
run;

```

The “Observation Information” and “Summary Statistics of Dependent Variable” tables shown in [Figure 19.1](#) contain some details about the observations in the data set and the dependent variable.

Figure 19.1 Information about Observations and the Dependent Variable

Getting Started Example: Stochastic Frontier Production Model

The FRONTIER Procedure

Observation Information				
Number of Observations				25
Number of Missing Observations				0

Summary Statistics of Dependent Variable				
Standard				
Variable	Mean	Error	Minimum	Maximum
LNV	5.812092	1.375304	3.122365	8.313743

The “Model Fit Summary” table shown in [Figure 19.2](#) lists several details about the model. By default, PROC FRONTIER uses the Newton-Raphson optimization technique, and the estimated covariance matrix is calculated as the inverse of the negative Hessian. For the available optimization and estimation techniques, see the section “[PROC FRONTIER Statement](#)” on page 1155. The maximum log-likelihood value is shown, in addition to two information measures—Akaike’s information criterion (AIC) and Schwarz’s Bayesian information criterion (SBC)—that can be used to compare competing production models. Smaller values of these criteria indicate better models.

Figure 19.2 Estimation Summary Table for Half-Normal Production Model

Model Fit Summary	
Dependent Variable	LNV
Data Set	TRANSPEQP
Model	Production
Inefficiency Term Distribution	Half-normal
Log Likelihood	2.469522
Maximum Absolute Gradient	3.942E-6
Number of Iterations	11
Optimization Method	Newton-Raphson
AIC	5.060956
SBC	11.15533
Covariance Estimation	Hessian

Figure 19.3 shows the parameter estimates of the model and their standard errors. Both input variables are significant predictors of the log of value added. `_Sigma_v` is the estimate of the standard deviation of the idiosyncratic component of the error term that is specific to the firm and that could enter the model with either sign. `_Sigma_u` is the estimate of the standard deviation of the inefficiency component. When the data are in log terms, the inefficiency component becomes a measure of the percentage by which a particular observation fails to achieve an ideal production rate.

Figure 19.3 Parameter Estimates of Half-Normal Production Model

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	2.081134	0.281648	7.39	<.0001
LNK	1	0.258548	0.098766	2.62	0.0089
LNL	1	0.780245	0.119945	6.51	<.0001
<code>_Sigma_v</code>	1	0.175169	0.054265	3.23	0.0012
<code>_Sigma_u</code>	1	0.221507	0.123706	1.79	0.0734

Figure 19.4 shows the estimates of two important variance statistics that are helpful for model diagnosis. `Sigma2` is the estimate of the total error variance. It is calculated as the sum of the idiosyncratic error variance and the variance of the technical inefficiency term. `Gamma` is the estimate of how much the technical inefficiency contributes to the total variation in the model. It is calculated as the ratio of the variance of the technical inefficiency term to the total error variance. In this example, the technical inefficiency explains most of the variation in the model.

Figure 19.4 Estimates of Important Variance Statistics for Half-Normal Production Model

Variance Statistics		
Parameter	Estimate	Standard Error
<code>Sigma2</code>	0.079750	0.042699
<code>Gamma</code>	0.615244	0.385748

The following statements estimate a stochastic frontier exponential production model that uses the same data:

```

/*-- Stochastic Frontier Production Model: Exponential --*/
proc frontier data=mylib.transpEqp;
  model LNV = LNK LNL;
  output out=mylib.out_te_exp  te1=TE1_exp te2=TE2_exp copyvars=( state );
run;

```

The default model is the exponential model if you do not specify the TYPE= option in the MODEL statement.

Figure 19.5 shows some of the results from this production model.

Figure 19.5 Estimation Summary and Parameter Estimates for Exponential Production Model

Getting Started Example: Stochastic Frontier Production Model

The FRONTIER Procedure

Model Fit Summary					
Dependent Variable	LNV				
Data Set	TRANSP EQP				
Model	Production				
Inefficiency Term Distribution	Exponential				
Log Likelihood	2.86049				
Maximum Absolute Gradient	4.215E-6				
Number of Iterations	11				
Optimization Method	Newton-Raphson				
AIC	4.279021				
SBC	10.3734				
Covariance Estimation	Hessian				

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Intercept	1	2.069242	0.235632	8.78	<.0001
LNK	1	0.262486	0.092001	2.85	0.0043
LNL	1	0.770380	0.110964	6.94	<.0001
_Sigma_v	1	0.171392	0.038449	4.46	<.0001
_Sigma_u	1	0.135169	0.062685	2.16	0.0311

Variance Statistics		
Parameter	Estimate	Standard Error
Sigma2	0.047646	0.015793
Gamma	0.383467	0.285232

You can obtain estimates of the efficiency terms by using the OUTPUT statement. PROC FRONTIER offers two types of technical efficiency terms that are proposed by Battese and Coelli (1988) and Jondrow et al. (1982). The OUTPUT statement in the previous and following statements specify the two technical efficiency terms TE1 and TE2. These terms for each observation are written in the data set that you specify in the OUT= option. In these examples, the technical efficiency terms are calculated for each state and included in mylib.out_te_exp for the exponential model and mylib.out_te_half for the half-normal model.

```

/*-- Obtaining Technical Efficiency Terms for Half-Normal Model --*/
proc frontier data=mylib.transpEqp;
    model LNV = LNK LNL / type=half;
    output out=mylib.out_te_half te1=TE1_half te2=TE2_half copyvars=( state );
run;

```

The following statements merge the two output data sets and sort the new data set with respect to the state variable:

```

/*-- Merging the Two Output Data Sets --*/
data mylib.out_te;
    merge mylib.out_te_half mylib.out_te_exp;
    by state;
run;

proc sort data=mylib.out_te out=out_te_sorted;
    by state;
run;

proc print data = out_te_sorted;
    var State TE1_half TE1_exp TE2_half TE2_exp;
    title 'TEs from Half-Normal and Exponential Models';
run;

```

These statistics for each state are shown in [Figure 19.6](#).

The values of each technical efficiency term from the half-normal model are close to the corresponding values from the exponential model.

Syntax: FRONTIER Procedure

The following statements are available in the FRONTIER procedure. Items in angle brackets (< >) are optional.

```

PROC FRONTIER < options > ;
  BOUNDS bound1 < , bound2 ... > ;
  BY variables ;
  CLASS variable < (options) > ... < variable < (options) > > < / global-options > ;
  DISPLAY < table-list > < / options > ;
  DISPLAYOUT table-spec-list < / options > ;
  FREQ freq-variable ;
  INIT initialization1 < , initialization2 ... > ;
  MODEL dependent-variable = regressors < / options > ;
  OUTPUT < output-options > ;
  RESTRICT restriction1 < , restriction2 ... > ;
  TEST equation1 < , equation2 ... > < / test-options > ;
  WEIGHT variable < / option > ;

```

Functional Summary

Table 19.1 summarizes the statements and options available in the FRONTIER procedure.

Table 19.1 Functional Summary

Description	Statement	Option
Data Table Options		
Specifies the input data table	PROC FRONTIER	DATA=
Writes estimates to an output data table	OUTPUT	OUT=
Declaring the Role of Variables		
Specifies BY-group processing	BY	
Specifies the classification variables	CLASS	
Specifies an optional frequency variable	FREQ	
Specifies an optional weight variable	WEIGHT	NONNORMALIZE
Printing Control Options		
Prints the correlation matrix of the estimates	PROC FRONTIER	CORRB
Prints the covariance matrix of the estimates	PROC FRONTIER	COVB
Suppresses the normal printed output	PROC FRONTIER	NOPRINT
Requests all printing options	PROC FRONTIER	PRINTALL
Prints the names used internally for the parameters	PROC FRONTIER	PRINTINTERNALNAMES
Options to Control the Optimization Process		
Selects the iterative minimization method to use	PROC FRONTIER	METHOD=
Specifies maximum number of iterations allowed	PROC FRONTIER	MAXITER=

Table 19.1 *continued*

Description	Statement	Option
Specifies maximum number of function calls	PROC FRONTIER	MAXFUNC=
Specifies the upper limit of CPU time in seconds	PROC FRONTIER	MAXTIME=
Sets boundary restrictions on parameters	BOUNDS	
Sets initial values for parameters	INIT	
Sets linear restrictions on parameters	RESTRICT	
Model Estimation Options		
Specifies the type of covariance matrix	PROC FRONTIER	COVEST=
Suppresses the intercept parameter	MODEL	NOINT
Specifies a stochastic frontier production model	MODEL	PRODUCTION
Specifies a stochastic frontier cost model	MODEL	COST
Specifies the distribution for the inefficiency term	MODEL	TYPE=
Output Control Options		
Specifies the ODS tables to display	DISPLAY	
Specifies the ODS tables to save as output tables	DISPLAYOUT

PROC FRONTIER Statement

PROC FRONTIER <options> ;

You can specify the following *options* in the PROC FRONTIER statement.

Input Data Table Options

DATA=*libref.data-table*

names the input data table for PROC FRONTIER to use. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section “Using CAS Sessions and CAS Engine Librefs” on page 1147.

data-table specifies the name of the input data table.

Printing Options

CORRB

prints the correlation matrix of the parameter estimates.

COVB

prints the covariance matrix of the parameter estimates.

ITPRINT

prints the initial parameter estimates, convergence criteria, and all constraints of the optimization. At each iteration, the objective function value, step size, maximum gradient, and slope of search direction are also printed.

NOPRINT

suppresses all printed output.

PRINTALL

requests all printing options.

PRINTINTERNALNAMES

prints the internal names that are assigned to parameters.

Estimation Control Options

COVEST=HESSIAN | OP | QML

specifies the type of covariance matrix for the parameter estimates. You can specify the following values:

HESSIAN	specifies the covariance from the Hessian matrix.
OP	specifies the covariance from the outer-product matrix.
QML	specifies the covariance from the outer-product and Hessian matrices.

By default, COVEST=HESSIAN.

Optimization Control Options

PROC FRONTIER uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. You can specify the following *options*:

MAXFUNC=*i*

MAXFU=*i*

specifies the maximum number of function calls in the optimization process. By default, MAXFUNC=1000. The optimization can terminate only after completing a full iteration. Therefore, the number of function calls that are actually performed can exceed the number of calls that you specify in this option.

MAXITER=*i*

MAXIT=*i*

specifies the maximum number of iterations in the optimization process. By default, MAXITER=200.

MAXTIME=*r*

specifies an upper limit of *r* seconds of CPU time for the optimization process. The default value is the largest floating-point double representation of your computer. The time that you specify in this option is checked only once at the end of each iteration. Therefore, the actual run time can be much longer than *r*. The actual run time includes the remaining time needed to finish the iteration and the time that is needed to generate the output of the results.

METHOD=*value*

specifies the iterative minimization method to use. You can specify the following *values*:

CONGRA	specifies the conjugate-gradient method.
DBLDOG	specifies the double-dogleg method.
NEWRAP	specifies the Newton-Raphson method.
NONE	specifies that no optimization be performed beyond using the ordinary least squares method to compute the parameter estimates.
NRRIDG	specifies the Newton-Raphson ridge method.
QUANEW	specifies the quasi-Newton method.
TRUREG	specifies the trust region method.

By default, METHOD=NEWRAP.

BOUNDS Statement

BOUNDS *bound1* < , *bound2* ... > ;

The BOUNDS statement imposes simple boundary constraints on the parameter estimates. You can specify any number of BOUNDS statements.

Each *bound* is composed of parameter names, constants, and inequality operators as follows:

item operator item < *operator item* < *operator item* ... > >

Each *item* is a constant, a parameter name, or a list of parameter names. Each *operator* is <, >, <=, or >=. Parameter names are as shown in the Parameter column of the “Parameter Estimates” table. If a parameter name contains a blank or some other special character (such as ‘*’, ‘-’, ‘(’, or ‘)’), then you must use the internal name of the parameter to refer to that parameter in the BOUNDS statement. You can specify the PRINTINTERNALNAMES option in the PROC FRONTIER statement if you want to see the internal names of the parameters. When you specify the PRINTINTERNALNAMES option, an extra column that shows the internal name of each parameter is added to the “Parameter Estimates” table.

For more information about how parameters are named, see the section “[Parameter Naming Conventions for the RESTRICT, TEST, BOUNDS, and INIT Statements](#)” on page 1171.

You can use both the BOUNDS statement and the RESTRICT statement to impose boundary constraints. However, the BOUNDS statement provides a simpler syntax for specifying these kinds of constraints. For more information, see the section “[RESTRICT Statement](#)” on page 1163.

The following BOUNDS statement illustrates the use of parameter lists to specify boundary constraints. It constrains the estimates of the constant term, the intercept, to be negative; the parameters for the input price P1 to be between 0 and 1; and the technical inefficiency term to be greater than 0.5.

```
bounds intercept < 0,
          0 < P1 < 1,
          _sigma_u > 0.5;
```

Note that operators to select or construct effects, such as “-”, “*”, or “|”, are not allowed in the BOUND statement.

BY Statement

BY *variables* ;

A BY statement can be used with PROC FRONTIER to obtain separate analyses of observations in groups that are defined by the BY *variables*.

CLASS Statement

CLASS *variable* < (*options*) > . . . < *variable* < (*options*) > > < / *global-options* > ;

The CLASS statement names the classification variables to be used as explanatory variables in the analysis. [Table 19.2](#) summarizes the values that you can use for either an *option* or a *global-option*. The options are fully documented in the section “[CLASS Statement](#)” on page 56 in Chapter 4, “[Shared Concepts](#).”

Table 19.2 CLASS Statement Options

Option	Description
DESCENDING	Reverses the sort order
MISSING	Treats missing values as valid levels
ORDER=	Specifies the sort order for the levels
PARAM=	Specifies the parameterization of the variable
REF=	Specifies the reference level of the variable

By default, REF=LAST.

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > ;

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section “[ODS Table Names](#)” on page 1175. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying “/tions/” selects all pathnames that contain the substring “tions”; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying “!/tions/” selects all pathnames that do not contain the substring “tions”; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE

performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetted for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE

displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL

suppresses display of all tables. This option takes precedence over the other options.

TRACE

displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > ;

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key=value* format or a *key* format:

key=value specifies *key* as the ODS table name, path, or partial pathname, and specifies *value* as the output table name.

key specifies *key* as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section “[ODS Table Names](#)” on page 1175. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the [DISPLAY](#) statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL

creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE

does not replace any existing output table of the same name.

REPEATED

replicates all output tables on all nodes.

FREQ Statement

FREQ *freq-variable* ;

The FREQ statement identifies a variable (*freq-variable*) that contains the frequency of occurrence of each observation. PROC FRONTIER treats each observation as if it appears n times, where n is the value of *freq-variable* for the observation. If the value for the observation is not an integer, it is truncated to an integer. If the value is less than 1 or missing, the observation is not used in fitting the model. When the FREQ statement is omitted, each observation is assigned a frequency of 1.

INIT Statement

INIT *initialization1* < , *initialization2* ... > ;

The INIT statement sets initial values for parameters in the optimization.

Each *initialization* is written as a parameter or parameter list, followed by an optional equal sign (=), followed by a number:

parameter < = > *number*

Parameter names are as shown in the Parameter column of the “Parameter Estimates” table. If a parameter name contains a blank or some other special character (such as ‘*’, ‘-’, ‘(’, or ‘)’), then you must use the internal name of the parameter to refer to that parameter in the INIT statement. You can specify the PRINTINTERNALNAMES option in the PROC FRONTIER statement if you want to see the internal names of the parameters. When you specify the PRINTINTERNALNAMES option, an extra column that shows the internal name of each parameter is added to the “Parameter Estimates” table.

For more information about how parameters are named, see the section “[Parameter Naming Conventions for the RESTRICT, TEST, BOUNDS, and INIT Statements](#)” on page 1171.

MODEL Statement

MODEL *dependent-variable* = *regressors* < / *options* > ;

The MODEL statement specifies the dependent variable and independent regressor variables for a stochastic frontier model.

Only one MODEL statement can be specified. You can specify the following *options* after a slash (/):

COST | PRODUCTION

specifies that the estimated model be a cost or production function.

If neither COST nor PRODUCTION is specified, a production function is estimated by default.

NOINT

suppresses the intercept parameter.

TYPE=EXPONENTIAL | HALF | TRUNCATED**DIST=EXPONENTIAL | HALF | TRUNCATED**

specifies the type of distribution for the inefficiency term. You can specify the following types:

EXPONENTIAL specifies an exponential distribution for the inefficiency term.

HALF specifies a half-normal distribution for the inefficiency term.

TRUNCATED specifies a truncated-normal distribution for the inefficiency term.

By default, TYPE=EXPONENTIAL.

OUTPUT Statement

OUTPUT OUT=*libref.data-table* < *output-options* > ;

The OUTPUT statement creates a new data table that includes variables created by the *output-options*. These variables include the estimates of $\mathbf{x}_i'\boldsymbol{\beta}$, the residual, the predicted value of the response variable, and technical efficiency measures.

When the response values are missing for an observation, all output estimates except the residual for that observation are still computed as long as none of the explanatory variables are missing. This enables you to compute these statistics for prediction.

You can specify only one OUTPUT statement.

You must specify the OUT= option:

OUT=*libref.data-table*

names the output data table for PROC FRONTIER to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section “Using CAS Sessions and CAS Engine Librefs” on page 1147.

data-table specifies the name of the output data table.

You can specify one or more of the following *output-options*:

COPYVAR=(*SAS-variable-names*)

COPYVARS=(*SAS-variable-names*)

adds SAS variables to the output data table.

PRED=*name*

MEAN=*name*

names the variable to contain the predicted value of the response variable.

RESIDUAL=*name*

RESID=*name*

names the variable to contain estimates of residuals of the response variable.

TE1=*name*

names the variable to contain estimates of technical efficiency as suggested by Battese and Coelli (1988).

TE2=*name*

names the variable to contain estimates of technical efficiency as suggested by Jondrow et al. (1982).

XBETA=*name*

names the variable to contain estimates of $\mathbf{x}_i' \boldsymbol{\beta}$.

RESTRICT Statement

RESTRICT *restriction1* <, *restriction2* ... > ;

The RESTRICT statement imposes linear restrictions on the parameter estimates. You can specify any number of RESTRICT statements.

Each *restriction* is written either as a single linear equation or as a comma-separated list of two or more linear equations. A restriction equation consists of an *expression*, followed by an equality *operator* (=) or an inequality *operator* (<, >, <=, >=), followed by a second *expression*:

expression operator expression

The *operator* can be =, <, >, <=, or >=.

RESTRICT Statement Expressions

A restriction expression is composed of parameter names, constants, and the operators times (*), plus (+), and minus (−). Each restriction expression must be a linear function of the parameters in the model. In addition, no grouping symbols (such as parentheses) are allowed, and the constant factor in any product can appear only on the left-hand side of the times (*) operator.

The following statements illustrate the use of the RESTRICT statement:

```
proc frontier data=mylib.dataset;
  model y = x1-x10 / production type=exponential;
  restrict x1*x2 <= x2 + x3;
run;
```

It is important to keep in mind that the parameters that are associated with the variables, not the variables themselves, are restricted. Thus, in the preceding RESTRICT statement, the variable names “x1”, “x2”, and “x3” refer to the parameters that are associated with the variables x1, x2, and x3, respectively, not to the variables themselves.

Parameter names are shown in the Parameter column of the “Parameter Estimates” table. If a parameter name contains a blank or some other special character (such as ‘*’, ‘-’, ‘(’, or ‘)’), then you must use the internal name of the parameter to refer to that parameter in the RESTRICT statement. You can specify the PRINTINTERNALNAMES option in the PROC FRONTIER statement if you want to see the internal names of the parameters. When you specify the PRINTINTERNALNAMES option, an extra column that shows the internal name of each parameter is added to the “Parameter Estimates” table.

For more information about how parameters are named, see the section “[Parameter Naming Conventions for the RESTRICT, TEST, BOUNDS, and INIT Statements](#)” on page 1171.

All restriction equations in all RESTRICT statements are applied jointly.

RESTRICT Statement Examples

Examples of valid RESTRICT statements include the following:

```
restrict x1=0.1;
restrict a+b=1;
restrict a-b=0, b+c=1.5;
restrict 2*f=g+h, intercept+f=0;
```

Examples of invalid RESTRICT statements include the following:

```
restrict x1^2=4;
restrict x1*x3=4;
restrict x1/x3=2;
restrict sin(a)=0;
restrict a*0.5=1;
restrict 2*(f+h)=1;
```

In the first four examples of invalid RESTRICT statements, the equation is nonlinear. The fifth example is invalid because the constant factor (0.5) cannot appear on the right-hand side of the times (*) operator. The last example is invalid because grouping symbols are prohibited.

The set of restrictions should be consistent and not redundant. For example, you cannot specify the following statement because the three restrictions are not consistent:

```
restrict f-g=0,
       f-intercept=0,
       g-intercept=1;
```

Lagrange multipliers are reported in the “Parameter Estimates” table for all the active linear constraints. They are identified by the names Restrict1, Restrict2, and so on. The test statistics and *p*-values for these restrictions are computed using the Lagrange multiplier test that is described in the section “[Tests on Parameters](#)” on page 1174. Nonactive (nonbinding) restrictions have no effect on the estimation results and are not noted in the output.

TEST Statement

`<label:> TEST <'string'> equation1 <, equation2... > /<test-options> ;`

The TEST statement performs Wald, Lagrange multiplier, and likelihood ratio tests of linear hypotheses about the regression parameters that are specified in the preceding MODEL statement.

Each test is written either as a single linear *equation* or as a comma-separated list of two or more linear *equations*. A test *equation* specifies a linear hypothesis to be tested and consists of an *expression*, followed by the equality operator (=), followed by a second expression:

expression = *expression*

The rules for valid test expressions are the same as those for restriction expressions. For more information, see the section “[RESTRICT Statement Expressions](#)” on page 1163.

All hypotheses in one TEST statement are tested jointly.

You can specify the following *test-options* after a slash (/):

ALL

performs the Wald, Lagrange multiplier, and likelihood ratio tests.

LM

performs the Lagrange multiplier test.

LR

performs the likelihood ratio test.

WALD

performs the Wald test.

By default, the Wald test is performed. Each type of test is described in the section “[Tests on Parameters](#)” on page 1174.

You can add a label (which is printed in the output) to a TEST statement in two ways: by adding an unquoted *label* followed by a colon before the TEST keyword, or by adding a quoted *string* after the TEST keyword. The unquoted *label* cannot contain any spaces. If you include both an unquoted *label* and a quoted *string*, PROC FRONTIER uses only the unquoted *label*. If you specify neither an unquoted *label* nor a quoted *string*, PROC FRONTIER automatically labels the tests.

The following example illustrates the use of the TEST statement:

```
proc frontier;
  model y = x1 x2 x3;
  test x1 = 0, 1.5 * x2 + 2 * x3 = 0;
  test_int: test intercept = 0, x3 = 0.75;
run;
```

In the example, two separate tests are performed. The first test investigates the joint hypothesis that

$$\beta_1 = 0$$

and

$$1.5\beta_2 + 2\beta_3 = 0$$

The second test is labeled “test_int” and investigates the joint hypothesis that

$$\beta_{\text{Intercept}} = 0$$

and

$$\beta_3 = 0.75$$

WEIGHT Statement

WEIGHT *variable* </ *option* > ;

The WEIGHT statement specifies a variable to supply weighting values to use for each observation in estimating parameters. The log likelihood for each observation is multiplied by the corresponding weight variable value.

If the weight of an observation is nonpositive, that observation is not used in the estimation.

You can specify the following *option* in the WEIGHT statement after a slash (/):

NONNORMALIZE

does not normalize the weights. (By default, the weights are normalized so that they add up to the actual sample size. The weights w_i are normalized by multiplying them by $\frac{n}{\sum_{i=1}^n w_i}$, where n is the sample size.) If the weights must be used as they are, then you must specify this option.

Details: FRONTIER Procedure

Stochastic frontier production models were first developed by Aigner, Lovell, and Schmidt (1977) and Meeusen and van den Broeck (1977). Specification of these models allows for random shocks of the production or cost but also includes a term for technical or cost inefficiency. Assuming that the production function takes a log-linear Cobb-Douglas form, the stochastic frontier production model can be written as

$$\ln(y_i) = \beta_0 + \sum_n \beta_n \ln(x_{ni}) + \epsilon_i$$

where $\epsilon_i = v_i - u_i$. The v_i term represents the stochastic error component, and u_i is the nonnegative, technical inefficiency error component. The v_i error component is assumed to be distributed iid normal and independently from u_i . Given that $u_i > 0$, the error term, ϵ_i , is negatively skewed and represents technical inefficiency.

For the stochastic frontier cost model, $\epsilon_i = v_i + u_i$. The v_i term represents the stochastic error component, and u_i is the nonnegative, cost inefficiency error component. Given that $u_i > 0$, the error term, ϵ_i , is positively skewed and represents cost inefficiency. PROC FRONTIER models the u_i error component as a half-normal, exponential, or truncated-normal distribution.

The Normal–Half Normal Model

In case of the normal–half normal model, v_i is iid $N(0, \sigma_v^2)$ and u_i is iid $N^+(0, \sigma_u^2)$, with v_i and u_i independent of each other. Given the independence of the error terms, the joint density of v and u can be written as

$$f(u, v) = \frac{2}{2\pi\sigma_u\sigma_v} \exp \left\{ -\frac{u^2}{2\sigma_u^2} - \frac{v^2}{2\sigma_v^2} \right\}$$

Substituting $v = \epsilon + u$ into the preceding equation gives

$$f(u, \epsilon) = \frac{2}{2\pi\sigma_u\sigma_v} \exp \left\{ -\frac{u^2}{2\sigma_u^2} - \frac{(\epsilon + u)^2}{2\sigma_v^2} \right\}$$

Integrating u out to obtain the marginal density function of ϵ results in the form

$$\begin{aligned} f(\epsilon) &= \int_0^\infty f(u, \epsilon) du \\ &= \frac{2}{\sqrt{2\pi}\sigma} \left[1 - \Phi \left(\frac{\epsilon\lambda}{\sigma} \right) \right] \exp \left\{ -\frac{\epsilon^2}{2\sigma^2} \right\} \\ &= \frac{2}{\sigma} \phi \left(\frac{\epsilon}{\sigma} \right) \Phi \left(-\frac{\epsilon\lambda}{\sigma} \right) \end{aligned}$$

where $\lambda = \sigma_u/\sigma_v$ and $\sigma = \sqrt{\sigma_u^2 + \sigma_v^2}$.

In the case of a stochastic frontier cost model, $v = \epsilon - u$ and

$$f(\epsilon) = \frac{2}{\sigma} \phi \left(\frac{\epsilon}{\sigma} \right) \Phi \left(\frac{\epsilon\lambda}{\sigma} \right)$$

The log-likelihood function for the production model with N producers is written as

$$\ln L = \text{constant} - N \ln \sigma + \sum_i \ln \Phi \left(-\frac{\epsilon_i \lambda}{\sigma} \right) - \frac{1}{2\sigma^2} \sum_i \epsilon_i^2$$

The Normal-Exponential Model

Under the normal-exponential model, v_i is iid $N(0, \sigma_v^2)$ and u_i is iid exponential with scale parameter σ_u . Given the independence of the error term components v_i and u_i , the joint density of v and u can be written as

$$f(u, v) = \frac{1}{\sqrt{2\pi}\sigma_u\sigma_v} \exp \left\{ -\frac{u}{\sigma_u} - \frac{v^2}{2\sigma_v^2} \right\}$$

The marginal density function of ϵ for the production function is

$$\begin{aligned} f(\epsilon) &= \int_0^\infty f(u, \epsilon) du \\ &= \left(\frac{1}{\sigma_u} \right) \Phi \left(-\frac{\epsilon}{\sigma_v} - \frac{\sigma_v}{\sigma_u} \right) \exp \left\{ \frac{\epsilon}{\sigma_u} + \frac{\sigma_v^2}{2\sigma_u^2} \right\} \end{aligned}$$

and the marginal density function for the cost function is equal to

$$f(\epsilon) = \left(\frac{1}{\sigma_u} \right) \Phi \left(\frac{\epsilon}{\sigma_v} - \frac{\sigma_v}{\sigma_u} \right) \exp \left\{ -\frac{\epsilon}{\sigma_u} + \frac{\sigma_v^2}{2\sigma_u^2} \right\}$$

The log-likelihood function for the normal-exponential production model with N producers is

$$\ln L = \text{constant} - N \ln \sigma_u + N \left(\frac{\sigma_v^2}{2\sigma_u^2} \right) + \sum_i \frac{\epsilon_i}{\sigma_u} + \sum_i \ln \Phi \left(-\frac{\epsilon_i}{\sigma_v} - \frac{\sigma_v}{\sigma_u} \right)$$

The Normal–Truncated Normal Model

The normal–truncated normal model is a generalization of the normal–half normal model in which the mean of u_i is allowed to differ from zero. Under the normal–truncated normal model, the error term component v_i is iid $N(0, \sigma_v^2)$ and u_i is iid $N^+(\mu, \sigma_u^2)$. The joint density of v_i and u_i can be written as

$$f(u, v) = \frac{1}{2\pi\sigma_u\sigma_v\Phi(\mu/\sigma_u)} \exp \left\{ -\frac{(u - \mu)^2}{2\sigma_u^2} - \frac{v^2}{2\sigma_v^2} \right\}$$

The marginal density function of ϵ for the production function is

$$\begin{aligned} f(\epsilon) &= \int_0^\infty f(u, \epsilon) du \\ &= \frac{1}{\sqrt{2\pi}\sigma\Phi(\mu/\sigma_u)} \Phi \left(\frac{\mu}{\sigma\lambda} - \frac{\epsilon\lambda}{\sigma} \right) \exp \left\{ -\frac{(\epsilon + \mu)^2}{2\sigma^2} \right\} \\ &= \frac{1}{\sigma} \phi \left(\frac{\epsilon + \mu}{\sigma} \right) \Phi \left(\frac{\mu}{\sigma\lambda} - \frac{\epsilon\lambda}{\sigma} \right) \left[\Phi \left(\frac{\mu}{\sigma_u} \right) \right]^{-1} \end{aligned}$$

and the marginal density function for the cost function is

$$f(\epsilon) = \frac{1}{\sigma} \phi \left(\frac{\epsilon - \mu}{\sigma} \right) \Phi \left(\frac{\mu}{\sigma\lambda} + \frac{\epsilon\lambda}{\sigma} \right) \left[\Phi \left(\frac{\mu}{\sigma_u} \right) \right]^{-1}$$

The log-likelihood function for the normal–truncated normal production model with N producers is

$$\begin{aligned} \ln L &= \text{constant} - N \ln \sigma - N \ln \Phi \left(\frac{\mu}{\sigma_u} \right) + \sum_i \ln \Phi \left(\frac{\mu}{\sigma\lambda} - \frac{\epsilon_i\lambda}{\sigma} \right) \\ &\quad - \frac{1}{2} \sum_i \left(\frac{\epsilon_i + \mu}{\sigma} \right)^2 \end{aligned}$$

For more information about normal–half normal, normal-exponential, and normal-truncated models, see Kumbhakar and Lovell (2000) and Coelli, Prasada Rao, and Battese (1998).

OUTPUT OUT= Data Table

The OUTPUT statement creates a new data table that contains various estimates that you specify. You can request that the output data table contain the estimates of $\mathbf{x}_i'\boldsymbol{\beta}$, the residual, the predicted values, and the two types of technical efficiency statistics. Except for the residual, these statistics are computed for all observations in which the regressors are not missing, even if the response is missing.

Because of potential space limitations on the client workstation, the data table that the OUTPUT statement creates does not automatically contain the variables in the input data table. You can include the input variables in the output data table by specifying the COPYVAR= option.

XBeta, Predicted, and Residual

XBeta is the structural part on the right-hand side of the model. The value of Predicted is the predicted dependent variable value. The value of Residual is defined as

$$\text{Residual} = \text{Observed} - \text{Predicted}$$

Technical Efficiency: TE1, TE2

In general, the stochastic production frontier can be written as

$$y_i = f(x_i; \beta) \exp\{v_i\} \text{TE}_i$$

where y_i denotes producer i 's actual output; $f(\cdot)$ is the deterministic part of the production frontier; $\exp\{v_i\}$ is a producer-specific error term; and TE_i is the technical efficiency coefficient, which can be written as

$$\text{TE}_i = \frac{y_i}{f(x_i; \beta) \exp\{v_i\}}$$

In the case of a Cobb-Douglas production function, $\text{TE}_i = \exp\{-u_i\}$. For more information, see the section “[Details: FRONTIER Procedure](#)” on page 1166.

Cost frontier can be written in general as

$$E_i = c(y_i, w_i; \beta) \exp\{v_i\} / \text{CE}_i$$

where w_i denotes producer i 's input prices; $c(\cdot)$ is the deterministic part of the cost frontier; $\exp\{v_i\}$ is a producer-specific error term; and CE_i is the cost efficiency coefficient, which can be written as

$$\text{CE}_i = \frac{c(x_i, w_i; \beta) \exp\{v_i\}}{E_i}$$

In the case of a Cobb-Douglas cost function, $\text{CE}_i = \exp\{-u_i\}$. For more information, see the section “[Details: FRONTIER Procedure](#)” on page 1166. Hence, both technical and cost efficiency coefficients are the same. The estimates of technical efficiency are provided in the following subsections.

Normal-Half Normal Model

Define $\mu_* = -\epsilon\sigma_u^2/\sigma^2$ and $\sigma_*^2 = \sigma_u^2\sigma_v^2/\sigma^2$. Then, as shown by Jondrow et al. (1982), the conditional density is as follows:

$$f(u|\epsilon) = \frac{f(u, \epsilon)}{f(\epsilon)} = \frac{1}{\sqrt{2\pi}\sigma_*} \exp\left\{-\frac{(u - \mu_*)^2}{2\sigma_*^2}\right\} \Bigg/ \left[1 - \Phi\left(-\frac{\mu_*}{\sigma_*}\right)\right]$$

Hence, $f(u|\epsilon)$ is the density for $N^+(\mu_*, \sigma_*^2)$.

Using this result, it follows that the estimate of technical efficiency (Battese and Coelli 1988) is

$$TE1_i = E(\exp\{-u_i\}|\epsilon_i) = \left[\frac{1 - \Phi(\sigma_* - \mu_{*i}/\sigma_*)}{1 - \Phi(-\mu_{*i}/\sigma_*)} \right] \exp \left\{ -\mu_{*i} + \frac{1}{2}\sigma_*^2 \right\}$$

The second version of the estimate (Jondrow et al. 1982) is

$$TE2_i = \exp\{-E(u_i|\epsilon_i)\}$$

where

$$E(u_i|\epsilon_i) = \mu_{*i} + \sigma_* \left[\frac{\phi(-\mu_{*i}/\sigma_*)}{1 - \Phi(-\mu_{*i}/\sigma_*)} \right] = \sigma_* \left[\frac{\phi(\epsilon_i \lambda / \sigma)}{1 - \Phi(\epsilon_i \lambda / \sigma)} - \left(\frac{\epsilon_i \lambda}{\sigma} \right) \right]$$

Normal-Exponential Model

Define $A = -\tilde{\mu}/\sigma_v$ and $\tilde{\mu} = -\epsilon - \sigma_v^2/\sigma_u$. Then, as it is shown by Kumbhakar and Lovell (2000), the conditional density is as follows:

$$f(u|\epsilon) = \frac{1}{\sqrt{2\pi}\sigma_v\Phi(-\tilde{\mu}/\sigma_v)} \exp \left\{ -\frac{(u - \tilde{\mu})^2}{2\sigma^2} \right\}$$

Hence, $f(u|\epsilon)$ is the density for $N^+(\tilde{\mu}, \sigma_v^2)$.

Using this result, it follows that the estimate of technical efficiency is

$$TE1_i = E(\exp\{-u_i\}|\epsilon_i) = \left[\frac{1 - \Phi(\sigma_v - \tilde{\mu}_i/\sigma_v)}{1 - \Phi(-\tilde{\mu}_i/\sigma_v)} \right] \exp \left\{ -\tilde{\mu}_i + \frac{1}{2}\sigma_v^2 \right\}$$

The second version of the estimate is

$$TE2_i = \exp\{-E(u_i|\epsilon_i)\}$$

where

$$E(u_i|\epsilon_i) = \tilde{\mu}_i + \sigma_v \left[\frac{\phi(-\tilde{\mu}_i/\sigma_v)}{1 - \Phi(-\tilde{\mu}_i/\sigma_v)} \right] = \sigma_v \left[\frac{\phi(A)}{\Phi(-A)} - A \right]$$

Normal-Truncated Normal Model

Define $\tilde{\mu} = (-\sigma_u^2\epsilon_i + \mu\sigma_v^2)/\sigma^2$ and $\sigma_*^2 = \sigma_u^2\sigma_v^2/\sigma^2$. Then, as it is shown by Kumbhakar and Lovell (2000), the conditional density is as follows:

$$f(u|\epsilon) = \frac{1}{\sqrt{2\pi}\sigma_*[1 - \Phi(-\tilde{\mu}/\sigma_*)]} \exp \left\{ -\frac{(u - \tilde{\mu})^2}{2\sigma_*^2} \right\}$$

Hence, $f(u|\epsilon)$ is the density for $N^+(\tilde{\mu}, \sigma_*^2)$.

Using this result, it follows that the estimate of technical efficiency is

$$TE1_i = E(\exp\{-u_i\}|\epsilon_i) = \frac{1 - \Phi(\sigma_* - \tilde{\mu}_i/\sigma_*)}{1 - \Phi(-\tilde{\mu}_i/\sigma_*)} \exp \left\{ -\tilde{\mu}_i + \frac{1}{2}\sigma_*^2 \right\}$$

The second version of the estimate is

$$TE2_i = \exp\{-E(u_i|\epsilon_i)\}$$

where

$$E(u_i|\epsilon_i) = \tilde{\mu}_i + \sigma_* \left[\frac{\phi(\tilde{\mu}_i/\sigma_*)}{1 - \Phi(-\tilde{\mu}_i/\sigma_*)} \right]$$

Parameter Naming Conventions for the RESTRICT, TEST, BOUNDS, and INIT Statements

This section describes how you can refer to the parameters in the MODEL statement when you use the RESTRICT, TEST, BOUNDS, or INIT statement. The following examples use the RESTRICT statement, but the same remarks apply to naming parameters when you use the TEST, BOUNDS, or INIT statement. The names of the parameters are shown in the “Parameter Estimates” table if you specify the PRINTINTERNALNAMES option. If a parameter name contains a blank or some other special character (such as ‘*’, ‘-’, ‘(’, or ‘)’), then you must use the internal name of the parameter to refer to that parameter in the RESTRICT, TEST, BOUNDS, or INIT statement. You can specify the PRINTINTERNALNAMES option in the PROC FRONTIER statement if you want to see the internal names of the parameters. When you specify the PRINTINTERNALNAMES option, an extra column that shows the internal name of each parameter is added to the “Parameter Estimates” table.

To impose a restriction on a parameter that is related to a regressor in the MODEL statement, you simply use the name of the regressor itself to refer to its associated parameter. Suppose your model is

```
model y = x1 x2 x5;
```

where x1 through x5 are continuous variables. To restrict the parameter that is associated with the regressor x5 to be greater than 1.7, use the following statement:

```
RESTRICT x5 > 1.7;
```

Referring to Class-Level Parameters

When your MODEL statement includes a classification variable, you can impose restrictions on the parameters that are associated with each level that is related to the classification variable as follows.

Suppose that your classification variable is named C and has three levels: 0, 1, 2. Suppose that your model is the following:

```
class C;
model y = x1 x2 C / cost type=half;
```

Adding a classification variable as a regressor to your model introduces additional parameters into your model, each of which is associated with one of the levels of the classification variable. You can form the name of the parameter that is associated with a particular level of your classification variable by inserting an underscore between the name of the classification variable and the value of the level. Thus, to restrict the parameter that is associated with level 0 of the classification variable C to always be greater than 0.7, you refer to the parameter as C_0 and provide the following statement:

```
RESTRICT C_0 > 0.7;
```

Referring to Parameters Associated with Interactions between Regressors

When a regressor in your model involves an interaction between other regressors, you can impose restrictions on the parameters that are associated with the interaction.

Suppose you have the following model:

```
model y = x1 x2 x3*x4 / cost type=half;
```

You can form the name of the parameter that is associated with the interaction regressor $x3*x4$ by replacing the multiplication sign with an underscore. Thus, $x3_x4$ refers to the parameter that is associated with the interaction regressor $x3*x4$.

You use the same approach to refer to interactions between regressors and classification variables. Suppose you have a classification variable that is named C and has three levels: 0, 1, 2. Suppose that your model is the following:

```
class C;
model y = x1 x2 C*x3 / cost type=half;
```

The interaction between the continuous variable $x3$ and the classification variable C introduces three additional parameters, which are named $x3_C_0$, $x3_C_1$, and $x3_C_2$. Note that, although the order of the terms in the interaction is C followed by $x3$, the name of the parameter associated with the interaction is formed by placing the name of the continuous variable $x3$ first, followed by an underscore, followed by the name of the classification variable C , followed by an underscore, and then followed by the level value. Once again, depending on the parameterization that you specify in your CLASS statement, for each interaction in your model that involves a classification variable, one of the parameters associated with that interaction might be dropped from your model before optimization.

The name of a parameter that is associated with a nested interaction is formed in a slightly different way. Suppose you have a classification variable that is named C and has three levels: 0, 1, 2. Suppose that your model is the following:

```
class C;
model y = x1 x2 x3(C) / cost type=half;
```

The nested interaction between the continuous variable $x3$ and the classification variable C introduces three additional parameters, which are named $x3_C_0$, $x3_C_1$, and $x3_C_2$. Note that the name in each case is formed from the name of the regressor by replacing the left and right parentheses with underscores and then appending another underscore, followed by the level value.

Referring to Class-Level Parameters with Negative Values

When the value of a level is a negative number, you must replace the minus sign with an underscore when you form the name of the parameter that is associated with that particular level of the classification variable. For example, suppose that your classification variable is named D and has four levels: -1 , 0, 1, 2. Suppose that your model is the following:

```
class D;
model y = x1 x2 D / cost type=half;
```

To restrict the parameter that is associated with level -1 of the classification variable D to always be less than 0.4, you refer to the parameter as D_1 (note that there are two underscores in this parameter name: one

to connect the name of the classification variable to its value, and the other to replace the minus sign in the value itself) and provide the following statement:

```
RESTRICT D__1 < 0.4;
```

Dropping a Class-Level Parameter to Avoid Collinearity

Depending on the parameterization that you impose on your classification variable, one of the parameters that are associated with its levels might be dropped from your model before optimization in order to avoid collinearity. For example, when the default parameterization is imposed, the parameter that is associated with the last level of your classification variable is dropped before optimization. If you attempt to impose a restriction on a dropped parameter by using the *RESTRICT* statement, PROC FRONTIER issues an error message in the log.

For example, suppose again that your classification variable is named *C* and has three levels: 0, 1, 2. Suppose that your model is the following:

```
class C;
model y = x1 x2 C / cost type=half;
```

Because no additional options are specified in the *CLASS* statement, the default parameterization is assumed. This means that the parameter named *C_2* (which is the parameter associated with the last level of your classification variable) is dropped from your model before the optimizer is invoked. Therefore, an error occurs if you attempt to restrict the *C_2* parameter in any way by referring to it in a *RESTRICT* statement. In this example, the following *RESTRICT* statement generates an error:

```
RESTRICT C_2 < 0.3;
```

Referring to Implicit Parameters

Unless you specify the *NOINT* option, you can impose a restriction on the parameter that is associated with the intercept in your model simply by referring to it by name: *Intercept*.

When you specify the inefficiency term as truncated-normal, PROC FRONTIER automatically adds the *_Mu* parameter, the mean of the truncated normal distribution, to your model prior to optimization. Also, for each model, PROC FRONTIER includes the parameters *_Sigma_v* and *_Sigma_u*, which are the estimates of the standard deviation of the idiosyncratic and technical inefficiency terms of the model error, respectively. You can impose restrictions on these implicit parameters.

For example, for the truncated-normal model, you can restrict *_Mu* to be positive as follows:

```
RESTRICT _Mu > 0;
```

Tests on Parameters

In general, you can write the tested hypothesis as

$$H_0 : \mathbf{h}(\theta) = 0$$

where $\mathbf{h}(\theta)$ is an $r \times 1$ vector-valued function of the parameters θ that is given by the r expressions that you specify in the TEST statement.

Let $\hat{V}$ be the estimate of the covariance matrix of $\hat{\theta}$. Let $\hat{\theta}$ be the unconstrained estimate of θ , and let $\tilde{\theta}$ be the constrained estimate of θ such that $\mathbf{h}(\tilde{\theta}) = 0$. Let

$$A(\theta) = \partial \mathbf{h}(\theta) / \partial \theta \big|_{\hat{\theta}}$$

Using this notation, you compute the test statistics for the three types of tests as follows:

- The Wald test statistic is defined as

$$W = \mathbf{h}'(\hat{\theta}) \left(A(\hat{\theta}) \hat{V} A'(\hat{\theta}) \right)^{-1} \mathbf{h}(\hat{\theta})$$

The Wald test is not invariant to reparameterization of the model (Gregory and Veall 1985; Gallant 1987, p. 219). For more information about the theoretical properties of the Wald test, see Phillips and Park (1988).

- The Lagrange multiplier test statistic is

$$LM = \lambda' A(\tilde{\theta}) \tilde{V} A'(\tilde{\theta}) \lambda$$

where λ is the vector of Lagrange multipliers from the computation of the restricted estimate $\tilde{\theta}$.

- The likelihood ratio test statistic is

$$LR = 2 \left(L(\hat{\theta}) - L(\tilde{\theta}) \right)$$

where $\tilde{\theta}$ represents the constrained estimate of θ and L is the concentrated log-likelihood value.

For each type of test, under the null hypothesis the test statistic is asymptotically distributed as a χ^2 random variable with r degrees of freedom, where r is the number of expressions that you specify in the TEST statement. The p -values that are reported for the tests are computed from the $\chi^2(r)$ distribution and are only asymptotically valid.

Monte Carlo simulations suggest that the asymptotic distribution of the Wald test is a poorer approximation of its small sample distribution than that of the other two tests. However, the Wald test has the lowest computational cost, because it does not require computation of the constrained estimate $\tilde{\theta}$.

The following statements use the TEST statement to perform a likelihood ratio test:

```

proc frontier;
  class cl;
  model y = x1 x2 cl / production type=trunc;
  test x1 = 0, x2 * .5 + 2 * x1 = 0 /lr;
run;

```

For more information, see *SAS/ETS User's Guide*.

ODS Table Names

PROC FRONTIER assigns a name to each table that it creates. You can use these names to denote the table when you use the Output Delivery System (ODS) to select tables and create output data tables. These table names are listed in [Table 19.3](#).

Table 19.3 ODS Tables Produced by PROC FRONTIER

Table Name	Description	Statement	Option

Examples: The FRONTIER Procedure

Example 19.1: Stochastic Frontier Production Model: Truncated-Normal

This example shows how to estimate a stochastic frontier production model in which the inefficiency term has a truncated-normal distribution.

The following DATA step generates a data table that contains 100,000 observations from this model. The model contains three input variables, one of which is a classification variable.

```
data input_dataset;
  keep y x1 x2 c1 j;
  call streaminit(24569);
  do j = 1 to 100000;
    x1 = 2 + rand("normal");
    x2 = rand("uniform");
    c1 = rand("bernoulli",0.4);
    sigma_v = rand("normal");
    sigma_u = 0;
    do until(sigma_u > 0);
      sigma_u = rand("normal",0.75,1.3);
    end;
    xb = 5 - 0.5*x1 + 0.8*x2 - 0.65*(c1 = 0);
    y = xb + sigma_v - sigma_u;
    output;
  end;
run;

data mylib.input_dataset;
  set input_dataset;
run;
```

The following statements estimate the model:

```
/*-- Stochastic Frontier Production Model: Truncated-Normal --*/
proc frontier data=mylib.input_dataset method=quanew;
  class c1;
  model y = x1 x2 c1/ production type=trunc;
run;
```

In addition to the parameters that are estimated for the other stochastic frontier models, PROC FRONTIER also estimates the parameter `_Mu` for truncated-normal models. `_Mu` is the mean of the truncated-normal distribution. The parameter `cl_1` indicates the classification variable for the level 1 and is dropped in the estimation to prevent perfect collinearity in the model. For more information, see the section “[Dropping a Class-Level Parameter to Avoid Collinearity](#)” on page 1173.

Example 19.2: Stochastic Frontier Cost Models

This example shows how to estimate the three types of stochastic frontier cost models.

The data for the cost model are provided by Christensen and Greene (1976). The data describe costs and production inputs of 145 US electricity producers in 1955. The model that is estimated follows the nonhomogeneous version of the Cobb-Douglas cost function:

$$\log\left(\frac{\text{Cost}}{\text{FPrice}}\right) = \beta_0 + \beta_1 \log\left(\frac{\text{KPrice}}{\text{FPrice}}\right) + \beta_2 \log\left(\frac{\text{LPrice}}{\text{FPrice}}\right) + \beta_3 \log(\text{Output}) + \beta_4 \frac{1}{2} \log(\text{Output})^2 + \epsilon$$

All dollar values are normalized by fuel price. The quadratic log of the output is added to capture nonlinearities due to scale effects in cost functions. Five new variables, `log_C_PF`, `log_PK_PF`, `log_PL_PF`, `log_y`, and `log_y_sq`, are created to reflect transformations. The following statements create the data set and transformed variables:

```

Overview: HMM Procedure

The HMM procedure supports hidden Markov models (HMMs), which have been widely applied in economics, finance, science, and engineering. The hidden Markov models have many well-known aliases, such as the general state space model (GSSM), regime-switching model (RSM), Markov-switching model (MSM), and Markov regime-switching model (MRSM). PROC HMM supports the finite hidden Markov model (finite HMM), the Poisson hidden Markov model (Poisson HMM), the Gaussian hidden Markov model (Gaussian HMM), the Gaussian mixture hidden Markov model (GM HMM), the regime-switching regression model (RS REG, also known as the regression hidden Markov model or REG HMM), and the regime-switching autoregression model (RS AR, also known as the autoregressive hidden Markov model or AR HMM) in both the standard and mean-adjusted forms.

The HMM procedure supports the following:

- cross-sectional time series data
- the maximum likelihood (ML) method and the maximum a posteriori (MAP) method for parameter estimation, which is a nonlinear optimization problem
- the prior distribution for parameters when you use the MAP method

- four types of optimization algorithms: the expectation-maximization (EM) algorithm, the active set algorithm, the interior point algorithm, and the stochastic gradient descent (SGD) algorithm
- multistart mode for the active set and interior point optimization algorithms; in this mode, the local solver approaches the problem from multiple starting points, possibly finding a better local optimum as a result. However, the computing cost in multistart mode can be huge.
- specification of initial values for optimization
- state-independent constraints on parameters
- output of parameter estimates to a data table, which can be read back later in order to use those parameter estimates as the initial values for a new estimation
- output of the covariance matrix of parameter estimates
- specification of the order in which to label the states (and components in the case of GM HMMs) in order to solve the label switching problem, and output of the changes of state labels (and component labels in the case of GM HMMs)
- estimation of several models that have different numbers of states or different orders of autoregressive process (or both) in order to help you with the important and difficult task of model selection
- output of the filtering, smoothing, and decoding results
- output of the mean, standard error, covariance matrix, median, and confidence interval of forecasts of dependent variables
- output of the probabilities of states in the forecasts
- multistep forecasts after each observation
- output of the log likelihood up to any observation
- output of the following information criteria: Akaike's information criterion (AIC), the corrected AIC (AICC), the Bayesian information criterion (BIC), and the Hannan-Quinn criterion (HQC)
- saving the model information and using it later to score other new data
- the analytic store technology. You can even apply HMMs to new data on a platform that does not support the HMM procedure.

PROC HMM requires SAS Cloud Analytic Services (CAS) in order to run, and it does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- exploits all the available cores and concurrent threads

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);  
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;  
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “[Introduction to Shared Concepts](#)” on page 54 in Chapter 4, “[Shared Concepts](#).”

Getting Started: HMM Procedure

This section provides several examples of the types of models that the HMM procedure supports.

Gaussian Hidden Markov Model

Let $\mathbf{Y}_t = (y_{1t}, \dots, y_{pt})'$, $t = 1, \dots, T$, denote a p -dimensional time series vector of random variables. Conditional on a latent variable $\mathbf{S}_t$, $\mathbf{Y}_t$ follows a normal distribution,

$$\mathbf{Y}_t | \mathbf{S}_t \sim N(\mu_{\mathbf{S}_t}, \Sigma_{\mathbf{S}_t})$$

where $\mu_{\mathbf{S}_t}$ and $\Sigma_{\mathbf{S}_t}$ are mean and covariance parameters whose values depend on the variable $\mathbf{S}_t$. The variable $\mathbf{S}_t$, the so-called state, follows the first-order Markov chain; that is,

$$p(\mathbf{S}_t | \mathbf{S}_{t-1}, \mathbf{S}_{t-2}, \dots, \mathbf{S}_1) = p(\mathbf{S}_t | \mathbf{S}_{t-1})$$

where $p(\cdot | \cdot)$ denotes the conditional probability. The range of $\mathbf{S}_t$ is a finite set, $\{1, \dots, K\}$. The transition probability from state i to state j is expressed as

$$a_{ij} = p(\mathbf{S}_t = j | \mathbf{S}_{t-1} = i)$$

The $K \times K$ matrix $\mathbf{A} = \{a_{ij}\}$ is called the transition probability matrix (TPM). The last element in the model is the initial state probability vector (ISPV), π , of the first state $\mathbf{S}_1$:

$$\pi = \{\pi_i = p(\mathbf{S}_1 = i), i = 1, \dots, K\}$$

Because the variable $\mathbf{S}_t$ is unobservable and follows a Markov chain and because $\mathbf{Y}_t$ follows a Gaussian distribution conditional on $\mathbf{S}_t$, the model is called the Gaussian hidden Markov model (Gaussian HMM). The Gaussian HMM is sometimes described as $\{\pi, \mathbf{A}, \mathbf{B}\}$, where $\mathbf{B} \equiv \{\mu_i, \Sigma_i, i = 1, \dots, K\}$, consisting of parameters that define the state-dependent distribution of observable variables.

Consider a bivariate Gaussian HMM that has the following parameter values:

$$\pi = \begin{pmatrix} 0.5 \\ 0.5 \end{pmatrix}, \mathbf{A} = \begin{pmatrix} 0.001 & 0.999 \\ 0.999 & 0.001 \end{pmatrix}$$

$$\mu_1 = \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \Sigma_1 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \mu_2 = \begin{pmatrix} -1 \\ -1 \end{pmatrix}, \Sigma_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

The following statements simulate the bivariate vector time series from the previous model to provide test data for the HMM procedure:

```

%let pi1 = 0.5;
%let a11 = 0.001;
%let a22 = 0.001;
%let mu1_1 = 1;
%let mu1_2 = 1;
%let sigma1_11 = 1;
%let sigma1_21 = 0;
%let sigma1_22 = 1;
%let mu2_1 = -1;
%let mu2_2 = -1;
%let sigma2_11 = 1;
%let sigma2_21 = 0;
%let sigma2_22 = 1;
%let T = 10000;
%let seed = 1234;

data DGPone;
  retain cd1_11 cd1_21 cd1_22 cd2_11 cd2_21 cd2_22;
  do t = 1 to &T.;
    if(t=1) then do;
      /* initial probability distribution */
      p = &pi1.;
      /* Cholesky decomposition of sigma1 */
      cd1_11 = sqrt(&sigma1_11.);
      cd1_21 = &sigma1_21./sqrt(&sigma1_11.);
      cd1_22 = sqrt(&sigma1_22.-&sigma1_21.*&sigma1_21./&sigma1_11.);
      /* Cholesky decomposition of sigma2 */
      cd2_11 = sqrt(&sigma2_11.);
      cd2_21 = &sigma2_21./sqrt(&sigma2_11.);
      cd2_22 = sqrt(&sigma2_22.-&sigma2_21.*&sigma2_21./&sigma2_11.);
    end;
    else do;
      /* transition probability matrix */
      if(lags=1) then p = &a11.;
      else p = 1-&a22.;
    end;
    u = uniform(&seed.);
    if(u<=p) then s=1;
    else s = 2;
    e1 = normal(&seed.); e2 = normal(&seed.);
    if(s=1) then do;
      /* (x,y) ~ N(mu1, Sigma1) at state 1 */
      x = &mu1_1. + cd1_11*e1;
      y = &mu1_2. + cd1_21*e1+cd1_22*e2;
    end;
    else do;
      /* (x,y) ~ N(mu2, Sigma2) at state 2 */
      x = &mu2_1. + cd2_11*e1;
      y = &mu2_2. + cd2_21*e1+cd2_22*e2;
    end;
    output;
    lags = s;
  end;
end;

```

```
run;

data One;
  set DGPone;
  keep t x y;
run;
```

In general, the data generating process is unknown. What can be seen is the data table One, but not the data table DGPone.

The following statements plot the simulated series x :

```
proc sgplot data=One;
  series x=t y=x;
run;
```

Figure 20.1 shows the plot of x , whose points seem to fall randomly around 0.

Figure 20.1 Plot of Time Series x

The following statements plot the simulated series y :

```
proc sgplot data=One;
  series x=t y=y;
run;
```

Figure 20.2 shows the plot of y , whose points also seem to fall randomly around 0.

Figure 20.2 Plot of Time Series y

Ignoring the sequential information, the following statements plot the observed points (x, y) :

```
proc sgplot data=One;
  scatter y=y x=x;
run;
```

As shown in Figure 20.3, it seems that the points come from two different cluster centers, and many of them lie between two cluster centers.

Figure 20.3 Unclassified Observations

It is very difficult for any cluster analysis methods that cannot use the sequential information to find the correct states for the points that lie between two cluster centers. The simplest cluster analysis method to classify the points, because of the symmetry shown in Figure 20.3, is to draw a line $y = -x$, classify all points above the line to one state, and classify all points below the line to another state.¹ The following statements implement this simplest cluster analysis method and calculate the accuracy, based on the data table DGPone:

```
/* classify the data points by the line  $y = -x$  */
data Cluster;
  set One;
  if (y > -x) then state = 1;
  else state = 2;
  keep t state;
run;

data clusterCheck;
  merge DGPone(in=a) Cluster(in=b);
```

¹In theory, no cluster analysis method, without using the sequential information, could do a better job on this data table than this simplest cluster analysis method.

```

    by t;
    if(s=state) then correct = 1;
    else correct = 0;
    if(a=b);
    keep correct;
run;

data clusterAccuracy;
    set clusterCheck;
    retain count 0 correctCount 0;
    count = count + 1;
    correctCount = correctCount + correct;
    if(count>=T.-0.5) then do;
        accuracy = correctCount / count;
        if (accuracy<0.5) then accuracy = 1 - accuracy;
        output;
    end;
    keep accuracy;
run;

proc print data = clusterAccuracy noobs; run;

```

The accuracy of the cluster analysis, which is shown in [Figure 20.4](#), is 92.02%. This implies that the cluster analysis cannot choose the correct states for about 800 data points!

Figure 20.4 Accuracy of Cluster Analysis

<u>accuracy</u>
0.9202

What is the big difference that you get by using the sequential information through HMMs? Before estimating any model, make a copy of the data in the library:

```
data mylib.One; set One; run;
```

The following statements estimate the two-state Gaussian HMM and then classify the data points through decoding; here decoding means to find the best possible state path for the observed data. The SORT=DESC(MU) option requests that the states be labeled in descending order of the mean parameter values; for more information about the label switching problem, see the section “[Label Switching Problem](#)” on page 1321.

```

proc hmm data=mylib.One labelSwitch=(sort=desc(mu));
    id time=t;
    model x y / type=gaussian nstate=2;
    optimize printLevel=3 printIterFreq=1;
    decode out=mylib.oneDecode;
run;

```

The number of observations and model information are shown in [Figure 20.5](#).

HQC	56970.737507

The accuracy of classification through the Gaussian HMM is calculated by the following statements:

```

data gHmmCheck;
  merge DGPone(in=a) mylib.oneDecode(in=b);
  by t;
  if(s=state) then do; correct=1; ds = s; end;
  else do; correct=0; ds = -s; end;
  if(a=b);
  keep t x y s correct ds;
run;

%let qFlipState = -1;
data gHmmAccuracy;
  set gHmmCheck;
  retain count 0 correctCount 0;
  count = count + 1;
  correctCount = correctCount + correct;
  if(count>&T.-0.5) then do;
    accuracy = correctCount / count;
    if(accuracy<0.5) then call symputx("qFlipState",1,'G');
    else call symputx("qFlipState",0,'G');
    if(accuracy<0.5) then accuracy = 1 - accuracy;
    output;
  end;
  keep accuracy;
run;

data gHmmCheck;
  set gHmmCheck;
  if(&qFlipState.=1) then do;
    ds = -ds;
    correct = 1 - correct;
  end;
run;

proc print data = gHmmAccuracy noobs; run;

```

The accuracy of the Gaussian HMM, which is shown in [Figure 20.16](#), is 99.99%. This means that the Gaussian HMM successfully takes advantage of the sequential information: only 1 data point cannot be correctly classified, compared to about 800 points that cannot be correctly classified by the cluster analysis method without the sequential information.

Figure 20.16 Accuracy of Decoding by the Gaussian HMM

accuracy
0.9999

To show how well the data are classified, the previous statements label any incorrectly classified data points with negative state values. In this example, only 1 point is not correctly classified. You plot the classified data points by using the following statements. The plot is shown in [Figure 20.17](#).

```
proc sgplot data=gHmmCheck;
  scatter y=y x=x / group=ds;
run;
```

Figure 20.17 Classified Data Points by Gaussian HMM

Gaussian Hidden Markov Model for Cross-Sectional Time Series Data

Cross-sectional time series data consist of observations over both time and many subjects (such as individuals, objects, firms, or geographical areas). Let $\mathbf{Y}_{n,t} = (y_{n,1t}, \dots, y_{n,pt})'$, where $n = 1, \dots, N$ and $t = 1, \dots, T_n$, denote a p -dimensional vector of random variables at the t th position in the n th section, where T_n is the sample size of the n th section. The $\mathbf{Y}_{n,t}$ follows the Gaussian HMM; that is,

$$\mathbf{Y}_{n,t} | \mathbf{S}_{n,t} \sim N(\mu_{\mathbf{S}_{n,t}}, \Sigma_{\mathbf{S}_{n,t}})$$

where $\mu_{\mathbf{S}_{n,t}}$ and $\Sigma_{\mathbf{S}_{n,t}}$ are mean and covariance parameters, respectively, whose values depend on the state variable $\mathbf{S}_{n,t}$. $\mathbf{S}_{n,t}$ follows the first-order Markov chain; that is,

$$p(\mathbf{S}_{n,t} | \mathbf{S}_{n,t-1}, \mathbf{S}_{n,t-2}, \dots, \mathbf{S}_{n,1}) = p(\mathbf{S}_{n,t} | \mathbf{S}_{n,t-1})$$

where $p(.|.)$ denotes the conditional probability. $\mathbf{S}_{n,t}$ is independent of any $\mathbf{S}_{m,s}, m = 1, \dots, N, s = 1, \dots, T_m$, and $m \neq n$. The range of $\mathbf{S}_{n,t}$ is a finite set, $\{1, \dots, K\}$. The transition probability from state i to state j is expressed as

$$a_{ij} = p(\mathbf{S}_{n,t} = j | \mathbf{S}_{n,t-1} = i)$$

The $K \times K$ matrix $\mathbf{A} = \{a_{ij}\}$ is called the transition probability matrix (TPM). The initial state probability vector (ISPV), π , of the first state $\mathbf{S}_{n,1}$ is

$$\pi = \{\pi_i = p(\mathbf{S}_{n,1} = i), i = 1, \dots, K\}$$

The Gaussian HMM for cross-sectional time series data, which is the same as the Gaussian HMM for time series data, can be described as $\{\pi, \mathbf{A}, \mathbf{B}\}$, where $\mathbf{B} \equiv \{\mu_i, \Sigma_i, i = 1, \dots, K\}$, which consists of parameters that define the state-dependent distribution of observable variables.

Consider a univariate six-state Gaussian HMM that has the following parameter values:

$$\pi = \begin{pmatrix} \frac{1}{6} \\ \frac{1}{6} \\ \frac{1}{6} \\ \frac{1}{6} \\ \frac{1}{6} \\ \frac{1}{6} \end{pmatrix}, \mathbf{A} = \begin{pmatrix} 0.95 & 0.01 & 0.01 & 0.01 & 0.01 & 0.01 \\ 0.01 & 0.95 & 0.01 & 0.01 & 0.01 & 0.01 \\ 0.01 & 0.01 & 0.95 & 0.01 & 0.01 & 0.01 \\ 0.01 & 0.01 & 0.01 & 0.95 & 0.01 & 0.01 \\ 0.01 & 0.01 & 0.01 & 0.01 & 0.95 & 0.01 \\ 0.01 & 0.01 & 0.01 & 0.01 & 0.01 & 0.95 \end{pmatrix}$$

$$\mathbf{B} = \left\{ \begin{pmatrix} \mu_1 \\ \mu_2 \\ \mu_3 \\ \mu_4 \\ \mu_5 \\ \mu_6 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} \Sigma_1 \\ \Sigma_2 \\ \Sigma_3 \\ \Sigma_4 \\ \Sigma_5 \\ \Sigma_6 \end{pmatrix} = \begin{pmatrix} 0.0625 \\ 0.25 \\ 1 \\ 4 \\ 16 \\ 64 \end{pmatrix} \right\}$$

The following statements simulate the 10,000-section time series from the previous model to provide test data for the HMM procedure:

```
%let nSections = 10000;
%let T = 100;
%let seed = 1234;
%let nStates = 6;
%let mu1 = 0;
%let sigma1 = 0.0625;
%let mu2 = 0;
%let sigma2 = 0.25;
%let mu3 = 0;
%let sigma3 = 1;
%let mu4 = 0;
%let sigma4 = 4;
```

```

%let mu5 = 0;
%let sigma5 = 16;
%let mu6 = 0;
%let sigma6 = 64;
%let selfTransProb = 0.95;

%macro createCstsTable(tableName);
  data &tableName.;
    do sec = 1 to &nSections.;
      state = ceil(uniform(&seed.)*&nStates.);
      do t = 1 to &T.;
        %do i = 1 %to &nStates.;
          if(state=&i.) then do;
            y = &mu&i.. + sqrt(&sigma&i..)*normal(&seed.);
            output;
          end;
        %end;
        u = uniform(&seed.);
        if(u>&selfTransProb.) then do;
          u = (u-&selfTransProb.)/(1-&selfTransProb.)*(&nStates.-1);
          state=state + ceil(u);
          if(state>&nStates.) then state = state - &nStates.;
        end;
      end;
    end;
  run;
%mend;

%createCstsTable(cstsDGP);

data mylib.cstsDGP;
  set cstsDGP;
run;

```

The following statements estimate the Gaussian HMM:

```

proc hmm data=mylib.cstsDGP
  outstat=mylib.cstsStat;
  id section=sec time=t;
  model y / method=ml type=gaussian nstate=6;
  optimize ALGORITHM=activeset printlevel=3 printIterFreq=1;
  estimate out=mylib.cstsEst;
  evaluate out=mylib.cstsEval;
  decode out=mylib.cstsDecode;
  filter out=mylib.cstsFilter;
  smooth out=mylib.cstsSmooth;
  forecast out=mylib.cstsForecast;
  score outmodel=mylib.cstsModel;
run;

```

The estimates of the ISPV, TPM, mean parameters, and covariance parameters are shown in [Figure 20.18](#), [Figure 20.19](#), [Figure 20.20](#), and [Figure 20.21](#), respectively. They are all very close to the true parameters that are used in the data generating process.

Gaussian Mixture Hidden Markov Model for Time Series Data and Cross-Sectional Time Series Data

Let $\mathbf{Y}_t = (y_{1t}, \dots, y_{pt})'$, $t = 1, \dots, T$, denote a p -dimensional time series vector of random variables. Conditional on a latent variable $\mathbf{S}_t$, $\mathbf{Y}_t$ follows a Gaussian mixture distribution,

$$\mathbf{Y}_t | \mathbf{S}_t \sim \text{GM}(\{w_{\mathbf{S}_t,1}, \dots, w_{\mathbf{S}_t,M}\}, \{\mu_{\mathbf{S}_t,1}, \dots, \mu_{\mathbf{S}_t,M}\}, \{\Sigma_{\mathbf{S}_t,1}, \dots, \Sigma_{\mathbf{S}_t,M}\})$$

where the variable $\mathbf{S}_t$ is the (hidden) state; $\text{GM}(\dots)$ represents the Gaussian mixture distribution; M is the number of components at each state; and the $w_{\mathbf{S}_t,j}$, $j = 1, \dots, M$, are mixture component probabilities (MCPs, also called mixture weights), which satisfy the basic requirement for weights ($w_{\mathbf{S}_t,j} \geq 0$, $j = 1, \dots, M$, and $\sum_{j=1}^M w_{\mathbf{S}_t,j} = 1$). The $\mu_{\mathbf{S}_t,j}$ and $\Sigma_{\mathbf{S}_t,j}$, $j = 1, \dots, M$, are the mean and covariance parameters for the j th Gaussian component at state $\mathbf{S}_t$, and their values depend on the variable $\mathbf{S}_t$. The state variable $\mathbf{S}_t$ follows the first-order Markov chain; that is,

$$p(\mathbf{S}_t | \mathbf{S}_{t-1}, \mathbf{S}_{t-2}, \dots, \mathbf{S}_1) = p(\mathbf{S}_t | \mathbf{S}_{t-1})$$

where $p(\cdot | \cdot)$ denotes the conditional probability. The range of $\mathbf{S}_t$ is a finite set, $\{1, \dots, K\}$. The transition probability from state i to state j is expressed as

$$a_{ij} = p(\mathbf{S}_t = j | \mathbf{S}_{t-1} = i)$$

The $K \times K$ matrix $\mathbf{A} = \{a_{ij}\}$ is called the transition probability matrix (TPM). The last element in the model is the initial state probability vector (ISPV), π , of the first state $\mathbf{S}_1$:

$$\pi = \{\pi_i = p(\mathbf{S}_1 = i), i = 1, \dots, K\}$$

Because the variable $\mathbf{S}_t$ is unobservable and follows a Markov chain and because $\mathbf{Y}_t$ follows a Gaussian mixture distribution conditional on $\mathbf{S}_t$, the model is called the Gaussian mixture hidden Markov model (GM HMM). The GM HMM is sometimes described as $\{\pi, \mathbf{A}, \mathbf{B}\}$, where $\mathbf{B} \equiv \{w_{ij}, \mu_{ij}, \Sigma_{ij}, i = 1, \dots, K, j = 1, \dots, M\}$, and it consists of parameters that define the state-dependent distribution of observable variables.

The GM HMM for cross-sectional time series data is similar to the extension from Gaussian HMM to Gaussian HMM for cross-sectional time series data; for more information, see the section “[Gaussian Hidden Markov Model for Cross-Sectional Time Series Data](#)” on page 1198.

Consider a bivariate bi-component GM HMM that has the following parameter values. The ISPV and TPM are

$$\pi = \begin{pmatrix} 0.75 \\ 0.25 \end{pmatrix}, \mathbf{A} = \begin{pmatrix} 0.95 & 0.05 \\ 0.15 & 0.85 \end{pmatrix}$$

At state 1, the two components have weights

$$c_{11} = 0.6, c_{12} = 0.4$$

and the mean and covariance parameters for two components are

$$\mu_{11} = \begin{pmatrix} 1 \\ 1 \end{pmatrix}, \Sigma_{11} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \mu_{12} = \begin{pmatrix} -3 \\ -3 \end{pmatrix}, \Sigma_{12} = \begin{pmatrix} 1.69 & 1.00 \\ 1.00 & 1.69 \end{pmatrix}$$

At state 2, the two components have weights

$$c_{21} = 0.7, c_{22} = 0.3$$

and the mean and covariance parameters for two components are

$$\mu_{21} = \begin{pmatrix} -1 \\ -1 \end{pmatrix}, \Sigma_{22} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \mu_{22} = \begin{pmatrix} 3 \\ 3 \end{pmatrix}, \Sigma_{22} = \begin{pmatrix} 1.69 & 1.00 \\ 1.00 & 1.69 \end{pmatrix}$$

The following statements simulate the bivariate vector time series from the previous model to provide test data for the HMM procedure:

```
%let a11 = 0.98;
%let a22 = 0.95;
%let c1_1 = 0.6;
%let c1_2 = 0.4;
%let c2_1 = 0.7;
%let c2_2 = 0.3;
%let mu1_1_1 = 1;
%let mu1_1_2 = 1;
%let mu1_2_1 = -3;
%let mu1_2_2 = -3;
%let sigma1_1_11 = 1;
%let sigma1_1_21 = 0;
%let sigma1_1_22 = 1;
%let sigma1_2_11 = 1.69;
%let sigma1_2_21 = 1;
%let sigma1_2_22 = 1.69;
%let mu2_1_1 = -1;
%let mu2_1_2 = -1;
%let mu2_2_1 = 3;
%let mu2_2_2 = 3;
%let sigma2_1_11 = 1;
%let sigma2_1_21 = 0;
%let sigma2_1_22 = 1;
%let sigma2_2_11 = 1.69;
%let sigma2_2_21 = 1;
%let sigma2_2_22 = 1.69;
%let seed = 1234;
%let T = 200000;

data gmDGP;
    retain cd1_1_11 cd1_1_21 cd1_1_22
           cd1_2_11 cd1_2_21 cd1_2_22
           cd2_1_11 cd2_1_21 cd2_1_22

  e1 = normal(&seed.); e2 = normal(&seed.);
  if(s=1) then do;
    * choose component;
    u = uniform(&seed.);
    if(u<=&c1_1.) then do;
      * (x,y) ~ N(mu, Sigma) at state 1, component 1;
      x = &mu1_1_1. + cd1_1_11*e1;
      y = &mu1_1_2. + cd1_1_21*e1+cd1_1_22*e2;
    end;
    else do;
      * (x,y) ~ N(mu, Sigma) at state 1, component 2;
      x = &mu1_2_1. + cd1_2_11*e1;
      y = &mu1_2_2. + cd1_2_21*e1+cd1_2_22*e2;
    end;
  end;
  else do;
    * choose component;
    u = uniform(&seed.);
    if(u<=&c2_1.) then do;
      * (x,y) ~ N(mu, Sigma) at state 2, component 1;
      x = &mu2_1_1. + cd2_1_11*e1;
      y = &mu2_1_2. + cd2_1_21*e1+cd2_1_22*e2;
    end;
    else do;
      * (x,y) ~ N(mu, Sigma) at state 2, component 2;
      x = &mu2_2_1. + cd2_2_11*e1;
      y = &mu2_2_2. + cd2_2_21*e1+cd2_2_22*e2;
    end;
  end;
end;

```

```

        end;
        output;
        lags = s;
    end;
run;

data gmTrain;
    set gmDGP(where=(t<=&T./2));
    keep t x y;
run;

data gmTest;
    set gmDGP(where=(t>&T./2));
    keep t x y;
run;

```

In general, the data generating process is unknown. The data tables gmTrain and gmTest can be seen, but the data table gmDGP cannot be seen.

First, assume that the following statements plot the simulated series x that is contained in the data table gmTrain:

```

proc sgplot data=gmTrain;
    series x=t y=x;
run;

```

Figure 20.22 shows the plot of x , whose points seem to fall randomly around 0.

Figure 20.22 Plot of Time Series x 

The following statements plot the simulated series y that is contained in the data set `gmTrain`:

```
proc sgplot data=gmTrain;  
  series x=t y=y;  
run;
```

Figure 20.23 shows the plot of y , whose points also seem to fall randomly around 0.

Figure 20.23 Plot of Time Series y 

Ignoring the sequential information, the following statements plot the observed points (x, y) that are contained in the data table gmTrain:

```
proc sgplot data=gmTrain;  
    scatter y=y x=x;  
run;
```

Figure 20.24 Unclassified Observations

As shown in [Figure 20.24](#), it seems that all points come from one bivariate Gaussian distribution that has a high positive correlation. However, according to the true DGP, some points are from state 1, in which there are two clusters, as shown in [Figure 20.25](#):

```
proc sgplot data=gmdgp (where=(t<=&t./2 and s=1));
  scatter y=y x=x;
run;
```

Figure 20.25 Observations from State 1

Other points are from state 2 in which there are two clusters, as shown in [Figure 20.26](#):

```
proc sgplot data=gmdGP (where=(t<=&T./2 and s=2));
  scatter y=y x=x;
run;
```

Figure 20.26 Observations from State 2

Without considering the sequential order, it is impossible to distinguish the two states.

Before you estimate any model, you should make a copy of the data in the library, as in the following DATA steps:

```
data mylib.gmTrain; set gmTrain; run;  
data mylib.gmTest; set gmTest; run;
```

The following statements estimate the bivariate bi-component GM HMM. The type of model is specified in the `TYPE=` option in the `MODEL` statement. The number of states is specified in the `NSTATE=` option in the `MODEL` statement. The number of components for each state is specified in the `NCOMPONENT=` option in the `MODEL` statement. The `OUTMODEL=` option in the `SCORE` statement outputs the model information for future scoring on new data table. The `LABELSWITCH=(SORT=NONE)` option in the `PROC HMM` statement suppresses the relabeling of states and components; for more information about the label switching problem, see the section “[Label Switching Problem](#)” on page 1321.

```
proc hmm data=mylib.gmTrain labelSwitch=(sort=none);
  id time=t;
  model x y / type=gaussianMixture nstate=2 ncomponent=2;
  optimize printLevel=3 printIterFreq=1;
  score outmodel=mylib.gmModel;
run;
```

These statements assume that your engine libref is named `mylib`, but you can substitute any appropriately defined engine libref.

The number of observations and model information are shown in [Figure 20.27](#).

The estimates of all parameters are shown in [Figure 20.37](#), which displays columns for the parameter name, estimate value, standard error, t value, and p -value. The state labels (“1” and “2” in this example) and the

component labels (“1” and “2” in this example) might exchange randomly, compared to the true DGP. In the preceding estimation, the state labels are the same as the labels in the DGP. The component labels for state 1 are also the same as the ones in the DGP, but the component labels for state 2 do exchange! Compared to the parameter values in the DGP, the estimates are very accurate.

The estimates from the data table `gmTrain` are used to score the testing data table `gmTest` to check the predictability in the following statements:

```
proc hmm data=mylib.gmTest;
  score inmodel=mylib.gmModel;
  decode out=mylib.gmDecode;
run;
```

The accuracy of classification through the GM HMM is calculated by the following statements:

```
data gmHmmCheck;
  merge gmDGP(in=a where=(t>&T./2)) mylib.gmDecode(in=b);
  by t;
  if(s=state) then do; correct=1; ds = s; end;
  else do; correct=0; ds = -s; end;
  if(a=b);
  keep t x y s correct ds;
run;

%let qFlipState = -1;
data gmHmmAccuracy;
  set gmHmmCheck;
  retain count 0 correctCount 0;
  count = count + 1;
  correctCount = correctCount + correct;
  if(count>&T./2-0.5) then do;
    accuracy = correctCount / count;
    if(accuracy<0.5) then call symputx("qFlipState",1,'G');
    else call symputx("qFlipState",0,'G');
    if(accuracy<0.5) then accuracy = 1 - accuracy;
    output;
  end;
  keep accuracy;
run;

data gmHmmCheck;
  set gmHmmCheck;
  if(&qFlipState.=1) then do;
    ds = -ds;
    correct = 1 - correct;
  end;
run;

proc print data = gmHmmAccuracy noobs; run;
```

The accuracy of the GM HMM, which is shown in [Figure 20.39](#), is about 98%. This means that the GM HMM successfully takes advantage of the sequential information.

Figure 20.39 Accuracy of Decoding by the GM HMM

accuracy
0.97835

Now, consider the GM HMM for cross-sectional time series data. Each section's data follow the same GM HMM as described previously. The following statements generate the data table for analysis. There are 200 sections in the data table, and each section of time series consist of 1,000 observations.

```
%let a11 = 0.98;

You can apply the estimates from the data table gmTrain to the testing data table gmTest to check the predictability in the following statements:

```
proc hmm data=mylib.gmTest;
  score inmodel=mylib.gmModel;
  decode out=mylib.gmDecode;
  filter out=mylib.gmFilter2;
  evaluate out=mylib.gmEval2;
run;

data gmHmmCheck;
  merge gmDGP(in=a where=(sec>&nSections./2)) mylib.gmDecode(in=b);
  by t;
  if(s=state) then do; correct=1; ds = s; end;
  else do; correct=0; ds = -s; end;
  if(a=b);
  keep sec t x y s correct ds;
```

```

run;

%let qFlipState = -1;
data gmHmmAccuracy;
  set gmHmmCheck;
  retain count 0 correctCount 0;
  count = count + 1;
  correctCount = correctCount + correct;
  if(count>&T./2-0.5) then do;
    accuracy = correctCount / count;
    if(accuracy<0.5) then call symputx("qFlipState",1,'G');
    else call symputx("qFlipState",0,'G');
    if(accuracy<0.5) then accuracy = 1 - accuracy;
    output;
  end;
  keep accuracy;
run;

data gmHmmCheck;
  set gmHmmCheck;
  if(&qFlipState.=1) then do;
    ds = -ds;
    correct = 1 - correct;
  end;
run;

proc print data = gmHmmAccuracy noobs; run;

```

The accuracy of the GM HMM for cross-sectional time series data, which is shown in [Figure 20.42](#), is also around 98%.

Figure 20.42 Accuracy of Decoding by the GM HMM for Cross-Sectional Time Series Data

accuracy
0.97827

Regime-Switching Regression Model

Let $\mathbf{Y}_t = (y_{1t}, \dots, y_{pt})'$, $t = 1, \dots, T$, denote a p -dimensional time series vector of random variables. The $\mathbf{Y}_t$ can be modeled in the regression

$$\mathbf{Y}_t = \beta_{\mathbf{S}_t} z_t + \varepsilon_t$$

where $\varepsilon_t \sim N(0, \Sigma_{\mathbf{S}_t})$, the regressor z_t is observable, the latent variable $\mathbf{S}_t$ is the so-called state, and $\beta_{\mathbf{S}_t}$ and $\Sigma_{\mathbf{S}_t}$ are mean and covariance parameters whose values depend on the state $\mathbf{S}_t$. The variable $\mathbf{S}_t$ follows the first-order Markov chain; that is,

$$p(\mathbf{S}_t | \mathbf{S}_{t-1}, \mathbf{S}_{t-2}, \dots, \mathbf{S}_1) = p(\mathbf{S}_t | \mathbf{S}_{t-1})$$

where $p(\cdot|\cdot)$ denotes the conditional probability. The range of $\mathbf{S}_t$ is a finite set, $\{1, \dots, K\}$. The transition probability from state i to state j is expressed as

$$a_{ij} = p(\mathbf{S}_t = j | \mathbf{S}_{t-1} = i)$$

The $K \times K$ matrix $\mathbf{A} = \{a_{ij}\}$ is called the transition probability matrix (TPM). The last element in the model is the initial state probability vector (ISPV), π , of the first state $\mathbf{S}_1$:

$$\pi = \{\pi_i = p(\mathbf{S}_1 = i), i = 1, \dots, K\}$$

Because the regression parameters depend on the state, the $\mathbf{Y}_t$ follows different regressions in different regimes; hence, this type of model is called the regime-switching regression model.

Consider a univariate regime-switching regression model that has two regimes and two regressors (an intercept and an exogenous variable):

$$y_t = \begin{cases} x_t + \varepsilon_t, \varepsilon_t \sim N(0, 2.56) & \text{if } \mathbf{S}_t = 1 \\ 4 + 1.5x_t + \varepsilon_t, \varepsilon_t \sim N(0, 4) & \text{if } \mathbf{S}_t = 2 \end{cases}$$

The initial state probability vector and transition probability matrix are as follows:

$$\pi = \begin{pmatrix} 0.5 \\ 0.5 \end{pmatrix}, \mathbf{A} = \begin{pmatrix} 0.9 & 0.1 \\ 0.1 & 0.9 \end{pmatrix}$$

The following statements simulate the time series from the previous model to provide test data for the HMM procedure:

```
%let x_lb = -8;
%let x_ub = 0;
%let pi1 = 0.5;
%let a11 = 0.95;
%let a22 = 0.95;

```

```

        cd1_11 = sqrt(&cov1_11.);
        /* Cholesky decomposition of COV2 */
        cd2_11 = sqrt(&cov2_11.);
    end;
    else do;
        /* transition probability matrix */
        if(lags=1) then p = &a11.;
        else p = 1-&a22.;
    end;
    u = uniform(&seed.);
    if(u<=p) then s=1;
    else s = 2;
    x = &x_lb. + (&x_ub. - &x_lb.)*uniform(&seed.);
    e = normal(&seed.);
    if(s=1) then do;
        /* y ~ N(beta1_0+beta1_1*x, Sigma1) at state 1 */
        y = &const1_1. + &x11_0_1_1 * x + cd1_11*e;
    end;
    else do;
        /* y ~ N(beta2_0+beta2_1*x, Sigma2) at state 2 */
        y = &const2_1. + &x12_0_1_1 * x + cd2_11*e;
    end;
    output;
    lags = s;
end;
run;

data rsreg;
    set rsregdgp;
    keep t y x;
run;

```

The following statements create the scatter plot in [Figure 20.43](#):

```

proc sgplot data=rsreg;
    scatter y=y x=x;
run;

```

Figure 20.43 Scatter Plot of Data Points

As shown in Figure 20.43, when the time dependence is ignored, it is difficult—if not impossible—to distinguish the two regimes.

The following code uploads the data table and estimates the regime-switching regression model:

```
data mylib.rsreg; set rsreg; run;
proc hmm data=mylib.rsreg;
  id time=t;
  model y = x / type=reg nstate=2 method=ml;
  optimize algorithm=activeset maxiter=256 printLevel=3 printIterFreq=1;
  learn out=mylib.mylearn;
  filter out=mylib.myfilter;
  smooth out=mylib.mysmooth;
  decode out=mylib.mydecode;
  evaluate out=mylib.myeval;
run;
```

These statements assume that your engine libref is named mylib, but you can substitute any appropriately defined engine libref.

The estimates of all parameters are shown in [Figure 20.44](#), which displays columns for the parameter name, estimate value, standard error, t value, and p -value. The parameter estimates are very close to the true parameter values that are used in the data generating process.

Figure 20.44 Parameter Estimates

Parameter Estimates				
Parameter	Estimate	Standard Error	t Value	Pr > t
TPM1_1	0.950779	0.006259	151.91	<.0001
TPM1_2	0.049221	0.006259	7.86	<.0001
TPM2_1	0.057042	0.007335	7.78	<.0001
TPM2_2	0.942958	0.007335	128.56	<.0001
CONST1_1	-0.058860	0.079933	-0.74	0.4616
CONST2_1	4.105147	0.113280	36.24	<.0001
XL1_0_1_1	0.986513	0.016304	60.51	<.0001
XL2_0_1_1	1.513899	0.022254	68.03	<.0001
COV1_1_1	2.563899	0.094248	27.20	<.0001
COV2_1_1	3.839914	0.143172	26.82	<.0001

The accuracy of classification through the regime-switching regression model is calculated by the following statements:

```
data rsregCheck;
    merge rsregdgp(in=a) mylib.mydecode(in=b);
    by t;
    if(s=state) then do; correct=1; ds = s; end;
    else do; correct=0; ds = -s; end;
    if(a=b);
    keep t x y s correct ds;
run;

%let qFlipState = -1;
data rsregAccuracy;
    set rsregCheck;
    retain count 0 correctCount 0;
    count = count + 1;
    correctCount = correctCount + correct;
    if(count>&T.-0.5) then do;
        accuracy = correctCount / count;
        if(accuracy<0.5) then call symputx("qFlipState",1,'G');
        else call symputx("qFlipState",0,'G');
        if(accuracy<0.5) then accuracy = 1 - accuracy;
        output;
    end;
    keep accuracy;
run;

data rsregCheck;
    set rsregCheck;
    if(&qFlipState.=1) then do;
        ds = -ds;
        correct = 1 - correct;
    end;
run;
```

```
proc print data = rsregAccuracy noobs; run;
```

The accuracy of the regime-switching regression model, which is shown in [Figure 20.45](#), is close to 90%. This means that the regime-switching regression model successfully distinguishes the two regimes.

Figure 20.45 Accuracy of Decoding by the Regime-Switching Regression Model

accuracy
0.89925

The following statements create the scatter plot in [Figure 20.46](#) to show how well the data points are classified:

```
proc sgplot data=rsregCheck;
  scatter y=y x=x / group=ds;
run;
```

Figure 20.46 Scatter Plot of Data Points

Regime-Switching Autoregression Model

Let $\mathbf{Y}_t = (y_{1t}, \dots, y_{pt})'$, $t = 1, \dots, T$, denote a p -dimensional time series vector of random variables. The $\mathbf{Y}_t$ can be modeled in the regression

$$\mathbf{Y}_t = \beta_{\mathbf{S}_t} z_t + \varepsilon_t$$

where $\varepsilon_t \sim N(0, \Sigma_{\mathbf{S}_t})$, the regressor z_t is observable and contains the lagged dependent variables, the latent variable $\mathbf{S}_t$ is the so-called state, and $\beta_{\mathbf{S}_t}$ and $\Sigma_{\mathbf{S}_t}$ are mean and covariance parameters whose values depend on the state $\mathbf{S}_t$. The variable $\mathbf{S}_t$ follows the first-order Markov chain; that is,

$$p(\mathbf{S}_t | \mathbf{S}_{t-1}, \mathbf{S}_{t-2}, \dots, \mathbf{S}_1) = p(\mathbf{S}_t | \mathbf{S}_{t-1})$$

where $p(\cdot | \cdot)$ denotes the conditional probability. The range of $\mathbf{S}_t$ is a finite set, $\{1, \dots, K\}$. The transition probability from state i to state j is expressed as

$$a_{ij} = p(\mathbf{S}_t = j | \mathbf{S}_{t-1} = i)$$

The $K \times K$ matrix $\mathbf{A} = \{a_{ij}\}$ is called the transition probability matrix (TPM). The last element in the model is the initial state probability vector (ISPV), π , of the first state $\mathbf{S}_1$:

$$\pi = \{\pi_i = p(\mathbf{S}_1 = i), i = 1, \dots, K\}$$

Because the lagged dependent variables are included in the regressors and the autoregression parameters depend on the state, the $\mathbf{Y}_t$ follows different autoregressions in different regimes; hence, this type of model is called the regime-switching autoregression model.

Consider a univariate regime-switching autoregression model that has two regimes:

$$y_t = \begin{cases} 0.8 * y_{t-1} + \varepsilon_t, \varepsilon_t \sim N(0, 2.56) & \text{if } \mathbf{S}_t = 1 \\ -0.7 * y_{t-1} + \varepsilon_t, \varepsilon_t \sim N(0, 4) & \text{if } \mathbf{S}_t = 2 \end{cases}$$

The initial state probability vector and transition probability matrix are as follows:

$$\pi = \begin{pmatrix} 0.5 \\ 0.5 \end{pmatrix}, \mathbf{A} = \begin{pmatrix} 0.95 & 0.05 \\ 0.05 & 0.95 \end{pmatrix}$$

The following statements simulate the time series from the previous model to provide test data for the HMM procedure:

```
%let pi1 = 0.5;
%let a11 = 0.95;
%let a22 = 0.95;
%let ar1_1_1_1 = 0.8;
%let cov1_11 = 2.56;
%let ar2_1_1_1 = -0.7;
```

```

%let cov2_11 = 4;
%let T = 1000;
%let seed = 1234;

data rsardgp;
  retain cd1_11 cd2_11;
  ylag = 0;
  do t = 1 to &T.;
    if(t=1) then do;
      /* initial probability distribution */
      p = &p11.;
      /* Cholesky decomposition of COV1 */
      cd1_11 = sqrt(&cov1_11.);
      /* Cholesky decomposition of COV2 */
      cd2_11 = sqrt(&cov2_11.);
    end;
    else do;
      /* transition probability matrix */
      if(lags=1) then p = &a11.;
      else p = 1-&a22.;
    end;
    u = uniform(&seed.);
    if(u<=p) then s=1;
    else s = 2;
    e = normal(&seed.);
    if(s=1) then do;
      /* y ~ N(beta1*ylag, Sigma1) at state 1 */
      y = &ar1_1_1_1 * ylag + cd1_11*e;
    end;
    else do;
      /* y ~ N(beta2*ylag, Sigma2) at state 2 */
      y = &ar2_1_1_1 * ylag + cd2_11*e;
    end;
    output;
    lags = s;
    ylag = y;
  end;
run;

data rsar;
  set rsardgp;
  keep t y;
run;

```

The following statements create the series plot in [Figure 20.47](#). It is difficult to tell directly from the plot that the series are from two different regimes.

```

proc sgplot data=rsar;
  series y=y x=t;
run;

```

Figure 20.47 Series Plot of Data Points

The following code uploads the data table and estimates the regime-switching autoregression model:

```
data mylib.rsar; set rsar; run;
proc hmm data=mylib.rsar;
  id time=t;
  model y / type=ar noint ylag=1 nstate=2 method=ml;
  optimize algorithm=activeset printLevel=3 printIterFreq=1;
  learn out=mylib.mylearn;
  filter out=mylib.myfilter;
  smooth out=mylib.mysmooth;
  decode out=mylib.mydecode;
  evaluate out=mylib.myeval;
run;
```

These statements assume that your engine libref is named mylib, but you can substitute any appropriately defined engine libref.

The estimates of all parameters are shown in [Figure 20.48](#), which displays columns for parameter name, estimate value, standard error, t value, and p -value. The parameter estimates are very close to the true parameter values that are used in the data generating process.

Figure 20.48 Parameter Estimates

Parameter Estimates				
Parameter	Estimate	Standard		
		Error	t Value	Pr > t
TPM1_1	0.937990	0.013985	67.07	<.0001
TPM1_2	0.062010	0.013985	4.43	<.0001
TPM2_1	0.056595	0.013425	4.22	<.0001
TPM2_2	0.943405	0.013425	70.27	<.0001
AR1_1_1_1	0.759087	0.032724	23.20	<.0001
AR2_1_1_1	-0.630710	0.037261	-16.93	<.0001
COV1_1_1	2.687805	0.198060	13.57	<.0001
COV2_1_1	4.225692	0.280319	15.07	<.0001

The accuracy of classification through the regime-switching autoregression model is calculated by the following statements:

```

data rsarCheck;
    merge rsardgp(in=a) mylib.mydecode(in=b);
    by t;
    if(s=state) then do; correct=1; ds = s; end;
    else do; correct=0; ds = -s; end;
    if(a=b);
    keep t y s correct ds;
run;

%let qFlipState = -1;
data rsarAccuracy;
    set rsarCheck;
    retain count 0 correctCount 0;
    count = count + 1;
    correctCount = correctCount + correct;
    if(count>&T.-0.5) then do;
        accuracy = correctCount / count;
        if(accuracy<0.5) then call symputx("qFlipState",1,'G');
        else call symputx("qFlipState",0,'G');
        if(accuracy<0.5) then accuracy = 1 - accuracy;
        output;
    end;
    keep accuracy;
run;

data rsarCheck;
    set rsarCheck;
    if(&qFlipState.=1) then do;
        ds = -ds;
        correct = 1 - correct;
    end;
run;

proc print data = rsarAccuracy noobs; run;

```

The accuracy of the regime-switching autoregression model, which is shown in [Figure 20.49](#), is more than 92%. This means that the regime-switching autoregression model successfully distinguishes the two regimes.

0.927

The following statements create the scatter plot in [Figure 20.50](#) to show how well the data points are classified:

```
proc sgplot data=rsarCheck;
  scatter y=y x=t / group=ds;
run;
```

Figure 20.50 Scatter Plot of Data Points

Finite Hidden Markov Model

Let $\mathbf{Y}_t, t = 1, \dots, T$, denote a random discrete variable whose sample space is a finite set of nominal classes. These values from this sample space can be represented by the finite integers $1, \dots, M$. $\mathbf{Y}_t$ can be modeled in a categorical distribution,

$$\mathbf{Y}_t | \mathbf{S}_t = i \sim C(b_{i1}, \dots, b_{iM})$$

where the category probability b_{ij} is the probability of observing $Y_t = j, j = 1, \dots, M$, conditional on the latent variable $\mathbf{S}_t = i, i = 1, \dots, K$. The $K \times M$ category probability matrix (CPM) $\mathbf{B} \equiv (b_{ij})$ is used to define the state-dependent categorical distribution of observable variables. The variable $\mathbf{S}_t$ is the so-called state and follows the first-order Markov chain; that is,

$$p(\mathbf{S}_t | \mathbf{S}_{t-1}, \mathbf{S}_{t-2}, \dots, \mathbf{S}_1) = p(\mathbf{S}_t | \mathbf{S}_{t-1})$$

where $p(\cdot | \cdot)$ denotes the conditional probability. The range of $\mathbf{S}_t$ is a finite set, $\{1, \dots, K\}$. The transition probability from state i to state j is expressed as

$$a_{ij} = p(\mathbf{S}_t = j | \mathbf{S}_{t-1} = i)$$

The $K \times K$ matrix $\mathbf{A} = \{a_{ij}\}$ is called the transition probability matrix (TPM). The last element in the model is the initial state probability vector (ISPV), π , of the first state, $\mathbf{S}_1$:

$$\pi = \{\pi_i = p(\mathbf{S}_1 = i), i = 1, \dots, K\}$$

Because the variable $\mathbf{S}_t$ is unobservable and follows a Markov chain and $\mathbf{Y}_t$ is from a finite support, the model is called the finite hidden Markov model (finite HMM). The finite HMM is sometimes described as $\{\pi, \mathbf{A}, \mathbf{B}\}$.

Consider a standard die with six faces, numbered 1 through 6. A fair die has an equal probability of displaying 1 to 6; that is, $\mathbf{Y}_t \sim C(1/6, 1/6, 1/6, 1/6, 1/6, 1/6)$. In order to tell whether a die is fair, checking whether the opportunity of displaying each number is equal might not be enough.

The following data record the results from the roll of a die 1,000 times:

```
data mylib.finitel;
    input t    y ;
datalines;
1      6
2      3
3      6
4      5
5      1
6      2
7      1
8      6

... more lines ...
```

```

993 2
994 3
995 6
996 6
997 5
998 5
999 2
1000 6
;

```

The following statements estimate the unistate finite HMM:

```

proc hmm data=mylib.finitel;
  id time=t;
  model y / type=finite nstate=1 nCategory=6;
  estimate outall=mylib.myEstimate;
run;

```

The number of observations and model information are shown in [Figure 20.51](#).

The estimates of the initial state probability vector (ISPV) and the transition probability matrix are trivial. The category probability matrix is shown in [Figure 20.52](#), which shows the probabilities of occurrence of each number.

Figure 20.52 Estimates of Category Probability Matrix

Estimated Category Probability Matrix						
Category						
State	1	2	3	4	5	6
1	0.16300	0.15400	0.16600	0.16700	0.17400	0.17600

The estimates of all parameters are shown in [Figure 20.53](#), which displays columns for parameter name, estimated value, standard error, t value, and p -value.

Figure 20.53 Parameter Estimates

Parameter Estimates				
Parameter	Estimate	Standard		
		Error	t Value	Pr > t
TPM1_1	1.000000	0		
CPM1_1	0.163000	0.011680	13.96	<.0001
CPM1_2	0.154000	0.011414	13.49	<.0001
CPM1_3	0.166000	0.011766	14.11	<.0001
CPM1_4	0.167000	0.011795	14.16	<.0001
CPM1_5	0.174000	0.011988	14.51	<.0001
CPM1_6	0.176000	0.012043	14.61	<.0001

The following statements run a Wald test under the null hypothesis that all category probabilities are equal to 1/6:

```
proc iml;
  use mylib.myEstimate;
  read all var {Estimate cov_2 cov_3 cov_4 cov_5 cov_6} into m;
  close mylib.myEstimate;

  cov = m[2:6,2:6];
  invcov = inv(cov);
  v = m[2:6,1];
  c = 1/6 // 1/6 // 1/6 // 1/6 // 1/6 ;
  v1 = v-c;

  stat = v1`*invcov*v1;
  df = 5;
  pvalue = 1- cdf('CHISQ',stat,df);
  varname={"stat" "df" "pvalue"};
  create table var varname;
  append;
  close table;
  quit;

proc print data=table noobs label;
  label stat="Stat" df = "DF" pvalue = "Pr > ChiSq";
run;
```

The p -value shown in [Figure 20.54](#) is very large, which means that the test cannot reject the null hypothesis that the category probabilities are equal to 1/6 at the 10% significance level. The die looks fair.

In Figure 20.60, you see that the category probabilities for small numbers (1, 2, 3) in the first state and the category probabilities for large numbers (4, 5, 6) in the second state are not significant at the 10% significance level. This indicates that the small numbers appear only in one state and the large numbers appear only in the other state.

The log likelihood and information criteria are shown in Figure 20.61.

Figure 20.61 Log Likelihood and Information Criteria

Fit Statistics	
Log Likelihood	-1697.866801
AIC	3423.7336013
AICC	3424.1599972
BIC	3492.4421752
HQC	3449.8476538

All the information criteria from the bivariate finite HMM are smaller than those from the univariate finite HMM. This indicates that the bivariate finite HMM is a better model. The trivariate finite HMM, which is not shown here, is also beaten by the bivariate finite HMM for this case.

The casino game sic bo involves whether you will get a small or big number when you roll a die. A small bet is when you predict that the die will display a 1, 2, or 3. A big bet is when you predict that the die will display a 4, 5, or 6. If your guess is correct, you get a reward; otherwise you lose the bet.

You can use PROC HMM to test the bivariate finite HMM's ability to forecast the result of this game. The following data record the results from the roll of a die 100 times:

```
data mylib.finite2;
    input t y ;
datalines;
1    6
2    4
3    6
4    1
5    1
6    1
7    1
8    4

  by t;
run;
data fnHmmCheck;
  set fnHmmCheck;
  *for first round bet according to initial probability;
  if(t=1) then bet=1;
  if(big=bet) then gain=1;
  else gain=-1;
  keep t y gain;
run;
data totalgain;
  set fnHmmCheck;
  Totalgain + gain;
  if (t=100) then do
    Zscore = Totalgain/10;
    pvalue = 2*(1- cdf('NORMAL', Zscore));
    output totalgain;
  end;
  keep Totalgain Zscore pvalue;
run;
proc print data = totalgain noobs label;
  label totalgain = "Total gain" Zscore="Z-score" pvalue="Pr > |z|";
run;

```

The total gain from rolling the die 100 times is shown in Figure 20.62. Under the null hypothesis that the die is fair, according to the central limit theorem the expected return of betting 100 times is 0 with a standard error of 10 units. The values shown in Figure 20.62 indicate that the null hypothesis is rejected even at the 1% significance level. This means that the finite HMM successfully detects the loaded die.

Figure 20.62 Gain of Forecasting by the Finite HMM

Total gain	Z-score	Pr > z
48	4.8	.000001587

The data generating process behind the observed data sets is as follows:

$$Y_t \sim \begin{cases} C(1/3, 1/3, 1/3, 0, 0, 0) & \text{if } S_t = 1 \\ C(0, 0, 0, 1/3, 1/3, 1/3) & \text{if } S_t = 2 \end{cases}$$

The initial state probability vector and transition probability matrix are as follows:

$$\pi = \begin{pmatrix} 0.5 \\ 0.5 \end{pmatrix}, A = \begin{pmatrix} 0.75 & 0.25 \\ 0.25 & 0.75 \end{pmatrix}$$

The following statements simulate the original time series data for this example:

```
%let pil = 0.5; *initial probability in state 1;
%let a11 = 0.75;
%let a22 = 0.75;

%macro simData(name, T, seed);
data mylib.&name.(keep = t y);
  p = &pil.;
  call streaminit(&seed);
  do t = 1 to &T.;
    if(t=1) then
      /* initial probability distribution */
      p = &pil.;
    else
      /* transition probability matrix */
      if(lagx=1) then p = &a11.;
      else p = 1-&a22.;
      u = rand("Uniform");
      if(u<=p) then x=1;
      *Using the random value u to control regimes, set x=number of regimes;
      else x = 2;
      if(x=1) then
        do;
          /* at state 1 */
          y = rand("Table", 1/3, 1/3, 1/3, 0 , 0 , 0);
        end;
      else do;
        /* at state 2 */
        y = rand("Table", 0 , 0 , 0 , 1/3, 1/3, 1/3);
      end;
      output;
      lagx=x;
    end;
  run;
%mend;

%simData(finite1,1000, 3);
%simData(finite2,100, 4);
```

PROC HMM assumes that values of the response variables are consecutive natural numbers that start from 1. If this is not the case, you might need to preprocess the input data set before running PROC HMM. You can use the SAS macro %FiniteHMM for automatic preprocessing and postprocessing. For more information about %FiniteHMM, see the section “[The %FiniteHMM Macro](#)” on page 1278.

Poisson Hidden Markov Model

Let $y_t, t = 1, \dots, T$, denote a discrete time-series random variable whose sample space is a set of nonnegative integers.

The variable y_t is said to follow a Poisson HMM distribution, with the parameter $\lambda_{s_t} > 0$, if it follows a Poisson distribution in each state S_t . The conditional probability distribution is denoted as $y_t | S_t = i \sim \text{Pois}(\lambda_{S_t})$, where i is a positive integer.

The variable S_t is the so-called state and follows the first-order Markov chain; that is,

$$p(S_t | S_{t-1}, S_{t-2}, \dots, S_1) = p(S_t | S_{t-1})$$

where $p(\cdot | \cdot)$ denotes the conditional probability. The range of S_t is a finite set, $\{1, \dots, K\}$. The transition probability from state i to state j is expressed as

$$a_{ij} = p(S_t = j | S_{t-1} = i)$$

The $K \times K$ matrix $\mathbf{A} = \{a_{ij}\}$ is called the transition probability matrix (TPM). The last element in the model is the initial state probability vector (ISPV), π , of the first state, S_1 :

$$\pi = \{\pi_i = p(S_1 = i), i = 1, \dots, K\}$$

Because the state variable S_t is unobservable and follows a Markov chain, and because y_t is from a Poisson distribution that depends on a different state, the model is called the Poisson hidden Markov model (Poisson HMM).

Consider a univariate Poisson HMM model $y_t \sim \text{Pois}(\lambda_{s_t})$ that has two regimes, $\lambda_1 = 5$ and $\lambda_2 = 10$.

The initial state probability vector and transition probability matrix are as follows:

$$\pi = \begin{pmatrix} 0.7 \\ 0.3 \end{pmatrix}, \quad \mathbf{A} = \begin{pmatrix} 0.9 & 0.1 \\ 0.2 & 0.8 \end{pmatrix}$$

```
%let pi1 = 0.7;
%let a11 = 0.9;
%let a22 = 0.8;
%let lambda1 = 5;
%let lambda2 = 10;

%macro dgpSHMM(table, T, nSections, seed);
data &table;
  call streaminit(&seed.);
  secLen = ceil(&T./&nSections.);
  do t = 1 to &T.;
    sec = floor((t-1)/secLen)+1;
    if(t=1) then do;
```

```

/* initial probability distribution */
p = &pil.;
end;
else do;
/* transition probability matrix */
if(lags=1) then p = &a11.;
else p = 1-&a22.;
end;
u = rand("Uniform");
if(u<=p) then s=1;
else s = 2;
if(s=1) then do;
/* at state 1 */
y = rand("Poisson",&lambda1.);
end;
else do;
/* at state 2 */
y = rand("Poisson",&lambda2.);
end;
output;
lags = s;
end;
run;
proc sort data=&table.; by sec t; run;
%mend;

%let T = 1000 ;
%let nSections = 2;
%let seed = 1234;
%dgppSHMM(hmmpsdt, &T., &nSections., &seed.);

data mylib.hmmpsdt;
set hmmpsdt;
run;

```

The following code estimates a bivariate Poisson HMM:

```

proc hmm data=mylib.hmmpsdt;
id time=t;
model y / type=Poisson nstate=2;
run;

```

The number of observations and model information are shown in [Figure 20.63](#).

Functional Summary

The statements and options available in the HMM procedure are summarized in [Table 20.1](#).

Table 20.1 Functional Summary

Description	Statement	Option
Input Data Table Options		
Specifies the input data table	PROC HMM	DATA=
Specifies the input data table for parameter estimation	ESTIMATE	IN=
Specifies the input data table for model information	SCORE	INMODEL=

Table 20.1 *continued*

Description	Statement	Option
Output Data Table Options		
Writes the log likelihood and information criteria to the specified output data table	PROC HMM	OUTSTAT=
Writes the parameter estimates to the specified output data table	ESTIMATE	OUT=
Writes the parameter estimates and their standard errors and covariance matrix to the specified output data table	ESTIMATE	OUTALL=
Writes the evaluation results to the specified output data table	EVALUATE	OUT=
Writes the decoding results to the specified output data table	DECODE	OUT=
Writes the filtering results to the specified output data table	FILTER	OUT=
Writes the forecasting results to the specified output data table	FORECAST	OUT=
Writes the state distributions, means, standard errors, confidence intervals, medians, and covariance matrices of forecasts for dependent variables to the specified output data table	FORECAST	OUTALL=
Writes the model information to the specified output data table	SCORE	OUTMODEL=
Writes the smoothing results to the specified output data table	SMOOTH	OUT=
Writes the model information to the specified output data table that can be processed by the ASTORE procedure	STORE	OUT=
ID Variable		
Specifies the variable that identifies the time or sequence	ID	TIME=
Specifies the variable that identifies the section	ID	SECTION=
Model Options		
Specifies the mean form in a regime-switching autoregression model	MODEL	ARMEAN=
Estimates the initial state probability vector (ISPV)	MODEL	ESTISPV
Specifies the estimation method	MODEL	METHOD=
Specifies the number of categories in a state for a finite HMM	MODEL	NCATEGORY
Specifies the number of components in a state in a Gaussian mixture HMM (GM HMM)	MODEL	NCOMPONENT
Suppresses the present values of the exogenous variables	MODEL	NOCURRENTX

Table 20.1 *continued*

Description	Statement	Option
Suppresses the constant (intercept) parameters	MODEL	NOINT
Specifies the number of seasonal periods	MODEL	NSEASON=
Specifies the number or the range of numbers of hidden states	MODEL	NSTATE=
Centers seasonal dummies	MODEL	SCENTER
Specifies the state-independent parameters	MODEL	STATEINDEPENDENT=
Specifies the degree of deterministic time trend	MODEL	TREND=
Specifies the type of model of interest	MODEL	TYPE=
Specifies the lags of exogenous (independent) variables	MODEL	XLAG=
Specifies the order or the range of orders of the autoregressive process	MODEL	YLAG=
Optimization Options		
Specifies a nonnegative integer to use as the seed for generating random number sequences	PROC HMM	SEED=
Specifies the initial parameter values for optimization	INITIAL	
Specifies the optimization algorithm	OPTIMIZE	ALGORITHM=
Specifies whether to calculate the covariance of parameters	OPTIMIZE	COVOFPARM=
Specifies the maximum number of iterations in the optimization process	OPTIMIZE	MAXITER=
Specifies the maximum time (in seconds) allowed for optimization	OPTIMIZE	MAXTIME=
Specifies the print iteration frequency	OPTIMIZE	PRINTITERFREQ=
Specifies the print level	OPTIMIZE	PRINTLEVEL=
Specifies the priors for parameters	PRIOR	
Optimization Suboptions for the Active-Set or Interior Point Algorithm		
Specifies the range from which each variable can take values during the sampling process in multistart mode	OPTIMIZE	MSRANGE=
Specifies whether to enable multistart mode	OPTIMIZE	MULTISTART=
Specifies the upper limit on the magnitude of the objective value	OPTIMIZE	OBJLIMIT=
Specifies the tolerance for infeasibility	OPTIMIZE	FEASTOL=
Specifies the tolerance for the optimality error	OPTIMIZE	OPTTOL=
Specifies whether the optimizer should return only a solution that is locally optimal	OPTIMIZE	SOLTYPE=
Optimization Suboption for the Expectation-Maximization (EM) Algorithm		
Specifies the minimum number of iterations in the optimization process	OPTIMIZE	MINITER=

Table 20.1 *continued*

Description	Statement	Option
Executes the EM algorithm in a single thread on a single node	OPTIMIZE	SINGLE
Optimization Suboptions for the Stochastic Gradient Descent (SGD) Algorithm		
Specifies the annealing rate	OPTIMIZE	ANNEALINGRATE=
Specifies the learning rate	OPTIMIZE	LEARNINGRATE=
Specifies the size of the minibatches to use	OPTIMIZE	MINIBATCHSIZE=
Specifies the value for momentum	OPTIMIZE	MOMENTUM=
Suppresses the adaptive gradient descent algorithm	OPTIMIZE	NONADUPDATE
Specifies the value of adaptive rate	OPTIMIZE	ADAPTIVEDECAY=
Requests that computational threads share a common weight vector and that they update the weight vector without race conditions	OPTIMIZE	USELOCKING=
Specifies the length of a chain in a minibatch	OPTIMIZE	CHAIN=(LENGTH=)
Specifies the buffer length on the left side of a chain in a minibatch	OPTIMIZE	CHAIN=(BUFFER=)
Optimization Suboptions for the Distributed Multistart Option		
Specifies the number of CAS subsessions that are dedicated to the function evaluations	OPTIMIZE	FESESSIONS=
Specifies the number of computing nodes in each CAS subsession that are dedicated to the function evaluations	OPTIMIZE	FESESSNODES=
Specifies the maximum number of starting points to be used by the multistart algorithm	OPTIMIZE	MAXSTARTS=
Specifies the ratio of the total number of sample points to be generated to the value of the MAXSTARTS= option	OPTIMIZE	SAMPSELRATIO=
Specifies the number of computing nodes in the CAS session dedicated to the multistart algorithm	OPTIMIZE	SESSNODES=
Forecasting Options		
Specifies a nonnegative integer to use as the seed for generating random number sequences	PROC HMM	SEED=
Specifies the size of confidence limits for forecasting	FORECAST	ALPHA=
Starts forecasting before the end of the input data	FORECAST	BACK=
Specifies how many periods to forecast	FORECAST	LEAD=
Specifies the number of paths to simulate in the forecasting of a regime-switching autoregression model	FORECAST	NSIM=
Specifies whether to perform forecasts after each observation	FORECAST	ONLINE

Table 20.1 *continued*

Description	Statement	Option
Output Control Options		
Specifies the order in which to label the states (and components)	PROC HMM	LABELSWITCH=
Specifies the ODS tables to display	DISPLAY	
Specifies the ODS tables to save as output tables	DISPLAYOUT	

PROC HMM Statement

PROC HMM DATA=*libref.data-table* < options > ;

The PROC HMM statement invokes the HMM procedure. You must specify the following *option*:

DATA=*libref.data-table*

names the input data table for PROC HMM to use. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section “Using CAS Sessions and CAS Engine Librefs” on page 1186.

data-table specifies the name of the input data table.

You can also specify the following *options*:

LABELSWITCH=(*options*)

specifies the order in which to label the states (and components). The label switching problem is a common issue for HMMs because any two HMMs are mathematically equivalent if the only difference between two models is that the states are labeled in different ways. For example, consider the following two univariate bistate Gaussian HMMs, which are described by the parameters $\{\pi, \mathbf{A}, \mathbf{B}\}$, where π is the initial state probability vector, $\mathbf{A}$ is the transition probability matrix, $\mathbf{B} \equiv \{\mu_1, \Sigma_1, \mu_2, \Sigma_2\}$, μ_1 and Σ_1 are mean and covariance parameters for state 1, and μ_2 and Σ_2 are mean and covariance parameters for state 2:

$$\text{model 1: } \pi = \begin{pmatrix} 0.75 \\ 0.25 \end{pmatrix}, \mathbf{A} = \begin{pmatrix} 0.9 & 0.1 \\ 0.3 & 0.7 \end{pmatrix}, \mu_1 = 1, \Sigma_1 = 1, \mu_2 = -1, \Sigma_2 = 4$$

$$\text{model 2: } \pi = \begin{pmatrix} 0.25 \\ 0.75 \end{pmatrix}, \mathbf{A} = \begin{pmatrix} 0.7 & 0.3 \\ 0.1 & 0.9 \end{pmatrix}, \mu_1 = -1, \Sigma_1 = 4, \mu_2 = 1, \Sigma_2 = 1$$

In theory, these two models are equivalent, and just the state labels “1” and “2” are switched. When the labels are switched, it is inconvenient to compare any state-related results, such as filtered or smoothed probabilities or decoded path. The LABELSWITCH= option helps you define the order of the state (and component) labels. You can specify the following *options*:

OUT=*libref.data-table*

writes the changes of state labels (and component labels in the case of GM HMMs) to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1186.

REORDER=(*number-list*)

specifies the new order of the state labels, where the *number-list* directly specifies the new order of the states. The *number-list* must be a permutation of numbers 1 to K , where K is the number of states; that is, the size of the *number-list* must be K , and each element in the *number-list* must be unique and between 1 and K . For example, **REORDER=**(3 1 2) implies that the original state 1 becomes state 3, state 2 becomes state 1, and state 3 becomes state 2. If you specify this option, the **SORT=** option is ignored.

REORDERCOMPONENT=(*number-list*)

specifies the new order of the component labels in the case of GM HMMs, where the *number-list* directly specifies the new order of the components for each state. For a K -state M -component GM HMM, the size of the *number-list*, $\{n_{11}, \dots, n_{1M}, \dots, n_{K1}, \dots, n_{KM}\}$, must be KM , and each sublist $\{n_{i1}, \dots, n_{iM}\}$, $i = 1, \dots, K$, must be a permutation of numbers 1 to M —that is, each element in the sublist $\{n_{i1}, \dots, n_{iM}\}$ must be unique and between 1 and M . For example, **REORDERCOMPONENT=**(3 2 1 2 1 3) for a bistate tricomponent GM HMM implies that the original components 1, 2, and 3 for the original state 1 become components 3, 2, and 1, respectively, for the original state 1, and the original components 1, 2, and 3 for the original state 2 become components 2, 1, and 3, respectively, for the original state 2. If you specify this option, the labels for components in each state are not sorted.

SORT=*type* <(*name-list*)>

specifies whether to sort the labels of states (and components) and in which type of order. You can specify the following *types*:

ASC <(*name-list*)> sorts the labels in ascending order. You can add a *name-list* in parentheses in order to sort the labels of states (and components). The possible names that can appear in the *name-list* are ISPV, TPM, MCP, CPM, LAMBDA, MU, SIGMA, CONST, SDUMMY, LTREND, QTREND, XL, AR, and COV; the meanings of those names are defined in Table 20.4. Any parameters that are not in the model are ignored.

DESC <(*name-list*)> sorts the labels in descending order. You can add a *name-list* in parentheses in order to sort the labels of states (and components). The possible names that can appear in the *name-list* are ISPV, TPM, MCP, CPM, LAMBDA, MU, SIGMA, CONST, SDUMMY, LTREND, QTREND, XL, AR, and COV; the meanings of those names are defined in Table 20.4. Any parameters that are not in the model are ignored.

NONE does not sort the labels.

By default, if the **INMODEL=** option is not specified in the **SCORE** statement, **SORT=ASC(SIGMA)**; otherwise, **SORT=NONE**. For example, when the **ESTISPV** option is not specified, the ISPV is not in the stationary HMM; if you include ISPV in the *name-list*,

it is ignored. For a GM HMM, the labels of components for each state are first sorted by the parameters state by state if the REORDERCOMPONENT= option is not specified; then the labels of states are sorted by the parameters that are stacked in the new order of components.

For more details and examples, see the section “[Label Switching Problem](#)” on page 1321.

OUTSTAT=*libref.data-table*

writes the log likelihood and information criteria to the specified output data table. The information criteria include Akaike’s information criterion (AIC), the corrected Akaike’s information criterion (AICC), the Bayesian information criterion (BIC, also referred to as the Schwarz Bayesian criterion, SBC), and the Hannan-Quinn criterion (HQC). *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1186.

SEED=*number*

specifies a nonnegative integer to use as the seed for generating random number sequences. When the seed value is 0, random number sequences are generated by using the time of day from the computer’s clock. Seed values greater than 0 generate reproducible random number sequences. By default, SEED=1.

DECODE Statement

DECODE < *option* > ;

The DECODE statement solves the decoding problem by finding the best possible state path for the observations. You can specify the following *option*:

OUT=*libref.data-table*

writes the decoding results to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1186.

DISPLAY Statement

DISPLAY < *table-list* > < / *options* > ;

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE

statement is taking precedence because it can further filter the tables. For more information about ODS, see [SAS Output Delivery System: Procedures Guide](#).

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section “[ODS Table Names](#)” on page 1342. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *SelectionSummary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying “/tions/” selects all pathnames that contain the substring “tions”; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying “!/tions/” selects all pathnames that do not contain the substring “tions”; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE

performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetting for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE

displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL

suppresses display of all tables. This option takes precedence over the other options.

TRACE

displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > ;

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see [SAS Output Delivery System: Procedures Guide](#).

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key=value* format or a *key* format:

<i>key=value</i>	specifies <i>key</i> as the ODS table name, path, or partial pathname, and specifies <i>value</i> as the output table name.
<i>key</i>	specifies <i>key</i> as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section “[ODS Table Names](#)” on page 1342. You cannot specify the ODS table named `OutputCasTables` in the *table-spec-list*.

Table names and partial pathnames are discussed under the [DISPLAY](#) statement. The `DISPLAYOUT` statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL

creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE

does not replace any existing output table of the same name.

REPEATED

replicates all output tables on all nodes.

ESTIMATE Statement

ESTIMATE <options> ;

LEARN <options> ;

The `ESTIMATE` statement estimates the parameters. You can specify the following *options*:

IN=libref.data-table

specifies the input data table for parameter estimation. In general, the data table is an output data table that is produced by the `OUT=` option in the `ESTIMATE` statement in a previous call of the HMM procedure. To estimate each model that is specified in the `MODEL` statement, PROC HMM first checks whether an `INITIAL` statement is specified for the model. If the `INITIAL` statement exists for the model, the initial values that are specified in the `INITIAL` statement are used; otherwise, PROC HMM searches the `IN=` data table to see whether it contains a model that has the same model specification. If the `IN=` data table contains a matched model, its values are used as the initial values for the model that is specified in the `MODEL` statement. **NOTE:** When PROC HMM checks for matched models, the `ESTISPV` model option, which calculates the `ISPV` parameter, presents a special case. If the current model specification does not include the `ESTISPV` option, and the `IN=` table is a parameter estimate output table from a previous model specification that does include the `ESTISPV` option, then values in the `IN=` table are not used as initial values, even if all other specifications of the two models are the same.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1186.

OUT=libref.data-table

writes the parameter estimates to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1186.

OUTALL=libref.data-table

writes the parameter estimates and their standard errors and covariance matrix to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1186.

EVALUATE Statement

EVALUATE < option > ;

The EVALUATE statement evaluates the model by calculating the log likelihood. You can specify the following *option*:

OUT=libref.data-table

writes the evaluation results to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1186.

FILTER Statement

FILTER < option > ;

The FILTER statement solves the filtering problem, which is to find the probability distribution of the current state, conditional on the observations that precede and include the current observation. You can specify the following *option*:

OUT=libref.data-table

writes the filtering results to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1186.

FORECAST Statement

FORECAST <options> ;

The FORECAST statement finds the probability distribution of the future states and the dependent variables. You can specify the following *options*:

ALPHA=number

specifies the forecast confidence limit size, where *number* is between 0 and 1. When you specify this option, the upper and lower confidence limits define the $100\alpha\%$ confidence interval. By default, ALPHA=0.95, which produces 95% confidence intervals.

BACK=number

specifies the number of observations before the end of the data at which the multistep forecasts begin, where *number* must be less than or equal to the number of observations minus the number of lagged regressors in the model. By default, BACK=0, which means that the forecasts start at the end of the available data.

LEAD=number

specifies the number of multistep forecast values to compute, where *number* must be a nonnegative integer. By default, LEAD=1, which means that a one-step-ahead forecast is performed.

METHOD=ANALYTIC | SIMULATION

specifies the forecasting method. The SIMULATION option works only when you specify the TYPE=AR option in the MODEL statement. You can specify the following values:

ANALYTIC specifies the analytical method of forecasting.

SIMULATION specifies the simulation method of forecasting for autoregressive HMM.

By default, METHOD=SIMULATION for autoregressive HMM and METHOD=ANALYTIC for other types of HMM.

NSIM=number

specifies the number of paths to be simulated in the forecasting of a regime-switching autoregression model, where *number* must be a positive integer. By default, NSIM=100.

ONLINE

requests that the (multistep) forecasts be done after each observation. When you specify this option, the BACK= option is ignored.

OUT=libref.data-table

writes the forecasting results to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1186.

OUTALL=libref.data-table

writes the state distributions, means, standard errors, confidence intervals, medians, and covariance matrices of forecasts for dependent variables to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1186.

ID Statement

ID TIME=variable < SECTION=variable > ;

The ID statement identifies observations in the input data table by specifying a variable for the time series data or two variables for the cross-sectional time series data.

You must specify the following option:

TIME=variable

specifies the temporal or sequential order of the observations. The *variable* cannot have missing values. If you omit the SECTION= option, the *variable* cannot have duplicate values. If you specify the SECTION= option, the *variable* cannot have duplicate values within a section.

You can also specify the following option:

SECTION=variable

identifies the section of each observation for modeling cross-sectional time series data. The *variable* cannot have missing values.

INITIAL Statement

INITIAL equation < , . . . , equation > ;

The INITIAL statement specifies the initial parameter values for nonlinear optimization when the maximum likelihood method or the maximum a posteriori method is applied to the estimation of the HMMs (that is, METHOD=ML or METHOD=MAP, respectively, in the MODEL statement). Only one INITIAL statement is allowed. If you specify more than one *equation*, separate them with commas. The INITIAL statement supports only equations; hence, inequality comparison operators (<, <=, >, and >=) and the distribution operator (~) are not supported in the INITIAL statement. If you omit this statement, the initial values of parameters are determined by the input data.

If you specify the NSTATE= n_1 : n_2 option or the YLAG= m_1 : m_2 option (or both) in the MODEL statement to estimate multiple models, the INITIAL statement is applied to the first model that corresponds to the specification of NSTATE= n_1 or YLAG= m_1 (or that corresponds to both NSTATE= n_1 and YLAG= m_1 if both options are specified).

To use the INITIAL statement, you need to know the form of the model: different sets of parameters are available for different types of HMMs. Nonlinear equations on parameters are not supported.

The *equation* is in the form of a matrix expression. For more information about the matrix expression, see the section “[Matrix Expression](#)” on page 1311.

The initial parameter values are values that solve the specified linear equations. If you do not specify initial values for all parameters, the default initial value for any parameter that is not specified in the INITIAL statement is 0, except for the following:

- The diagonal elements of the **SIGMA** or **COV** parameter matrix are set to ones if the **SIGMA** or **COV** parameter matrix is to be estimated.
- If a row of the **TPM** parameter matrix contains all zeros, each element in the row is set to $1/K$, where K is the number of states; if a row of the **TPM** parameter matrix does not add up to one, the row is normalized by dividing each element in the row by the sum of the row.
- If all elements of the **ISPV** parameter vector are zeros, each element of the **ISPV** parameter vector is set to $1/K$, where K is the number of states; if the sum of the **ISPV** parameter vector is not equal to one, it is normalized by dividing each element of the **ISPV** parameter vector by the sum of the **ISPV** parameter vector.
- The value of the **LAMBDA** parameter vector for each state is set to one if the **LAMBDA** parameter vector is to be estimated.

The following example uses the INITIAL statement for a bivariate three-state Gaussian HMM, which PROC HMM estimates by the maximum likelihood method by default:

```
proc hmm data=One;
  id time = t;
  model y1 y2 / type=gaussian nstate=3;
  initial TPM={0.8 0.1 0.1, 0.2 0.7 0.1, 0.9 0.05 0.05},
            MU={-1 -1, 0 0, 1 1}` ,
            SIGMA(1)=4*I(2),
            SIGMA(2)=I(2),
            SIGMA(3)=4*I(2)+2;
run;
```

MODEL Statement

MODEL *dependents* < = *regressors* > < / *options* > ;

The MODEL statement specifies dependent (endogenous) variables and regressors (the independent or exogenous variables) for the HMM model. Only one MODEL statement is allowed.

You can specify the following *options* after a forward slash (/):

ARMEAN=ADJUSTED | STANDARD

specifies the mean form in a regime-switching autoregression model. The ARMEAN= option applies only when you specify the TYPE=AR option in the MODEL statement. You can specify the following values:

ADJUSTED	specifies the mean-adjusted form of regime-switching autoregression model.
STANDARD	specifies the standard regime-switching autoregression model.

By default, METHOD=STANDARD.

ESTISPV

estimates the initial state probability vector (ISPV). By default, the ISPV is fixed to the stationary distribution of the Markov chain. For the finite-state-space and homogeneous HMM, the stationary distribution of the Markov chain is the π such that $\pi' A = \pi'$, where A is the transition probability matrix (TPM); that is, π is the leading left eigenvector of A . If you do not specify this option but you do specify the ISPV function in the INITIAL or PRIOR statement, the HMM procedure issues errors and then stops.

METHOD=MAP | ML

requests the type of estimates to be computed. You can specify the following values:

MAP	specifies the maximum a posteriori method.
ML	specifies the maximum likelihood method.

By default, METHOD=ML.

NCATEGORY=number

specifies the number of categories in a state for a finite HMM, where *number* must be a positive integer. This option applies only when you specify TYPE=FINITE. By default, NCATEGORY=2.

NCOMPONENT=number

specifies the number of components in a state for a Gaussian mixture HMM (GM HMM), where *number* must be a positive integer. This option applies only when you specify TYPE=GAUSSIANMIXTURE. By default, NCOMPONENT=1.

NOCURRENTX

suppresses the present values of the exogenous variables. This option applies only when you specify TYPE=AR or TYPE=REG.

NOINT

suppresses the constant (intercept) parameters. This option applies only when you specify TYPE=AR or TYPE=REG.

NSEASON=s

specifies the number of seasonal periods (where *s* must be a positive integer) and adds (*s*−1) seasonal dummies to the regressors. This option applies only when you specify TYPE=AR or TYPE=REG and do not specify the NOINT option.

NSTATE=number1 < : number2 >

specifies the number or the range of numbers of hidden states, where *number1* and *number2* must be positive integers. If you specify NSTATE=*number1*, the number of hidden states is *number1*; if you specify NSTATE=*number1:number2*, multiple models whose number of hidden states is inclusively between *number1* and *number2* are estimated and inferred. If you specify the same number for both *number1* and *number2*, *number2* is ignored. By default, NSTATE=2.

SCENTER

centers seasonal dummies that are implied by the NSEASON= option. The centered seasonal dummies are generated by $c - \frac{1}{s}$, where c is a seasonal dummy that the NSEASON= s option generates. This option applies only when you specify the NSEASON= option and TYPE=AR or TYPE=REG.

STATEINDEPENDENT=(name-list)

specifies the parameters to be estimated independent of state. The names of the independent parameters are entered in the *name-list* in parentheses. The names that can appear in the *name-list* are ISPV, TPM, MCP, CPM, MU, SIGMA, CONST, SDUMMY, LTREND, QTREND, XL, AR, and COV. Table 20.4 gives the meanings of these names. This option does not support inputting the component index after the parameter names. For example, it supports COV but not COV(1,1,1). The name ISPV is ignored unless ESTISPV is also specified. Any parameters that are not in the model are ignored. Currently this option does not support ALGORITHM=SGD in the OPTIMIZE statement. The estimates are ordered by the names specified in the *name-list*.

To see how this option works, consider the following univariate bistate Gaussian HMM, which is described by the parameters $\{\pi, \mathbf{A}, \mathbf{B}\}$, where π is the initial state probability vector, $\mathbf{A}$ is the transition probability matrix, $\mathbf{B} \equiv \{\mu_1, \Sigma_1, \mu_2, \Sigma_2\}$, μ_1 and Σ_1 are the mean and covariance parameters for state 1, and μ_2 and Σ_2 are the mean and covariance parameters for state 2. STATEINDEPENDENT=(SIGMA) estimates the model with $\Sigma_1 = \Sigma_2$. The following statement specifies this option:

```
model y / stateindependent=(sigma);
```

For more details and an example, see “[Example 20.3: Analysis of the Business Cycle by Using the Regime-Switching Mean-Adjusted Autoregression Model](#)” on page 1395.

TREND=LINEAR | QUAD

specifies the degree of deterministic time trend that the model includes. You can specify the following values:

LINEAR	includes a linear time trend as a regressor.
QUAD	includes linear and quadratic time trends as regressors.

This option applies only when you specify TYPE=AR or TYPE=REG.

TYPE=AR | FINITE | GAUSSIAN | GAUSSIANMIXTURE | POISSON | REG

specifies the type of the model of interest to use. You can specify the following values:

AR	uses the regime-switching autoregression model (RS-AR, also known as the autoregressive hidden Markov model, AR HMM).
FINITE	uses the finite hidden Markov model (finite HMM).
GAUSSIAN	uses the Gaussian hidden Markov model (Gaussian HMM).
GAUSSIANMIXTURE	uses the Gaussian mixture hidden Markov model (GM HMM).
POISSON	uses the Poisson hidden Markov model (Poisson HMM).
REG	uses the regime-switching regression model (RS-REG, also known as the regression hidden Markov model, REG HMM).

By default, TYPE=GAUSSIAN.

XLAG=number

specifies the lags of exogenous (independent) variables. To exclude the present values of exogenous variables from the model, you must specify the NOCURRENTX option. This option applies only when you specify TYPE=AR or TYPE=REG. By default, XLAG=0.

YLAG=number1 < : number2 >

specifies the order or the range of orders of the autoregressive process, where *number1* and *number2* must be nonnegative integers. If you specify YLAG=*number1*, the order of the autoregressive process is *number1*; if you specify YLAG=*number1:number2*, multiple models whose order of the autoregressive process is inclusively between *number1* and *number2* are estimated and inferred. If you specify the same number for both *number1* and *number2*, *number2* is ignored. This option applies only when you specify TYPE=AR. By default, YLAG=0.

OPTIMIZE Statement

OPTIMIZE < *options* > ;

The OPTIMIZE statement optimizes the parameter estimation.

You can specify the following *options*:

ALGORITHM=type < (suboptions) >

specifies the optimization algorithm to use. You can specify the following *types*:

ACTIVESET < (suboptions) >

uses the active set algorithm. You can specify one or more of the following *suboptions* in parentheses:

FEASTOL=number

defines the feasible tolerance. The optimizer exits if the constraint violation is less than *number* and the scaled optimality conditions are less than the value of the OPTTOL= suboption. By default, FEASTOL= 10^{-6} .

MSRANGE=number

defines the range from which each variable can take values during the sampling process in multistart mode, where *number* is a positive number. This option is ignored if MULTI-START=0. This option affects only the sampling process that determines starting points for the local solver. It does not affect the bounds of the original nonlinear optimization problem. By default, MSRANGE=2.

MULTISTART=0 | 1 | (suboptions)

specifies whether to enable multistart mode or specifies *suboptions* to enable the distributed multistart mode. You can specify the following values:

- 0** disables multistart mode.
- 1** solves the problem from multiple starting points, possibly finding a better local optimum as a result. The computing cost in multistart mode might be huge.

By default, MULTISTART=0.

The following *suboptions*, which are specified in parentheses, are supported only in distributed (MPP) mode. If you specify empty parentheses, these *suboptions* are assigned their default values.

FESESSIONS=number

specifies the number of CAS subsessions that are dedicated to the function evaluations, where *number* is a positive integer. The default value is based on the setting of the CAS session.

FESESSNODES=number

specifies the number of computing nodes in each CAS subsession that are dedicated to the function evaluations, where *number* is a positive integer. The default value is based on the setting of the CAS session.

MAXSTARTS=number

specifies the maximum number of starting points to be used by the multistart algorithm, where *number* is a positive integer. By default, MAXSTARTS=100.

SAMPSELRATIO=number

specifies the ratio of the total number of sample points to be generated to the value of the MAXSTARTS= option, where *number* is a positive integer. By default, SAMPSELRATIO=20.

SESSNODES=number

specifies the number of computing nodes in the CAS session that are dedicated to the multistart algorithm, where *number* is a positive integer. The default value is based on the setting of the CAS session.

OBJLIMIT=number

specifies an upper limit on the magnitude of the objective value, where *number* is greater than or equal to 10^8 . If OBJLIMIT= M , the algorithm terminates when the objective value becomes less than $-M$ for a minimization problem or when the objective value exceeds M for a maximization problem. The termination of the algorithm implies that either the problem is unbounded or the algorithm diverges. If optimization were allowed to continue, numerical difficulty might be encountered. By default, OBJLIMIT= 10^{20} . If *number* is less than 10^8 , it is reset to the default value of 10^{20} .

OPTTOL= ϵ

specifies the measure by which the current iterate is determined to be an acceptable approximation of a local optimum, where ϵ is a positive real number. The optimizer determines that the current iterate is a local optimum when the norm of the scaled vector of the optimality conditions is less than ϵ and the true constraint violation is less than the value of the FEASTOL= option. By default, OPTTOL= 10^{-6} .

SOLTYPE=0 | 1

specifies the type of solution that the optimizer should return. You can specify the following values:

- 0** requests that the optimizer return a locally optimal solution, provided that it locates one.
- 1** requests that the optimizer return the best feasible solution that was found, provided that its objective value is better than that of the locally optimal solution that was found.

By default, SOLTYPE=1.

EM <(suboption)>

uses the expectation-maximization (EM) algorithm. This algorithm is supported only for the Gaussian HMM and the maximum likelihood method. You can specify the following *suboption* in parentheses:

MINITER=number

specifies the minimum number of iterations in the optimization process, where *number* must be a nonnegative integer. By default, MINITER=0.

SINGLE

executes the EM algorithm in a single thread on a single node. By default, the EM algorithm runs in parallel on multiple threads and nodes if you divide the data into sections and specify the SECTION= option in the ID statement.

INTERIORPOINT <(suboptions)>

uses the interior point algorithm. You can specify the same *suboptions* in parentheses that you can specify for ALGORITHM=ACTIVESET.

IPDIRECT <(suboptions)>

uses the interior point direct algorithm, in which the use of direct factorizations and other enhancements can reduce both the number of iterations and the CPU time for many problem types. You can specify the same *suboptions* in parentheses that you can specify for ALGORITHM=INTERIORPOINT.

SGD <(suboptions)>

uses the stochastic gradient descent algorithm. You can specify one or more of the following *suboptions* in parentheses:

ADAPTIVEDECAY=number

specifies the adaptive rate for the gradient descent algorithm when it is used, where the algorithm becomes ADAGRAD if ADAPTIVEDECAY=0 and becomes ADADELTA otherwise. By default, ADAPTIVEDECAY=0.95.

ANNEALINGRATE=number

specifies the annealing parameter, β , where *number* must be a nonnegative double. Annealing is a way to automatically reduce the learning rate as SGD progresses, causing smaller steps as SGD approaches a solution. Effectively, this option replaces the learning rate parameter, η , with

$$\eta' = \frac{\eta}{1 + \beta t}$$

where t is the number of iterations that SGD has performed. By default, ANNEALINGRATE= 10^{-5} .

CHAIN=(options)

specifies the options for the sequence data (which constitute a chain). You can specify the following *options* within parentheses:

LENGTH=number

specifies the length of a chain in a minibatch in optimization process, where *number* must be a positive integer. By default, LENGTH=1000.

BUFFER=number

specifies the buffer length on the left side of a chain in a minibatch in optimization process, where *number* must be a nonnegative integer. By default, BUFFER=20.

LEARNINGRATE=number

specifies the learning rate parameter, η , for SGD, where *number* must be a positive double. New iterates for SGD are found by using

$$\theta_{k+1} = \theta_k - \frac{\eta}{\|I_k\|} \sum_{(x_i, y_i) \in I_k} \nabla L(\theta_k; x_i, y_i)$$

where θ_k is the current weight vector, θ_{k+1} is the new weight vector, I_k is the minibatch that is used during iteration k , and $L(\theta_k; x_i, y_i)$ is the negative log likelihood that is associated with the i th chain of observation. If you see a huge objective value with SGD (especially with a small data table), it is likely that too large a value was specified for this option. By default, LEARNINGRATE=10.

MINIBATCHSIZE=number

specifies the size of the minibatches used in SGD, where *number* must be a positive integer. By default, MINIBATCHSIZE=1.

MOMENTUM=number

specifies the value for momentum parameter α , where *number* must be greater than or equal to 0 and less than 1. New iterates for SGD that uses the momentum method are found by using

$$\begin{aligned} \theta_{k+1} &= \theta_k + \nabla \theta_k \\ \nabla \theta_k &= \alpha \nabla \theta_k - \frac{\eta}{\|I_k\|} \sum_{(x_i, y_i) \in I_k} \nabla L(\theta_k; x_i, y_i) \end{aligned}$$

where θ_k is the current weight vector, θ_{k+1} is the new weight vector, I_k is the minibatch that is used during iteration k , and $L(\theta_k; x_i, y_i)$ is the negative log likelihood that is associated with the i th chain of observation. By default, MOMENTUM=0.

NONADUPDATE

suppresses the adaptive gradient descent algorithm.

USELOCKING

requests that computational threads share a common weight vector and that they update the weight vector without race conditions. By default, computational threads update a single weight vector simultaneously. This causes intentional race conditions and nondeterministic behavior, but it increases performance significantly.

By default, ALGORITHM=ACTIVESET.

COVOFPARM=YES | NO

specifies whether to calculate the covariance of parameters. You can specify the following values:

YES calculates the covariance of parameters.

NO suppresses the calculation of the covariance of parameters.

By default, COVOFPARM=YES. This option supports only the EM algorithm.

MAXITER=number

specifies the maximum number of iterations in the optimization process, where *number* must be a nonnegative integer. By default, MAXITER=128.

MAXTIME=t

specifies an upper limit of *t* seconds for the optimization process, including problem generation time and solution time, where *t* can be any positive number. The default value of *t* is the positive number that has the largest absolute value that your operating environment can represent. If you omit this option, the optimizer does not stop on the basis of the amount of time elapsed. This option is not supported for the EM algorithm.

PRINTITERFREQ=number

specifies how frequently to output the optimization process history, where *number* must be a nonnegative integer. If PRINTITERFREQ=0, no iterations are output. If *number*=*n* and *n* is positive, the optimization process history is output every *n* iterations. By default, PRINTITERFREQ=0.

PRINTLEVEL=0 | 1 | 2 | 3

specifies the print level. You can specify the following values:

0 suppresses output of the initial parameter values, the initial objective value, the algorithm information, the final parameter values, and the final objective value.

1 outputs the initial parameter values and the initial objective value.

2 outputs the initial parameter values, the initial objective value, and the algorithm information.

3 outputs the initial parameter values, the initial objective value, the algorithm information, the final parameter values, and the final objective value.

By default, PRINTLEVEL=0.

PRIOR Statement

PRIOR *distribution* < , . . . , *distribution* > ;

The PRIOR statement specifies the initial hyperparameter values in the prior distributions of the parameters when the maximum a posteriori method is applied to the estimation of the HMM (that is, when METHOD=MAP in the MODEL statement). If you specify the maximum likelihood (ML) method (METHOD=ML), the PRIOR statement is ignored. You can specify only one PRIOR statement. If you specify more than one *distribution*, separate them with commas.

If you specify the NSTATE= n_1 : n_2 option or the YLAG= m_1 : m_2 option (or both) in the MODEL statement to estimate multiple models, the PRIOR statement is applied to the first model that corresponds to the specification of NSTATE= n_1 or YLAG= m_1 (or that corresponds to both NSTATE= n_1 and YLAG= m_1 if both options are specified).

To use the PRIOR statement, you need to know the type of the model: different sets of prior distributions are available for different types of HMMs.

The *distribution* is in the following format:

parameter-name ~ *distribution-function*(*arguments*) ;

You can specify the following *parameter-names*:

CPM	indicates the category probability matrix in the finite HMM. The prior distribution must be the Dirichlet distribution.
ISPV	indicates the initial state probability vector. The prior distribution must be the Dirichlet distribution.
LAMBDA	indicates the mean vector in the Poisson HMM. The prior distribution must be the gamma distribution.
MCP	indicates the mixture component probabilities in the Gaussian mixture HMM (GM HMM). The prior distribution must be the Dirichlet distribution.
MUSIGMA	indicates the mean and covariance parameters for the observation distributions. For the Gaussian HMM, regime-switching regression model, or regime-switching autoregression model, the prior distribution of the mean and covariance parameters for each state must be the normal-inverse-Wishart (NIW) distribution. For the GM HMM, the prior distribution of the mean and covariance parameters for each component at each state must be the normal-inverse-Wishart (NIW) distribution.
TPM	indicates the transition probability matrix. The prior distribution must be the Dirichlet distribution.

You can specify the following *distribution-functions*:

DIR	specifies the Dirichlet distribution. There is one <i>argument</i> for the Dirichlet distribution, and it must be a valid matrix expression of the proper size. For example, if the Dirichlet distribution is the prior distribution of the ISPV, MCP, CPM or TPM, the size of the <i>argument</i> must be the same as the size of the ISPV, MCP, CPM or TPM. All elements of the <i>argument</i> should be positive. If you specify any nonpositive element in the <i>argument</i> ,
------------	---

the nonpositive element is changed to the machine precision. For information about how to define the matrix expressions, see the section “[Matrix Expression](#)” on page 1311. For more information about the Dirichlet distribution, see the section “[Maximum a Posteriori \(MAP\) Method](#)” on page 1304.

GAMMA

specifies the gamma distribution. There are two *arguments* (α, β) for the gamma distribution, and they must be a valid matrix expression of the proper size. The size of the *arguments* must be a $K \times 2$ matrix. All elements of the *arguments* should be positive. If you specify any nonpositive element in the *argument*, the nonpositive element is changed to the machine precision. For information about how to define the matrix expressions, see the section “[Matrix Expression](#)” on page 1311. For more information about the gamma distribution, see the section “[Maximum a Posteriori \(MAP\) Method](#)” on page 1304.

NIW

specifies the normal-inverse-Wishart (NIW) distribution. There are four *arguments* for the NIW distribution ($\tilde{\mu}$, $\tilde{\Sigma}$, $\tilde{\kappa}$, and $\tilde{\nu}$), and they must be valid matrix expressions of the proper size. If the NIW distribution is the prior distribution of the MUSIGMA for Gaussian HMM, then the following statements are true:

- $\tilde{\mu}$ is a $K \times k_y$ matrix, where K is the number of states, and k_y is the number of dependent variables.
- $\tilde{\Sigma}$ is a $k_y K \times k_y$ matrix.
- $\tilde{\kappa}$ is a $K \times 1$ vector.
- $\tilde{\nu}$ is a $K \times 1$ vector.

If the NIW distribution is the prior distribution of the MUSIGMA for GM HMM, then the following statements are true:

- $\tilde{\mu}$ is a $KM \times k_y$ matrix, where K is the number of states, M is the number of components at a state, and k_y is the number of dependent variables.
- $\tilde{\Sigma}$ is a $k_y KM \times k_y$ matrix.
- $\tilde{\kappa}$ is a $KM \times 1$ vector.
- $\tilde{\nu}$ is a $KM \times 1$ vector.

If the NIW distribution is the prior distribution of the MUSIGMA for regime-switching regression or regime-switching autoregression, then the following statements are true:

- $\tilde{\mu}$ is a $K \times k_y k_z$ matrix, where K is the number of states, k_y is the number of dependent variables, and k_z is the number of regressors in each equation. (For more information about how to calculate k_z , see the sections “[Regime-Switching Regression Model](#)” on page 1273 and “[Regime-Switching Autoregression Model](#)” on page 1274.)
- $\tilde{\Sigma}$ is a $k_y K \times k_y$ matrix.
- $\tilde{\kappa}$ is a $k_z K \times k_z$ matrix.
- $\tilde{\nu}$ is a $K \times 1$ vector.

For information about how to define the matrix expressions, see the section “[Matrix Expression](#)” on page 1311. For more information about the normal-inverse-Wishart (NIW) distribution, see the section “[Maximum a Posteriori \(MAP\) Method](#)” on page 1304.

The following statements specify the PRIOR statement for the ISPV, TPM, and MUSIGMA in a bivariate three-state Gaussian HMM:

```

proc hmm data=mylib.One;
  id time=t;
  model x y / type=gaussian nstate=3 estispv method=map;
  prior ISPV ~ dir(J(3,1,1)),
          TPM ~ dir(I(3)*100+J(3,3,1)),
          MUSIGMA ~ niw(J(1,2,-1) // J(1,2,0) // J(1,2,1),
                        J(3,1,1)@(I(2)*10),
                        5*J(3,1,1),
                        10*J(3,1,1));
run;

```

SCORE Statement

SCORE *options* ;

The SCORE statement specifies options that are related to scoring data. You can specify the following *options*:

INMODEL=*libref.data-table*

specifies the input data table for model information. The data table must be an output data table that is produced by the OUTMODEL= option in a previous call of the HMM procedure. When you specify this option, the IN= option in the ESTIMATE statement and the ID, INITIAL, MODEL, OPTIMIZE, and PRIOR statements are ignored. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the DATA= option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1186.

OUTMODEL=*libref.data-table*

writes the model information to the specified output data table. The output data table consists of binary large object columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters because the data type of each column is binary. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1186.

SMOOTH Statement

SMOOTH *option* ;

The SMOOTH statement specifies options that are related to the smoothing problem, which is to find the probability distribution of the state, conditional on all available observations. You can specify the following *option*:

OUT=*libref.data-table*

writes the smoothing results to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1186.

STORE Statement

STORE < **OUT=** >*libref.data-table* ;

The STORE statement saves the model information to the specified output data table that can be processed by the ASTORE procedure. An example of using analytic store technology is to perform a time-consuming model learning (that is, parameter estimation) and to store the learned model by using the STORE statement. Later you can perform the inference (namely, evaluating, filtering, smoothing, decoding, and forecasting) based on the saved model from the previous analysis, without having to learn the model again. For more information about the ASTORE procedure, see the chapter “The ASTORE Procedure” in *SAS Viya: Machine Learning Procedures*. The output data table consists of binary large object columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters, because the data type of each column is binary.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section “Using CAS Sessions and CAS Engine Librefs” on page 1186.

Details: HMM Procedure

Hidden Markov Model

This section is a brief review of the hidden Markov model. For more information, see Rabiner (1989), Krolzig (1997), Frühwirth-Schnatter (2006), and Cappé, Moulines, and Rydén (2010).

The hidden Markov model (HMM) is a bivariate discrete time process $\{\mathbf{S}_t, \mathbf{Y}_t\}$, where $\{\mathbf{S}_t\}$ is a (hidden) Markov chain; conditional on $\{\mathbf{S}_t\}$, the observable process $\{\mathbf{Y}_t\}$ is a sequence of independent random variables such that the conditional distribution of $\mathbf{Y}_t$ depends only on $\mathbf{S}_t$. The $\mathbf{S}_t$ is often called the state. In general, the HMM can be expressed in three equations:

1. Initialization equation: $\mathbf{S}_1 \sim h_\theta(\cdot)$
2. Transition equation: $\mathbf{S}_t \sim f_\theta(\cdot|\mathbf{S}_{t-1})$
3. Observation equation: $\mathbf{Y}_t \sim g_\theta(\cdot|\mathbf{S}_t)$

Here the initial probability distribution function $h_\theta(\cdot)$ is the probability distribution function for initial state $\mathbf{S}_1$; the transition probability distribution function $f_\theta(\cdot|\mathbf{S}_{t-1})$ is the probability distribution function of current state $\mathbf{S}_t$ conditional on the past state $\mathbf{S}_{t-1}$; the observation probability distribution function $g_\theta(\cdot|\mathbf{S}_t)$ is the probability distribution function of current observation $\mathbf{Y}_t$ conditional on the current state $\mathbf{S}_t$; and all probability distribution functions might depend on the parameter θ .

There is no restriction on the dimensionality of $\mathbf{S}_t$ and $\mathbf{Y}_t$; that is, they might be scalars, vectors, or matrices.

If the transition probability distribution function $f_\theta(\cdot|\cdot)$ is time-independent (that is, the Markov chain is time-homogeneous), then the HMM is called the (time-)homogeneous HMM; otherwise, the HMM is called the (time-)inhomogeneous HMM.

The state $\mathbf{S}_t$ could take discrete or continuous values or even a mix of discrete and continuous values.² In the simplest and most popular case, $\mathbf{S}_t$ is a scalar and takes finite discrete values; that is, $\mathbf{S}_t \in \{1, \dots, K\}$. In this case, the HMM could be called the finite-state-space HMM.

For the finite-state-space HMM, the initial state distribution function $h_\theta(\cdot)$ can be expressed as a $K \times 1$ vector π , which is called the initial state probability vector (ISPV); that is,

$$\pi = \{\pi_i = p(\mathbf{S}_1 = i), i = 1, \dots, K\}$$

For the finite-state-space and homogeneous HMM, the transition probability distribution function $f_\theta(\cdot|\cdot)$ can be expressed as a $K \times K$ matrix $\mathbf{A}$, which is called the transition probability matrix (TPM), where an element a_{ij} of $\mathbf{A}$ denotes the probability transitioning from past state i to current state j ; that is,

$$a_{ij} = p(\mathbf{S}_t = j | \mathbf{S}_{t-1} = i)$$

There are six common problems to solve for an HMM:

²In some literature, the HMM is referred to only as the discrete-state-space HMM (that is, the state can take only discrete values). The name “state space model” is used for the continuous-state-space HMM (that is, the state can take only continuous values).

- Filtering problem: What is $p(\mathbf{S}_t | \mathbf{Y}_1, \dots, \mathbf{Y}_t)$, the probability distribution of state $\mathbf{S}_t$ given observations $\mathbf{Y}_1, \dots, \mathbf{Y}_t$?
- Smoothing problem: What is $p(\mathbf{S}_t | \mathbf{Y}_1, \dots, \mathbf{Y}_T)$, the probability distribution of state $\mathbf{S}_t$ given observations $\mathbf{Y}_1, \dots, \mathbf{Y}_T$, where T is the sample size?
- Forecasting problem: What is $p(\mathbf{S}_{t+h} | \mathbf{Y}_1, \dots, \mathbf{Y}_t)$, $h > 0$, the probability distribution of state $\mathbf{S}_{t+h}$ given observations $\mathbf{Y}_1, \dots, \mathbf{Y}_t$?
- Evaluating problem: What is $p(\mathbf{Y}_1, \dots, \mathbf{Y}_T)$, the probability (or the likelihood) of observations $\mathbf{Y}_1, \dots, \mathbf{Y}_T$?
- Decoding problem: What is $\arg \max_{\mathbf{S}_1, \dots, \mathbf{S}_T} p(\mathbf{S}_1, \dots, \mathbf{S}_T, \mathbf{Y}_1, \dots, \mathbf{Y}_T)$, the most likely sequence of hidden states $\mathbf{S}_1, \dots, \mathbf{S}_T$ given observations $\mathbf{Y}_1, \dots, \mathbf{Y}_T$, where T is the sample size?
- Learning problem: How do you estimate the unknown parameter θ given observations $\mathbf{Y}_1, \dots, \mathbf{Y}_T$, where T is the sample size?

In most cases, the learning problem is the most difficult one. You might apply the maximum likelihood (ML) method or the maximum a posteriori (MAP) method to get the point estimate of parameter θ . For more information, see the section “[Parameter Estimation Methods](#)” on page 1304.

Several algorithms are helpful in solving the problems for the HMMs. Three of them are the forward algorithm, the backward algorithm, and the Viterbi algorithm. They might be generalized to support many types of HMMs. The following sections focus on applying them to the finite-state-space and homogeneous HMM.

Forward Algorithm

The forward algorithm recursively calculates the joint probability distribution of a state at time t , $\mathbf{S}_t$, and all observations up to time t , $\mathbf{Y}_1, \dots, \mathbf{Y}_t$. First, define $\alpha_t(i)$, $i = 1, \dots, K$, as the joint probability of $(\mathbf{S}_t = i)$ and $\mathbf{Y}_1, \dots, \mathbf{Y}_t$:

$$\alpha_t(i) \equiv p(\mathbf{S}_t = i, \mathbf{Y}_1, \dots, \mathbf{Y}_t)$$

Then, $\alpha_t(i)$ can be recursively calculated by the following steps:

1. Calculate $\alpha_1(i)$, $i = 1, \dots, K$, by

$$\alpha_1(i) = \pi_i g_\theta(\mathbf{Y}_1 | \mathbf{S}_1 = i)$$

2. Calculate $\alpha_t(i)$, $i = 1, \dots, K$, $t = 2, \dots, T$, by

$$\alpha_t(i) = \left(\sum_{j=1}^K \alpha_{t-1}(j) a_{ji} \right) g_\theta(\mathbf{Y}_t | \mathbf{S}_t = i)$$

You can solve the evaluating problem by

$$L_t \equiv p(\mathbf{Y}_1, \dots, \mathbf{Y}_t) = \sum_{j=1}^K \alpha_t(j)$$

Because the likelihood of all observations, L_T , can be calculated, you can apply the maximum likelihood method to estimate the unknown parameter θ ; if the prior distribution of the parameter θ is given, you can also apply the MAP method. That is, you might use the forward algorithm in the learning problem.

You can solve the filtering problem by

$$p_t^{(f)}(i) \equiv p(\mathbf{S}_t = i | \mathbf{Y}_1, \dots, \mathbf{Y}_t) = \alpha_t(i) / L_t$$

When the filtering problem is solved, you can solve the forecast problem, because the h -step-ahead prediction of the state probability can be calculated by

$$p_{t+h|t}^{(p)} = (\mathbf{A}')^h p_t^{(f)}$$

where $p_t^{(f)}$ is the $K \times 1$ vector with the i th element as $p_t^{(f)}(i)$, and $p_{t+h|t}^{(p)}$ is the $K \times 1$ vector with the i th element as $p_{t+h|t}^{(p)}(i)$:

$$p_{t+h|t}^{(p)}(i) \equiv p(\mathbf{S}_{t+h} = i | \mathbf{Y}_1, \dots, \mathbf{Y}_t)$$

The distribution of $\mathbf{Y}_{t+h}$ conditional on observations $\mathbf{Y}_1, \dots, \mathbf{Y}_t$ is the following mixture distribution:

$$\mathbf{Y}_{t+h} | \mathbf{Y}_1, \dots, \mathbf{Y}_t \sim \sum_{i=1}^K p_{t+h|t}^{(p)}(i) g_{\theta}(\cdot | \mathbf{S}_{t+h} = i)$$

Backward Algorithm

To solve the smoothing problem, in addition to the forward algorithm, you also need the backward algorithm. Define $\beta_t(i)$ as the probability of observing the future observations $\mathbf{Y}_{t+1}, \dots, \mathbf{Y}_T$ conditional on the current state $\mathbf{S}_t = i$:

$$\beta_t(i) \equiv p(\mathbf{Y}_{t+1}, \dots, \mathbf{Y}_T | \mathbf{S}_t = i)$$

The backward algorithm recursively calculates $\beta_t(i)$ as follows:

1. Set $\beta_T(i) = 1, i = 1, \dots, K$.
2. Calculate $\beta_t(i), i = 1, \dots, K, t = T - 1, \dots, 1$, by

$$\beta_t(i) = \sum_{j=1}^K a_{ij} g_{\theta}(\mathbf{Y}_{t+1} | \mathbf{S}_{t+1} = j) \beta_{t+1}(j)$$

When you calculate both $\alpha_t(i)$ and $\beta_t(i)$, $i = 1, \dots, K$, $t = 1, \dots, T$, by using the forward algorithm and backward algorithm, the smoothing problem is solved, because you can calculate the probability of state $\mathbf{S}_t$ taking value i given all observations $\mathbf{Y}_1, \dots, \mathbf{Y}_T$ as follows:

$$\gamma_t(i) \equiv p(\mathbf{S}_t = i | \mathbf{Y}_1, \dots, \mathbf{Y}_T) = \frac{\alpha_t(i)\beta_t(i)}{\sum_{j=1}^K \alpha_t(j)\beta_t(j)}$$

Viterbi Algorithm

You use the Viterbi algorithm to solve the decoding problem. First, define the highest probability of a single state path ending in state $\mathbf{S}_t = i$ and observations $\mathbf{Y}_1, \dots, \mathbf{Y}_t$ as follows:

$$V_t(i) = \max_{\mathbf{S}_1, \dots, \mathbf{S}_{t-1}} p(\mathbf{S}_1, \dots, \mathbf{S}_{t-1}, \mathbf{S}_t = i, \mathbf{Y}_1, \dots, \mathbf{Y}_t)$$

To keep track of the best path, for $t = 2, \dots, T$, define

$$v_t(i) = \arg \max_j V_{t-1}(j) a_{ji}$$

Then, $V_t(i)$ and $v_t(i)$ can be recursively calculated as follows:

1. Calculate $V_1(i)$, $i = 1, \dots, K$, by

$$V_1(i) = \pi_i g_\theta(\mathbf{Y}_1 | \mathbf{S}_1 = i)$$

2. Calculate $V_t(i)$ and $v_t(i)$, $i = 1, \dots, K$, $t = 2, \dots, T$, by

$$\begin{aligned} V_t(i) &= \left(\max_j V_{t-1}(j) a_{ji} \right) g_\theta(\mathbf{Y}_t | \mathbf{S}_t = i) \\ v_t(i) &= \arg \max_j V_{t-1}(j) a_{ji} \end{aligned}$$

Then, the probability of the best path is

$$V^* = \max_i V_T(i)$$

Define $v_T^* = \arg \max_i V_T(i)$, and the best state path can be backtracked by

$$v_t^* = v_{t+1}(v_{t+1}^*), t = T-1, \dots, 1$$

That is, $\{v_t^*\}_{t=1, \dots, T}$ is the best state path. The decoding problem is solved.

Gaussian Hidden Markov Model

The Gaussian hidden Markov model (Gaussian HMM) is a type of finite-state-space and homogeneous HMM where the observation probability distribution is the normal distribution,

$$\mathbf{Y}_t | \mathbf{S}_t \sim N(\mu_{\mathbf{S}_t}, \Sigma_{\mathbf{S}_t})$$

where $\mu_{\mathbf{S}_t}$ and $\Sigma_{\mathbf{S}_t}$ are mean and covariance parameters at state $\mathbf{S}_t$, $\mathbf{S}_t = 1, \dots, K$. Hence, the initial state probability vector (ISPV) π , the transition probability matrix (TPM) $\mathbf{A}$, and the observation parameter $\mathbf{B}$ ($\equiv \{\mu_i, \Sigma_i\}_{i=1, \dots, K}$, which consists of mean and covariance parameters) together specify the Gaussian HMM; that is, the parameter θ of the Gaussian HMM is $\{\pi, \mathbf{A}, \mathbf{B}\}$.

Because the Gaussian HMM is a type of finite-state-space and homogeneous HMM, the six common problems—the filtering, smoothing, forecasting, evaluating, decoding, and learning problems—can be solved using the three algorithms introduced in the section “[Hidden Markov Model](#)” on page 1268. That is, you can solve the evaluating, filtering, and forecasting problems by using the forward algorithm; the smoothing problem by using the forward algorithm and backward algorithm; the decoding problem by using the Viterbi algorithm; and the learning problem, if solved through the maximum likelihood or maximum a posteriori method, by using the forward algorithm to calculate the likelihood.

Gaussian Mixture Hidden Markov Model

The Gaussian mixture hidden Markov model (GM HMM) is a type of finite-state-space and homogeneous HMM in which the observation probability distribution is the Gaussian mixture distribution,

$$\mathbf{Y}_t | \mathbf{S}_t \sim \text{GM}(\{w_{\mathbf{S}_t,1}, \dots, w_{\mathbf{S}_t,M}\}, \{\mu_{\mathbf{S}_t,1}, \dots, \mu_{\mathbf{S}_t,M}\}, \{\Sigma_{\mathbf{S}_t,1}, \dots, \Sigma_{\mathbf{S}_t,M}\})$$

where the variable $\mathbf{S}_t$ is the (hidden) state; $\text{GM}(\dots)$ represents the Gaussian mixture distribution; M is the number of components at each state; and the $w_{\mathbf{S}_t,j}$, $j = 1, \dots, M$, are mixture component probabilities (MCPs, also called mixture weights), which satisfy the basic requirement for weights ($w_{\mathbf{S}_t,j} \geq 0$, $j = 1, \dots, M$, and $\sum_{j=1}^M w_{\mathbf{S}_t,j} = 1$). The $\mu_{\mathbf{S}_t,j}$ and $\Sigma_{\mathbf{S}_t,j}$, $j = 1, \dots, M$, are the mean and covariance parameters for the j th Gaussian component at state $\mathbf{S}_t$, and their values depend on the variable $\mathbf{S}_t$. Hence, the initial state probability vector (ISPV) π , the transition probability matrix (TPM) $\mathbf{A}$, and the observation parameter $\mathbf{B}$ ($\equiv \{w_{ij}, \mu_{ij}, \Sigma_{ij}, i = 1, \dots, K, j = 1, \dots, M\}$, which consists of the mixture component probabilities, the mean and covariance parameters for all components) together specify the GM HMM; that is, the parameter θ of the GM HMM is $\{\pi, \mathbf{A}, \mathbf{B}\}$.

Because the GM HMM is a type of finite-state-space and homogeneous HMM, the six common problems—the filtering, smoothing, forecasting, evaluating, decoding, and learning problems—can be solved using the three algorithms that are introduced in the section “[Hidden Markov Model](#)” on page 1268. That is, you can solve the evaluating, filtering, and forecasting problems by using the forward algorithm; the smoothing problem by using the forward algorithm and backward algorithm; the decoding problem by using the Viterbi algorithm; and the learning problem, if solved through the maximum likelihood or maximum a posteriori method, by using the forward algorithm to calculate the likelihood.

Regime-Switching Regression Model

The regime-switching regression model (RS REG, also known as the regression hidden Markov model or REG HMM) is a type of finite-state-space and homogeneous HMM in which the observation probability distribution is the normal distribution conditional on the specified regressors,

$$\mathbf{Y}_t | z_t, \mathbf{S}_t \sim N(\mathbf{B}_{\mathbf{S}_t} z_t, \Sigma_{\mathbf{S}_t})$$

where the variable $\mathbf{S}_t$ is the (hidden) state; $\mathbf{B}_{\mathbf{S}_t}$ and $\Sigma_{\mathbf{S}_t}$ are the mean and covariance parameters, respectively, at state $\mathbf{S}_t$, $\mathbf{S}_t = 1, \dots, K$. Hence, the initial state probability vector (ISPV) π , the transition probability matrix (TPM) $\mathbf{A}$, and the observation parameter $\mathbf{B}$ ($\equiv \{\mathbf{B}_i, \Sigma_i\}_{i=1, \dots, K}$, which consists of mean and covariance parameters) together specify the RS REG; that is, the parameter θ of the RS REG is $\{\pi, \mathbf{A}, \mathbf{B}\}$.

Let k_z denote the number of regressors. The regressors, a $k_z \times 1$ vector z_t , might contain the constant, seasonal dummies, linear time trend, quadratic time trend, and exogenous variables and their lagged values. That is,

$$z_t = \left(\left(z_t^{(\text{CONST})} \right)' \left(z_t^{(\text{SD})} \right)' \left(z_t^{(\text{LTREND})} \right)' \left(z_t^{(\text{QTREND})} \right)' \left(z_t^{(\text{XL})} \right)' \right)'$$

where

- $z_t^{(\text{CONST})}$ is empty if the NOINT option is specified; otherwise, $z_t^{(\text{CONST})} = (1)$.
- $z_t^{(\text{SD})}$ is empty if the NSEASON= option is not specified; otherwise, $z_t^{(\text{SD})} = (sd_t^{(1)} \dots sd_t^{(n_s-1)})'$, where $sd_t^{(i)}$, $i = 1, \dots, n_s - 1$, denote the values of seasonal dummies at time t and where n_s is the value specified in the NSEASON= n_s option.
- $z_t^{(\text{LTREND})}$ is empty if the TREND= option is not specified; otherwise, $z_t^{(\text{LTREND})} = (t)$.
- $z_t^{(\text{QTREND})}$ is empty if the TREND=QUAD option is not specified; otherwise, $z_t^{(\text{QTREND})} = (t^2)$.
- $z_t^{(\text{XL})}$ is empty if no exogenous variables are specified in the model, or if the NOCURRENTX option is specified when the XLAG option is not specified or XLAG=0; otherwise, $z_t^{(\text{XL})}$ is determined as follows, where XLAG= s and k_x is the number of exogenous variables:
 - If the NOCURRENTX option is specified,

$$z_t^{(\text{XL})} = (x_{1,t-1} \dots x_{k_x,t-1} \dots x_{1,t-s} \dots x_{k_x,t-s})'$$

- If the NOCURRENTX option is not specified,

$$z_t^{(\text{XL})} = (x_{1,t} \dots x_{k_x,t} \ x_{1,t-1} \dots x_{k_x,t-1} \dots x_{1,t-s} \dots x_{k_x,t-s})'$$

The statement

```
model y = x1 x2 x3 / type=reg nstate=2;
```

defines the regression for state $i, i = 1, \dots, K$ ($K = 2$ in this case), as

$$\begin{aligned} y_t &= b_{i,1} + b_{i,2}x1_t + b_{i,3}x2_t + b_{i,4}x3_t + \varepsilon_t \\ &= (b_{i,1} \ b_{i,2} \ b_{i,3} \ b_{i,4})z_t + \varepsilon_t \end{aligned}$$

where $\varepsilon_t \sim N(0, \Sigma_i)$, $z_t = (1 \ x1_t \ x2_t \ x3_t)'$, and $k_z = 4$.

In the following statement, $z_t = (1 \ sd_t^{(1)} \ sd_t^{(2)} \ sd_t^{(3)} \ t \ t^2 \ x1_t \ x2_t \ x3_t \ x1_{t-1} \ x2_{t-1} \ x3_{t-1})'$, where $sd_t^{(i)}, i = 1, 2, 3$, denote the values of seasonal dummies at time t and where $k_z = 12$:

```
model y = x1 x2 x3 / trend=quad nseason=4 xlag=1 type=reg nstate=2;
```

In the following statement, $z_t = (x1_{t-1} \ x2_{t-1} \ x3_{t-1})'$ and $k_z = 3$:

```
model y = x1 x2 x3 / noint xlag=1 nocurrentx type=reg nstate=2;
```

The number of dependent variables, k_y , can be greater than 1; in that case, $\mathbf{B}_i, i = 1, \dots, K$, is the $k_y \times k_z$ matrix, and $\Sigma_i, i = 1, \dots, K$, is the $k_y \times k_y$ symmetric positive definite matrix.

In the INITIAL statement, the **CONST**, **SD**, **LTREND**, **QTREND**, and **XL** functions refer to the mean parameters that correspond to $z_t^{(\text{CONST})}$, $z_t^{(\text{SD})}$, $z_t^{(\text{LTREND})}$, $z_t^{(\text{QTREND})}$, and $z_t^{(\text{XL})}$, respectively; the **COV** function refers to the covariance parameters $\Sigma = (\Sigma_1 \ \dots \ \Sigma_K)'$, where K is the number of states.

The Gaussian HMM can be regarded as a special case of the RS REG when there is only one regressor constant.

Because the RS REG is a type of finite-state-space and homogeneous HMM, the six common problems—the filtering, smoothing, forecasting, evaluating, decoding, and learning problems—can be solved using the three algorithms introduced in the section “[Hidden Markov Model](#)” on page 1268. That is, you can solve the evaluating, filtering, and forecasting problems by using the forward algorithm; the smoothing problem by using the forward algorithm and backward algorithm; the decoding problem by using the Viterbi algorithm; and the learning problem, if solved through the maximum likelihood or maximum a posteriori method, by using the forward algorithm to calculate the likelihood.

Regime-Switching Autoregression Model

The regime-switching autoregression model (RS AR, also known as the autoregressive hidden Markov model or AR HMM) is a type of finite-state-space and homogeneous HMM in which the observation probability distribution is the normal distribution conditional on the specified regressors. For a standard form of RS AR,

$$\mathbf{Y}_t | z_t, \mathbf{S}_t \sim N(\mathbf{B}_{\mathbf{S}_t} z_t, \Sigma_{\mathbf{S}_t})$$

where the variable $\mathbf{S}_t$ is the (hidden) state; $\mathbf{B}_{\mathbf{S}_t}$ and $\Sigma_{\mathbf{S}_t}$ are mean and covariance parameters at state $\mathbf{S}_t, \mathbf{S}_t = 1, \dots, K$. Hence, the initial state probability vector (ISPV) π , the transition probability matrix (TPM) $\mathbf{A}$, and the parameter $\mathbf{B} (\equiv \{\mathbf{B}_i, \Sigma_i\}_{i=1, \dots, K})$, which consists of mean and covariance parameters) together specify the RS AR; that is, the parameter θ of the RS AR is $\{\pi, \mathbf{A}, \mathbf{B}\}$.

Let k_z denote the number of regressors. The regressors, a $k_z \times 1$ vector z_t , might contain the constant, seasonal dummies, linear time trend, quadratic time trend, exogenous variables and their lagged values, and the lagged values of the dependent variables. That is,

$$z_t = \left(\left(z_t^{(\text{CONST})} \right)' \left(z_t^{(\text{SD})} \right)' \left(z_t^{(\text{LTREND})} \right)' \left(z_t^{(\text{QTREND})} \right)' \left(z_t^{(\text{XL})} \right)' \left(z_t^{(\text{AR})} \right)' \right)'$$

where

- $z_t^{(\text{CONST})}$ is empty if the NOINT option is specified; otherwise, $z_t^{(\text{CONST})} = (1)$.
- $z_t^{(\text{SD})}$ is empty if the NSEASON= option is not specified; otherwise, $z_t^{(\text{SD})} = (sd_t^{(1)} \dots sd_t^{(n_s-1)})'$, where $sd_t^{(i)}, i = 1, \dots, n_s - 1$, denote the values of seasonal dummies at time t and where n_s is the value specified in the NSEASON= n_s option.
- $z_t^{(\text{LTREND})}$ is empty if the TREND= option is not specified; otherwise, $z_t^{(\text{LTREND})} = (t)$.
- $z_t^{(\text{QTREND})}$ is empty if the TREND=QUAD option is not specified; otherwise, $z_t^{(\text{QTREND})} = (t^2)$.
- $z_t^{(\text{XL})}$ is empty if no exogenous variables are specified in the model, or if the NOCURRENTX option is specified when the XLAG option is not specified or XLAG=0; otherwise, $z_t^{(\text{XL})}$ is determined as follows, where XLAG= s and k_x is the number of exogenous variables:
 - If the NOCURRENTX option is specified,

$$z_t^{(\text{XL})} = (x_{1,t-1} \dots x_{k_x,t-1} \dots x_{1,t-s} \dots x_{k_x,t-s})'$$

- If the NOCURRENTX option is not specified,

$$z_t^{(\text{XL})} = (x_{1,t} \dots x_{k_x,t} x_{1,t-1} \dots x_{k_x,t-1} \dots x_{1,t-s} \dots x_{k_x,t-s})'$$

- $z_t^{(\text{AR})}$ is empty if the YLAG= option is not specified or YLAG=0 is specified; otherwise, $z_t^{(\text{AR})}$ is determined as follows, where YLAG= p and k_y is the number of dependent variables:

$$z_t^{(\text{AR})} = (y_{1,t-1} \dots y_{k_y,t-1} \dots y_{1,t-p} \dots y_{k_y,t-p})'$$

The statement

```
model y = x1 x2 x3 / ylag=2 type=ar nstate=2;
```

defines the autoregression for state $i, i = 1, \dots, K$ ($K = 2$ in this case), as

$$\begin{aligned} y_t &= b_{i,1} + b_{i,2}x_{1t} + b_{i,3}x_{2t} + b_{i,4}x_{3t} + b_{i,5}y_{t-1} + b_{i,6}y_{t-2} + \varepsilon_t \\ &= (b_{i,1} \ b_{i,2} \ b_{i,3} \ b_{i,4} \ b_{i,5} \ b_{i,6})z_t + \varepsilon_t \end{aligned}$$

where $\varepsilon_t \sim N(0, \Sigma_i)$, $z_t = (1 \ x_{1t} \ x_{2t} \ x_{3t} \ y_{t-1} \ y_{t-2})'$, and $k_z = 6$.

In the following statement, $z_t = (1 \ sd_t^{(1)} \ sd_t^{(2)} \ sd_t^{(3)} \ t \ t^2 \ x_{1t} \ x_{2t} \ x_{3t} \ x_{1,t-1} \ x_{2,t-1} \ x_{3,t-1} \ y_{t-1} \ y_{t-2})'$, where $sd_t^{(i)}, i = 1, 2, 3$, denote the values of seasonal dummies at time t , and $k_z = 14$:

```
model y = x1 x2 x3 / ylag=2 trend=quad nseason=4 xlag=1 type=reg nstate=2;
```

In the following statement, $z_t = (x1_{t-1} \ x2_{t-1} \ x3_{t-1} \ y1_{t-1} \ y2_{t-1} \ y1_{t-2} \ y2_{t-2})'$ and $k_z = 7$:

```
model y1 y2 = x1 x2 x3 / ylag=2 noint xlag=1 nocurrentx type=reg nstate=2;
```

The number of dependent variables, k_y , can be greater than 1 (for example, $k_y = 2$ in the previous statement); in that case, $\mathbf{B}_i, i = 1, \dots, K$, is the $k_y \times k_z$ matrix, and $\Sigma_i, i = 1, \dots, K$, is the $k_y \times k_y$ symmetric positive definite matrix. When $k_y > 1$, the model is called the vector autoregressive hidden Markov model (VAR HMM) in some literature.

In the INITIAL statement, the **CONST**, **SD**, **LTREND**, **QTREND**, **XL**, and **AR** functions refer to the mean parameters that correspond to $z_t^{(\text{CONST})}$, $z_t^{(\text{SD})}$, $z_t^{(\text{LTREND})}$, $z_t^{(\text{QTREND})}$, $z_t^{(\text{XL})}$, and $z_t^{(\text{AR})}$, respectively; the **COV** function refers to the covariance parameters $\Sigma = (\Sigma_1 \ \dots \ \Sigma_K)'$, where K is the number of states.

The RS REG can be regarded as a special case of the RS AR when YLAG=0 is specified.

Because the RS AR is a type of finite-state-space and homogeneous HMM, the six common problems—the filtering, smoothing, forecasting, evaluating, decoding, and learning problems—can be solved using the three algorithms introduced in the section “[Hidden Markov Model](#)” on page 1268. That is, you can solve the evaluating, filtering, and forecasting problems by using the forward algorithm; the smoothing problem by using the forward algorithm and backward algorithm; the decoding problem by using the Viterbi algorithm; and the learning problem, if solved through the maximum likelihood or maximum a posteriori method, by using the forward algorithm to calculate the likelihood.

Regime-Switching Mean-Adjusted Autoregression Model

The regime-switching mean-adjusted autoregression model (also known as the mean-adjusted autoregressive hidden Markov model) is a type of finite-state-space and homogeneous HMM. For a regime-switching mean-adjusted autoregression model, the observation $\mathbf{Y}_t$ follows the normal distribution as

$$\mathbf{Y}_t | \mathbf{Y}_t, \dots, \mathbf{Y}_{t-p}, z_t, \dots, z_{t-p}, \mathbf{S}_t, \mathbf{S}_{t-1}, \dots, \mathbf{S}_{t-p} \sim N(\mathbf{B}_{\mathbf{S}_t}^{(R)} z_t + \sum_{\tau=1}^p \mathbf{B}_{\mathbf{S}_{t-\tau}}^{(A)} (\mathbf{Y}_{t-\tau} - \mathbf{B}_{\mathbf{S}_{t-\tau}}^{(R)} z_{t-p}), \Sigma_{\mathbf{S}_t})$$

where p is the autoregressive order, the variable $\mathbf{S}_t$ is the (hidden) state, $\mathbf{B}_{\mathbf{S}_{t-\tau}}^{(A)}$ is the autoregressive part of mean parameters at state $\mathbf{S}_t$, $\mathbf{B}_{\mathbf{S}_t}^{(R)}$ is the remaining mean parameters at state $\mathbf{S}_t$, and $\Sigma_{\mathbf{S}_t}$ is the covariance parameters at state $\mathbf{S}_t$ for $\mathbf{S}_t = 1, \dots, K$. Hence, the initial state probability vector (ISPV) π , the transition probability matrix (TPM) $\mathbf{A}$, and the parameter $\mathbf{B} (\equiv \{\mathbf{B}_i^{(A)}, \mathbf{B}_i^{(R)}, \Sigma_i\}_{i=1, \dots, K})$ together specify the regime-switching mean-adjusted autoregression model; that is, the parameter θ of the regime-switching mean-adjusted autoregression model is $\{\pi, \mathbf{A}, \mathbf{B}\}$.

Let k_z denote the number of regressors. The regressors, a $k_z \times 1$ vector z_t , might contain the constant, seasonal dummies, linear time trend, quadratic time trend, exogenous variables. That is,

$$z_t = \left(\left(z_t^{(\text{CONST})} \right)' \left(z_t^{(\text{SD})} \right)' \left(z_t^{(\text{LTREND})} \right)' \left(z_t^{(\text{QTREND})} \right)' \left(z_t^{(\text{XL})} \right)' \right)'$$

where

- $z_t^{(\text{CONST})}$ is empty if the NOINT option is specified; otherwise, $z_t^{(\text{CONST})} = (1)$.
- $z_t^{(\text{SD})}$ is empty if the NSEASON= option is not specified; otherwise, $z_t^{(\text{SD})} = (sd_t^{(1)} \cdots sd_t^{(n_s-1)})'$, where $sd_t^{(i)}, i = 1, \dots, n_s - 1$, denote the values of the seasonal dummies at time t and where n_s is the value specified in the NSEASON= n_s option.
- $z_t^{(\text{LTREND})}$ is empty if the TREND= option is not specified; otherwise, $z_t^{(\text{LTREND})} = (t)$.
- $z_t^{(\text{QTREND})}$ is empty if the TREND=QUAD option is not specified; otherwise, $z_t^{(\text{QTREND})} = (t^2)$.
- $z_t^{(\text{XL})}$ is empty if no exogenous variables are specified in the model or if the NOCURRENTX option is specified when the XLAG option is not specified or XLAG=0; otherwise, $z_t^{(\text{XL})}$ is determined as follows, where XLAG= s and k_x is the number of exogenous variables:

– If the NOCURRENTX option is specified,

$$z_t^{(\text{XL})} = (x_{1,t-1} \cdots x_{k_x,t-1} \cdots x_{1,t-s} \cdots x_{k_x,t-s})'$$

– If the NOCURRENTX option is not specified,

$$z_t^{(\text{XL})} = (x_{1,t} \cdots x_{k_x,t} \ x_{1,t-1} \cdots x_{k_x,t-1} \cdots x_{1,t-s} \cdots x_{k_x,t-s})'$$

The ARMEAN=ADJUSTED option in the following statement specifies the following regime-switching mean-adjusted autoregression model:

```
model y = x / armean=adjusted ylag=1 type=ar nstate=2;
```

$$\begin{aligned} y_t &= c\mathbf{S}_t + b\mathbf{S}_t x_t + a\mathbf{S}_t (y_{t-1} - c\mathbf{S}_{t-1} - b\mathbf{S}_{t-1} x_{t-1}) + \varepsilon_t \\ &= (c\mathbf{S}_t \ b\mathbf{S}_t) z_t + a\mathbf{S}_t (y_{t-1} - (c\mathbf{S}_{t-1} \ b\mathbf{S}_{t-1}) z_{t-1}) + \varepsilon_t \\ &= \begin{cases} c_1 + b_1 x_t + a_1 (y_{t-1} - c_1 - b_1 x_{t-1}) + \varepsilon_t, & \mathbf{S}_t = 1, \mathbf{S}_{t-1} = 1, \\ c_2 + b_2 x_t + a_2 (y_{t-1} - c_1 - b_1 x_{t-1}) + \varepsilon_t, & \mathbf{S}_t = 2, \mathbf{S}_{t-1} = 1, \\ c_1 + b_1 x_t + a_1 (y_{t-1} - c_2 - b_2 x_{t-1}) + \varepsilon_t, & \mathbf{S}_t = 1, \mathbf{S}_{t-1} = 2, \\ c_2 + b_2 x_t + a_2 (y_{t-1} - c_2 - b_2 x_{t-1}) + \varepsilon_t, & \mathbf{S}_t = 2, \mathbf{S}_{t-1} = 2. \end{cases} \end{aligned}$$

where $\varepsilon_t \sim N(0, \Sigma_{\mathbf{S}_t})$, $z_t = (1 \ x_t)'$, and $k_z = 2$.

The number of dependent variables, k_y , can be greater than 1; in that case, $\Sigma_i, i = 1, \dots, K$, is the $k_y \times k_y$ symmetric positive definite matrix. When $k_y > 1$, the model is called the vector autoregressive hidden Markov model (VAR HMM) in some literature.

In the INITIAL statement, the **CONST**, **SD**, **LTREND**, **QTREND**, and **XL** functions refer to the mean parameters that correspond to $z_t^{(\text{CONST})}$, $z_t^{(\text{SD})}$, $z_t^{(\text{LTREND})}$, $z_t^{(\text{QTREND})}$, $z_t^{(\text{XL})}$, respectively; the **AR** function refers to the mean parameters that correspond to demeaned lagged dependent variables $(\mathbf{Y}_{t-\tau} - \mathbf{B}_{\mathbf{S}_{t-\tau}}^{(R)} z_{t-\tau})$, $\tau = 1, \dots, p$; and the **COV** function refers to the covariance parameters $\Sigma = (\Sigma_1 \cdots \Sigma_K)'$, where K is the number of states.

Because the regime-switching mean-adjusted autoregression model is a type of finite-state-space and homogeneous HMM, the six common problems—the filtering, smoothing, forecasting, evaluating, decoding, and learning problems—can be solved using the three algorithms that are introduced in the section “[Hidden Markov Model](#)” on page 1268. That is, you can solve the evaluating, filtering, and forecasting problems by using the forward algorithm; the smoothing problem by using the forward algorithm and backward algorithm; the decoding problem by using the Viterbi algorithm; and the learning problem, if solved through the maximum likelihood or maximum a posteriori method, by using the forward algorithm to calculate the likelihood.

Finite Hidden Markov Model

The finite hidden Markov model (finite HMM) is a type of finite-state-space and homogeneous HMM in which the observation probability distribution is the categorical distribution whose support is finite,

$$Y_t | \mathbf{S}_t \sim C(b_{\mathbf{S}_t,1}, \dots, b_{\mathbf{S}_t,M})$$

where the variable $\mathbf{S}_t$ is the (hidden) state; $C(\dots)$ represents the categorical distribution; M is the number of categories at each state; and the $b_{\mathbf{S}_t,j}$, $j = 1, \dots, M$, are category probabilities, satisfying ($b_{\mathbf{S}_t,j} \geq 0$, $j = 1, \dots, M$, and $\sum_{j=1}^M b_{\mathbf{S}_t,j} = 1$).

Hence, the initial state probability vector (ISPV) π , the transition probability matrix (TPM) $\mathbf{A}$, and the probability of observational outcomes $\mathbf{B} (\equiv \{b_{ij}, i = 1, \dots, K, j = 1, \dots, M\})$ together specify the finite HMM; that is, the parameter θ of the finite HMM is $\{\pi, \mathbf{A}, \mathbf{B}\}$.

Because the finite HMM is a type of finite-state-space and homogeneous HMM, the six common problems—the filtering, smoothing, forecasting, evaluating, decoding, and learning problems—can be solved using the three algorithms that are introduced in the section “[Hidden Markov Model](#)” on page 1268. That is, you can solve the evaluating, filtering, and forecasting problems by using the forward algorithm; the smoothing problem by using the forward algorithm and backward algorithm; the decoding problem by using the Viterbi algorithm; and the learning problem, if solved through the maximum likelihood or maximum a posteriori method, by using the forward algorithm to calculate the likelihood. The dependent variable for the finite HMM must be an integer greater than or equal to 1 and less than or equal to the number of the category. The number of dependent variables for finite HMM must be 1. It is a trivial case when NSTATE=1 and NCATEGORY=1 for the finite HMM, and the program will stop processing.

The %FiniteHMM Macro

Although in theory, finite HMM assumes that the response variable is discrete (whether it is numeric or categorical), PROC HMM assumes that the response variable is composed of consecutive natural numbers that start with 1. However, for most real-world business data, the variable of interest could be recorded in other formats, such as categorical levels, decimals, negative numbers, and so on. In other cases, a response variable could be recorded as nonconsecutive natural numbers. Therefore it is likely that you will need to preprocess the data before using PROC HMM to perform finite HMM.

For example, if you are interested in modeling the dynamic feature of receiving promotion channels for a buyer, the response variable y_1 could have values such as ‘aa email’, ‘bb mail’, ‘cc phone’, ‘dd flyer’, ‘ee

seminar', and 'ff forum'. To use PROC HMM for finite HMM on y_1 , you would need to preprocess the data by creating a natural-number-valued variable y and model on y instead. If you assume that y_1 is in the data set `finite1`, the following SAS program does the preprocessing:

```
data finite1;
  set finite1;
  if y1='aa email'  ' then y=1;
  if y1='bb mail'   ' then y=2;
  if y1='cc phone'  ' then y=3;
  if y1='dd flyer'  ' then y=4;
  if y1='ee seminar' then y=5;
  if y1='ff forum'  ' then y=6;
run;
```

Then you can use PROC HMM for finite HMM on y as follows after you upload the data set to a SAS data library named `mylib`. Here the SAS data library `mylib` must already be defined.

```
ods output CPM=my_cpm_0
ParameterEstimates=my_est_0;
proc hmm data=mylib.finite1;
  id time=t section=section;
  model y / type=finite nstate=3 nCategory=6 method=MAP;
  estimate out=mylib.est_0 outall=mylib.estall_0;
  forecast out=mylib.fcst_0 lead=4;
run;
```

Because y has values 1 to 6, the output tables have information only about the levels of y , not the levels of y_1 . To understand and analyze the results for the original y_1 , you need to do postprocessing by manually matching the y levels to the levels of y_1 . This can be tedious if y_1 has too many levels. The SAS macro %FiniteHMM helps you do the preprocessing and postprocessing automatically in such cases. The %FiniteHMM macro is a wrapper for finite HMM with PROC HMM. It treats the response variable as a categorical variable, and it automatically preprocesses the data and postprocesses the results. This macro is useful in the following three cases:

- The response variable contains values other than natural numbers.
- The response variable is composed of nonconsecutive natural numbers.
- The response variable is composed of consecutive natural numbers but does not start with 1.

Be aware that there are limits to using the %FiniteHMM macro. In particular, it does not currently support n -literal response variable names and does not support interior quotation marks in response variable values.

Specifically, the %FiniteHMM macro does the following:

- treats the response variable for finite HMM as a categorical variable
- creates the internal response variable `_mody_` with consecutive natural numbers as its values, and links each natural number to the corresponding categorical level of the original response variable
- updates the `NCATEGORY=` option value to the actual number of levels of the original response variable

- applies PROC HMM to the internally created response variable `_mody_` for finite HMM
- for the ODS CPM output table and the output forecast table, updates the label of categorical columns with their corresponding levels in the original response variable
- for both the ODS table and the output parameter estimates table, adds a column named `RespVarLevel` that indicates the corresponding levels in the original response variable

These updated tables from the `%FiniteHMM` macro are ready for analysis on the original response variable because the parameters are linked to the original response variable levels through labels or through the additional column `RespVarLevel`. The ODS CPM output table and output forecast table will have labels of the variables `Category1` to `Categoryk` that are linked to the levels of the original variable. The parameter estimates table will have an additional column called `RespVarLevel` to indicate the levels of the original variable.

The parameters of the `%FiniteHMM` macro are defined to correspond to the statements in PROC HMM. The options in each statement of PROC HMM become the parameter values in the macro. Two additional parameters are added to the macro:

- `DATA=%str()`, which contains the name of the two-level input data set for PROC HMM
- `ODSOUT=%str()`, which contains the ODS table specification in the ODS OUTPUT statement of PROC HMM

Because the value of the `DATA=` option in PROC HMM is defined as a separate parameter in the `%FiniteHMM` macro, the PROC parameter in the macro contains only options other than the `DATA=` option of PROC HMM. To prevent ambiguity with the special symbols, it is suggested that the value of each parameter be quoted in `%str( )`. The following parameters are defined in the `%FiniteHMM` macro:

DATA

specifies the two-level input table name.

DECODE

specifies options for the DECODE statement.

ESTIMATE

specifies options for the ESTIMATE statement.

EVALUATE

specifies options for the EVALUATE statement.

FILTER

specifies options for the FILTER statement.

FORECAST

specifies options for the FORECAST statement.

ID

specifies options for the ID statement.

INITIAL

specifies options for the INITIAL statement.

MODEL

specifies options for the MODEL statement.

ODSOUT

specifies options for the ODS OUTPUT statement.

OPTIMIZE

specifies options for the OPTIMIZE statement.

PRIOR

specifies options for the PRIOR statement.

PROC

specifies options in the PROC HMM statement, excluding the DATA= option.

SCORE

specifies options for the SCORE statement.

SMOOTH

specifies options for the SMOOTH statement.

Among the macro parameters, only DATA, ID, and MODEL are required. All others are optional. For example, say that you run finite HMM by using the following PROC HMM specification:

```
ods output CPM=my_cpm_1
  ParameterEstimates=my_est_1;
proc hmm data=mylib.finitel;
  id time=t section=section;
  model y / type=finite nstate=3 nCategory=6 method=MAP;
  estimate out=mylib.est_1 outall=mylib.estall_1;
  forecast out=mylib.fcst_1 lead=4;
run;
```

The corresponding %FiniteHMM macro syntax would be as follows:

```
%FiniteHMM(
  data = %str(mylib.finitel),
  id = %str(time=t section=section),
  model = %str(y / type=finite nstate=3 nCategory=6 method=MAP),
  estimate = %str(out=mylib.est_1 outall=mylib.estall_1),
  forecast = %str(out=mylib.fcst_1 lead=4),
  odsout = %str(CPM=my_cpm_1
    ParameterEstimates=my_est_1));
```

Note that in the preceding example, because DATA=MYLIB.FINITE1 is the only option in the PROC HMM statement, the PROC parameter is not needed in the %FiniteHMM macro syntax. The NCATEGORY=6 option is not required in this macro because this value is determined by input data; hence, even if you specify it as shown here, it will be overwritten according to the data.

Now say that you have a more complicated specification of PROC HMM, such as the following:

```

ods output CPM=my_cpm_0
      ParameterEstimates=my_est_0;
proc hmm data=mylib.finitel labelSwitch=(sort=asc(tpm));
  id time=t section=section;
  model y1 / type=finitel nstate=3 nCategory=6 method=MAP;
  score outmodel=mylib.myScore_0;
  estimate out=mylib.est_0 outall=mylib.estall_0;
  forecast out=mylib.fcst_0 lead=4;
  decode out=mylib.decode_0;
  evaluate out=mylib.eval_0;
  filter out=mylib.flt_0;
  smooth out=mylib.smth_0;
  optimize printlevel=3 printiterfreq=2 maxiter=10;
  prior CPM ~ dir({1 1 1 2 2 2,
                  2 2 2 3 3 3,
                  2 2 2 4 4 4});
  initial TPM = {0.97 0.02 0.01,
                0.015 0.98 0.005,
                0.01 0.03 0.96},
  CPM = {0.09 0.32 0.57 0.01 0.01 0.00,
        0.01 0.08 0.28 0.61 0.01 0.01,
        0.01 0.02 0.01 0.08 0.29 0.59};

run;

```

The corresponding %FiniteHMM macro syntax would look like this:

```

%FiniteHMM(
  data = %str(mylib.finitel),
  proc = %str(labelSwitch=(sort=asc(tpm))),
  id = %str(time=t section=section),
  model = %str(y1 / type=finitel nstate=3 nCategory=6 method=MAP),
  score = %str(outmodel=mylib.myScore_0),
  estimate = %str(out=mylib.est_0 outall=mylib.estall_0),
  forecast = %str(out=mylib.fcst_0 lead=4),
  decode = %str(out=mylib.decode_0),
  evaluate = %str(out=mylib.eval_0),
  filter = %str(out=mylib.flt_0),
  smooth = %str(out=mylib.smth_0),
  optimize = %str(printlevel=3 printiterfreq=2 maxiter=10),
  prior = %str(CPM ~ dir({1 1 1 2 2 2,
                        2 2 2 3 3 3,
                        2 2 2 4 4 4})),
  initial = %str(TPM = {0.97 0.02 0.01,
                      0.01 0.98 0.01,
                      0.01 0.03 0.96},
  CPM = {0.09 0.32 0.57 0.01 0.01 0.00,
        0.01 0.08 0.28 0.61 0.01 0.01,
        0.01 0.02 0.01 0.08 0.29 0.59}),
  odsout = %str(CPM=my_cpm_0
  ParameterEstimates=my_est_0));

```

Note that in the preceding example, PROC HMM has the LABELSWITCH=(SORT=ASC(TPM)) option in addition to the DATA= option, so a PROC parameter is included in the macro call to contain this option.

The sections that follow present several examples to demonstrate how to use the %FiniteHMM macro. First, a data set needs to be simulated for these macro examples. The following PROC IML and DATA step code simulates a data set on the basis of a finite HMM model with the parameters $\{\pi, \mathbf{A}, \mathbf{B}\}$:

$$\pi = \begin{pmatrix} 0.45 \\ 0.25 \\ 0.30 \end{pmatrix}, \quad \mathbf{A} = \begin{pmatrix} 0.98 & 0.015 & 0.005 \\ 0.02 & 0.97 & 0.01 \\ 0.01 & 0.01 & 0.98 \end{pmatrix}, \quad \mathbf{B} = \begin{pmatrix} 0.5 & 0.5 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0.5 & 0.5 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0.5 & 0.5 \end{pmatrix}$$

where π is the initial state probability vector, or ISPV; $\mathbf{A}$ is the transition probability matrix, or TPM; and $\mathbf{B}$ is the category probability matrix, or CPM. The simulated data set, finite1, has 1,500 observations in three sections. Each section has 500 observations. The data set has three variables: y, t, and section.

        else y = 6;
    end;
    else if statel=2 then do;
        u = uniform(&simseed2.);
        if (u <= 0) then y=1;
        else if( 0 <u <= 0) then y=2;
        else if( 0 <u <= 1/2) then y=3;
        else if( 1/2 <u <= 2/2) then y=4;
        else if( 2/2 <u <= 1) then y=5;
        else y = 6;
    end;
    else do;
        u = uniform(&simseed2.);
        if (u <= 0) then y=1;
        else if( 0 <u <= 0) then y=2;
        else if( 0 <u <= 0) then y=3;
        else if( 0 <u <= 0) then y=4;
        else if( 0 <u <= 1/2) then y=5;
        else y = 6;
    end;
    output;
run;
data finitel;
    set finitel temnm;

```

```
run;
```

The variable `y` in the `finite1` data set has values of the consecutive natural numbers 1 to 6. In this case, you can use either PROC HMM or the `%FiniteHMM` macro on `y` for a finite HMM. The results should be the same.

The following SAS code saves the `finite1` data set to the `mylib` library:

```
data mylib.finite1;
    set finite1;
run;
```

Macro Example 1: Finite HMM with Consecutive Natural Number Responses

In this example, both PROC HMM and the `%FiniteHMM` macro should give you the same numeric results. Both the ODS table and the output parameter estimates table that this macro produces have an additional column named `RespVarLevel` to indicate the levels of the response variable. In practice, if a response variable has values of consecutive natural numbers, you can use PROC HMM directly.

The first part of the following SAS code uses PROC HMM on `y`. The ODS output tables for CPM and the parameter estimates are stored in `my_cpm_0` and `my_est_0`, respectively. Then `%FiniteHMM` is used on `y` for the same model specification. The ODS output tables for CPM and the parameter estimates are stored in `my_cpm_1` and `my_est_1`, respectively.

```
*** Using PROC HMM on y *****;
ods listing close;
ods output CPM=my_cpm_0
           ParameterEstimates=my_est_0;
proc hmm data=mylib.finite1 ;
    id time=t section=section;
    model y / type=finite nstate=3 nCategory=6 method=MAP;
    estimate out=mylib.est_0 outall=mylib.estall_0;
    forecast out=mylib.fcst_0 lead=4;
run;
*** Using %FiniteHMM on y *****;
%FiniteHMM(
    data=%str(mylib.finite1),
    id = %str(time=t section=section),
    model = %str(y / type=finite nstate=3 nCategory=6 method=MAP),
    estimate = %str(out=mylib.est_1 outall=mylib.estall_1),
    forecast = %str(out=mylib.fcst_1 lead=4),
    odsout = %str(CPM=my_cpm_1
                  ParameterEstimates=my_est_1)
);
```

The following SAS code prints the ODS CPM output table from PROC HMM. The table is shown in Figure 20.68.

```
proc print data=my_cpm_0 label noobs;
    format category: 8.5;
run;
```

Figure 20.71 shows that the parameter estimates table that the %FiniteHMM macro produces has an additional column named RespVarLevel to indicate the levels of the original response variable.

Macro Example 2: Finite HMM with Categorical Responses

In this example, the variable y_1 has the categorical values ‘aa email’, ‘bb mail’, ‘cc phone’, ‘dd flyer’, ‘ee seminar’, and ‘ff forum’. In this case, directly applying PROC HMM to y_1 generates error messages, and PROC HMM quits. Using the %FiniteHMM macro on y_1 gives you the expected results.

The following SAS code creates the finite2 data set:

```
data finite2;
  set finitel;
  if y=1 then y1='aa email  ';
  if y=2 then y1='bb mail   ';
  if y=3 then y1='cc phone  ';
  if y=4 then y1='dd flyer  ';
  if y=5 then y1='ee seminar';
  if y=6 then y1='ff forum  ';
```

```
run;
data mylib.finite2;
  set finite2;
run;
```

The following SAS code uses PROC HMM:

```
ods output CPM=my_cpm_0
           ParameterEstimates=my_est_0;
proc hmm data=mylib.finite2;
  id time=t section=section;
  model y1 / type=finite nstate=3 nCategory=6 method=MAP;
  estimate out=mylib.est_0 outall=mylib.estall_0;
  forecast out=mylib.fcst_0 lead=4;
run;
ERROR: The data type of dependent variables must be numeric.
```

The following SAS code applies the %FiniteHMM macro:

```
%FiniteHMM(
  data = %str(mylib.finite2),
  proc = %str(labelSwitch=(sort=asc(cpm))),
  id = %str(time=t section=section),
  model = %str(y1 / type=finite nstate=3 nCategory=6 method=MAP),
  estimate = %str(out=mylib.est_1 outall=mylib.estall_1),
  forecast = %str(out=mylib.fcst_1 lead=4),
  odsout = %str(CPM=my_cpm_1
                ParameterEstimates=my_est_1));
```

The following SAS code prints the ODS CPM output table from the %FiniteHMM macro. The table is shown in [Figure 20.72](#).

```
proc print data=my_cpm_1 label noobs;
  format category: 8.5;
run;
```

The RespVarLevel column in Figure 20.73 provides information about the levels of response variables for the CPM parameters. The labels in Figure 20.74 clearly show the categorical levels of the response variable y_1 .

Macro Example 3: Finite HMM for Responses with Nonconsecutive Natural Number Values

In this example, although y_1 has values of 2 and 6, PROC HMM still assumes that it has consecutive values of 1, 2, 3, 4, 5, and 6, and the output tables for CPM and the forecast will contain extra columns for the values 1, 3, 4, and 5. The %FiniteHMM macro will consider 2 and 6 as two categorical values, so it will give you the desired results.

The following SAS code creates the finite3 data set:

```
data finite3;
    set finitel;
    if y<=3 then y1=2; else y1=6;
run;
data mylib.finite3;
    set finite3;
run;
```

The following SAS code uses PROC HMM on y_1 :

```
ods output CPM=my_cpm_0
           ParameterEstimates=my_est_0;
proc hmm data=mylib.finite3 labelSwitch=(sort=asc(cpm));
    id time=t section=section;
    model y1 / type=finite nstate=3 nCategory=6 method=MAP;
    estimate out=mylib.est_0 outall=mylib.estall_0;
    forecast out=mylib.fcst_0 lead=4;
run;
```

The following SAS code prints the ODS CPM output table, parameter estimates table, and output forecast table, respectively, from PROC HMM. The results are shown in Figure 20.75, Figure 20.76, and Figure 20.77.

```

proc print data=my_cpm_0 label noobs;
  format Category: 8.5;
run;

proc print data=my_est_0 label noobs;
  format Estimate StdErr 8.5;
run;

proc print data=mylib.fcst_0 label noobs;
  format State: Category: 8.5;
run;

```

If you use the %FiniteHMM macro on y_1 , as in the following code, the results become concise and correct. Be aware that because the number of levels of the response variable differs in these three instances, the output state orders could be different even if you use the same LABELSWITCH= option value in both PROC HMM and the %FiniteHMM macro.

The following SAS program uses %FiniteHMM on y_1 :

```
%FiniteHMM(
  data = %str(mylib.finite3),
  proc = %str(labelSwitch=(sort=asc(cpm))),
  id = %str(time=t section=section),
  model = %str(y1 / type=finit nstate=3 nCategory=6 method=MAP),
  estimate = %str(out=mylib.est_1 outall=mylib.estall_1),
  forecast = %str(out=mylib.fcst_1 lead=4),
  odsout = %str(CPM=my_cpm_1
    ParameterEstimates=my_est_1));
```

The following three SAS programs print the ODS CPM output table, parameter estimates table, and output forecast table, respectively, from the %FiniteHMM macro. The results are shown in [Figure 20.78](#), [Figure 20.79](#), and [Figure 20.80](#).

```
proc print data=my_cpm_1 label noobs;
  format Category: 8.5;
run;

proc print data=my_est_1 label noobs;
  format Estimate StdErr 8.5;
run;

proc print data=mylib.fcst_1 label noobs;
  format State: Category: 8.5;
run;
```

Figure 20.75 shows that the CPM output table from PROC HMM has six columns, but only two columns contain useful information. Similarly, the parameter estimates table from PROC HMM also contains extra parameters. On the other hand, results from the %FiniteHMM macro contain information for two levels of the values 2 and 6 only. On a large scale, if y_1 has values of 1 and 100, then PROC HMM assumes that it has the consecutive values 1 through 100, and the CPM output table for y_1 has 100 columns, of which only two

columns contain useful information. The %FiniteHMM macro gives you results on two categories, 1 and 100, and is much more efficient. The RespVarLevel column in Figure 20.79 provides information about the levels of response variables for the CPM parameters. The labels in Figure 20.80 clearly show the categorical levels of the response variable y_1 .

Macro Example 4: Automatic Handling of the NCATEGORY= Option in the %FiniteHMM Macro

In this example, y_1 has integer values of 1, 3, 4, and 6. In PROC HMM, you get an error message if the value of the NCATEGORY= option is less than the maximum value of y_1 , which is 6. On the other hand, if the NCATEGORY= option value is greater than the maximum value of y_1 , PROC HMM assumes that y_1 has consecutive values from 1 to the NCATEGORY= option value. Hence the results will contain extra columns or parameters similar to those in Macro Example 3.

If you apply the %FiniteHMM macro, the NCATEGORY= option value is automatically updated to the number of levels of the response variable. There will be no error message if the NCATEGORY= option value is less than the maximum value of the response variable, and the results are more desirable.

The following SAS code creates the finite4 data set:

```
data finite4;
    set finitel;
    y1 = y;
    if y=2 then y1=1;
    if y=5 then y1=4;
run;
data mylib.finite4;
    set finite4;
run;
```

The following SAS code specifies NCATEGORY=4. PROC HMM generates an error message.

```
ods output CPM=my_cpm_0
           ParameterEstimates=my_est_0;
proc hmm data=mylib.finite4 labelSwitch=(sort=asc(cpm));
    id time=t section=section;
    model y1 / type=finite nstate=3 nCategory=4 method=MAP;
    estimate out=mylib.est_0 outall=mylib.estall_0;
    forecast out=mylib.fcst_0 lead=4;
run;
ERROR: The dependent variable for the finite HMM must be an integer between 1
       and the number of the categories which is specified in the NCATEGORY= option
       in the MODEL statement. To correct this, you can either preprocess your data
       or specify a larger value in the NCATEGORY= option.
```

The following SAS code specifies NCATEGORY=8. PROC HMM assumes that y_1 has the consecutive integer values 1 through 8.

```
ods output CPM=my_cpm_0
           ParameterEstimates=my_est_0;
proc hmm data=mylib.finite4 labelSwitch=(sort=asc(cpm));
    id time=t section=section;
    model y1 / type=finite nstate=3 nCategory=8 method=MAP;
    estimate out=mylib.est_0 outall=mylib.estall_0;
    forecast out=mylib.fcst_0 lead=4;
```

```
run;
```

The following SAS code prints the ODS CPM output table from PROC HMM when NCATEGORY=8. The table is shown in [Figure 20.81](#).

```
proc print data=my_cpm_0 label noobs;
format Category: 8.5;
run;
```

Figure 20.81 ODS CPM Output Table from PROC HMM When NCATEGORY=8

Group	State	1	2	3	4	5	6	7	8
ParameterMatrices	1	0.00000	0.00000	0.00000	0.51379	0.00000	0.48621	0.00000	0.00000
ParameterMatrices	2	0.00000	0.00000	0.47630	0.52370	0.00000	0.00000	0.00000	0.00000
ParameterMatrices	3	1.00000	0.00000	0.00000	0.00000	0.00000	0.00000	0.00000	0.00000

If you use the %FiniteHMM macro as in the following program, the NCATEGORY= option value is always updated to the actual number of levels of the response variable and a message is displayed. The ODS CPM output tables when NCATEGORY=4 and 8 are shown in [Figure 20.82](#) and [Figure 20.83](#), respectively.

```
%FiniteHMM(
  data = %str(mylib.finite4),
  proc = %str(labelSwitch=(sort=asc(cpm))),
  id = %str(time=t section=section),
  model = %str(y1 / type=finite nstate=3 nCategory=4 method=MAP),
  estimate = %str(out=mylib.est_1 outall=mylib.estall_1),
  forecast = %str(out=mylib.fcst_1 lead=4),
  odsout = %str(CPM=my_cpm_1
    ParameterEstimates=my_est_1));
```

NOTE: The NCATEGORY= option value is always updated to the number of levels of the response variable.

```
%FiniteHMM(
  data = %str(mylib.finite4),
  proc = %str(labelSwitch=(sort=asc(cpm))),
  id = %str(time=t section=section),
  model = %str(y1 / type=finite nstate=3 nCategory=8 method=MAP),
  estimate = %str(out=mylib.est_2 outall=mylib.estall_2),
  forecast = %str(out=mylib.fcst_2 lead=4),
  odsout = %str(CPM=my_cpm_2
    ParameterEstimates=my_est_2));
```

NOTE: The NCATEGORY= option value is always updated to the number of levels of the response variable.

The following SAS code prints the ODS CPM output table from the %FiniteHMM macro when NCATEGORY=4. The table is shown in [Figure 20.82](#).

```
proc print data=my_cpm_1 label noobs;
format Category: 8.5;
run;
```

Figure 20.82 ODS CPM Table from the %FiniteHMM Macro When NCATEGORY=4

Group	State	1	3	4	6
ParameterMatrices	1	0.00000	0.47630	0.52370	0.00000
ParameterMatrices	2	0.00000	0.00000	0.51379	0.48621
ParameterMatrices	3	1.00000	0.00000	0.00000	0.00000

The following SAS code prints the ODS CPM output table from the %FiniteHMM macro when NCATEGORY=8. The table is shown in Figure 20.83.

```
proc print data=my_cpm_2 label noobs;
format Category: 8.5;
run;
```

Figure 20.83 ODS CPM Table from the %FiniteHMM Macro When NCATEGORY=8

Group	State	1	3	4	6
ParameterMatrices	1	0.00000	0.47630	0.52370	0.00000
ParameterMatrices	2	0.00000	0.00000	0.51379	0.48621
ParameterMatrices	3	1.00000	0.00000	0.00000	0.00000

Macro Example 5: Finite HMM with Decimal-Valued or Negative-Valued Responses

In this example, the response variable y_1 has decimal values, and the response variable y_2 has values of negative integers. PROC HMM generates an error message for both y_1 and y_2 . But using the %FiniteHMM macro gives you correct and complete results.

The following SAS code creates the finite5 data set:

```
data finite5;
  set finitel;
  y1 = y/100;
  y2 = -y;
run;
data mylib.finite5;
  set finite5;
run;
```

Using PROC HMM on y_1 and y_2 as follows generates error messages:

```
ods output CPM=my_cpm_1
           ParameterEstimates=my_est_1;
proc hmm data=mylib.finite5 labelSwitch=(sort=asc(cpm));
  id time=t section=section;
  model y1 / type=finite nstate=3 nCategory=6 method=MAP;
  estimate out=mylib.est_1 outall=mylib.estall_1;
  forecast out=mylib.fcst_1 lead=4;
run;
ERROR: For finite HMM, the series variable must be integer-valued.

ods output CPM=my_cpm_2
           ParameterEstimates=my_est_2;
```

```
proc hmm data=mylib.finite5 labelSwitch=(sort=asc(cpm));
  id time=t section=section;
  model y2 / type=finite nstate=3 nCategory=6 method=MAP;
  estimate out=mylib.est_2 outall=mylib.estall_2;
  forecast out=mylib.fcst_2 lead=4;
run;
ERROR: The dependent variable for the finite HMM must be an integer between 1
       and the number of the categories which is specified in the NCATEGORY=
       option in the MODEL statement. To correct this, you can either
       preprocess your data or specify a larger value in the NCATEGORY= option.
```

Using the %FiniteHMM macro on y_1 and y_2 as follows provides the expected results:

```
%FiniteHMM(
  data = %str(mylib.finite5),
  proc = %str(labelSwitch=(sort=asc(cpm))),
  id = %str(time=t section=section),
  model = %str(y1 / type=finite nstate=3 nCategory=6 method=MAP),
  estimate = %str(out=mylib.est_1 outall=mylib.estall_1),
  forecast = %str(out=mylib.fcst_1 lead=4),
  odsout = %str(CPM=my_cpm_1
                ParameterEstimates=my_est_1));

%FiniteHMM(
  data = %str(mylib.finite5),
  proc = %str(labelSwitch=(sort=asc(cpm))),
  id = %str(time=t section=section),
  model = %str(y2 / type=finite nstate=3 nCategory=6 method=MAP),
  estimate = %str(out=mylib.est_2 outall=mylib.estall_2),
  forecast = %str(out=mylib.fcst_2 lead=4),
  odsout = %str(CPM=my_cpm_2
                ParameterEstimates=my_est_2));
```

The following SAS code prints the ODS CPM output table of y_1 from the %FiniteHMM macro. The table is shown in [Figure 20.84](#).

```
proc print data=my_cpm_1 label noobs;
  format Category: 8.5;
run;
```

Poisson Hidden Markov Model

The Poisson hidden Markov model (Poisson HMM) is a type of finite-state-space and homogeneous HMM in which the observation probability distribution is the Poisson distribution whose support is nonnegative integers. The observation y_t is said to have a Poisson distribution, with the parameter $\lambda_{\mathbf{S}_t} > 0$, if it has a probability mass function given by

$$p(y_t = k | \mathbf{S}_t) = \frac{e^{-\lambda_{\mathbf{S}_t}} \lambda_{\mathbf{S}_t}^k}{k!}$$

where the variable $\mathbf{S}_t$ is the (hidden) state, k is the number of occurrences, and $!$ is the factorial function. The positive real number $\lambda_{\mathbf{S}_t}$ is equal to the expected value of y_t and also to its variance in its hidden state.

Hence, the initial state probability vector (ISPV) π , the transition probability matrix (TPM) $\mathbf{A}$, and the probability of observational outcomes $\mathbf{B} (\equiv \{b_{ij}, i = 1, \dots, K, j = 1, \dots, M\})$ together specify the Poisson HMM; that is, the parameter θ of the Poisson HMM is $\{\pi, \mathbf{A}, \mathbf{B}\}$.

Because the Poisson HMM is a type of finite-state-space and homogeneous HMM, you can solve the six common problems—the filtering, smoothing, forecasting, evaluating, decoding, and learning problems—by using the three algorithms that are introduced in the section “[Hidden Markov Model](#)” on page 1268. That is, you can solve the filtering, forecasting, and evaluating problems by using the forward algorithm; the smoothing problem by using the forward algorithm and backward algorithm; the decoding problem by using the Viterbi algorithm; and the learning problem, if solved through the maximum likelihood or maximum a posteriori method, by using the forward algorithm to calculate the likelihood. The dependent variable for the finite HMM must be a nonnegative integer. The number of dependent variables for the finite HMM must be one.

Parameter Estimation Methods

For the parameter estimation (the learning problem) of the HMM, the HMM procedure supports two methods: the maximum likelihood (ML) method and the maximum a posteriori (MAP) method.

Maximum Likelihood (ML) Method

For the ML method, the parameter estimator is obtained as

$$\hat{\theta} = \arg \max_{\theta} \log (L_T(\mathbf{Y}_1, \dots, \mathbf{Y}_T; \theta))$$

where $L_T(\cdot; \theta)$ is the likelihood of all observations for a particular parameter θ . The $\hat{\theta}$ is obtained through gradient-based optimization; the covariance matrix estimator of the $\hat{\theta}$ is obtained through the inverse of the negative Hessian.

Maximum a Posteriori (MAP) Method

For the MAP method, the parameter estimator is obtained as

$$\hat{\theta} = \arg \max_{\theta} \log (L_T(\mathbf{Y}_1, \dots, \mathbf{Y}_T; \theta)) + \log (p(\theta))$$

where $p(\theta)$ is the prior distribution function of parameter θ . The prior distribution can be specified in the PRIOR statement. The $\hat{\theta}$ is obtained through gradient-based optimization; the covariance matrix estimator of the $\hat{\theta}$ is obtained through the inverse of the negative Hessian.

In theory, the likelihood of the hidden Markov model (HMM) is unbounded and “the ML estimator as a global maximizer of the likelihood function does not exist” (Frühwirth-Schnatter 2006, page 173). The introduction of the proper prior distribution of the parameters in the MAP method can solve the unboundedness problem.

Prior Distribution of the Initial State Probability Vector

The prior distribution of the initial state probability vector (ISPV), π , is the Dirichlet distribution,

$$\pi \sim \text{Dir}(\alpha)$$

where the hyperparameter α is the $K \times 1$ vector and K is the number of states. The probability density function (PDF) of the Dirichlet distribution is

$$f(x, \alpha) = \frac{1}{B(\alpha)} \prod_{i=1}^K x_i^{\alpha_i - 1}$$

where $x = (x_1 \cdots x_K)'$, $x_i > 0, i = 1, \dots, K$, and $\sum_{i=1}^K x_i = 1$; $\alpha = (\alpha_1 \cdots \alpha_K)'$ and $\alpha_i > 0, i = 1, \dots, K$; $B(\alpha)$ is the beta function,

$$B(\alpha) = \frac{\prod_{i=1}^K \Gamma(\alpha_i)}{\Gamma(\sum_{i=1}^K \alpha_i)}$$

Prior Distribution of the Transition Probability Matrix

The prior distribution of each row of the transition probability matrix (TPM), $\mathbf{A}$, is the Dirichlet distribution,

$$a'_i \sim \text{Dir}(\alpha^{(i)}), i = 1, \dots, K$$

where a_i is the i th row of the TPM $\mathbf{A}$, $\alpha^{(i)}$ is the $K \times 1$ vector, and K is the number of states. To simplify notation, the following matrix form of the Dirichlet distribution is used,

$$\mathbf{A} \sim \text{Dir}(\tilde{\mathbf{A}})$$

where the hyperparameter $\tilde{\mathbf{A}} = (\alpha^{(1)} \dots \alpha^{(K)})'$, which is the $K \times K$ matrix that results from stacking the transpose of $\alpha^{(i)}$, $i = 1, \dots, K$.

Prior Distribution of the Category Probability Matrix

The prior distribution of each row of the category probability matrix (CPM), $\mathbf{B}$, is the Dirichlet distribution,

$$b'_i \sim \text{Dir}(b^{(i)}), i = 1, \dots, K$$

where b_i is the i th row of the CPM, $\mathbf{B}$; $b^{(i)}$ is the $M \times 1$ vector; M is the number of categories at a state; and K is the number of states. To simplify notation, the following matrix form of the Dirichlet distribution is used,

$$\mathbf{B} \sim \text{Dir}(\tilde{\mathbf{B}})$$

where the hyperparameter $\tilde{\mathbf{B}} = (b^{(1)} \dots b^{(K)})'$, which is the $K \times M$ matrix that results from stacking the transpose of $b^{(i)}$, $i = 1, \dots, K$.

Prior Distribution of the Mixture Component Probabilities

The prior distribution of each row of the mixture component probabilities (MCP), $\mathbf{W}$, is the Dirichlet distribution,

$$w'_i \sim \text{Dir}(\alpha^{(i)}), i = 1, \dots, K$$

where w_i is the i th row of the MCP $\mathbf{W}$, $\alpha^{(i)}$ is the $M \times 1$ vector, M is the number of components at a state, and K is the number of states. To simplify notation, the following matrix form of the Dirichlet distribution is used,

$$\mathbf{W} \sim \text{Dir}(\tilde{\mathbf{A}})$$

where the hyperparameter $\tilde{\mathbf{A}} = (\alpha^{(1)} \dots \alpha^{(K)})'$, which is the $K \times M$ matrix that results from stacking the transpose of $\alpha^{(i)}$, $i = 1, \dots, K$.

Prior Distribution of the Observation Parameters

Gaussian HMM In the Gaussian HMM, the observation parameters are $\{\mu_i, \Sigma_i\}, i = 1, \dots, K$, where μ_i and Σ_i are the mean and covariance parameters for state i . The prior distribution of μ_i and Σ_i is the normal-inverse-Wishart (NIW) distribution,

$$\mu_i, \Sigma_i \sim \text{NIW}(\tilde{\mu}_i, \tilde{\Sigma}_i, \tilde{\kappa}_i, \tilde{\nu}_i), i = 1, \dots, K$$

which is equivalent to

$$\begin{aligned}\mu_i | \Sigma_i &\sim N(\tilde{\mu}_i, \tilde{\kappa}_i^{-1} \Sigma_i) \\ \Sigma_i &\sim \text{IW}(\tilde{\Sigma}_i, \tilde{\nu}_i)\end{aligned}$$

where the hyperparameter $\tilde{\mu}_i$ is a $k_y \times 1$ vector; the hyperparameter $\tilde{\Sigma}_i$ is a $k_y \times k_y$ symmetric positive definite matrix; the hyperparameter $\tilde{\kappa}_i$ is a positive scalar; the hyperparameter $\tilde{\nu}_i$ is a positive scalar, $\tilde{\nu}_i > k_y + 3$; K is the number of states; and k_y is the number of dependent variables.

The probability density function (PDF) of the NIW distribution is

$$\begin{aligned}f_{\text{NIW}}(\mu, \Sigma, \tilde{\mu}, \tilde{\Sigma}, \tilde{\kappa}, \tilde{\nu}) &= f_N(\mu, \tilde{\mu}, \tilde{\kappa}^{-1} \Sigma) f_{\text{IW}}(\Sigma, \tilde{\Sigma}, \tilde{\nu}) \\ f_N(\mu, \tilde{\mu}, \tilde{\kappa}^{-1} \Sigma) &= \frac{1}{\sqrt{(2\pi)^k |\tilde{\kappa}^{-1} \Sigma|}} \exp\left(-\frac{1}{2}(\mu - \tilde{\mu})'(\tilde{\kappa}^{-1} \Sigma)^{-1}(\mu - \tilde{\mu})\right) \\ f_{\text{IW}}(\Sigma, \tilde{\Sigma}, \tilde{\nu}) &= \frac{|\tilde{\Sigma}|^{\frac{\tilde{\nu}}{2}}}{2^{\frac{\tilde{\nu}k}{2}} \Gamma_k(\frac{\tilde{\nu}}{2})} |\Sigma|^{-\frac{\tilde{\nu}+k+1}{2}} \exp\left(-\frac{1}{2}\text{tr}(\tilde{\Sigma} \Sigma^{-1})\right)\end{aligned}$$

where the parameter μ is a $k \times 1$ vector; the parameter Σ is a $k \times k$ symmetric positive matrix; the hyperparameter $\tilde{\mu}$ is a $k \times 1$ vector; the hyperparameter $\tilde{\Sigma}$ is a $k \times k$ symmetric positive definite matrix; the hyperparameter $\tilde{\kappa}$ is a positive scalar; and the hyperparameter $\tilde{\nu}$ is a positive scalar, $\tilde{\nu} > k + 3$. The $\Gamma_k(\cdot)$ is the multivariate gamma function, which is defined as

$$\Gamma_k(x) = \pi^{\frac{k(k-1)}{4}} \prod_{j=1}^k \Gamma\left(x + \frac{1-j}{2}\right)$$

In the PRIOR statement, the arguments for the NIW function are constructed by stacking the hyperparameters for each state,

$$\begin{aligned}\tilde{\mu} &= (\tilde{\mu}_1 \cdots \tilde{\mu}_K)' \\ \tilde{\Sigma} &= (\tilde{\Sigma}_1 \cdots \tilde{\Sigma}_K)' \\ \tilde{\kappa} &= (\tilde{\kappa}_1 \cdots \tilde{\kappa}_K)' \\ \tilde{\nu} &= (\tilde{\nu}_1 \cdots \tilde{\nu}_K)'\end{aligned}$$

where $\tilde{\mu}$ is a $K \times k_y$ matrix, $\tilde{\Sigma}$ is a $k_y K \times k_y$ matrix, $\tilde{\kappa}$ is a $K \times 1$ vector, $\tilde{\nu}$ is a $K \times 1$ vector, K is the number of states, and k_y is the number of dependent variables.

GM HMM In the GM HMM, the mean and covariance parameters for component j at state i are $\{\mu_{ij}, \Sigma_{ij}\}, i = 1, \dots, K, j = 1, \dots, M$, where M is the number of components at a state and K is the number of states.

The prior distribution of μ_{ij} and Σ_{ij} is the normal-inverse-Wishart (NIW) distribution,

$$\mu_{ij}, \Sigma_{ij} \sim \text{NIW}(\tilde{\mu}_{ij}, \tilde{\Sigma}_{ij}, \tilde{\kappa}_{ij}, \tilde{\nu}_{ij}), i = 1, \dots, K, j = 1, \dots, M$$

which is equivalent to

$$\begin{aligned} \mu_{ij} | \Sigma_{ij} &\sim N(\tilde{\mu}_{ij}, \tilde{\kappa}_{ij}^{-1} \Sigma_{ij}) \\ \Sigma_{ij} &\sim \text{IW}(\tilde{\Sigma}_{ij}, \tilde{\nu}_{ij}) \end{aligned}$$

where the hyperparameter $\tilde{\mu}_{ij}$ is a $k_y \times 1$ vector; the hyperparameter $\tilde{\Sigma}_{ij}$ is a $k_y \times k_y$ symmetric positive definite matrix; the hyperparameter $\tilde{\kappa}_{ij}$ is a positive scalar; the hyperparameter $\tilde{\nu}_{ij}$ is a positive scalar, $\tilde{\nu}_{ij} > k_y + 3$; and k_y is the number of dependent variables.

The probability density function (PDF) of the NIW distribution is

$$\begin{aligned} f_{\text{NIW}}(\mu, \Sigma, \tilde{\mu}, \tilde{\Sigma}, \tilde{\kappa}, \tilde{\nu}) &= f_N(\mu, \tilde{\mu}, \tilde{\kappa}^{-1} \Sigma) f_{\text{IW}}(\Sigma, \tilde{\Sigma}, \tilde{\nu}) \\ f_N(\mu, \tilde{\mu}, \tilde{\kappa}^{-1} \Sigma) &= \frac{1}{\sqrt{(2\pi)^k |\tilde{\kappa}^{-1} \Sigma|}} \exp\left(-\frac{1}{2}(\mu - \tilde{\mu})'(\tilde{\kappa}^{-1} \Sigma)^{-1}(\mu - \tilde{\mu})\right) \\ f_{\text{IW}}(\Sigma, \tilde{\Sigma}, \tilde{\nu}) &= \frac{|\tilde{\Sigma}|^{\frac{\tilde{\nu}}{2}}}{2^{\frac{\tilde{\nu}k}{2}} \Gamma_k\left(\frac{\tilde{\nu}}{2}\right)} |\Sigma|^{-\frac{\tilde{\nu}+k+1}{2}} \exp\left(-\frac{1}{2}\text{tr}(\tilde{\Sigma} \Sigma^{-1})\right) \end{aligned}$$

where the parameter μ is a $k \times 1$ vector; the parameter Σ is a $k \times k$ symmetric positive matrix; the hyperparameter $\tilde{\mu}$ is a $k \times 1$ vector; the hyperparameter $\tilde{\Sigma}$ is a $k \times k$ symmetric positive definite matrix; the hyperparameter $\tilde{\kappa}$ is a positive scalar; and the hyperparameter $\tilde{\nu}$ is a positive scalar, $\tilde{\nu} > k + 3$. The $\Gamma_k(\cdot)$ is the multivariate gamma function defined as

$$\Gamma_k(x) = \pi^{\frac{k(k-1)}{4}} \prod_{j=1}^k \Gamma\left(x + \frac{1-j}{2}\right)$$

In the PRIOR statement, the arguments for the NIW function are constructed by stacking the hyperparameters for each state,

$$\begin{aligned} \tilde{\mu} &= (\tilde{\mu}_{11} \cdots \tilde{\mu}_{1M} \tilde{\mu}_{21} \cdots \tilde{\mu}_{2M} \cdots \tilde{\mu}_{K1} \cdots \tilde{\mu}_{KM})' \\ \tilde{\Sigma} &= (\tilde{\Sigma}_{11} \cdots \tilde{\Sigma}_{1M} \tilde{\Sigma}_{21} \cdots \tilde{\Sigma}_{2M} \cdots \tilde{\Sigma}_{K1} \cdots \tilde{\Sigma}_{KM})' \\ \tilde{\kappa} &= (\tilde{\kappa}_{11} \cdots \tilde{\kappa}_{1M} \tilde{\kappa}_{21} \cdots \tilde{\kappa}_{2M} \cdots \tilde{\kappa}_{K1} \cdots \tilde{\kappa}_{KM})' \\ \tilde{\nu} &= (\tilde{\nu}_{11} \cdots \tilde{\nu}_{1M} \tilde{\nu}_{21} \cdots \tilde{\nu}_{2M} \cdots \tilde{\nu}_{K1} \cdots \tilde{\nu}_{KM})' \end{aligned}$$

where $\tilde{\mu}$ is a $KM \times k_y$ matrix, $\tilde{\Sigma}$ is a $k_y KM \times k_y$ matrix, $\tilde{\kappa}$ is a $KM \times 1$ vector, $\tilde{\nu}$ is a $KM \times 1$ vector, M is the number of components at a state, K is the number of states, and k_y is the number of dependent variables.

Regime-Switching Regression Model and Regime-Switching Autoregression Model In regime-switching regression models and regime-switching autoregression models, the observation parameters are $\{\mathbf{B}_i, \Sigma_i\}, i = 1, \dots, K$, where $\mathbf{B}_i$ and Σ_i are the mean and covariance parameters for state i . Because $\mathbf{B}_i z_t = (z_t' \otimes I_{k_y}) \text{vec}(\mathbf{B}_i) = (z_t' \otimes I_{k_y}) \beta_i$, where vec is the column stacking operator, the observation parameters in this section are denoted by $\{\beta_i, \Sigma_i\}, i = 1, \dots, K$. The prior distribution of β_i and Σ_i is the normal-inverse-Wishart (NIW) distribution,

$$\beta_i, \Sigma_i \sim \text{NIW}(\tilde{\mu}_i, \tilde{\Sigma}_i, \tilde{\kappa}_i, \tilde{\nu}_i), i = 1, \dots, K$$

which is equivalent to

$$\begin{aligned} \beta_i | \Sigma_i &\sim N(\tilde{\mu}_i, \tilde{\kappa}_i^{-1} \otimes \Sigma_i) \\ \Sigma_i &\sim \text{IW}(\tilde{\Sigma}_i, \tilde{\nu}_i) \end{aligned}$$

where the hyperparameter $\tilde{\mu}_i$ is a $k_y k_z \times 1$ vector; the hyperparameter $\tilde{\Sigma}_i$ is a $k_y \times k_y$ symmetric positive definite matrix; the hyperparameter $\tilde{\kappa}_i$ is a $k_z \times k_z$ symmetric positive definite matrix; the hyperparameter $\tilde{\nu}_i$ is a positive scalar, $\tilde{\nu}_i > k_y + 3$; K is the number of states; k_y is the number of dependent variables; and k_z is the number of regressors. For information about how to calculate k_z , see the sections “[Regime-Switching Regression Model](#)” on page 1273 and “[Regime-Switching Autoregression Model](#)” on page 1274.

The probability density function (PDF) of the NIW distribution is

$$\begin{aligned} f_{\text{NIW}}(\beta, \Sigma, \tilde{\mu}, \tilde{\Sigma}, \tilde{\kappa}, \tilde{\nu}) &= f_N(\beta, \tilde{\mu}, \tilde{\kappa}^{-1} \otimes \Sigma) f_{\text{IW}}(\Sigma, \tilde{\Sigma}, \tilde{\nu}) \\ f_N(\beta, \tilde{\mu}, \tilde{\kappa}^{-1} \otimes \Sigma) &= \frac{1}{\sqrt{(2\pi)^{k_1 k_2} |\tilde{\kappa}^{-1} \otimes \Sigma|}} \exp\left(-\frac{1}{2}(\beta - \tilde{\mu})'(\tilde{\kappa}^{-1} \otimes \Sigma)^{-1}(\beta - \tilde{\mu})\right) \\ f_{\text{IW}}(\Sigma, \tilde{\Sigma}, \tilde{\nu}) &= \frac{|\tilde{\Sigma}|^{\frac{\tilde{\nu}}{2}}}{2^{\frac{\tilde{\nu} k_1}{2}} \Gamma_{k_1}(\frac{\tilde{\nu}}{2})} |\Sigma|^{-\frac{\tilde{\nu} + k_1 + 1}{2}} \exp\left(-\frac{1}{2} \text{tr}(\tilde{\Sigma} \Sigma^{-1})\right) \end{aligned}$$

where the parameter β is a $k_1 k_2 \times 1$ vector; the parameter Σ is a $k_1 \times k_1$ symmetric positive matrix; the hyperparameter $\tilde{\mu}$ is a $k_1 k_2 \times 1$ vector; the hyperparameter $\tilde{\Sigma}$ is a $k_1 \times k_1$ symmetric positive definite matrix; the hyperparameter $\tilde{\kappa}$ is a $k_2 \times k_2$ symmetric positive definite matrix; and the hyperparameter $\tilde{\nu}$ is a positive scalar, where $\tilde{\nu} > k_1 + 3$. The $\Gamma_k(\cdot)$ is the multivariate gamma function defined as

$$\Gamma_k(x) = \pi^{\frac{k(k-1)}{4}} \prod_{j=1}^k \Gamma\left(x + \frac{1-j}{2}\right)$$

In the PRIOR statement, the arguments for the NIW function are constructed by stacking the hyperparameters for each state,

$$\begin{aligned} \tilde{\mu} &= (\tilde{\mu}_1 \cdots \tilde{\mu}_K)' \\ \tilde{\Sigma} &= (\tilde{\Sigma}_1 \cdots \tilde{\Sigma}_K)' \\ \tilde{\kappa} &= (\tilde{\kappa}_1 \cdots \tilde{\kappa}_K)' \\ \tilde{\nu} &= (\tilde{\nu}_1 \cdots \tilde{\nu}_K)' \end{aligned}$$

where $\tilde{\mu}$ is a $K \times k_y k_z$ matrix, $\tilde{\Sigma}$ is a $k_y K \times k_y$ matrix, $\tilde{\kappa}$ is a $k_z K \times k_z$ matrix, $\tilde{\nu}$ is a $K \times 1$ vector, K is the number of states, k_y is the number of dependent variables, and k_z is the number of regressors.

Poisson HMM In the Poisson HMM, the mean and variance for state i are both equal to $\lambda_i, i = 1, \dots, K$. The prior distribution of λ_i , the gamma distribution, is

$$\lambda \sim \text{gamma}(\alpha, \beta)$$

where the hyperparameter α, β is the $K \times 2$ matrix and K is the number of states. The probability density function (PDF) of the gamma distribution is

$$f(\lambda) = \frac{\beta^\alpha}{\Gamma(\alpha)} \lambda^{(\alpha-1)} \exp(-\beta\lambda)$$

where $\lambda > 0$.

Optimization Algorithms

The HMM procedure supports four types of optimization algorithms: the expectation-maximization (EM) algorithm, the active-set algorithm, the interior point algorithm, and the stochastic gradient descent (SGD) algorithm.

The EM algorithm is an iterative method of finding the local maximum likelihood estimates of parameters in models. After initializing the parameters—the ISPV π , the TPM A , the mean μ , and the covariance Σ —the EM algorithm iterates between two steps: the expectation (E) step and the maximization (M) step.

In the E step, γ_t and ξ_t are computed using α_t and β_t , which are based on the forward and backward algorithm:

$$\gamma_t(i) = \frac{\alpha_t(i)\beta_t(i)}{\sum_{j=1}^K \alpha_t(j)\beta_t(j)}$$

$$\xi_t(i, j) = \frac{\alpha_t(i)a_{ij}p(y_{t+1}|s_{t+1}=j)\beta_{t+1}(j)}{\sum_{i=1}^K \sum_{j=1}^K \alpha_t(i)a_{ij}p(y_{t+1}|s_{t+1}=j)\beta_{t+1}(j)}$$

where $i, j \in [1, K]$. In the M step, the parameters are updated using γ_t and ξ_t from the E step: When ESTISPV is specified, ISPV is updated according to $\pi_i = \gamma_1(i)$. For finite-state-space and homogeneous HMM, the stationary distribution of the Markov chain is the value of π such that $\pi' A = \pi'$, where A is the transition probability matrix (TPM); that is, π is the leading left eigenvector of A . Other parameters are updated according to the following equations, if there are no sections in the data:

$$a_{ij} = \frac{\sum_{t=1}^{T-1} \xi_t(i, j)}{\sum_{t=1}^{T-1} \gamma_t(i)}$$

$$\mu_i = \frac{\sum_{t=1}^T y_t * \gamma_t(i)}{\sum_{t=1}^T \gamma_t(i)}$$

$$\Sigma_i = \frac{\sum_{t=1}^T (y_t - \mu_i) * (y_t - \mu_i)^T * \gamma_t(i)}{\sum_{t=1}^T \gamma_t(i)}$$

Otherwise, the preceding equations become

$$\begin{aligned}\pi_i &= \frac{\sum_{s=1}^{\text{nsec}} \gamma_1^{(s)}(i)}{\text{nsec}} \\ a_{ij} &= \frac{\sum_{s=1}^{\text{nsec}} \sum_{t=1}^{T^{(s)}-1} \xi_t(i, j)}{\sum_{s=1}^{\text{nsec}} \sum_{t=1}^{T^{(s)}-1} \gamma_t^{(s)}(i)} \\ \mu_i &= \frac{\sum_{s=1}^{\text{nsec}} \sum_{t=1}^{T^{(s)}} y_t * \gamma_t^{(s)}(i)}{\sum_{s=1}^{\text{nsec}} \sum_{t=1}^{T^{(s)}} \gamma_t^{(s)}(i)} \\ \Sigma_i &= \frac{\sum_{s=1}^{\text{nsec}} \sum_{t=1}^{T^{(s)}} (y_t - \mu_i) * (y_t - \mu_i)^T * \gamma_t^{(s)}(i)}{\sum_{s=1}^{\text{nsec}} \sum_{t=1}^{T^{(s)}} \gamma_t^{(s)}(i)}\end{aligned}$$

where s is the index of section and nsec is the number of sections. Notice that μ_i is used to demean y_t when Σ_i is updated. The EM algorithm is supported only for the Gaussian HMM and the maximum likelihood method.

Starting in version 2023.05, you can execute the EM algorithm in parallel on multiple threads and nodes if you divide the data into sections and specify the `SECTION=` option in the `ID` statement. In this case, each thread is assigned some sections of the data on the available nodes. Or if backward compatibility is a concern, you can run the EM algorithm in nonparallel mode by specifying the `SINGLE` option in the `OPTIMIZE` statement. Parallel mode can reduce run time and improve the algorithm's performance. Also, there might be a numerical difference between your results in these two modes.

For more information about the active set and interior point algorithms and their related options, see the chapter “The Nonlinear Programming Solver” in *SAS/OR User's Guide: Mathematical Programming*. For more information about the SGD algorithm, see the section “[OPTIMIZE Statement](#)” on page 1259.

Distributed Multistart

In the distributed multistart algorithm, the local optimizations that start from various initial points run concurrently. Each of these local optimizations requires evaluation of the objective or constraints as well as their first or second derivatives at different points, which are referred to as function evaluations. If function evaluations are performed in distributed mode, as in the case of `PROC HMM`, the evaluations necessary for each local optimization are performed in a subsession that stems from the current main CAS session. You can specify the `SESSNODES=`, `FESESSIONS=`, and `FESESSNODES=` options to achieve a balanced and more efficient usage of the computing resources, in particular the available nodes and the threads on each node.

Suppose that there are a total of W worker nodes in the current main CAS session and you specify `SESSNODES= $m$` , `FESESSIONS= $s$` , and `FESESSNODES= $n$` . Then m out of W worker nodes are dedicated to the local optimizations of the multistart algorithm. Hence the total number of local optimizations that run concurrently is

$$N_{\text{locopt}} = \sum_{i=1}^m t_i$$

where t_i is the number of threads on node i . In addition, s subsessions, each of which has n worker nodes, are created and dedicated to function evaluations. When a function evaluation is requested in one of N_{locopt} local

optimizations, the request is sent to one of the s subsessions. Use the following guidelines when you select the values of the `SESSNODES=`, `FESESSIONS=`, and `FESESSNODES=` options:

- The value of m or n should never be greater than W .
- The total number of local optimizations N_{locopt} should be as close to s as possible. This allows a good balance between the resources for local optimizations and function evaluations.
- If you have a limited number of worker nodes W , then in order to achieve the correct balance, preference is often given to a combination that favors a larger s and smaller n over one that favors a smaller s and larger n . This helps reduce the number of function evaluation requests that are waiting to be processed in a function evaluation subsession.
- Avoid a scenario in which $m + sn$ is far greater than W . In such a scenario, competition for resources would occur and would degrade performance.

Matrix Expression

The `INITIAL` and `PRIOR` statements operate on matrices. That is, you can specify the parameter matrices or constant matrices through the `INITIAL` and `PRIOR` statements' built-in operators and functions. You can add elements of the matrices **A** and **B** by using the expression **A+B**, perform matrix multiplication by using the expression **A*B**, and perform elementwise multiplication by using the expression **A#B**. You can get the diagonal elements of the matrix **A** by using the function `DIAG (A)`, and you can get the $n \times n$ identity matrix by using the function `I (n)`.

Each equation is written as a matrix expression that is composed of constants, operators, and functions.

Constants

Constants are either scalar constants (such as -1.2 , 0.3 , and so on) or matrix constants enclosed in braces (such as the 2×2 matrix `{1 2, 3 4}` or the 1×3 row vector `{-0.2 5.3 12}`).

The matrix constant cannot be the first item in the `INITIAL` statement unless you enclose it in parentheses. For example, you cannot specify the following statement:

```
initial {-0.1 -0.2, -0.3 -0.4} = MU;
```

You can specify the preceding example by enclosing the first matrix constant in parentheses, as follows:

```
initial ({-0.1 -0.2, -0.3 -0.4}) = MU;
```

Operators

Operators define the operations on operands. [Table 20.2](#) lists all built-in operators that the `INITIAL` statement supports.

Table 20.2 Operators

Operator	Name	Description
+	Addition	Adds corresponding matrix elements
=	Comparison, equal	Compares matrix elements
<	Comparison, less than	Compares matrix elements
<=	Comparison, not greater than	Compares matrix elements
>	Comparison, greater than	Compares matrix elements
>=	Comparison, not less than	Compares matrix elements
	Concatenation, horizontal	Concatenates matrices horizontally
//	Concatenation, vertical	Concatenates matrices vertically
@	Direct product	Takes the direct product of two matrices
~	Distribution	Links the distribution function to the matrix elements
:	Index creation	Creates an index vector
#	Multiplication, elementwise	Performs elementwise multiplication
*	Multiplication, matrix	Performs matrix multiplication
—	Sign reverse	Reverses the signs of elements
[]	Subscripts	Selects submatrices
—	Subtraction	Subtracts corresponding matrix elements
`	Transpose	Transposes a matrix

For more information about each operator, see the section “[Details of Operators](#)” on page 1316.

[Table 20.3](#) shows the precedence of matrix operators.

Table 20.3 Precedence of Operators

Priority Group	Operators
I (highest)	[] (subscripts) ` (transpose)
II	— (sign reverse)
III	* # @
IV	— (subtraction) +
V	// :
VI (lowest)	= < <= > >= ~

Each equation can be a compound expression that involves several matrix operators and operands. The rules for evaluating compound expressions are as follows:

- Evaluation follows the order of operator precedence as described in [Table 20.3](#). Group I has the highest priority; that is, Group I operators are evaluated first. Group II operators are evaluated after Group I operators, and so on. For example, $1 + 2 * 3$ returns 7.
- If neighboring operators in an expression have equal precedence, the expression is evaluated from left to right, except for the Group I operators. For example, $1 - 2 - 3$ returns -4 .
- All expressions in parentheses are evaluated first, following the two preceding rules. For example, $3 * (2 + 1)$ returns 9.

Functions

Functions are divided into two types. One type of function refers to parameters to be estimated; examples are **MU**(**K**, **I**) and **SIGMA**(**K**, **I**, **J**). The other type does not; examples are **I**(**n**) and **DIAG**(**A**).

Functions that refer to parameters are listed in Table 20.4. The arguments of functions can be matrices. The simplest case, scalar arguments, is discussed first. For convenience, the scalar indices **i** and **j** refer to the position of the element in the coefficient matrix, the scalar **l** refers to the lag value, the scalar **c** refers to the component index, and the scalar **k** refers to the state value.

Table 20.4 Functions That Refer to Parameters

Function	Description
AR (k , l , i , j)	Autoregressive parameter of the lag l of the j th dependent variable, $y_{j,t-l}$, to the i th dependent variable at time t , y_{it} , for state k in regime-switching autoregression
CONST (k , i)	Intercept parameter of the i th time series, y_{it} , for state k in regime-switching regression or regime-switching autoregression, or the alias of MU for Gaussian HMM or GM HMM
COV (k , i , j)	Covariance of innovations parameter between the i th and j th error processes for state k in regime-switching regression or regime-switching autoregression, or the alias of SIGMA for Gaussian HMM or GM HMM
CPM (i , j)	The (i, j) th element in the category probability matrix in the finite HMM
LAMBDA (K)	Mean parameter of the time series, y_{it} , for state k in the Poisson HMM
ISPV (i)	The i th element in the initial state probability vector
LTREND (k , i)	Linear trend parameter of the i th time series, y_{it} , for state k in regime-switching regression or regime-switching autoregression when the TREND = option is specified in the MODEL statement
MCP (i , j)	The (i, j) th element in the mixture component probabilities in the GM HMM
MU (k , i)	Mean parameter of the i th time series, y_{it} , for state k in the Gaussian HMM, or alias for CONST for regime-switching regression or regime-switching autoregression
MU (k , c , i)	Mean parameter of the i th time series, y_{it} , for the c th component at state k in the GM HMM
QTREND (k , i)	Quadratic trend parameter of the i th time series, y_{it} , for state k in regime-switching regression or regime-switching autoregression when TREND = QUAD is specified in the MODEL statement
SD (k , i , j)	Alias of SDUMMY
SDUMMY (k , i , j)	The j th seasonal dummy of the i th time series at time t , y_{it} , for state k in regime-switching regression or regime-switching autoregression, where $j = 1, \dots, (nseason-1)$, where $nseason$ is the value of the NSEASON = option in the MODEL statement
SIGMA (k , i , j)	Covariance parameter between the i th and j th time series, y_{it} and y_{jt} , for state k in the Gaussian HMM, or the alias of COV for regime-switching regression or regime-switching autoregression
SIGMA (k , c , i , j)	Covariance parameter between the i th and j th time series, y_{it} and y_{jt} , for c th component at state k in the GM HMM
TPM (i , j)	The (i, j) th element in the transition probability matrix

Table 20.4 *continued*

Function	Description
XL (k , l , i , j)	Exogenous parameter of the lag l of the j th exogenous variable, $x_{j,t-l}$, to the i th dependent variable at time t , y_{it} , for state k in regime-switching regression or regime-switching autoregression

The functions that refer to parameters, as shown in Table 20.4, are valid only when the parameters are included in the model. For example, the **ISPV** function is valid only when you specify the **ESTISPV** option in the **MODEL** statement; otherwise, the HMM procedure issues errors and then stops.

The functions that refer to parameters, as shown in Table 20.4, accept vector and matrix arguments and return the matrix that is constructed by the corresponding parameters. According to the number of arguments, the following list shows what matrix a function returns when the arguments are vectors:

- A function, **FUNC**₁, that has one vector argument I , where $I = (i_1 \ i_2 \ \dots \ i_{n_I})'$, returns a vector $R = (r_1 \ r_2 \ \dots \ r_{n_I})'$, where $r_k = \mathbf{FUNC}_1(i_k)$, $k = 1, \dots, n_I$. **ISPV** is a type of **FUNC**₁.
- A function, **FUNC**₂, that has two vector arguments I and J , where $I = (i_1 \ i_2 \ \dots \ i_{n_I})'$ and $J = (j_1 \ j_2 \ \dots \ j_{n_J})'$, returns a matrix,

$$R = \begin{pmatrix} r_{1,1} & r_{1,2} & \cdots & r_{1,n_J} \\ r_{2,1} & r_{2,2} & \cdots & r_{2,n_J} \\ \cdots & & & \\ r_{n_I,1} & r_{n_I,2} & \cdots & r_{n_I,n_J} \end{pmatrix}$$

where $r_{k,m} = \mathbf{FUNC}_2(i_k, j_m)$, $k = 1, \dots, n_I$, $m = 1, \dots, n_J$. **CONST**, **LTREND**, **MU**, **QTREND**, and **TPM** are types of **FUNC**₂.

- A function, **FUNC**_N, that has N vector arguments $I_1, I_2, \dots$, and I_N , where $N > 2$ and N is odd and where $I_n = (i_{n,1} \ i_{n,2} \ \dots \ i_{n,j_n})'$, $n = 1, \dots, N$, returns a block matrix,

$$R = \begin{pmatrix} B_1 \\ B_2 \\ \cdots \\ B_{j_n} \end{pmatrix}$$

where $B_k = \mathbf{FUNC}_N(i_{1,k}, I_2, \dots, I_N)$, $k = 1, \dots, j_1$, and B_k is constructed in the same way as **FUNC**_{N-1}($I_2, \dots, I_N$).

For example, a function, **FUNC**₃, that has three vector arguments K , I , and J , where $K = (k_1 \ k_2 \ \dots \ k_{n_K})'$, $I = (i_1 \ i_2 \ \dots \ i_{n_I})'$, and $J = (j_1 \ j_2 \ \dots \ j_{n_J})'$, returns a matrix,

$$R = \begin{pmatrix} r_{1,1} & r_{1,2} & \cdots & r_{1,n_J} \\ r_{2,1} & r_{2,2} & \cdots & r_{2,n_J} \\ \cdots & & & \\ r_{n_K n_I,1} & r_{n_K n_I,2} & \cdots & r_{n_K n_I,n_J} \end{pmatrix}$$

where $r_{u,v} = \mathbf{FUNC}_3(k_{d_1(u,n_I)}, i_{d_2(u,n_I)}, j_v)$, $u = 1, \dots, n_{Kn_I}$, $v = 1, \dots, n_J$, and $d_1(m, n)$ is the integer such that $d_1(m, n)n \geq m > (d_1(m, n) - 1)n$ and $d_2(m, n) = m - (d_1(m, n) - 1)n$. **COV** and **MU** for GM HMM and **SIGMA** for Gaussian HMM are types of **FUNC**₃.

- A function, **FUNC**_N, that has N vector arguments $I_1, I_2, \dots$, and I_N , where $N > 2$ and N is even and where $I_n = (i_{n,1} \ i_{n,2} \ \dots \ i_{n,j_n})'$, $n = 1, \dots, N$, returns a block matrix,

$$R = \begin{pmatrix} B_{1,1} & B_{1,2} & \cdots & B_{1,j_2} \\ B_{2,1} & B_{2,2} & \cdots & B_{2,j_2} \\ \cdots & & & \\ B_{j_1,1} & B_{j_1,2} & \cdots & B_{j_1,j_2} \end{pmatrix}$$

where $B_{k,l} = \mathbf{FUNC}_N(i_{1,k}, i_{2,l}, I_3, \dots, I_N)$, $k = 1, \dots, j_1$, $l = 1, \dots, j_2$, and $B_{k,l}$ is constructed in the same way as **FUNC**_{N-2}($I_3, \dots, I_N$).

For example, a function, **FUNC**₄, that has four vector arguments K, L, I , and J , where $K = (k_1 \ k_2 \ \dots \ k_{n_K})'$, $L = (l_1 \ l_2 \ \dots \ l_{n_L})'$, $I = (i_1 \ i_2 \ \dots \ i_{n_I})'$, and $J = (j_1 \ j_2 \ \dots \ j_{n_J})'$, returns a matrix,

$$R = \begin{pmatrix} r_{1,1} & r_{1,2} & \cdots & r_{1,n_L n_J} \\ r_{2,1} & r_{2,2} & \cdots & r_{2,n_L n_J} \\ \cdots & & & \\ r_{n_{Kn_I},1} & r_{n_{Kn_I},2} & \cdots & r_{n_{Kn_I},n_L n_J} \end{pmatrix}$$

where $r_{u,v} = \mathbf{FUNC}_4(k_{d_1(u,n_I)}, l_{d_1(v,n_J)}, i_{d_2(u,n_I)}, j_{d_2(v,n_J)})$, $u = 1, \dots, n_{Kn_I}$, $v = 1, \dots, n_{Ln_J}$, where $d_1(m, n)$ is the integer such that $d_1(m, n)n \geq m > (d_1(m, n) - 1)n$ and $d_2(m, n) = m - (d_1(m, n) - 1)n$. **AR** and **SIGMA** for GM HMM and **XL** are types of **FUNC**₄.

The functions that refer to parameters can accept empty arguments or omit any number of last arguments. The empty or omitted arguments are replaced by all possible values for those arguments. For example, PROC HMM is used to fit a bivariate three-state Gaussian HMM as follows:

```
model y1 y2 / type=gaussian nstate=3;
```

In order to initialize the second row of **TPM** to be {0.1 0.7 0.2}, you can use the following statement:

```
initial tpm(2, {1 2 3}) = {0.1 0.7 0.2};
```

Taking advantage of empty arguments, you can specify the preceding example as follows:

```
initial tpm(2,) = {0.1 0.7 0.2};
```

To get all coefficients of the covariance matrix for state 2, you can use **SIGMA**(2, {1 2}, {1 2}), or **SIGMA**(2, ,), or **SIGMA**(2). To get all coefficients of exogenous variables on dependent variables, you can use **SIGMA**({1 2 3}, {1 2}, {1 2}), or **SIGMA**(, ,), or **SIGMA**(), or even just **SIGMA**.

Another type of function does not refer to parameters but generates useful matrices. Table 20.5 lists all built-in functions.

Table 20.5 Functions That Do Not Refer to Parameters

Function	Description
DIAG (A)	Creates a diagonal matrix from a vector or extracts the diagonal elements of a matrix
I (n)	Creates an $n \times n$ identity matrix
J (m, n, elem)	Creates an $m \times n$ matrix whose elements are all equal to elem
SHAPE (A, m, n)	Creates an $m \times n$ matrix whose elements are from matrix A

For more information about each function in [Table 20.5](#), see the section “[Details of Functions](#)” on page 1320.

Details of Operators

This section describes all operators that are available in the HMM procedure. Each subsection describes the operator and shows how it is used.

Addition Operator: +

The addition operator (+) computes a new matrix whose elements are the sums of corresponding elements of the two operands. Following are examples of how the addition operator is used:

matrix1 + matrix2	adds the element in the i th row and j th column of the first matrix to the element in the i th row and j th column of the second matrix, for $i = 1, \dots, n$, $j = 1, \dots, p$, where matrix1 and matrix2 are both $n \times p$ matrices. For example, {1 2 3, 4 5 6} + {7 8 9, 10 11 12} results in {8 10 12, 14 16 18}.
matrix + scalar	adds the scalar value to each element of the matrix . For example, you can obtain {2 3 4, 5 6 7} from {1 2 3, 4 5 6} + 1.
matrix + vector	adds the vector value to each row or column of the $n \times p$ matrix : • If you add an $n \times 1$ column vector, each row of the vector is added to each row of the matrix. For example, you can obtain {2 3 4, 5 6 7} from {1 2 3, 4 5 6} + {1, 1}. • If you add a $1 \times p$ row vector, each column of the vector is added to each column of the matrix. For example, you can obtain {2 3 4, 5 6 7} from {1 2 3, 4 5 6} + {1 1 1}.

Comparison Operators: =, <, <=, >, >=

The comparison operators (=, <, <=, >, >=) compare two matrices element by element and return a list of equivalent restrictions on only scalar constants and parameters.

```

matrix1 = matrix2
matrix1 < matrix2
matrix1 <= matrix2
matrix1 > matrix2

```

```
matrix1 >= matrix2
```

For example, the INITIAL statement with matrix expressions

```
initial SIGMA(1, {1, 2}, {1, 2}) = SIGMA(2, {3, 4}, {3, 4});
```

is transformed into the following equivalent INITIAL statement with scalar parameters:

```
initial SIGMA(1, 1, 1) = SIGMA(2, 3, 3),
        SIGMA(1, 1, 2) = SIGMA(2, 3, 4),
        SIGMA(1, 2, 1) = SIGMA(2, 4, 3),
        SIGMA(1, 2, 2) = SIGMA(2, 4, 4);
```

You can also use the comparison operators to conveniently compare all elements of a matrix to a scalar. If either argument is a scalar, then the HMM procedure performs an elementwise comparison between each element of the matrix and the scalar.

You can also compare an $n \times p$ matrix to a row or column vector:

- If the comparison is to an $n \times 1$ column vector, the HMM procedure compares each row of the vector to each row of the matrix.
- If the comparison is to a $1 \times p$ row vector, the HMM procedure compares each column of the vector to each column of the matrix.

For example, the following statements are equivalent:

```
initial SIGMA(1, 4:5, 1:3) = 0.2;

initial SIGMA(1, 4:5, 1:3) = {0.2, 0.2};

initial SIGMA(1, 4:5, 1:3) = {0.2 0.2 0.2};
```

Concatenation Operator, Horizontal: ||

The horizontal concatenation operator (||) produces a new matrix by horizontally joining **matrix1** and **matrix2**.

```
matrix1 || matrix2
```

The matrices must have the same number of rows, which is also the number of rows in the new matrix. The number of columns in the new matrix is the number of columns in **matrix1** plus the number of columns in **matrix2**.

For example, {1 1 1, 7 7 7} || {0 0 0, 8 8 8} returns {1 1 1 0 0 0, 7 7 7 8 8 8}.

Concatenation Operator, Vertical: //

The vertical concatenation operator (//) produces a new matrix by vertically joining **matrix1** and **matrix2**.

```
matrix1 // matrix2
```

The matrices must have the same number of columns, which is also the number of columns in the new matrix. The number of rows in the new matrix is the number of rows in **matrix1** plus the number of rows in **matrix2**.

For example, {1 1 1} // {0 0 0, 8 8 8} returns {1 1 1, 0 0 0, 8 8 8}.

Direct Product Operator: @

The direct product operator (@) computes a new matrix that is the direct product (also called the Kronecker product) of **matrix1** and **matrix2**.

matrix1 @ matrix2

For matrices **A** and **B**, the direct product is denoted by $\mathbf{A} \otimes \mathbf{B}$. The number of rows in the new matrix equals the product of the number of rows in **matrix1** and the number of rows in **matrix2**; the number of columns in the new matrix equals the product of the number of columns in **matrix1** and the number of columns in **matrix2**.

Specifically, if **A** is an $n \times p$ matrix and **B** is an $m \times q$ matrix, then the Kronecker product $\mathbf{A} \otimes \mathbf{B}$ is the following $nm \times pq$ block matrix:

$$\mathbf{A} \otimes \mathbf{B} = \begin{bmatrix} A_{11}B & \cdots & A_{1p}B \\ \vdots & \ddots & \vdots \\ A_{n1}B & \cdots & A_{np}B \end{bmatrix}$$

For example, $\{1 \ 2, \ 3 \ 4\} @ \{0 \ 2\}$ returns $\{0 \ 2 \ 0 \ 4, \ 0 \ 6 \ 0 \ 8\}$, and $\{0 \ 2\} @ \{1 \ 2, \ 3 \ 4\}$ returns $\{0 \ 0 \ 2 \ 4, \ 0 \ 0 \ 6 \ 8\}$. Note that the direct product of two matrices is not commutative.

Distribution Operator: ~

The distribution operator links the matrix to its distribution function.

matrix ~ distribution-function

This operator is used in the PRIOR statement. For more information, see the section “PRIOR Statement” on page 1264.

For example, $\mathbf{ISPV} \sim \mathbf{DIR}(\{1, 1, 1\})$ means that the initial state probability vector (ISPV) follows a Dirichlet distribution with an argument of a 3×1 vector $\{1, 1, 1\}$.

Index Creation Operator: :

The index creation operator (:) creates a column vector whose first element is **value1**, second element is **value1+1**, and so on, until the last element, which is less than or equal to **value2**.

value1 : value2

For example, $3 : 6$ returns $\{3 \ 4 \ 5 \ 6\}$.

If **value1** is greater than **value2**, a reverse-order index is created. For example, $6 : 3$ returns $\{6 \ 5 \ 4 \ 3\}$.

Neither **value1** nor **value2** is required to be an integer.

Multiplication Operator, Elementwise: #

The elementwise multiplication operator (#) computes a new matrix whose elements are the products of the operands. Following are examples of how the elementwise multiplication operator is used:

matrix1 # matrix2 computes a new matrix whose elements are the products of the corresponding elements of **matrix1** and **matrix2**.

For example, $\{1 \ 2, \ 3 \ 4\} \# \{4 \ 8, \ 0 \ 5\}$ returns $\{4 \ 16, \ 0 \ 20\}$.

matrix # scalar multiplies each element in **matrix** by the **scalar** value.

matrix # vector multiplies each row or column of the $n \times p$ matrix by a corresponding element of the vector:

- If you multiply by an $n \times 1$ column vector, each row of the matrix is multiplied by the corresponding row of the vector.
- If you multiply by a $1 \times p$ row vector, each column of the matrix is multiplied by the corresponding column of the vector.

For example, a 2×3 matrix can be multiplied on either side by a 2×3 , 1×3 , 2×1 , or 1×1 scalar.

The product of elementwise multiplication is also known as the Schur or Hadamard product. Elementwise multiplication (which uses the # operator) should not be confused with matrix multiplication (which uses the * operator).

Multiplication Operator, Matrix: *

The matrix multiplication operator (*) computes a new matrix by performing matrix multiplication.

matrix1 * matrix2

The first matrix must have the same number of columns as the second matrix has rows. The new matrix has the same number of rows as the first matrix and the same number of columns as the second matrix. That is, if **A** is an $n \times p$ matrix and **B** is a $p \times m$ matrix, then the product **A * B** is an $n \times m$ matrix. The (i, j) element of the product is the sum $\sum_{k=1}^p A_{ik} B_{kj}$.

For example, **{1 2, 3 4} * {1, 2}** returns **{5, 11}**.

Sign Reversal Operator: -

The sign reversal operator (-) computes a new matrix whose elements are formed by reversing the sign of each element in **matrix**. The sign reversal operator is also called the unary minus operator.

- matrix

For example, **-{-1 7 6, 2 0 -8}** returns **{1 -7 -6, -2 0 8}**.

Subscripts: []

Subscripts are used with matrices to select submatrices, where **rows**, **columns**, and **elements** are expressions that evaluate to scalars or vectors. If these expressions are numeric, they must contain valid subscript values of rows and columns, or the indices, in the argument matrix.

matrix[rows, columns]

matrix[elements]

For example, **{1 2 3, 4 5 6, 7 8 9}[2,3]** returns **6**; **{1 2 3, 4 5 6, 7 8 9}[2,1:3]** returns **{4 5 6}**; and **{1 2 3, 4 5 6, 7 8 9}[,3]** returns **{3, 6, 9}**. Because the HMM procedure stores matrices in row-major order, **{11 22 33, 44 55 66, 77 88 99} [{3 5 9}]** returns **{33, 55, 99}**.

Subtraction Operator: -

The subtraction operator (-) computes a new matrix whose elements are formed by subtracting the corresponding elements of the second operand from the first operand.

matrix1 - matrix2	computes a new matrix whose elements are formed by subtracting the corresponding elements of matrix2 from those of matrix1 . For example, {1 2 3, 4 5 6} - {1 1 1, 1 1 1} returns {0 1 2, 3 4 5}.
matrix - scalar	subtracts the scalar value from each element of the matrix . For example, {1 2 3, 4 5 6} - 1 returns {0 1 2, 3 4 5}.
matrix - vector	subtracts the vector from each element of the matrix : • If you subtract an $n \times 1$ column vector, each row of the vector is subtracted from each row of the matrix. For example, {1 2 3, 4 5 6} - {1, 1} returns {0 1 2, 3 4 5}. • If you subtract a $1 \times p$ row vector, each column of the vector is subtracted from each column of the matrix. For example, {1 2 3, 4 5 6} - {1 1 1} returns {0 1 2, 3 4 5}.

Transpose Operator: `

The transpose operator, denoted by the backquote (`), exchanges the rows and columns of **matrix**, producing the transpose of **matrix**.

matrix`

If v is the value in the i th row and j th column of **matrix**, then the transpose of **matrix** contains v in the j th row and i th column. If **matrix** contains n rows and p columns, the transpose has p rows and n columns.

For example, {1 2, 3 4, 5 6}` returns {1 3 5, 2 4 6}.

Details of Functions**DIAG Function**

The **DIAG** function creates a diagonal matrix from a vector or extracts the diagonal elements of a matrix.

DIAG(matrix)

The **matrix** argument can be either a square matrix or a vector:

- If **matrix** is a square matrix, the **DIAG** function creates a vector from the diagonal elements of the matrix.
For example, **DIAG**({1 2 3, 4 5 6, 7 8 9}) returns {1, 5, 9}.
- If **matrix** is a vector, the **DIAG** function creates a matrix whose diagonal elements are the values in the vector. All off-diagonal elements are zeros.
For example, **DIAG**({1 5 9}) or **DIAG**({1, 5, 9}) returns {1 0 0, 0 5 0, 0 0 9}.

You can call the **DIAG** function repeatedly. For example, **DIAG**(**DIAG**({1 2 3, 4 5 6, 7 8 9})) returns {1 0 0, 0 5 0, 0 0 9}.

I Function

The **I** function creates an identity matrix that contains **dim** rows and columns.

I(dim)

The diagonal elements of an identity matrix are ones; all other elements are zeros. The value of **dim** must be an integer greater than or equal to 1. Noninteger operands are rounded to the nearest integer.

For example, **I(3)** returns {1 0 0, 0 1 0, 0 0 1}.

J Function

The **J** function creates a matrix that contains **nrow** rows and **ncol** columns, in which all elements are equal to **value**.

J(nrow, ncol, value)

The arguments **nrow** and **ncol** are both integers; **value** can be any expression that returns a linear combination of scalar constants and parameters.

For example, **J(2, 3, 1)** returns {1 1 1, 1 1 1}.

SHAPE Function

The **SHAPE** function creates a new matrix from data in **matrix**.

SHAPE(matrix, nrow, ncol)

The values **nrow** and **ncol** specify the number of rows and columns, respectively, in the new matrix. The **SHAPE** function produces the new matrix by traversing the argument matrix in row-major order until it reaches the specified number of elements. If necessary, the **SHAPE** function reuses elements.

For example, **SHAPE({1 2 3, 4 5 6}, 3, 2)** returns {1 2, 3 4, 5 6}; **SHAPE({1 2 3, 4 5 6}, 5, 2)** returns {1 2, 3 4, 5 6, 1 2, 3 4}; and **SHAPE({1 2 3, 4 5 6}, 1, 4)** returns {1 2 3 4}.

Label Switching Problem

Label switching is an important and severe problem for all kinds of HMMs. Nonidentifiability is caused by invariance to relabeling the states of the hidden Markov chain (or the components of the mixture distribution in the case of GH HMMs); for further discussion and illustration, see Frühwirth-Schnatter (2006, page 15 and 173) and the references therein.

Any two HMMs are mathematically equivalent if the only difference between them is that the states or components are labeled in different ways. For example, consider the following models, which are both univariate bistate Gaussian HMMs described by the parameters $\{\pi, \mathbf{A}, \mathbf{B}\}$, where π is the initial state probability vector, $\mathbf{A}$ is the transition probability matrix, $\mathbf{B} \equiv \{\mu_1, \Sigma_1, \mu_2, \Sigma_2\}$, and μ_1 and Σ_1 are mean and covariance parameters for state 1, and μ_2 and Σ_2 are mean and covariance parameters for state 2:

$$\text{model 1: } \pi = \begin{pmatrix} 0.75 \\ 0.25 \end{pmatrix}, \mathbf{A} = \begin{pmatrix} 0.9 & 0.1 \\ 0.3 & 0.7 \end{pmatrix}, \mu_1 = 1, \Sigma_1 = 1, \mu_2 = -1, \Sigma_2 = 4$$

$$\text{model 2: } \pi = \begin{pmatrix} 0.25 \\ 0.75 \end{pmatrix}, \mathbf{A} = \begin{pmatrix} 0.7 & 0.3 \\ 0.1 & 0.9 \end{pmatrix}, \mu_1 = -1, \Sigma_1 = 4, \mu_2 = 1, \Sigma_2 = 1$$

In theory, these two models are equivalent, and just the state labels “1” and “2” are switched. When the labels are switched, it is inconvenient to compare any state-related results, such as filtered or smoothed probabilities or decoded path. Because of the randomness in the optimization, you might even get “different” estimation results every time because of label switching.

You can use the LABELSWITCH= option in the PROC HMM statement to solve the label switching problem. When the INMODEL= option in the SCORE statement is not specified, the LABELSWITCH=(SORT=ASC(SIGMA)) option is applied by default; that is, the states are labeled in the ascending order of the covariance parameter estimates. When the INMODEL= option in the SCORE statement is specified, the LABELSWITCH=(SORT=NONE) option is applied by default; that is, there is no relabeling. You can specify additional suboptions in the LABELSWITCH= option to label the states (and components) in whichever way you prefer.

An Example to Illustrate the LABELSWITCH= Option

The following data are simulated for this example. The data generating process (DGP) follows a bistate tricomponent GM HMM.

```
%let a11 = 0.98;
%let a22 = 0.98;
%let c1_1 = 0.3;
%let c1_2 = 0.4;
%let c1_3 = 0.3;
%let c2_1 = 0.3;
%let c2_2 = 0.4;
%let c2_3 = 0.3;
%let mu1_1_1 = -1;
%let mu1_2_1 = -6;
%let mu1_3_1 = -11;
%let sigma1_1_11 = 1;
%let sigma1_2_11 = 2;
%let sigma1_3_11 = 3;
%let mu2_1_1 = 6;
%let mu2_2_1 = 12;
%let mu2_3_1 = 20;
%let sigma2_1_11 = 4;
%let sigma2_2_11 = 5;
%let sigma2_3_11 = 6;
%let seed = 1234;
%let T = 400000;
%let nSections = 200;

data labelSwitchDGP;
  do t = 1 to &T.;
    sec = ceil(t*&nSections./&T.);
    if(t=1) then do;
      * initial probability distribution;
      p = (1-&a22.)/((1-&a11.)+(1-&a22.));
    end;
    else do;
      * transition probability matrix;
      if(lags=1) then p = &a11.;
      else p = 1-&a22.;
    end;
  end;
```

```

end;
u = uniform(&seed.);
if(u<=p) then s=1;
else s = 2;
e1 = normal(&seed.);
if(s=1) then do;
  * choose component;
  u = uniform(&seed.);
  if(u<=&c1_1.) then do;
    * x ~ N(mu, Sigma) at state 1, component 1;
    x = &mu1_1_1. + sqrt(&sigma1_1_11.)*e1;
  end;
  else do;
    if(u<=&c1_1.+&c1_2.) then do;
      * x ~ N(mu, Sigma) at state 1, component 2;
      x = &mu1_2_1. + sqrt(&sigma1_2_11.)*e1;
    end;
    else do;
      * x ~ N(mu, Sigma) at state 1, component 3;
      x = &mu1_3_1. + sqrt(&sigma1_3_11.)*e1;
    end;
  end;
end;
else do;
  * choose component;
  u = uniform(&seed.);
  if(u<=&c2_1.) then do;
    * x ~ N(mu, Sigma) at state 2, component 1;
    x = &mu2_1_1. + sqrt(&sigma2_1_11.)*e1;
  end;
  else do;
    if(u<=&c1_1.+&c1_2.) then do;
      * x ~ N(mu, Sigma) at state 2, component 2;
      x = &mu2_2_1. + sqrt(&sigma2_2_11.)*e1;
    end;
    else do;
      * x ~ N(mu, Sigma) at state 2, component 3;
      x = &mu2_3_1. + sqrt(&sigma2_3_11.)*e1;
    end;
  end;
end;
output;
lags = s;
end;
run;

```

The following statements plot the histogram of the simulated x by ignoring the sectional and sequential information.

```

proc sgplot data=labelSwitchDGP;
  histogram x;
run;

```

Figure 20.90 shows the histogram of x , in which there are six modes around 20, 12, 6, -1 , -6 , and -11 , as expected.

Figure 20.90 Plot of Histogram of x 

The following statements make a copy of the data in the library:

```
data mylib.labelSwitchDGP; set labelSwitchDGP; run;
```

The following statements estimate the six-state Gaussian HMM by using the initial values {20, 12, 6, -1, -6, -11} for the mean parameter:

```
proc hmm data=mylib.labelSwitchDGP;
  id time=t section=sec;
  model x / type=gaussian nstate=6;
  optimize printLevel=3 printIterFreq=1 algorithm=interiorpoint;
  initial mu={20, 12, 6, -1, -6, -11};
run;
```

The final parameter estimates after optimization, which are shown in Figure 20.91, are totally different from the reported parameter estimates in Figure 20.92. In Figure 20.91, the six states, described as Gaussian distribution, are in order $N(20, 6)$, $N(12, 5)$, $N(6, 4)$, $N(-1, 1)$, $N(-6, 2)$, and $N(-11, 3)$; however, in Figure 20.92, the six states are in order $N(-1, 1)$, $N(-6, 2)$, $N(-11, 3)$, $N(6, 4)$, $N(12, 5)$, and $N(20, 6)$. The difference is caused by the states being relabeled, by default, according to the estimates of the covariance matrix parameter of each state in ascending order; that is, the LABELSWITCH=(SORT=ASC(SIGMA)) option is applied by default.

The following statements explicitly show how the states are relabeled by using the LABELSWITCH=(OUT=) option:

```
proc hmm data=mylib.labelSwitchDGP labelSwitch=(out=mylib.olabel1);
  id time=t section=sec;
  model x / type=gaussian nstate=6;
  optimize printLevel=3 printIterFreq=1 algorithm=interiorpoint;
  initial mu={20, 12, 6, -1, -6, -11};
run;

data olabel1; set mylib.olabel1; run;
proc sort data=olabel1; by oldStateLabel; run;
proc print data=olabel1 noobs label; run;
```

The first row in [Figure 20.93](#) shows that the old state label “1” is relabeled as the new state “6”; that is, $N(20, 6)$ was labeled as state 1 but is relabeled as state 6. The same logic applies to other rows. The second row in [Figure 20.93](#) shows that the old state label “2” is relabeled as the new state “5”; the third row shows the old state label “3” is relabeled as the new state “4”; and so on. Note that all parameter estimates (ISPV, TPM, and so on) are permuted accordingly after the states are relabeled.

Figure 20.93 Old and New Labels of States

Old State Label	New State Label
1	6
2	5
3	4
4	1
5	2
6	3

The following statements request that the states be labeled in ascending order of the mean parameter estimates. As shown in [Figure 20.94](#), all parameters are permuted according to the new state labels.

```
proc hmm data=mylib.labelSwitchDGP labelSwitch=(sort=asc(mu) out=mylib.olabel2);
  id time=t section=sec;
  model x / type=gaussian nstate=6;
  optimize printLevel=3 printIterFreq=1 algorithm=interiorpoint;
  initial mu={20, 12, 6, -1, -6, -11};
run;
```

Figure 20.94 Parameter Estimates

Parameter	Parameter Estimates

The following statements estimate the bivariate tricomponent GM HMM. If you compare the final parameter estimates after optimization that are shown in [Figure 20.95](#) and the parameter estimates that are reported in [Figure 20.96](#), you see that the states and components are relabeled. State labels are exchanged, and the labels of component 1 and 3 for old state 1 are also exchanged, which is clearly shown in [Figure 20.97](#).

```
proc hmm data=mylib.labelSwitchDGP labelSwitch=(out=mylib.olabel3);
  id time=t section=sec;
  model x / type=gaussianMixture nstate=2 ncomponent=3;
  optimize printLevel=3 printIterFreq=1 algorithm=interiorpoint;
  initial mu={20, 12, 6, -1, -6, -11};
  score outmodel=mylib.odel;
run;

data olabel3; set mylib.olabel3; run;
proc sort data=olabel3; by oldStateLabel oldComponentLabel; run;
proc print data=olabel3 noobs label; run;
```

Figure 20.97 Old and New Labels of States and Components

Old State Label	Old Component Label	New State Label	New Component Label
1	1	2	3
1	2	2	2
1	3	2	1
2	1	1	1
2	2	1	2
2	3	1	3

The following statements specify the INMODEL= option in the SCORE statement, which causes the LABELSWITCH=(SORT=NONE) option to be applied by default. It is not surprising to see that the parameter estimates in Figure 20.98 are exactly same as those in Figure 20.96; that is, labels of states and components are not reordered, as confirmed by Figure 20.99.

```
proc hmm data=mylib.labelSwitchDGP
    labelSwitch=(out=mylib.olabel4);;
    score inmodel=mylib.omodel;
run;
```

```
data olabel4; set mylib.odelabel4; run;
proc sort data=odelabel4; by oldStateLabel oldComponentLabel; run;
proc print data=odelabel4 noobs label; run;
```

Figure 20.98 Parameter Estimates

Parameter Estimates

MU1_3_1	-10.977185	0.014627	-750.48	<.0001
MU2_1_1	6.036275	0.023837	253.23	<.0001
MU2_2_1	12.015837	0.019464	617.34	<.0001
MU2_3_1	19.994224	0.018675	1070.63	<.0001
SIGMA1_1_1_1	1.007494	0.007789	129.35	<.0001
SIGMA1_2_1_1	1.987574	0.023804	83.50	<.0001
SIGMA1_3_1_1	3.042284	0.033806	89.99	<.0001
SIGMA2_1_1_1	4.037831	0.053783	75.08	<.0001
SIGMA2_2_1_1	4.882495	0.097590	50.03	<.0001
SIGMA2_3_1_1	6.081830	0.063045	96.47	<.0001

Figure 20.99 Old and New Labels of States and Components

Old State Label	Old Component Label	New State Label	New Component Label
1	1	1	1
1	2	1	2
1	3	1	3
2	1	2	1
2	2	2	2
2	3	2	3

However, you can reorder the labels of states and components in whichever way you prefer by using the LABELSWITCH=(REORDER=) and LABELSWITCH=(REORDERCOMPONENT=) options, as illustrated in the following statements:

```

proc hmm data=mylib.labelSwitchDGP
      labelSwitch=(reorder=(2 1) reorderComponent=(2 1 3 2 3 1)
                  out=mylib.olabel5);
      score inmodel=mylib.omodel;
run;

data olabel5; set mylib.olabel5; run;
proc sort data=olabel5; by oldStateLabel oldComponentLabel; run;
proc print data=olabel5 noobs label; run;

```

The parameter estimates are shown in Figure 20.100, and the label comparison is shown in Figure 20.101.

Figure 20.100 Parameter Estimates

Figure 20.101 Old and New Labels of States and Components

Old State Label	Old Component Label	New State Label	New Component Label
1	1	2	2
1	2	2	1
1	3	2	3
2	1	1	2
2	2	1	3
2	3	1	1

The preceding statements illustrate how to use and interpret the LABELSWITCH= option. The statements use both Gaussian HMMs and GM HMMs, which differ as follows: Although it is trivial to know that a K-state Gaussian HMM can be regarded as a special case of a K-state unicomponent GM HMM, a K-state M-component GM HMM can also be regarded as a special case of a KM-state Gaussian HMM. In most cases, a KM-state Gaussian HMM has many more parameters (because of the huge transition probability matrix) than a K-state M-component GM HMM has. For the preceding statements, all information criteria, although not reported here, prefer the bivariate tricomponent GM HMM (which the true data generating process follows) to the six-state Gaussian HMM.

Analytic Store Technology

Scoring new data is a common and important task in deploying a model. You can score new data by using the SCORE statement in the HMM procedure, or you can do it by taking advantage of the analytic store technology. By using the STORE statement, you can save estimated models in an analytic store table. Then, you can download the table to a local analytic store file. Later, you can load the model and score new data on any platform that supports the analytic store technology—and you do not even need to have the HMM procedure available on those platforms.

The following example illustrates how to use the analytic store technology.

Generate your training data and upload them to the library. The following statements assume that your engine libref is named mylib, but you can substitute any appropriately defined libref.

```
%let pi1 = 0.5;
%let a11 = 0.2;
%let a22 = 0.2;
%let mu1_1 = 1;
%let mu1_2 = 1;
%let sigma1_11 = 1;
%let sigma1_21 = 0;
%let sigma1_22 = 1;
%let mu2_1 = -1;
%let mu2_2 = -1;
%let sigma2_11 = 1;
%let sigma2_21 = 0;
%let sigma2_22 = 1;

%macro dgpGHMM(table,T,nSections,seed);
  data &table;
    retain cd1_11 cd1_21 cd1_22 cd2_11 cd2_21 cd2_22;
    secLen = ceil(&T./&nSections.);
    do t = 1 to &T.;
      sec = floor((t-1)/secLen)+1;
      if(t=1) then do;
        /* initial probability distribution */
        p = &pi1.;
        /* Cholesky decomposition of sigma1 */
        cd1_11 = sqrt(&sigma1_11.);
        cd1_21 = &sigma1_21./sqrt(&sigma1_11.);
        cd1_22 = sqrt(&sigma1_22.-&sigma1_21.*&sigma1_21./&sigma1_11.);
        /* Cholesky decomposition of sigma2 */
```

```

        cd2_11 = sqrt(&sigma2_11.);
        cd2_21 = &sigma2_21./sqrt(&sigma2_11.);
        cd2_22 = sqrt(&sigma2_22.-&sigma2_21.*&sigma2_21./&sigma2_11.);
    end;
    else do;
        /* transition probability matrix */
        if(lags=1) then p = &a11.;
        else p = 1-&a22.;
    end;
    u = uniform(&seed.);
    if(u<=p) then s=1;
    else s = 2;
    e1 = normal(&seed.); e2 = normal(&seed.);
    if(s=1) then do;
        /* (x,y) ~ N(mu1, Sigma1) at state 1 */
        x = &mu1_1. + cd1_11*e1;
        y = &mu1_2. + cd1_21*e1+cd1_22*e2;
    end;
    else do;
        /* (x,y) ~ N(mu2, Sigma2) at state 2 */
        x = &mu2_1. + cd2_11*e1;
        y = &mu2_2. + cd2_21*e1+cd2_22*e2;
    end;
    output;
    lags = s;
end;
run;
proc sort data=&table.; by sec t; run;
%mend;

* prepare the training data;
%let T = 10000;
%let nSections = 10;
%let seed = 1234;
%dgpGHMM(gHmTrain,&T.,&nSections.,&seed.);
data mylib.gHmTrain; set gHmTrain; run;

```

First, you estimate the model and store it in an analytic store table by using the STORE statement as follows: You must perform this step in the HMM procedure within a CAS session.

```

* estimate the model and save it in an analytic store table;
proc hmm data=mylib.gHmTrain labelSwitch=(sort=desc(mu));
    id time=t section=sec;
    model x y / type=gaussian nstate=2;
    store out=mylib.ghmmModel;
run;

```

Then, you produce a local analytic store file as follows. You must perform this step in a CAS session that has access to the mylib.ghmmModel data table.

```

* produce a local analytic store file;
proc astore;
    download rstore=mylib.ghmmModel store="ls_ghmm";
run;

```

Now, you can use the local analytic store file to score new data on the platform of interest. For example, you can score new data as in the following code. In the SETOPTION statements, you set the DECODE option to 1 and the DECODE_WINDOW option to 8 to request the decoding results for an 8-unit time window; you set the EVALUATE option to 1 to request the evaluation up to current observation; that is, the log likelihood; you set the FILTER option to 1 to request the filtered probabilities up to current observation; you set the FORECAST option to 1, the FORECAST_ALPHA to 0.8, the FORECAST_COV to 1, and the FORECAST_LEAD to 4 to request the 4-step-ahead forecasts, their covariance matrices, and their confidence intervals at the significance level 0.80; you set the SMOOTH option to 1 and the SMOOTH_WINDOW option to 12 to request the smoothing results for a 12-unit time window. You use the DESCRIBE statement to output the basic model information and the information about input and output variables. In the SCORE statement, you specify the data to be scored in the DATA= option, the local analytic store file in the STORE= option, and the output table for the scored result in the OUT= option. For more information about the ASTORE procedure, see the chapter “The ASTORE Procedure” in *SAS Viya: Machine Learning Procedures*.

```
* get new data;
%let T = 40;
%let nSections = 2;
%let seed = 12345;
%dgpGHMM(gHmmTest, &T., &nSections., &seed.);

* score new data;
proc astore;
  setoption decode 1;
  setoption decode_window 8;
  setoption evaluate 1;
  setoption filter 1;
  setoption forecast 1;
  setoption forecast_alpha 0.8;
  setoption forecast_cov 1;
  setoption forecast_lead 4;
  setoption smooth 1;
  setoption smooth_window 12;
  describe store="ls_ghmm";
  score data=gHmmTest store="ls_ghmm" out=ghmmOut;
run;
```

If you need to score new data within a session, you can upload the analytic store file first, and then score the new data by using the RSTORE= option in the ASTORE procedure, as in the following code. Of course, if your session has access to the original analytic store table mylib.ghmmModel, you can skip the uploading step and directly use the option RSTORE=mylib.ghmmModel.

```
* get new data;
%let T = 40;
%let nSections = 2;
%let seed = 12345;
%dgpGHMM(gHmmTest, &T., &nSections., &seed.);

To score new data, you can use the SCORE statement in the HMM procedure, or you can use the STORE statement in the HMM procedure and then use the ASTORE procedure or other products that support the analytic store technology. Sometimes the two methods do not generate the same inference results for the same data set, because these methods treat the data in different ways. That is, using the SCORE statement in the HMM procedure reads all observations in the data set and then scores them; this is the so-called batch mode. In contrast, the analytic store technology deals with observations one by one, which is extremely suitable for streaming analytics; this is the so-called online mode. The following list compares the different kinds of results that these two methods produce:

- For evaluation and filtered results, the two methods are the same.
- For smoothed and decoded results, the two methods are different. Let T be the sample size. For smoothing, in batch mode, $p(S_\tau = i | y_1, \dots, y_T)$, $1 \leq \tau \leq T$, can be calculated; but in online mode, at time t , only $y_1, \dots, y_t$ are available, and then $p(S_\tau = i | y_1, \dots, y_t)$ can be calculated only if $\tau \leq t$. Because of the memory decay of the Markovian structure, $p(S_\tau = i | y_1, \dots, y_t)$ can approximate $p(S_\tau = i | y_1, \dots, y_T)$ very well when $t - \tau$ is large enough. When you set the value of the SMOOTH_WINDOW option to w in the SETOPTION statement in PROC ASTORE, the smoothed probabilities $p(S_\tau = i | y_1, \dots, y_t)$, $\tau = t - w, \dots, t$, $i = 1, \dots, K$, are calculated and output, where K is the number of states. In some literature, the window length is also called the detection delay, because $p(S_{t-w} = i | y_1, \dots, y_t)$ is assumed to be close enough to $p(S_{t-w} = i | y_1, \dots, y_T)$; that is, additional data after time t would not increase the accuracy of the estimation of the smoothed probabilities at time $t - w$. The same logic can be applied to the decoded results.
- For forecasted results, the two methods are the same if there are no exogenous variables in the models; otherwise, the methods are different only if the values of the exogenous variables at time $t + h$, $h > 0$, are needed in some forecast at time t . Let x_t denote the exogenous variables at time t . In batch mode, the h -step-ahead forecast $p(y_{t+h} | y_1, \dots, y_t; x_1, \dots, x_{t+h})$, $h > 0$, can be calculated when $t + h \leq T$ or extra exogenous variable values after T are provided. However, in online mode, x_{t+h} , $h > 0$, is not available at time t , and then some forecasts that need x_{t+h} are not calculable. In practice, in order to use the analytic store technology in online mode, you must make sure that the h -step-ahead forecast of interest is calculable. For example, by using the NOCURRENTX option in the MODEL statement in PROC HMM, and later by setting the FORECAST_LEAD option to 1 in the SETOPTION statement in PROC ASTORE, you can get the one-step-ahead forecast of dependent variables.

Information Criteria

When you compare models, choose the model that has the smallest information criterion values. The information criteria include Akaike's information criterion (AIC), the corrected Akaike's information criterion (AICC), the Bayesian information criterion (BIC, also referred to as the Schwarz Bayesian criterion, SBC), and the Hannan-Quinn criterion (HQC). These criteria are defined as

$$\begin{aligned} \text{AIC} &= -2\ell + 2r \\ \text{AICC} &= -2\ell + 2rT/(T - r - 1) \\ \text{BIC} &= -2\ell + r \log(T) \\ \text{HQC} &= -2\ell + 2r \log(\log(T)) \end{aligned}$$

where ℓ is the log likelihood, r is the total number of parameters in the model, and T is the number of observations that are used to estimate the model.

Missing Values

Exogenous variables cannot have missing values in all types of models. Missing values of dependent variables are treated as follows:

- For Gaussian HMMs and Gaussian mixture HMMs, all or some of the dependent variables in an observation can be missing. The estimation and inference are based on all observations. For example, if the maximum likelihood method is applied, the likelihood of the nonmissing observations and the partially nonmissing observations is calculated and maximized.
- For the regime-switching regression models, all or some of the dependent variables in an observation can be missing. The estimation and inference are based on the observations from the beginning to the last nonmissing or partially nonmissing observation. For example, if the maximum likelihood method is applied, the likelihood of the nonmissing observations and the partially nonmissing observations is calculated and maximized. For the purpose of forecasting, at the end of the data table (or the end of each section if you specify the SECTION= option), the dependent variables can be set as missing values while the exogenous variables are provided.
- For the regime-switching autoregression models, missing values in the dependent variables are not supported. But at the end of the data table (or the end of each section if you specify the SECTION= option), for the purpose of forecasting, the dependent variables can be set as missing values while the exogenous variables are provided.

Data Table Output

The HMM procedure can create the data tables that are specified in the OUT= suboption of the LABELSWITCH= option in the PROC HMM statement; the OUTSTAT= option in the PROC HMM statement; the OUT= options in the DECODE, EVALUATE, FILTER, and SMOOTH statements; the OUT= and OUTALL= options in the ESTIMATE and FORECAST statements; and the OUTMODEL= option in the SCORE statement. The column information for each table is described in the following sections.

OUT= Data Table Generated from the LABELSWITCH= Option in the PROC HMM Statement

The output data table contains the following variables:

ModelIndex	model index, if multiple models are estimated or scored
NState	number of states, if you specify a range of numbers of states in the NSTATE= n_1 : n_2 option
YLAG	order of the autoregressive process, if you specify a range of orders of the autoregressive processes in the YLAG= n_1 : n_2 option
OldStateLabel	old label of the state
OldComponentLabel	old label of the component for a GM HMM
NewStateLabel	new label of the state
NewComponentLabel	new label of the component for a GM HMM

OUTSTAT= Data Table Generated from the PROC HMM Statement

The output data table contains the following variables:

ModelIndex	model index, if multiple models are estimated or scored
NState	number of states, if you specify a range of numbers of states in the NSTATE= n_1 : n_2 option
YLAG	order of the autoregressive process, if you specify a range of orders of the autoregressive processes in the YLAG= n_1 : n_2 option
LogLikelihood	log likelihood
AIC	Akaike's information criterion
AICC	corrected Akaike's information criterion
BIC	Bayesian information criterion (also referred to as the Schwarz Bayesian criterion, SBC)
HQC	Hannan-Quinn criterion

OUT= Data Table Generated from the DECODE Statement

The output data table contains the following variables:

ModelIndex	model index, if multiple models are estimated or scored
NState	number of states, if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option
YLAG	order of the autoregressive process, if you specify a range of orders of the autoregressive processes in the YLAG= $n_1 : n_2$ option
Section ID Variable	values of the variable that is specified in the SECTION= option in the ID statement
Time ID Variable	values of the variable that is specified in the TIME= option in the ID statement
State	state value in the most possible path

OUT= Data Table Generated from the ESTIMATE Statement

The output data table contains the following variables:

ModelIndex	model index, if multiple models are estimated or scored
NState	number of states, if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option
YLAG	order of the autoregressive process, if you specify a range of orders of the autoregressive processes in the YLAG= $n_1 : n_2$ option
Index	index of the parameter
Type	type of values in the State k variables: EST for estimate and STD for standard error
Parameter	parameter name
State k	value for state k , $k = 1, \dots, K$, where K is the number of states if you specify the NSTATE= K option; otherwise, $K = \max(n_1, n_2)$, the maximum of the range of numbers of states if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option

OUTALL= Data Table Generated from the ESTIMATE Statement

The output data table contains the following variables:

ModelIndex	model index, if multiple models are estimated or scored
NState	number of states, if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option
YLAG	order of the autoregressive process, if you specify a range of orders of the autoregressive processes in the YLAG= $n_1 : n_2$ option
Index	index of the parameter
Parameter	parameter name
Estimate	parameter estimate
StdErr	standard error

COV_	n	value for column n , $n = 1, \dots, N$, in the covariance matrix of parameter estimates, where N is the number of parameters if only one model is estimated or scored; otherwise, N is the maximum of numbers of parameters for all models
------	-----	---

OUT= Data Table Generated from the EVALUATE Statement

The output data table contains the following variables:

ModelIndex	model index, if multiple models are estimated or scored
NState	number of states, if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option
YLAG	order of the autoregressive process, if you specify a range of orders of the autoregressive processes in the YLAG= $n_1 : n_2$ option
Section ID Variable	values of the variable that is specified in the SECTION= option in the ID statement
Time ID Variable	values of the variable that is specified in the TIME= option in the ID statement
LogLikelihood	log likelihood

OUT= Data Table Generated from the FILTER Statement

The output data table contains the following variables:

ModelIndex	model index, if multiple models are estimated or scored
NState	number of states, if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option
YLAG	order of the autoregressive process, if you specify a range of orders of the autoregressive processes in the YLAG= $n_1 : n_2$ option
Section ID Variable	values of the variable that is specified in the SECTION= option in the ID statement
Time ID Variable	values of the variable that is specified in the TIME= option in the ID statement
State k	filtered probability value for state k , $k = 1, \dots, K$, where K is the number of states if you specify the NSTATE= K option; otherwise, $K = \max(n_1, n_2)$, the maximum of the range of numbers of states if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option

OUT= Data Table Generated from the FORECAST Statement

The output data table contains the following variables:

ModelIndex	model index, if multiple models are estimated or scored
NState	number of states, if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option
YLAG	order of the autoregressive process, if you specify a range of orders of the autoregressive processes in the YLAG= $n_1 : n_2$ option
Section ID Variable	values of the variable that is specified in the SECTION= option in the ID statement

Time ID Variable	values of the variable that is specified in the TIME= option in the ID statement
Step	value of h in the h -step-ahead forecast
State k	forecasted probability value for state k , $k = 1, \dots, K$, where K is the number of states if you specify the NSTATE= K option; otherwise, $K = \max(n_1, n_2)$, the maximum of the range of numbers of states if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option
{DV p }_Forecast	mean forecast for dependent variable p , $p = 1, \dots, k_y$, where k_y is the number of dependent variables; {DV p } stands for the name of dependent variable p
Q1	first quantile value, $(1 - \alpha)/2$, where α is specified in the ALPHA= α option in the FORECAST statement
{DV p }_Q1	first quantile forecast for dependent variable p , $p = 1, \dots, k_y$, where k_y is the number of dependent variables; {DV p } stands for the name of dependent variable p
Q2	second quantile value, $(1 + \alpha)/2$, where α is specified in the ALPHA= α option in the FORECAST statement
{DV p }_Q2	second quantile forecast for dependent variable p , $p = 1, \dots, k_y$, where k_y is the number of dependent variables; {DV p } stands for the name of dependent variable p
Q3	third quantile value, $1/2$, for median
{DV p }_Q3	median forecast for dependent variable p , $p = 1, \dots, k_y$, where k_y is the number of dependent variables; {DV p } stands for the name of dependent variable p

OUTALL= Data Table Generated from the FORECAST Statement

The output data table contains the following variables:

ModelIndex	model index, if multiple models are estimated or scored
NState	number of states, if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option
YLAG	order of the autoregressive process, if you specify a range of orders of the autoregressive processes in the YLAG= $n_1 : n_2$ option
Section ID Variable	values of the variable that is specified in the SECTION= option in the ID statement
Time ID Variable	values of the variable that is specified in the TIME= option in the ID statement
Step	value of h in the h -step-ahead forecast
Index	index of the dependent variable
Variable	dependent variable name
State k	forecasted probability value for state k , $k = 1, \dots, K$, where K is the number of states if you specify the NSTATE= K option; otherwise, $K = \max(n_1, n_2)$, the maximum of the range of numbers of states if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option
Forecast	mean forecast for the dependent variable
StdErr	standard error of forecast for the dependent variable
LowerCL	lower confidence limit of forecast for the dependent variable

UpperCL	upper confidence limit of forecast for the dependent variable
Median	median forecast for the dependent variable
COV_{DV p }	value for column p , $p = 1, \dots, k_y$, in the covariance matrix of forecasts of dependent variables, where k_y is the number of dependent variables; {DV p } stands for the name of the dependent variable p

OUTMODEL= Data Table Generated from the SCORE Statement

The output data table consists of binary large object columns to store the binary data, which should be consumed only by the INMODEL= option in the SCORE statement. The number of columns and the definition of columns might be changed without notice in future releases. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters because the data type of each column is binary.

OUT= Data Table Generated from the SMOOTH Statement

The output data table contains the following variables:

ModelIndex	model index, if multiple models are estimated or scored
NState	number of states, if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option
YLAG	order of the autoregressive process, if you specify a range of orders of the autoregressive processes in the YLAG= $n_1 : n_2$ option
Section ID Variable	values of the variable that is specified in the SECTION= option in the ID statement
Time ID Variable	values of the variable that is specified in the TIME= option in the ID statement
State k	smoothed probability value for state k , $k = 1, \dots, K$, where K is the number of states if you specify the NSTATE= K option; otherwise, $K = \max(n_1, n_2)$, the maximum of the range of numbers of states if you specify a range of numbers of states in the NSTATE= $n_1 : n_2$ option

ODS Table Names

The HMM procedure assigns a name to each table that it creates. You can use this name to refer to the table when using the Output Delivery System (ODS) to select tables and create output data tables. These names are listed in Table 20.6.

Table 20.6 ODS Tables Produced in the HMM Procedure

ODS Table Name	Description	Option
Algorithm	Option values for the optimization algorithm	PRINTLEVEL= n , where $n = 2$ or 3
ARCoef	Coefficients of autoregressive variables for a regime-switching autoregression model	Default

Table 20.6 *continued*

ODS Table Name	Description	Option
ConstCoef	Coefficients of constants for a regime-switching regression model or regime-switching autoregression model	Default
Cov	Covariance matrices for a regime-switching regression model or regime-switching autoregression model	Default
CPM	Category probability matrix for a finite HMM	Default
ExogCoef	Coefficients of exogenous variables for a regime-switching regression model or regime-switching autoregression model	Default
FinalObjectiveFunction	Objective function value at the end of the optimization	PRINTLEVEL=3
FinalParameterEstimates	Final parameter values at the end of the optimization	PRINTLEVEL=3
FitStatistics	Log likelihood and information criteria	Default
InitialObjectiveFunction	Objective function value at the start of the optimization	PRINTLEVEL= n , where $n = 1, 2$, or 3
InitialParameterEstimates	Initial parameter values at the start of the optimization	PRINTLEVEL= n , where $n = 1, 2$, or 3
ISPV	Initial state probability vector	Default
IterHistory	Optimization iterations for the active set and interior point algorithms	PRINTITERFREQ= n , $n > 0$
Lambda	Mean and variance vectors, λ , for a Poisson HMM	Default
LinearCoef	Coefficients of linear trends for a regime-switching regression model or regime-switching autoregression model	Default
MCP	Mixture component probabilities for a GM HMM	Default
ModelInfo	Model information	Default
Mu	Mean vectors, μ , for a Gaussian or GM HMM	Default
NObs	Observation information	Default
OptIterHistory	Optimization iterations for the SGD algorithm	PRINTITERFREQ= n , $n > 0$
ParameterEstimates	Model parameter estimates	Default
PriorHyperparm	Prior hyperparameters	METHOD=MAP

Table 20.6 *continued*

ODS Table Name	Description	Option
QuadCoef	Coefficients of quadratic trends for a regime-switching regression model or regime-switching autoregression model	Default
SeasCoef	Coefficients of seasonal dummies for a regime-switching regression model or regime-switching autoregression model	Default
Sigma	Covariance matrices, σ , for a Gaussian or GM HMM	Default
TPM	Transition probability matrix	Default

Several Types of Models as Special Cases of Hidden Markov Models

Several types of models can be treated as special cases of hidden Markov models, including Gaussian mixture models (GMMs), Gaussian mixture regressions (GMRs), regressions, autoregressive error models, vector autoregressions (VARs) with or without exogenous variables in the standard or mean-adjusted form, and so on. In this section, a few of these models are illustrated.

Gaussian Mixture Model and Gaussian Mixture Regressions

Let $\mathbf{Y}_i = (y_{1i}, \dots, y_{pi})'$, $i = 1, \dots, n$, denote a p -dimensional vector of random variables, and $\mathbf{Y}_i$ follows an iid Gaussian mixture distribution,

$$\mathbf{Y}_i \sim \text{GM}(\{w_1, \dots, w_M\}, \{\mu_1, \dots, \mu_M\}, \{\Sigma_1, \dots, \Sigma_M\})$$

where $\text{GM}(\cdot, \cdot, \cdot)$ represents the Gaussian mixture distribution; M is the number of components; and the w_j , $j = 1, \dots, M$, are mixture component probabilities (MCPs, also called mixture weights), which satisfy the basic requirement for weights ($w_j \geq 0$, $j = 1, \dots, M$, and $\sum_{j=1}^M w_j = 1$). The μ_j and Σ_j , $j = 1, \dots, M$, are the mean and covariance parameters, respectively, for the j th Gaussian component. The preceding model is the Gaussian mixture model (GMM). For more information about GMM, see Frühwirth-Schnatter (2006). For more information about Gaussian mixture regression (GMR) and its relationship to GMM, see Sung (2004).

Consider a bivariate Gaussian mixture model that has the following parameter values:

$$w = \begin{pmatrix} w_1 \\ w_2 \end{pmatrix} = \begin{pmatrix} 0.75 \\ 0.25 \end{pmatrix}, \mu_1 = \begin{pmatrix} 2 \\ 2 \end{pmatrix}, \Sigma_1 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \mu_2 = \begin{pmatrix} -2 \\ -2 \end{pmatrix}, \Sigma_2 = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

The following statements simulate the bivariate vectors from the previous model to provide training data. In fact, for GMMs, each observation is independent from the others. In order to use the HMM procedure to estimate the GMMs, you must assign each observation in the training data set a unique section ID and a constant time ID; that is, each section contains only one observation.

```

data one;
  call streaminit(12345);
  do sec = 1 to 10000;
    t = 1;
    u = rand('UNIFORM');
    if(u<=0.75) then do;
      s = 1;
      x = 2 + rand('NORMAL');
      y = 2 + rand('NORMAL');
    end;
    else do;
      s = 2;
      x = -2 + rand('NORMAL');
      y = -2 + rand('NORMAL');
    end;
    output;
  end;
run;

```

```
data mylib.one; set one; run;
```

The following statements plot the observed points (x, y) :

```

proc sgplot data=one;
  scatter x=x y=y / group=s;
run;

```

As shown in [Figure 20.102](#), it seems that the points come from two different clusters.

Figure 20.102 Unclassified Observations

The following statements estimate the two-component Gaussian mixture model and then classify the data points through decoding; here decoding means finding the most likely cluster for the observed data. The STORE statement is used to save the model in the analytic store table for future scoring.

```
proc hmm data=mylib.one labelSwitch=(sort=desc(mu));
  id time=t section=sec;
  model x y / nstate=2 type=gaussian estispv;
  decode out=mylib.mydecode;
  store mylib.mygmm;
run;
```

The estimates of all parameters are shown in [Figure 20.103](#), which displays columns for the parameter name, estimate value, standard error, t value, and p -value. The TPM parameters are meaningless in this context. The ISPV parameters are the mixture component probabilities. The parameter estimates are very close to the true parameter values in the DGP.

Figure 20.103 Parameter Estimates

Parameter Estimates				
Parameter	Estimate	Standard Error	t Value	Pr > t
ISPV1	0.741154	0.004402	168.35	<.0001
ISPV2	0.258846	0.004402	58.80	<.0001
TPM1_1	0.500000	0		
TPM1_2	0.500000	0		
TPM2_1	0.500000	0		
TPM2_2	0.500000	0		
MU1_1	2.017677	0.011520	175.14	<.0001
MU1_2	1.998486	0.011714	170.61	<.0001
MU2_1	-1.972142	0.019170	-102.88	<.0001
MU2_2	-1.971479	0.020118	-98.00	<.0001
SIGMA1_1_1	0.971840	0.016189	60.03	<.0001
SIGMA1_2_1	-0.003386	0.011752	-0.29	0.7732
SIGMA1_2_2	1.002999	0.016772	59.80	<.0001
SIGMA2_1_1	0.918582	0.026555	34.59	<.0001
SIGMA2_2_1	-0.009950	0.019897	-0.50	0.6170
SIGMA2_2_2	1.020699	0.029038	35.15	<.0001

The accuracy of classification through the GMM is calculated by the following statements:

```
data mydecode; set mylib.mydecode; run;
proc sort data=mydecode; by sec; run;

data combine;
  merge mydecode(in=a) one(in=b);
  by sec;
run;

data checkAccuracy;
  set combine;
  retain accuracy 0;
  if(state=s) then accuracy+1;
  if(_N_=10000) then do;
    accuracy = accuracy/_N_;
    output;
  end;
  keep accuracy;
run;

proc print data=checkAccuracy noobs; run;
```

The accuracy of the GMM, which is shown in [Figure 20.104](#), is very high. It implies that you can use the HMM procedure not only to learn but also to infer the GMM.

Figure 20.104 Accuracy of GMM on Training Data

accuracy
0.9985

To show how well the data are classified, the following statements plot the classified data points according to the estimated GMM. The plot is shown in [Figure 20.105](#). Comparing it to [Figure 20.102](#), you see that they are almost exactly same.

```
proc sgplot data=combine;
  scatter x=x y=y / group=state;
run;
```

Figure 20.105 Classified Data Points by GMM

It is also easy to apply the estimated GMM to score some new data set by using the analytic store technology. The following statements generate the testing data, apply the ASTORE procedure, and calculate the accuracy of classification. As [Figure 20.106](#) shows, the accuracy is still very high.

```
data two;
  call streaminit(12346);
  do sec = 1 to 10000;
    t = 1;
    u = rand('UNIFORM');
    if(u<=0.75) then do;
      s = 1;
      x = 2 + rand('NORMAL');
    end;
  end;
```

```

        y = 2 + rand('NORMAL');
    end;
    else do;
        s = 2;
        x = -2 + rand('NORMAL');
        y = -2 + rand('NORMAL');
    end;
    output;
end;
run;

proc astore;
    download rstore=mylib.mygmm store='ls_gmm';
    setoption decode 1;
    setoption decode_window 1;
    setoption evaluate 0;
    describe store='ls_gmm';
    score data=two store='ls_gmm' out=gmmout;
run;

data combine2;
    merge gmmout(in=a) two(in=b);
    by sec;
run;

data checkAccuracy2;
    set combine2;
    retain accuracy 0;
    if(DecodedState_BackStep0=s) then accuracy+1;
    if(_N_=10000) then do;
        accuracy = accuracy/_N_;
        output;
    end;
    keep accuracy;
run;

proc print data=checkAccuracy2 noobs; run;

```

Regression and Vector Autoregression

When you specify `NSTATE=1` in the `MODEL` statement for regime-switching regression or autoregression, you are dealing with the regression or vector autoregression (VAR). The autoregressive error model can be treated as a univariate VAR in the mean-adjusted form. For more information about the autoregressive error model, see the chapter “The AUTOREG Procedure” in *SAS/ETS User’s Guide*. For more information about the VARs with or without exogenous variables, see the chapter “The VARMAX Procedure” in *SAS/ETS User’s Guide*.

Examples: HMM Procedure

Example 20.1: Discovering the Hidden Market States by Using the Regime-Switching Autoregression Model

To buy or to sell, that is the question! If you knew it would be a bull market, you might choose to buy the stock; if you knew it would be a bear market, you might choose to sell the stock. However, you cannot directly observe these market states. What you can observe is the stock prices. So, how can you discover the hidden market states from the observable stock price? The question is answered in this example by using regime-switching autoregression models (RS ARs).

Data

Consider the following CRSP NYSE/NYSEMKT/Nasdaq/Arca Value-Weighted Market Index (Center for Research in Security Prices 2018) from January 19, 1926, to December 29, 2017. You can access the CRSP data through the SASECRSP interface engine; for more information, see the chapter “The SASECRSP Interface Engine” in *SAS/ETS User’s Guide*. You can also directly access the data if you install the CRSP data locally. If you install the CRSP data in the folder XXX, the following statements extract the daily stock prices (that is, market indices) into the data set vwmiO:

```
*****;
* DATA;
*****;

title 'Discovering the Hidden Market States';
libname crspInd "XXX";
data vwmiO;
    set crspInd.sfz_dind(where=(KYINDNO=1000200
        and caldt>='19JAN1926'd and caldt<='29DEC2017'd));
    format date MMDDYY10.;
    date = caldt; price = aind;
    keep date price;
run;
```

The stock-price series is nonstationary and not suitable to be directly modeled; hence, the stationary weekly-return series is modeled. The following code generates the weekly returns through the daily stock prices and saves them in two data sets. One data set, vwmi, is the full-sample data set, which contains all weekly returns. The other data set, vwmiln, is the in-sample data set, which contains weekly returns before December 31, 2000. The weekly returns after January 1, 2001, are in the out-of-sample period and are used for testing the models.

```
%let ds = vwmi;
%let cutDate = '31DEC2000'd;
data &ds. &ds.In;
    set &ds.O;
    retain cumReturn 0;
    return = (log(price)-log(lag(price)))*100;
    if(return~=. ) then cumReturn + return;
```

```

if(mod(_N_,5)=1 and _N_>1) then do;
    returnw = cumReturn;
    w + 1;
    output &ds.;
    if (date<=&cutDate.) then output &ds.In;
    cumReturn = 0;
end;
keep w date returnw price;
label w="Week Index" date="Date" returnw="Weekly Return"
      price="Market Index";
run;

```

The following statements plot the stock prices and weekly returns, as shown in [Output 20.1.1](#). The in-sample and out-of-sample periods are separated by a vertical line.

```

proc sgplot data=&ds.;
    series x=date y=returnw;
    series x=date y=price / y2axis;
    refline 0 / axis=y lineattrs=(color=gray thickness=1);
    refline &cutDate. / axis=x
                    lineattrs=(color=gray thickness=2 pattern=dash);
    yaxis max=20 min=-20;
run;

```

Output 20.1.1 Stock Prices and Weekly Returns

Before you estimate any model, make a copy of the data in the library, as in the following DATA steps:

```
data mylib.&ds.In; set &ds.In; run;
data mylib.&ds.; set &ds.; run;
```

Analysis with a Simple Model

Consider a simple case. First, assume that there are two hidden market states, bear market state and bull market state, which can be modeled by exactly two corresponding hidden states in an HMM; that is, consider a bistate HMM. Second, assume that the lagged weekly returns cannot help predict current weekly return at each hidden state; that is, the autoregressive order is zero at each hidden state. Hence, as a start, consider a bistate RS-AR(0) model. The following statements estimate the bistate RS-AR(0) model on weekly returns. The input data table, specified in the required DATA= option in the PROC HMM statement, contains the in-sample data. In order to estimate the model, the ID and MODEL statements must be specified. Since the data are sorted by the variable date, the variable date is assigned to the required TIME= option. However, since the data can also be regarded as being sorted by the variable w, the variable w, instead of the variable date, can be assigned to the TIME= option; if you do so, there is no impact on the model estimation. In the MODEL statement, the dependent variable, the weekly return returnw, is specified first; the TYPE= option is set to AR for the RS-AR model; the NSTATE= option is set to 2 for the bistate model; and the YLAG= option

is set to 0 for an AR(0) model. The SMOOTH, DECODE, and EVALUATE statements specify where to output, respectively, the smoothed probabilities, decoded state path, and log likelihood up to each time point.

```
*****;
* ANALYSIS WITH A SIMPLE MODEL
*****;

proc hmm data=mylib.&ds.In;
  id time=date;
  model returnw / type=ar nstate=2 ylag=0;
  smooth out=mylib.&ds.inSmooth_k2To2_p0To0;
  decode out=mylib.&ds.inDecode_k2To2_p0To0;
  evaluate out=mylib.&ds.inEval_k2To2_p0To0;
run;
```

The number of observations and model information are shown in [Output 20.1.2](#).

Output 20.1.2 Number of Observations and Model Information
Discovering the Hidden Market States

Observation Information

The smoothed probabilities of states for each observation are output in the data table `mylib.vwmilnSmooth_k2To2_p0To0`. This example discusses one type of inference. The mean and variance (or standard error) of each state can be calculated through the weighted sample, where the smoothed probabilities are the weights. The following statements calculate and print the sample mean and standard error of each state, as shown in [Output 20.1.9](#). In the case of an RS-AR(0) model that has no regressors other than the intercept (which is equivalent to the Gaussian HMM), the sample mean and standard error of each state are almost the same as, respectively, the intercept estimate and the square root of variance estimate of each state.

```

%else %do;
  proc sgplot data=&outds.;
    series x=date y=logLikelihood;
    yaxis label='Log Likelihood';
  run;
%end;
%mend plotEvaluation;

%plotEvaluation(mylib.&ds.inEval_k2to2_p0to0, &ds.inEval_k2to2_p0to0, 1);

```

Output 20.1.14 Conditional Log Likelihood

As shown in [Output 20.1.14](#), some observations are explained well by the model, but there are still many exceptional observations whose conditional log likelihoods are much smaller than others. This means that there might be model misspecification, which can be addressed by solving the model selection problem.

Model Selection

To model the weekly returns, how many states should be considered? How many AR lags should a state include? These are common questions in the model selection process. In this example, the best model is selected using Akaike's information criterion (AIC): the smaller the AIC, the better the model.

The following macro estimates the model or models according to the arguments:

```
*****;
* MODEL SELECTION;
*****;

%macro estimateRSAR(myds, inEstDs, kStart, kEnd, pStart, pEnd, method,
                    maxiter, qMultiStart);
  proc hmm data=&myds. labelSwitch=(sort=none)
    outstat=&myds.&method.Stat_k&kStart.To&kEnd._p&pStart.To&pEnd.;
    id time=date;
    model returnw / type=ar nstate=&kStart.:&kEnd. ylag=&pStart.:&pEnd.
      method=&method.;
    optimize printLevel=3 printIterFreq=1 algorithm=interiorpoint
      maxiter=&maxiter. Multistart=&qMultiStart.;
    score outmodel=&myds.&method.Model_k&kStart.To&kEnd._p&pStart.To&pEnd.;
    learn out=&myds.&method.Learn_k&kStart.To&kEnd._p&pStart.To&pEnd.
      %if %length(&inEstDs.)>0 %then %do; in=&inEstDs. %end;
    ;
    display / excludeall;
  run;
%mend;
```

First, the following statements estimate two- to nine-state RS-AR(0) models. The MAP method is applied to bound and smooth the objective functions. The parameter estimates are saved for further use as the initial values for new estimations. For the best results, multistart mode is strongly recommended, although it might be time consuming.

```
* (1) MAP + MULTISTART for AR(0);
* be aware that the following macro might take tens of hours to finish;
* uncomment it to run;
* %estimateRSAR(myds=mylib.&ds.In, inEstDs=,
  kStart=2, kEnd=9, pStart=0, pEnd=0,
  method=MAP, maxiter=128, qMultiStart=1);
```

Then, the following statements estimate two- to nine-state RS-AR(0) to AR(5) models. The ML method is used because the AIC is based on the log likelihood. The parameter estimates of RS AR(0) models from previous MAP method estimations are used to ensure that the estimates in the ML method are reasonable. The k -state RS AR(p) models, $k = 2, \dots, 9$, $p = 1, \dots, 5$, use the corresponding k -state RS AR($p - 1$) models' parameter estimates as initial values. This is the default implementation in the HMM procedure. The multistart mode is not needed any longer because the initial values are good.

```
* (2) ML + initial values estimated from MAP's AR(0) for AR(0)
  and initial values estimated from AR(p-1) for AR(p), p>0;
* be aware that the following macro might take tens of minutes to finish;
* uncomment it to run;
* %estimateRSAR(myds=mylib.&ds.In, inEstDs=mylib.&ds.InMAPLearn_k2to9_p0to0,
  kStart=2, kEnd=9, pStart=0, pEnd=5,
```

```
method=ML, maxiter=128, qMultiStart=0);
```

Estimating all 48 of the two- to nine-state RS AR(0) to AR(5) models produces AIC values. The following statements print the AIC values, which are shown in [Output 20.1.15](#):

```
* print fit statistics in matrix form;
data &ds.InMLStat_k2to9_p0to5; set mylib.&ds.InMLStat_k2to9_p0to5; run;
proc sort data=&ds.InMLStat_k2to9_p0to5; by modelIndex; run;
%macro printFitStat(fitStat);
  data &ds.In&fitStat.;
    set &ds.InMLStat_k2to9_p0to5 end=eof;
    array &fitStat.s{8,6} _TEMPORARY_;
    array yLags{6} yLag0-yLag5;
    &fitStat.s[nState-1,yLag+1] = &fitStat.;
    if eof then do;
      do i = 1 to 8;
        nState = i+1;
        do j = 1 to 6; yLags(j) = &fitStat.s[i,j]; end;
        output;
      end;
    end;
    keep nState yLag0-yLag5;
run;
proc print data=&ds.In&fitStat. label noobs
  style(header)={textalign=center};
  var nState yLag0-yLag5;
  label nState='k' yLag0='p = 0' yLag1='p = 1' yLag2='p = 2'
        yLag3='p = 3' yLag4='p = 4' yLag5='p = 5';
run;
%mend;
%printFitStat(AIC);

* Uncomment the following macros if you want to see other fit statistics;
* %printFitStat(logLikelihood);
* %printFitStat(AICC);
* %printFitStat(BIC);
* %printFitStat(HQC);
```

[Output 20.1.15](#) indicates that the smallest AIC corresponds to the eight-state RS AR(4) model.

Output 20.1.15 AICs for 48 RS AR Models

The Selected Model and In-Sample Inference

The following statements estimate the AIC-selected eight-state RS AR(4) model:

```
*****;
* THE SELECTED MODEL AND IN-SAMPLE INFERENCE
*****;

* select eight-state RS-AR(4) model according to AIC or AICC;
* adjust data to be the same sample size for AR(5);
proc hmm data=mylib.&ds.in(where=(date>='30JAN1926'd));
  id time=date;
  model returnw / type=ar nstate=8 ylag=4;
  optimize printLevel=3 algorithm=interiorpoint maxiter=0;
  score outmodel=mylib.&ds.inMLModel_k8To8_p4To4;
  learn out=mylib.&ds.inMLLearn_k8To8_p4To4
    in=mylib.&ds.inMLLearn_k2to9_p0to5;
  smooth out=mylib.&ds.inSmooth_k8to8_p4to4;
  decode out=mylib.&ds.inDecode_k8to8_p4to4;
  evaluate out=mylib.&ds.inEval_k8to8_p4to4;
  display tpm;
run;
```

The following statement plots the conditional log likelihoods. Compared to the bivariate RS-AR(0) model (as shown in [Output 20.1.14](#)), the eight-state RS-AR(0) model (as shown in [Output 20.1.16](#)) has much higher conditional log likelihoods, which means a much better in-sample goodness of fit.

```
%plotEvaluation(mylib.&ds.inEval_k8to8_p4to4, &ds.inEval_k8to8_p4to4, 1);
```

Output 20.1.16 Conditional Log Likelihoods

The selected model has 112 parameters. 48 of which are related to observation distributions and are often called observation parameters. The following statements print the observation parameters in [Output 20.1.17](#). The analysis of each AR(4) process for each state is beyond this example.

```
* print observation parameters;
data &ds.InObsParm;
  set mylib.&ds.InMLLearn_k8To8_p4To4(where=(type='EST' and index>=17));
  if(index=17) then parameter='Constant';
  if(index=19) then parameter='AR(1)';
  if(index=21) then parameter='AR(2)';
  if(index=23) then parameter='AR(3)';
  if(index=25) then parameter='AR(4)';
  if(index=27) then parameter='Variance';
run;
proc sort data=&ds.InObsParm; by index; run;
proc print data=&ds.InObsParm noobs label;
  var parameter state1-state8;
  label state1='State 1' state2='State 2' state3='State 3'
        state4='State 4' state5='State 5' state6='State 6'
        state7='State 7' state8='State 8';
run;
```

Output 20.1.19 Gaussian Kernels for Eight States

As shown in [Output 20.1.19](#), states 1, 2, and 4 seem like a bull market; they have positive expected returns with low risk. The remaining states seem like a bear market; they have negative expected returns or very high risk (or both). However, the market states and their corresponding states are not that simple. The transition probability matrix of the eight-state AR(4) model is shown in [Output 20.1.20](#).

Output 20.1.20 Estimates of Transition Probability Matrix

Discovering the Hidden Market States

Estimated Transition Probability Matrix								
State	1	2	3	4	5	6	7	8

8	0.00000	0.00000	0.00000	0.03679	0.00000	0.00000	0.02078	0.94243

The eight states seem to be categorized into three groups:

- States 1, 2, and 3 belong to first group. Although there are very upward-moving days (state 2) and somewhat downward-moving days (state 3), the main trend is upward (state 1). The risk in this group is pretty low.
- States 4, 5, and 6 belong to second group. There are good days (state 4), bad days (state 5), and even very bad days (state 6). This group has medium risk.
- States 7 and 8 belong to the third group, where the risk is extremely high.

The transition probability matrix tells the more detailed story:

- The first group has a 98% chance of switching to itself and a 2% chance of switching to the second group.
- The third group has a 97% chance of switching to itself and a 3% chance of switching to the second group.
- The second group has a 94% chance of switching to itself and equal 3% chances of switching to the first and third groups.
- The first and third group have zero chance of switching to each other.
- When the market is in one group, it lasts for a long time before switching to the other groups.

Hence, according to the eight-state RS-AR(4) model, there is one more market state besides the well-known bear market (the first group) and bull market (the third group): the transition market state (the second group). [Figure 20.107](#) shows the relationship between these market states.

Figure 20.107 Market States and Their Transitions

The Out-of-Sample Testing

In the model selection process, the AIC, but not the in-sample goodness of fit (that is, the log likelihood), is used as the criterion for selecting the best model because a bias-variance trade-off exists. In this section, three types of out-of-sample forecasts are tested to check whether the selected model has a good forecast performance.

The Value-at-Risk (VaR) Forecast

You can specify the INMODEL= option in the SCORE statement to forecast the VaRs at different levels, such as 1%, 5%, and 10%, as shown in [Output 20.1.27](#). The following macros can predict the VaRs for the out-of-sample period and evaluate the predictive performance by the likelihood ratio (LR) test for the unconditional coverage of the VaR forecast (Kuester, Mittnik, and Paolella 2006):

```
* print Predictive Performance of VaR Forecasts;
%let alpha1 = 0.80;
%let alpha2 = 0.90;
%let alpha3 = 0.98;
%macro forecastVaR(myLib, dsData, dsModel, timeId, varReturn,
    k, p, iStart, iEnd, oosStart, oosEnd,
```

```

dsForecastPrefix);
%do i = &iStart. %to &iEnd.;

  %evaluateVaR(dsData=&ds., dsForecastPrefix=&ds.Forecastk&k._p&p.,
    varReturn=returnw, k=&k., p=&p., iStart=1, iEnd=3, n=855,
    dsOut=VaR_outputk&k._p&p.);
%mend VaR;

%VaR(8,4);

```

Output 20.1.27 Predictive Performance of VaR Forecasts
Discovering the Hidden Market States

Number of AR States	AR Lag	Target Prob.	Violation Ratio	LR Stat.	Pr > ChiSq	Avg. of VaR
8	4	0.10	0.1053	0.2592	0.6107	-2.718
8	4	0.05	0.0538	0.2541	0.6142	-3.691
8	4	0.01	0.0129	0.6503	0.4200	-5.974

According to the p -values in the Pr > ChiSq column in [Output 20.1.27](#), at the 5% significance level, no tests can reject the null hypothesis that the number of violations is correct. Hence, the eight-state RS-AR(4) model has the correct unconditional coverage for the 1%, 5%, and 10% VaR forecasts.

The Out-of-Sample Log Likelihood

In fact, besides the good predictability of the tail of the distribution of weekly returns as shown in the VaR forecast analysis, the eight-state RS-AR(4) model also provides a very good prediction of the whole distribution of weekly returns, which can be seen by comparing the average weekly log likelihoods of the in-sample period and the out-of-sample period. As shown in [Output 20.1.28](#), compared to both the simplest model (the two-state RS-AR(0) model, which has the fewest parameters and the worst in-sample fit) and the most complex model (the nine-state RS-AR(5) model, which has the most parameters and the best in-sample fit), the eight-state RS-AR(4) model has the best out-of-sample forecast ability (that is, the largest average weekly log likelihood in the out-of-sample period).

```

Trading Strategies and Portfolio Values

As mentioned at the beginning of this example, if you knew it would be a bull market, you might choose to buy the stock; if you knew it would be a bear market, you might choose to sell the stock. In this section, the market states are forecasted and then several trading strategies are compared.

The following statements forecast and plot the probability distribution of market states in [Output 20.1.29](#). The forecast of market states is in probabilities, which is similar to a weather forecast. For example, a forecast of

60% chance of bear market, 39% chance of transition market, and 1% chance of bull market is comparable to a forecast of 60% chance of raining, 39% chance of being cloudy, and 1% chance of being sunny.

```

Output 20.1.29 Forecasted Probabilities of Market States

In this example, four simple trading strategies are considered:

- Risk-free strategy: hold the bond for the entire time period. This strategy does not depend on any forecast, and it is the first benchmark strategy.
- Market strategy: hold the stock for the entire time period. This strategy does not depend on any forecast, either. It reflects the market performance, and it is the second benchmark strategy.
- Bear strategy: sell the stock if the chance of a bear market in the next week is no less than 30%; otherwise, buy the stock.
- Bull strategy: buy the stock if the chance of a bull market in the next week is no less than 10%; otherwise, sell the stock.

The thresholds in bear and bull strategies, 30% and 10% respectively, are ad hoc, which reflect the investor's risk attitude. The trading strategy of switching between bond and stock can also be analogous to the decision of traveling with or without umbrella. The risk-free strategy is analogous to a decision to always travel with an umbrella; the market strategy is analogous to never traveling with umbrella; the bear strategy is analogous to traveling with an umbrella if the chance of raining tomorrow is no less than 30%; and the bull strategy is analogous to traveling without an umbrella if the chance of being sunny tomorrow is no less than 10%. The following statements plot the thresholds for the bear and bull trading strategies:

```
%let bearThreshold=0.30;
%let bullThreshold=0.10;
%let oneMinusBullThreshold=0.90;
%plotForecastAndTradingStrategies(ForecastProb, &bearThreshold.,
                                &bullThreshold., &oneMinusBullThreshold.);
```

Output 20.1.30 Thresholds for Bull and Bear Trading Strategies

Output 20.1.31 Wealth Curves of Four Trading Strategies

As shown in [Output 20.1.31](#), thanks to the forecast of market states by the eight-state RS-AR(4) model, both bear and bull strategies beat the market: compared to the market strategy, they increase the Sharpe ratio more than 50% and get higher portfolio values at the end of out-of-sample period.

Example 20.2: Clustering Time Series by Using the Gaussian Hidden Markov Model

Clustering time series is a very common method of analyzing cross-sectional time series data. For more information, see Liao (2005) and Rani and Sikka (2012) and references therein. Especially for methods that use hidden Markov models (HMMs), see Smyth (1997), Oates, Firoiu, and Cohen (1999), and Ghassempour, Girosi, and Maeder (2014).

This example illustrates an algorithm for quickly clustering time series. With prior knowledge of the number of clusters and the number of states for each cluster, the algorithm creates the initial clusters according to the distribution of the likelihoods on an arbitrary HMM. Then, one HMM on each cluster is estimated and the time series are moved between clusters according to their likelihoods on those HMMs. The process is repeated until the algorithm converges or the maximum number of iterations is reached (Liao 2005).

In this example, the data generating process (DGP) is the same one that is described in Smyth (1997). There are two bistate Gaussian HMMs. For the first Gaussian HMM, the parameters are

$$\pi = \begin{pmatrix} 0.5 \\ 0.5 \end{pmatrix}, \mathbf{A} = \begin{pmatrix} 0.6 & 0.4 \\ 0.4 & 0.6 \end{pmatrix}, \mathbf{B} = \left\{ \begin{pmatrix} \mu_1 \\ \mu_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 3 \end{pmatrix}, \begin{pmatrix} \Sigma_1 \\ \Sigma_2 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \end{pmatrix} \right\}$$

For the second Gaussian HMM, the parameters are

$$\pi = \begin{pmatrix} 0.5 \\ 0.5 \end{pmatrix}, \mathbf{A} = \begin{pmatrix} 0.4 & 0.6 \\ 0.6 & 0.4 \end{pmatrix}, \mathbf{B} = \left\{ \begin{pmatrix} \mu_1 \\ \mu_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 3 \end{pmatrix}, \begin{pmatrix} \Sigma_1 \\ \Sigma_2 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \end{pmatrix} \right\}$$

The only difference between these two Gaussian HMMs is that they have different transition probability matrices, so the time series that are generated from the first HMM have slower dynamics than those from the second HMM. Hence, the clustering time series algorithm should assign the time series that are generated from the first HMM to a cluster, and assign those from the second HMM to another cluster, if there is prior knowledge that the number of clusters is two and the number of states for each cluster is two.

The following macro generates the cross-sectional time series data table for analysis:

```

title "Clustering Time Series";

* create a data table dgpTable
consisting of nSections sections and T observations for each section;
* then copy the data table dgpTable to the data table trainingTable
and the data table libTrainingTable;
%macro createClustersTable(nSections,T,
                                dgpTable,trainingTable,libTrainingTable);

    %let seed = 12345;
    %let nClustersDGP = 2;
    %let clportion = 0.5;

    %let clpi1 = 0.5;
    %let cla11 = 0.6;
    %let cla22 = 0.6;
    %let clmu1 = 0;
    %let clsigma1 = 1;
    %let clmu2 = 3;
    %let clsigma2 = 1;

    %let c2pi1 = 0.5;
    %let c2a11 = 0.4;
    %let c2a22 = 0.4;
    %let c2mu1 = 0;
    %let c2sigma1 = 1;
    %let c2mu2 = 3;
    %let c2sigma2 = 1;
    data &dgpTable.;

```

```

do sec = 1 to &nSections.;
  * which cluster;
  * (1) randomly assign clusters;
  * u = uniform(&seed.);
  * if(u<=&clportion.) then cluster = 1;
  * else cluster = 2;
  * (2) all time series for one cluster are in one block;
  if(sec/&nSections.<=&clportion.) then cluster = 1;
  else cluster = 2;
  %do i = 1 %to &nClustersDGP.;
    if(cluster=&i.) then do;
      do t = 1 to &T.;
        if(t=1) then p = &c&i.p1;
        else do;
          if(lagState=1) then p = &c&i.a1;
          else p = 1-&c&i.a2;
        end;
        u = uniform(&seed.);
        if(u<=p) then state = 1;
        else state = 2;
        if(state=1) then
          y = &c&i.mu1. + sqrt(&c&i.sigma1.)*normal(&seed.);
        else
          y = &c&i.mu2. + sqrt(&c&i.sigma2.)*normal(&seed.);
        output;
        lagState = state;
      end;
    end;
  %end;
end;
run;

* trainingTable is sorted by sec and t;

  set &dgpTable.;
  keep sec t y;
run;

data &libTrainingTable.;
  set &trainingTable.;
run;
%mend;

```

The following macro initializes the clusters:

```

%macro estSection(libTrainingTable,casSectionTable,selectedSec,i,T,
                  evalTable,libModelTable);
  data &casSectionTable.&selectedSec.;
    set &libTrainingTable.;
    if(sec=&selectedSec.);
  run;

  proc hmm data=&casSectionTable.&selectedSec.;
    id section=sec time=t;

```

```

    model y / method=ml type=gaussian nstate=&k.;
    optimize ALGORITHM=interiorpoint printlevel=3 printIterFreq=1;
    score outmodel=&libModelTable.&i.;
run;

proc hmm data=&libTrainingTable.;
    evaluate out=mylib.tempEval;
    score inmodel=&libModelTable.&i.;
run;

data &evalTable.&i.;
    set mylib.tempEval;
    logLikelihood&i. = logLikelihood;
    if(t=&T.) then output;
    keep sec logLikelihood&i.;
run;

proc sort data=&evalTable.&i.; by sec; run;
%mend;

%macro assignSeriesToClusters(evalTable,nClusters);
    data &evalTable.;
        merge &evalTable.1 - &evalTable.&nClusters.;
        by sec;
        retain sumLogLikelihood 0;
        array arr[*] logLikelihood1 - logLikelihood&nClusters.;
        sumLogLikelihood = sumLogLikelihood + max(of arr[*]);
        pCluster = whichn(max(of arr[*]), of arr[*]);
        keep sec pCluster sumLogLikelihood;
    run;
%mend;

* initialize clusters;
* each section has T observations;
%macro ctsInitClusters(libTrainingTable,nClusters,nSections,T,
                      evalTable,libModelTable);
    * as a start, use first section or randomly select a section;
    %let selectedSec = 1;
    %let i = 0;
    %estSection(&libTrainingTable.,mylib.tempSection,
                &selectedSec.,&i.,&T.,
                &evalTable.,&libModelTable.);
    proc sort data=&evalTable.&i.; by descending logLikelihood&i.; run;

    %do i = 1 %to &nClusters.;
        data _null_;
            set &evalTable.0;
            pos = floor(1+(&nSections.-1)*(&i.-1)/(&nClusters.-1)+0.5);
            if(_N_=pos) then
                call symput('selectedSec',trim(left(put(sec,12)))));
        run;
        %estSection(&libTrainingTable.,mylib.tempSection,
                    &selectedSec.,&i.,&T.,
                    &evalTable.,&libModelTable.);
    %end;

```

```

%end;

%assignSeriesToClusters(&evalTable., &nClusters.);
%mend;

```

The following macro repeatedly moves the time series between clusters until no movement is necessary:

```

* estimate HMM for cluster i;
* each section has T observations;
%macro estCluster(libClusteredTable, libTrainingTable, i, T,
                  evalTable, libModelTable);
    data &libClusteredTable.&i.;
    set &libClusteredTable.;
    if(pCluster=&i.);
    run;

    proc hmm data=&libClusteredTable.&i.;
        id section=sec time=t;
        model y / method=ml type=gaussian nstate=&k.;
        optimize ALGORITHM=interiorpoint printlevel=3 printIterFreq=1;
        score outmodel=&libModelTable.&i.;
    run;

    proc hmm data=&libTrainingTable.;
        evaluate out=mylib.tempEval;
        score inmodel=&libModelTable.&i.;
    run;

    data &evalTable.&i.;
        set mylib.tempEval;
        logLikelihood&i. = logLikelihood;
        if(t=&T.) then output;
        keep sec logLikelihood&i.;
    run;

    proc sort data=&evalTable.&i.; by sec; run;
%mend;

* moves time series between clusters based on their likelihoods;
* each section has T observations;
* (1) &libModelTable.&i. has the model estimates for cluster i,
* and (2) &evalTable. has the clustering result;
%macro ctsClustering(trainingTable, libTrainingTable, nClusters, T,
                    libClusteredTable, evalTable, libModelTable);
    * save last clustering result;
    data prev&evalTable.; set &evalTable.; run;

    * clustering data;
    data &libClusteredTable.;
        merge &trainingTable. (in=a) &evalTable. (in=b);
        by sec;
    run;

    %do i = 1 %to &nClusters.;

```

```

    %estCluster(&libClusteredTable., &libTrainingTable., &i., &T.,
               &evalTable., &libModelTable.);
%end;

%assignSeriesToClusters(&evalTable., &nClusters.);

* compare current and previous clustering results;
proc compare data=&evalTable. compare=prev&evalTable.; run;
%let converged=%eval(&sysinfo.=0);
%let nIter=%eval(&nIter.+1);
%let done=%eval(&converged. or &nIter.>=&maxIter.);

%put nIter      = &nIter.;
%put converged = &converged.;
%put done      = &done.;
%mend;

* cluster time series;
* each section has T observations;
%macro ctsLoopClustering(trainingTable, libTrainingTable, nClusters, T,
                        libClusteredTable, evalTable, libModelTable);
%let done = 0;      * terminate clustering;
%do %while(&done.=0);
    %ctsClustering(&trainingTable., &libTrainingTable., &nClusters., &T.,
                  &libClusteredTable., &evalTable., &libModelTable.);
%end;
%mend;

```

Because the DGP is known, you can use the following macro to evaluate the performance of the clustering algorithm:

```

* compare the clustering results with the true clusters in the DGP;
* it is applicable only when the DGP is available;
%macro evaluateClusteringResults(dgpTable, evalTable, nSections, T);
    data true&evalTable.;
        set &dgpTable.;
        if(t=&T.);
            keep sec cluster;
    run;

    data ctsCheck;
        merge true&evalTable. (in=a) &evalTable. (in=b);
        by sec;
        if(cluster=pCluster) then do; correct=1; end;
        else do; correct=0; end;
        if(a=b);
    run;

    data ctsAccuracy;
        set ctsCheck;
        retain count 0 correctCount 0;
        count = count + 1;
        correctCount = correctCount + correct;
        if(count>&nSections.-0.5) then do;

```

```

        accuracy = correctCount / count;
        if (accuracy < 0.5) then accuracy = 1 - accuracy;
        nIterations = &nIter.;
        converged = &converged.;
        output;
    end;
    keep nIterations converged accuracy;
run;

proc print data = ctsAccuracy noobs;
    var nIterations converged accuracy;
    format accuracy 6.4;
run;
%mend;

```

As data become easy to access, the number of sections might become large. In this example, the number of sections is set to 10,000. As a start, the sample size for each time series is set to 200, which is the same as the sample size in Smyth (1997) and Oates, Firoiu, and Cohen (1999). In fact, the time series might have different lengths; if so, you should replace the log likelihood with the log likelihood per observation when you compare the time series.

The following macro calls simulate 10,000-section time series, apply the clustering algorithm, and then evaluate its performance:

```

%let N = 10000;
%let T = 200;
%createClustersTable(&N., &T., ctsDGP, ctsTrain, mylib.ctsTrain);
%let nClusters = 2; * number of clusters;
%let k=2;           * number of states in the HMM for each cluster;
%ctsInitClusters(mylib.ctsTrain, &nClusters., &N., &T.,
    evalCluster, mylib.modelCluster);
%let maxIter = 100; * maximum number of iterations;
%let nIter = 0;     * number of iterations;
%let converged = 0; * converge status;
%ctsLoopClustering(ctsTrain, mylib.ctsTrain, &nClusters., &T.,
    mylib.ctsTrainClustered, evalCluster, mylib.modelCluster);
%evaluateClusteringResults(ctsDGP, evalCluster, &N., &T.);

```

As shown in [Output 20.2.1](#), the accuracy of the clustering algorithm is very high.

Output 20.2.1 Clustering Accuracy ($N = 10,000$, $T = 200$)

Clustering Time Series

nIterations	converged	accuracy
5	1	0.9868

The following statements display the parameter estimates for cluster 1 and cluster 2 in [Output 20.2.2](#) and [Output 20.2.3](#), respectively:

```

* print parameter estimates for cluster 1;
proc hmm data=mylib.ctsTrain;
    score inmodel=mylib.modelCluster1;
run;

```

```

* print parameter estimates for cluster 2;
proc hmm data=mylib.ctsTrain;
  score inmodel=mylib.modelCluster2;
run;

```

As shown in [Output 20.2.2](#) and [Output 20.2.3](#), the parameter estimates of the Gaussian HMMs for the two clusters are very close to the true parameters in the DGP.

Output 20.2.2 Parameter Estimates for Cluster 1 ($N = 10,000$, $T = 200$)

Clustering Time Series

SIGMA2_1_1	0.999145	0.003447	289.87	<.0001

In the second scenario, the sample size of one time series is increased to 400:

```

%let N = 10000;
%let T = 400;
%createClustersTable(&N., &T., ctsDGP, ctsTrain, mylib.ctsTrain);
%let nClusters = 2; * number of clusters;
%let k=2;           * number of states in the HMM for each cluster;
%ctsInitClusters(mylib.ctsTrain, &nClusters., &N., &T.,
  evalCluster, mylib.modelCluster);
%let maxIter = 100; * maximum number of iterations;
%let nIter = 0;    * number of iterations;

```

```
%let converged = 0; * converge status;
%ctsLoopClustering(ctsTrain,mylib.ctsTrain,&nClusters.,&T.,
  mylib.ctsTrainClustered,evalCluster,mylib.modelCluster);
%evaluateClusteringResults(ctsDGP,evalCluster,&N.,&T.);
```

As the sample size increases, more information becomes available for each time series. As expected, the accuracy increases (to almost 100% in this case). [Output 20.2.4](#) shows the accuracy.

Output 20.2.4 Clustering Accuracy ($N = 10,000$, $T = 400$)

Clustering Time Series

nIterations	converged	accuracy
4	1	0.9989

The following statements print the parameter estimates for both clusters, which also become closer to the true parameter values, as shown in [Output 20.2.5](#) and [Output 20.2.6](#):

```
* print parameter estimates for cluster 1;
proc hmm data=mylib.ctsTrain;
  score inmodel=mylib.modelCluster1;
run;

* print parameter estimates for cluster 2;
proc hmm data=mylib.ctsTrain;
  score inmodel=mylib.modelCluster2;
run;
```

Output 20.2.5 Parameter Estimates for Cluster 1 ($N = 10,000$, $T = 400$)

SIGMA2_1_1	1.001528	0.002449	408.92	<.0001

In the last scenario, the sample size for each time series decreases to 20 (see the following statements), which is a very small number. This case is common when the sampling frequency cannot be high (for example, yearly tax return data from millions of families). The information in one time series is very limited; this might even hinder the estimation of the hidden Markov models. However, as shown in this example, by clustering the time series, you condense the common information in time series, and then the true DGP is recovered.

```
%let N = 10000;
%let T = 20;
%createClustersTable(&N., &T., ctsDGP, ctsTrain, mylib.ctsTrain);
%let nClusters = 2; * number of clusters;
%let k=2;           * number of states in the HMM for each cluster;
%ctsInitClusters(mylib.ctsTrain, &nClusters., &N., &T.,
    evalCluster, mylib.modelCluster);
%let maxIter = 100; * maximum number of iterations;
%let nIter = 0;    * number of iterations;
%let converged = 0; * converge status;
%ctsLoopClustering(ctsTrain, mylib.ctsTrain, &nClusters., &T.,
    mylib.ctsTrainClustered, evalCluster, mylib.modelCluster);
%evaluateClusteringResults(ctsDGP, evalCluster, &N., &T.);
```

As expected and as shown in [Output 20.2.7](#), the algorithm needs many more iterations to converge, and the accuracy of the clustering algorithm is not high.

Output 20.2.7 Clustering Accuracy ($N = 10,000$, $T = 20$)**Clustering Time Series**

nIterations	converged	accuracy
26	1	0.7552

The following statements print the parameter estimates for both clusters, which are shown in [Output 20.2.8](#) and [Output 20.2.9](#). Although each time series might contain little information, the parameter estimates of the Gaussian HMMs for the two clusters are very close to the true parameters in the DGP.

```

* print parameter estimates for cluster 1;
proc hmm data=mylib.ctsTrain;
  score inmodel=mylib.modelCluster1;
run;

* print parameter estimates for cluster 2;
proc hmm data=mylib.ctsTrain;
  score inmodel=mylib.modelCluster2;
run;

```

Output 20.2.8 Parameter Estimates for Cluster 1 ($N = 10,000$, $T = 20$)**Clustering Time Series**

Example 20.3: Analysis of the Business Cycle by Using the Regime-Switching Mean-Adjusted Autoregression Model

This example revisits the model in Hamilton (1989) to illustrate how the regime-switching mean-adjusted autoregression model is used to estimate the business cycle with quarterly US real gross national product (GNP) data from 1951 to 1984.

The following statements import the data and calculate the GNP growth rate (in percentage) to which the model applies:

```

title 'Analysis of the Business Cycle';
data gnpHamilton;
    input date: anydtdte. gnp;
    format date yyq6.;
    dgnp = 100*(log(gnp)-log(lag(gnp)));
    if cmiss(of _all_) then delete;
    label date="Date" gnp="GNP" dgnp="Growth Rate of GNP";
datalines;
1951q1  1286.6
1951q2  1320.4
1951q3  1349.8

    ... more lines ...

1982q4  3159.3
1983q1  3190.6
1983q2  3259.3
1983q3  3303.4
1983q4  3357.2
1984q1  3449.4
1984q2  3492.6
1984q3  3510.4
1984q4  3515.6
;

```

The following statements plot the data in [Output 20.3.1](#):

```

proc sgplot data=gnpHamilton;
    series x=date y=dgnp;
    series x=date y=gnp / y2axis;
    refline 0 / axis=y lineattrs=(color=gray thickness=1);
run;

```

Output 20.3.1 GNP and Growth Rate of GNP

Hamilton's model is a bivariate regime-switching mean-adjusted AR(4) model which can be described as

$$y_t = c^{(s_t)} + \sum_{\tau=1}^4 \alpha_{\tau}^{(s_t)} (y_{t-\tau} - c^{(s_{t-\tau})}) + \varepsilon_t, \quad \varepsilon_t \sim N(0, \Sigma^{(s_t)})$$

where $s_t \in \{1, 2\}$ is the unobserved state.

In Hamilton (1989), the autoregressive parameters α 's and variance parameters Σ 's are assumed to be state-independent, which means $\alpha_{\tau}^{(1)} = \alpha_{\tau}^{(2)}$, $\tau = 1, \dots, 4$, and $\Sigma^{(1)} = \Sigma^{(2)}$. The following statements re-create Hamilton's result by setting the initial parameter values as the parameter estimates in Table 1 in Hamilton (1989) and also setting the MAXITER= option in the OPTIMIZE statement to zero. The FILTER statement conducts the probabilities of state on the basis of data available up to the current period. The DECODE statement outputs the best possible path of states on the basis of all observations. The SMOOTH statement finds the probabilities of states on the basis of all observations.

```

data mylib.gnpHamilton; set gnpHamilton; run;
proc hmm data=mylib.gnpHamilton labelswitch=(sort=desc(const));
  id time=date;
  model dgnp / armean=adjusted type=ar ylag=4 method=ml nstate=2
              stateIndependent=(ar cov);
  optimize maxiter=0;
  initial tpm={0.9049 0.0951, 0.2450 0.7550},
    ar={0.014 -0.058 -0.247 -0.213, 0.014 -0.058 -0.247 -0.213},
    const={1.1643, -0.3577},
    cov={0.5914, 0.5914};
  filter out=mylib.filter;
  decode out=mylib.decode;
  smooth out=mylib.smooth;
run;

```

The following statements plot the filtered probabilities of state 2 in [Output 20.3.4](#), which is comparable to Figure 1 in Hamilton (1989). State 2 corresponds to recession because the intercept (and then the expected mean) in state 2 is negative.

```

data filter; set mylib.filter; run;
proc sort data=filter; by date; run;
proc sgplot data=filter;
    series x=date y=state2;
    yaxis label="Filtered Prob. of Recession";
run;

```

Output 20.3.4 Filter Plot of Economic Recession

In order to show how states correspond to the signs of GNP growth rate, the following statements overlay the decoded states on the GNP growth rate. Recession is from peak to trough, and boom is from trough to peak. As shown in [Output 20.3.5](#), the recession includes most periods that have a negative GNP growth rate.

```

data plot2state;
    merge mylib.decode mylib.gnpHamilton;
    if state=2 then do; recession=1; boom=0; end;
    else if state=1 then do; recession=0; boom=1; end;
    rec = recession*(-3);
    boo = boom*3;
    by date;
    if cmiss(of _all_) then delete;
run;

proc sgplot data=plot2state;

```

```

band x=date upper=0 lower=rec / legendlabel='Recession' type=step
                                fillattrs=(color=red);
band x=date upper=boo lower=0 / legendlabel='Boom' type=step
                                fillattrs=(color=green);
series x=date y=dgnp / lineattrs=(thickness=2);
run;

```

Output 20.3.5 Decoded Plot of Business Cycle

Hamilton (1989) also compares his choice of business-cycle dates with the historical business-cycle dates that are reported from the National Bureau of Economic Research (NBER). The following data step inputs the business-cycle dates from NBER:

```

data mylib.nber;
  input date: anydtdte. recessionNBER;
  format date yyq6.;
  label date="Date" recessionNBER="Recession Reported from NBER";
datalines;
1951q1  0
1951q2  0
1951q3  0
1951q4  0
1952q1  0

```

```

1952q2  0

... more lines ...

1982q4  1
1983q1  0
1983q2  0
1983q3  0
1983q4  0
1984q1  0
1984q2  0
1984q3  0
1984q4  0
;

```

The following statements plot together the recession dates that are found by the model and those that are reported from NBER. As shown in [Output 20.3.6](#), the recession dates that are found by Hamilton's model (the upper part) is extremely close to the dates that are reported from NBER (the lower part).

```

data gnpsmooth;
  merge mylib.smooth mylib.nber mylib.gnpHamilton;
  if state2>=0.5 then recession=1; else recession=0;
  by date;
  gnp2=gnp;
  if cmiss(of _all_) then delete;
  label recession="Recession Found by the Model" gnp2="GNP";
run;
proc transpose data=gnpsmooth out=gnpsmooth_t;
  by date;
  var recessionNBER recession;
run;
proc transpose data=gnpsmooth out=gnpsmooth_t2;
  by date;
  var gnp gnp2;
run;

  rowaxis display=(nolabel) values=(1000 to 3520 by 500);
run;

```

Output 20.3.6 Smoothed Plot of Economic Recession

The following statements use PROC HMM to estimate Hamilton's model while using the STATEINDEPENDENT=(AR COV) option in the MODEL statement so that the autoregression parameter and the variance are fixed across the states:

```
proc hmm data=mylib.gnpHamilton labelswitch=(sort=desc(const));
  id time=date;
  model dgnp / armean=adjusted type=ar ylag=4 method=ml nstate=2
    stateIndependent=(ar cov);
  optimize printIterFreq=1 printlevel=3 ;
  filter out=mylib.filter;
```

```

decode out=mylib.decode;
smooth out=mylib.smooth;
run;

```

The parameter estimates are shown in [Output 20.3.7](#), and the fit statistics are shown in [Output 20.3.8](#). The log likelihood value and the information criterion in [Output 20.3.8](#) show that this solution is better than the one in [Output 20.3.3](#) when MAXITER=0.

Output 20.3.7 Parameter Estimates

As shown in [Output 20.3.11](#), the recession dates that are found by the model (the upper part) are extremely close to the dates that are reported from NBER (the lower part).

Output 20.3.11 Smoothed Plot of Economic Recession

Example 20.4: Analysis of English Characters by Using a Finite HMM

In natural language processing (NLP), practitioners want to learn the structure of sentences and predict the sequences of words. HMMs have been widely applied for characterizing the statistical features of natural languages; for more information, see Jurafsky and Martin (2019). This example runs the model from Cave and Neuwirth (1980) to illustrate how to use the finite HMM to analyze the English language. The data set used in this example was extracted and converted from the classic novel *Vanity Fair*. To process the raw text, first remove all punctuation and numbers and convert all letters to lowercase.

The following statements create the table for the first 5,000 symbols. The table has two columns: column *t* is the position of the symbol, and column *character* is the value at time *t*.

```
data text;
    input t character $8. ;
datalines;
1    c
2    h
3    a
4    p
5    t
6    e
7    r
8

... more lines ...

4992    c
4993    k
4994
4995    o
4996    n
4997
4998    h
4999    e
5000    r
;
```

When you get data set *text*, you can translate the column value into integers. The following statements relabel the character variables as the unique integers that the finite HMM procedure uses:

```
data tbltemp;
    set text;
    _temp_count_ = 1;
run;

proc sql;
    create table f0 as
        SELECT tbl.character, /* any other columns to be grouped */
               sum(tbl._temp_count_) as count
        FROM tbltemp tbl
        group by tbl.character
        ;
quit;
```

```

data f0Id;
    set f0;
    y = _n_;
    keep character y;
run;

proc print data=f0Id; run;

proc sort data=text out=textSort;
    by character;
run;

PROC SQL;
    CREATE TABLE textLeft AS
    SELECT A.*, B.y
    FROM textSort A LEFT JOIN f0Id B
    ON A.character = B.character
    ORDER BY character;
QUIT;

proc sort data=textLeft out=textLeft;
    by t;
run;

data text2;
    set textLeft;
run;

data mylib.text;;
    set text2;
run;

```

This converts the novel into a sequence of 26 distinct letters and the word space, for a total of 27 symbols. Then, translate the characters to numbers, a to 2, b to 3, ..., z to 27, and word space to 1.

The conversion matching table is shown in [Figure 20.4.1](#).

Output 20.4.1 Matching Table

Obs	character	y
1		1
2	a	2
3	b	3
4	c	4
5	d	5
6	e	6
7	f	7
8	g	8
9	h	9
10	i	10
11	j	11
12	k	12
13	l	13
14	m	14
15	n	15
16	o	16
17	p	17
18	q	18
19	r	19
20	s	20
21	t	21
22	u	22
23	v	23
24	w	24
25	x	25
26	y	26
27	z	27

The following statements print the table after value conversion. The table, which is shown in [Figure 20.4.2](#), contains three columns: column *t* is the position of the symbol, column *character* is the original symbol, and column *y* is the translated value of the symbol at position *t*:

```
proc print data=text2(obs=10) noobs;
run;
```

Output 20.4.2 Converted Data of *Vanity Fair*

t	character	y
1	c	4
2	h	9
3	a	2
4	p	17
5	t	21
6	e	6
7	r	19
8		1
9	i	10
10	c	4

Cave and Neuwirth's model is assumed to have an underlying Markov chain with two hidden states. For each of these hidden states, assume that the 27 symbols appear according to a fixed probability distribution. The following statements estimate a finite HMM in which NSTATE=2 and NCATEGORY=27. There might be a lot of local maximums for the finite HMM; hence, you specify the multistart mode by specifying MULTISTART=1 in the OPTIMIZE statement.

```
data mylib.text;
  set text;
run;
proc hmm data=mylib.text ;
  id time=t;
  model y / type=finite nstate=2 nCategory=27;
  optimize algorithm=interiorpoint multistart=1;
run;
```

The number of observations and model information are shown in [Output 20.4.3](#).

Output 20.4.3 Number of Observations and Model Information

The most interesting part of this result is the result of the category probability matrix (CPM). In state 1, the probabilities of containing 3, 4, 5, . . . , 26, which correspond to the consonants, are significant. In state 2, the probabilities of containing 1, 2, 6, 10, 16, 22, which correspond to the vowels a, e, i, o, and u and the space, are significant. Without your having made any assumptions about the two hidden states, the CPM shows that one hidden state contains the vowels and the other hidden state contains the consonants. Interestingly, the space is treated more like a vowel in the context of English. The PROC HMM result shows that the distinction between vowels and consonants is a statistically significant feature inherent in the language. And thanks to HMMs, this could easily be deduced by someone who has no background knowledge of the language.

Overview: MKTATTRIBUTION Procedure

The MKTATTRIBUTION procedure supports different types of market attribution models, which have been used to identify which marketing channels drive customer conversions and to help optimize the investment in those channels. Customers are “converted” when they are persuaded by marketing content to take a particular action, such as buying a product, that a business wants them to take. As the array of media channels where businesses can promote their products and services grows, most customers engage with marketing content through multiple channels, such as in television advertising and in ads on social media. Businesses want to know to what degree each channel contributes to their marketing success. This is called the multichannel attribution problem. The Markov attribution model (MAM), one of the market attribution models, approaches the attribution problem in a probabilistic way by using a Markov chain, a particular stochastic process in which the probability distribution of any next state depends only on what the current state is, regardless of any preceding states. The MAM uses a first-order Markov chain to calculate the probability of interaction between pairs of channels in the customer journey and to evaluate the channel’s contribution to customer conversions through the so-called removal effect. The removal effect would enable a business to give a reliable assessment of the marketing contribution of each channel. In addition, the MKTATTRIBUTION procedure provides a number of heuristic attribution models: the first-touch, last-touch, linear, position-based, and time-decay attribution models.

PROC MKTATTRIBUTION requires SAS Cloud Analytic Services (CAS) in order to run, and it does the following: enables you to run on a cluster of machines that distribute the data and the computations, and exploits all the available cores and concurrent threads.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);  
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;  
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the `mylib` CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “[Introduction to Shared Concepts](#)” on page 54 in Chapter 4, “[Shared Concepts](#).”

Getting Started: MKTATTRIBUTION Procedure

This section provides a brief example of using the Markov attribution model that the MKTATTRIBUTION procedure supports.

Consider a market attribution model that has the following transition probability matrix (TPM) for five states $\{channel1, channel2, channel3, conversion, null\}$:

$$A = \begin{pmatrix} 0.0 & 0.2 & 0.4 & 0.3 & 0.1 \\ 0.1 & 0.0 & 0.4 & 0.5 & 0.0 \\ 0.3 & 0.2 & 0.0 & 0.3 & 0.2 \\ 0.0 & 0.0 & 0.0 & 1.0 & 0.0 \\ 0.0 & 0.0 & 0.0 & 0.0 & 1.0 \end{pmatrix}$$

It also has the following initial state probability vector (ISPV):

$$\pi = \begin{pmatrix} 0.3 \\ 0.3 \\ 0.4 \\ 0.0 \\ 0.0 \end{pmatrix}$$

The following statements simulate the channel visit history, or the customer journey, for 100 customers from the previous model in order to provide test data for PROC MKTATTRIBUTION. The test data table has three columns: *customerId* is the ID of each customer, *t* is the time period that the customer was in, and *c* is the channel that the customer visited at time *t*. Column *c* takes value *i* for channel *i*, *i* = 1, 2, and 3, and takes a value of 0 when customer conversion occurs. For a customer, if the last column *c* value is not 0, this means that the customer is not converted, which also means that the customer is in the null state. Note that, the channel variable takes the natural numbers sequentially from 1 and can't skip any numbers.

```
%let seed=1234;
%let T=10; *the maxsimustep for each customer;
%let nCustomers=100; *the number of customers;

data simu(keep = customerId t c);

  call streaminit(&seed);

  array p0[5] _temporary_ (0.3, 0.3, 0.4, 0, 0.0);
  array p1[5] _temporary_ (0, 0.2, 0.4, 0.3, 0.1);
  array p2[5] _temporary_ (0.1, 0, 0.4, 0.5, 0.0);
  array p3[5] _temporary_ (0.3, 0.2, 0, 0.3, 0.2);
  do customerId = 1 to &nCustomers;
    c_last=0;
    t=0;
    c=1;
    do while(t < &T. and 0<c<=3);
```

```

c_last=c;
t+1;
if t=1 then
  c = rand("Table", of p0[*]);
else do;
  if c_last=1 then
    c = rand("Table", of p1[*]);
  else if c_last=2 then
    c = rand("Table", of p2[*]);
  else if c_last=3 then
    c = rand("Table", of p3[*]);
  end;
  if c=4 then c=0;
  if c ne 5 then
    output;
  end; *for each customer;
end; *for all simulations;
run;

proc print data=simu (obs=10) noobs; run;

data mylib.marketData; set simu; run;

```

The first 10 observations of the simulated data are shown in [Figure 21.1](#).

Figure 21.1 Simulated Data

customerId	t	c
1	1	3
1	2	0
2	1	1
2	2	3
3	1	1
3	2	3
3	3	0
4	1	1
4	2	3
4	3	1

The following statements estimate the Markov attribution model that has three channels:

```

proc mktattribution data=mylib.marketData;
  id section=customerId time=t;
  model c / nchannel=3;
run;

```

The model information and number of observations are shown in [Figure 21.2](#).

Figure 21.2 Model Information and Number of Observations**The MKTATTRIBUTION Procedure**

PROC MKTATTRIBUTION Statement

PROC MKTATTRIBUTION *DATA=libref.data-table* ;

The PROC MKTATTRIBUTION statement invokes the MKTATTRIBUTION procedure. You must specify the following *option*:

DATA=*libref.data-table*

names the input data table for PROC MKTATTRIBUTION to use. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1416.

data-table specifies the name of the input data table.

ID Statement

ID *TIME=variable* **SECTION=variable** ;

The ID statement identifies observations in the input data table by specifying two variables for the cross-sectional time series data. That is, for each observation, the combination of the two variables' values must be unique.

You must specify the following options:

TIME=variable

specifies the temporal or sequential order of the observations. The *variable* cannot have missing values.

SECTION=variable

identifies the section or customer ID of each observation. The *variable* cannot have missing values.

MODEL Statement

MODEL *channel-variable* < / *options* > ;

The MODEL statement specifies the channel variable and the number of channels for the market attribution model. Only one MODEL statement is allowed.

You can specify the following *options* after a forward slash (/):

HALFLIFE=number

specifies the half-life the decaying attribution value for the time-decay attribution model. The *number* must be a positive number. By default, the value of the HALFLIFE= option is 1.

NCHANNEL=number

specifies the number of channels for the market attribution model. The *number* must be a positive integer. The *number* must be greater than the value the channel variable takes. If you specify a *number* greater than the maximum value of the channel variable in the input data set, the procedure produces useless information in the TPM. If you specify a *number* less than the maximum value of the channel variable in the input data set, the procedure stops running. By default, the value of the NCHANNEL= option is the maximum value of the channel variable in the input data set.

OUTPUT Statement

OUTPUT < options > ;

The OUTPUT statement saves the estimation results to the specified output data tables. You can specify the following options:

OUTCONTRIBUTION=*libref.data-table*

writes the contribution results to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1416.

OUTREMOVAL=*libref.data-table*

writes the removal effects to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1416.

OUTTPM=*libref.data-table*

writes the estimated transition probability matrix to the specified output data table. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1416.

Details: MKTATTRIBUTION Procedure

Markov Attribution Model

In the Markov attribution model (MAM), customer journeys are represented as Markov chains. A Markov chain is defined by a set of states $\mathbf{S}_t \in \{1, \dots, K\}$, where t is the time index and K is the number of states; an initial state probability vector (ISPV); and a transition probability matrix (TPM). The ISPV for the MAM can be expressed as a $K \times 1$ vector π , where an element π_i of π denotes the probability of moving from the starting position to the state i ; that is,

$$\pi_i = p(\mathbf{S}_1 = i), i = 1, \dots, K$$

The TPM for the MAM can be expressed as a $K \times K$ matrix $\mathbf{A}$, where an element a_{ij} of $\mathbf{A}$ denotes the probability of moving from past state i to current state j ; that is,

$$a_{ij} = p(\mathbf{S}_t = j | \mathbf{S}_{t-1} = i)$$

For example, if a business uses three different channels, C1, C2, and C3, in its online marketing strategy, the model would include three states, C1, C2, and C3. Additionally, all Markov chains contain two special states:

a conversion state that represents a successful conversion, and a null state for customer journeys that have not ended in a conversion during the observation period. The full set of states S in this example would therefore look like this: $S = \{C1, C2, C3, conversion, null\}$.

The number of states in the Markov chain is the number of marketing channels plus two states: conversion state and null state. If you assume that the number of marketing channels is N , then $K = N + 2$.

If a customer journey ends in a conversion state, the last channel in the journey is connected to the conversion state; otherwise it leads to the null state. For modeling reasons, the conversion state and the null state always lead to themselves and are considered absorbing states.

The conversion rate is defined as the number of conversions divided by the sum of the number of conversions and the number of null results. The removal effect of a channel is defined as the decrease in probability of reaching the conversion state when you remove the channel from the customer's journey. The normalized removal effect is well suited to measuring the contribution of each channel. The contribution per state as a percentage of the sum of all removal effects is reported (excluding the special conversion and null states).

Heuristic Attribution Models

In addition to providing the Markov attribution model, the PROC MKTATTRIBUTION provides several heuristic attribution models: the first-touch, last-touch, linear, position-based, and time-decay attribution models. The first-touch attribution model attributes all credit for the conversion to the first-visited channel in the customer journey. The last-touch attribution model attributes all credit for the conversion to the last-visited channel. The linear attribution model distributes the credit for the conversion equally across all visited channels in the path. The position-based attribution model attributes 40% of credit to the first-visited channel, 40% to the last-visited channel, and the remaining 20% credit equally to the channels in between, if there are more than two visits in the journey. Otherwise, the position-based attribution model is the same as the linear attribution model. The time-decay attribution model attributes the credit increasingly to the channel that is closer to the conversion.

Assuming that there are n customer journeys, the number of conversions is m , where $m \leq n$. $C_j(p)$ is the p th channel in customer j 's journey C_j with length l_j , $p = 1, \dots, l_j$, and $j = 1, \dots, n$. Let $f(C_j(p) = i | conversion) = 1, i = 1, \dots, K$, where K is the number of channels, if $C_j(p) = i$ and conversion occurs at the end of this journey; otherwise it equals 0. The contribution to channel i by the first-touch attribution model is calculated by

$$contribution(i) = \frac{\sum_{j=1}^n f(C_j(1) = i | conversion)}{m}$$

The bar chart in [Output 21.8](#) shows how the first-touch attribution model distributes the contributions for a journey that visits four channels.

Figure 21.8 Bar Chart for the First-Touch Attribution Model

The contribution to channel i by the last-touch attribution model is calculated similarly by

$$contribution(i) = \frac{\sum_{j=1}^n f(C_j(l_j) = i | conversion)}{m}$$

The bar chart in [Output 21.9](#) shows how the last-touch attribution model distributes the contributions for a journey that visits four channels.

Figure 21.9 Bar Chart for the Last-Touch Attribution Model

The contribution to channel i by the linear attribution model is calculated by

$$contribution(i) = \frac{\sum_{j=1}^n \sum_{p=1}^{l_j} f(C_j(p) = i | conversion) / l_j}{m}$$

The bar chart in [Output 21.10](#) shows how the linear attribution model distributes the contributions for a journey that visits four channels.

Figure 21.10 Bar Chart for the Linear Attribution Model

If $l_j \leq 2$, the position-based attribution model is the same as the linear attribution model. If $l_j > 2$, then let $h(C_j(p) = i | \text{conversion}) = 0.4$ and $e(C_j(p) = i | \text{conversion}) = 0.2(l_j - 2)^{-1}$ if $C_j(p) = i$ and if conversion occurs at the end of this journey; otherwise it equals 0. The contribution to channel i by the position-based attribution model is calculated by

$$\text{contribution}(i) = \frac{1}{m} \sum_{j=1}^n [\mathbf{A}(l_j \leq 2) + \mathbf{B}(l_j > 2)]$$

where $\mathbf{A}(l_j \leq 2) = \sum_{p=1}^{l_j} f(C_j(p) = i | \text{conversion}) / l_j$, if $l_j \leq 2$, and otherwise it equals 0; and $\mathbf{B}(l_j > 2) = h(C_j(1) = i | \text{conversion}) + h(C_j(l_p) = i | \text{conversion}) + \sum_{p=2}^{l_j-1} e(C_j(p) = i | \text{conversion})$, if $l_j > 2$, and otherwise it equals 0.

The bar chart in [Output 21.11](#) shows how the position-based attribution model distributes the contributions for a journey that visits four channels.

Figure 21.11 Bar Chart for the Position-Based Attribution Model

Let f be the half-life parameter, $g(C_j(p) = i | conversion) = (\frac{1}{2})^{(l_j - p)/f}$ if $C_j(p) = i$ and if conversion occurs at the end of this journey; otherwise it equals 0. The contribution to channel i by the time-decay attribution model is calculated by

$$contribution(i) = \frac{1}{m} \sum_{j=1}^n \left[\sum_{p=1}^{l_j} g(C_j(p) = i | conversion) / D \right]$$

where $D = \sum_{q=1}^{l_j} (\frac{1}{2})^{(l_j - q)/f}$ is the normalizing coefficient for journey j .

The bar chart in [Output 21.12](#) shows how the time-decay attribution model distributes the contributions for a journey that visits four channels.

Figure 21.12 Bar Chart for Time-Decay Attribution Model (HALFLIFE=1)

Input Data

The input data set must have three variables: section ID, time ID, and channel. The channel variable must be a nonnegative integer. The section ID variable identifies each customer. The time ID variable sorts the order of visits of each customer. The combination of section ID and time ID must be unique. The channels can appear in raw data as strings, such as “email”, “online search”, and so on. You need to convert them to the natural numbers and zero, where zero represents the conversion, and save them in the channel variable. So the largest value of the channel variable is the number of distinctive channels in the input data. Any customer journey that does not end with zero ends with a null state. Each customer can have at most only one conversion. The procedure skips records that have a missing channel variable. The procedure skips the records in which the conversion occurs at the beginning or middle of the journey. The procedure skips the records in which consecutive channels occur within the same customer journey, so the estimated TPM always has zero values in the diagonal positions.

Data Table Output

The MKTATTRIBUTION procedure can create the data tables that are specified in the following options in the OUTPUT statement: OUTCONTRIBUTION=, OUTREMOVAL=, and OUTTPM=. The column information that each table contains is described in the following sections.

OUTCONTRIBUTION= Data Table Generated from the OUTPUT Statement

The output data table contains the following variables (columns):

Channel	channel for which to calculate the removal effect
Markov Chain	contribution calculated using the Markov attribution model
First-Touch	contribution calculated using the first-touch model
Last-Touch	contribution calculated using the last-touch model
Linear	contribution calculated using the linear attribution model
Position-Based	contribution calculated using the position-based attribution model
Time-Decay	contribution calculated using the time-decay attribution model

OUTREMOVAL= Data Table Generated from the OUTPUT Statement

The output data table contains the following variables (columns):

Channel	channel for which to calculate the removal effect
Value	removal effect for the corresponding channel

OUTTPM= Data Table Generated from the OUTPUT Statement

The output data table contains the following variables (columns):

State	previous state in the Markov chain
Channel k	probability of transition to channel k , $k = 1, \dots, K$, where K is the number of channels
Conversion	probability of transition to the conversion state
Null	probability of transition to the null state

ODS Table Names

The MKTATTRIBUTION procedure assigns a name to each table that it creates. You can use this name to refer to the table when using the Output Delivery System (ODS) to select tables and create output data tables. These names are listed in [Table 21.2](#).

Table 21.2 ODS Tables Produced in the MKTATTRIBUTION Procedure

ODS Table Name	Description	Option
Contributions	Contribution value for each channel calculated for each model	Default
ConversionRates	Conversion rate calculated using input data and from the estimated TPM	Default
ISPV	Initial state probability vector	Default
ModelInfo	Model information	Default
NObs	Observation information	Default
RemovalEffects	Removal effect for each channel	Default
TPM	Transition probability matrix	Default

Examples: MKTATTRIBUTION Procedure

This section provides an example of the model that the MKTATTRIBUTION procedure supports.

The following statements read a data table that contains records of 2 million customer visits. The table has four columns: *sec* is the number to identify the customers, *time* is the time when the customer visits, *c* is a nonnegative integer variable that is converted from the channel variable and is to be used in the model, and *channel* is the channel that the customer visits at time *t*.

```

5	organic
6	paid search
7	paid social
8	phone
9	print
10	sms
11	social
12	video
13	web

In addition to the conversion, which equals 0, in the c variable, there are 13 distinctive channels shown in Output 21.13.

The following statements estimate the Markov attribution model that has 13 channels:

```

proc sort data=marketData out=marketData nodupkey;
  by sec time;
run;
data mylib.marketData2;
  set marketData;
run;
proc mktattribution data=mylib.marketData2;
  id section=sec time=time;
  model c / nchannel=13;
  output outremoval=mylib.rm outcontribution=mylib.contribution outtpm=mylib.tpm ;
run;

```

The model information and number of observations are shown in [Output 21.14](#).

The removal effect of a channel is the decrease in the probability of overall conversion if the channel were removed. In [Output 21.18](#), you see that channel 5 (organic) leads to the greatest decrease in the probability of conversion if it is missing.

The contributions are just normalized removal effects to indicate each channel's contribution to the conversion. The contributions of the Markov attribution model and the other three heuristic attribution models are shown side by side in [Output 21.19](#). The last-touch model does not place as much value on channel 1 (direct mail) as other methods do, but it attributes the most value to channel 5 (organic). The first-touch model does not value channel 4 (email) as much as other methods do, but it attributes the most value to channel 1 (direct mail). The Markov and linear attribution models have similar attribution values for most of the channels, except that there is a 9% difference between the two models on the contribution of channel 1 (direct mail). The position-based model and time-decay model both attribute less credit to channel 4 (email), which is the third most important channel according to the Markov model. The reason might be that the email channel always appears in the middle of the customer journey.

Overview: SASEBEA Interface Engine

The SASEBEA interface engine enables SAS users to retrieve time series data from the US Bureau of Economic Analysis (BEA) economic statistics website (www.bea.gov/data). This website offers access to economic statistics data at the industry, regional, national, and international levels.

The industry economic accounts provide a detailed view of the interrelationships between US producers and users. They are used extensively by both policymakers and businesses to understand industry interactions, productivity trends, and the changing structure of the US economy.

The regional economic accounts describe the geographic distribution of US economic activity and growth. The estimates of gross domestic product by state and of state and local personal income, and the accompanying details, help provide a consistent framework for analyzing and comparing individual state and local economies.

The national economic accounts include summary measures such as gross domestic product, corporate profits, personal income and spending, and personal saving.

The international economic accounts provide information about trade in goods and services, such as balance of payments and the balance of trade, investment income, and government and financial flows. These accounts measure the value of US international assets and liabilities and direct investment by multinational enterprises (MNEs). These direct investment data are used to assess the role that business enterprises play in the global economy.

The international transactions data include exports and imports of goods and services, receipts, and payments of income, and international transactions in financial assets and liabilities. The international trade in services data give detailed annual statistics for trade in services and for services provided through affiliates. The US international investment position accounts contain the end-of-period value of accumulated stocks of US financial assets and liabilities.

The input-output accounts focus on the interrelationships between US producers and users.

The SASEBEA interface engine uses the LIBNAME statement to enable you to download the BEA's online economic data from the website at the following root URL:

<https://apps.bea.gov/api/>

It also enables you to specify which time series you want to retrieve, by specifying the data set name and the parameters defined for that data set. You choose the time range of the retrieved data by specifying a list of years. You can then use the SAS DATA step to perform further subsetting, retrieve the data, and store the resulting time series in a SAS data set and in a CAS table (if desired).

You can view the catalog of available BEA databases on the web page at the following URL:

<https://apps.bea.gov/api/data?UserID=<Your-36character-key>&method=GETDATASETLIST>

Every user has a unique user ID key, which the user can obtain by registering at

<https://apps.bea.gov/api/signup/>

The SASEBEA interface engine supports Linux X64 (LAX) and Windows.

Although the SASEBEA engine uses the BEA Data Retrieval API, the interface is not endorsed or certified by the Bureau of Economic Analysis. By using the SASEBEA interface engine, you are agreeing to comply with the terms of service, which are described when you sign up for your user ID key.

To get started using the SASEBEA engine, see the section “[Getting Started: SASEBEA Interface Engine](#)” on page 1440, which shows how to view the National Income and Product Accounts (NIPA), Table T10101, “Percent Change from Preceding Period in Real Gross Domestic Product.” The sample SAS code for accessing the table appears at the end of that section.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the `mylib` CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “[Introduction to Shared Concepts](#)” on page 54 in Chapter 4, “[Shared Concepts](#).”

Getting Started: SASEBEA Interface Engine

As described in the preceding section, you need a user ID key to use the BEA economic statistics data web service.

The web page at the following URL describes how to use the BEA's Data Retrieval API:

https://apps.bea.gov/api/_pdf/bea_web_service_api_user_guide.pdf

The statements at the end of this section enable you to access the BEA National Income and Product Accounts (NIPA) Table T10101, which is described as “Table 1.1.1. Percent Change from Preceding Period in Real Gross Domestic Product [Percent] Seasonally Adjusted at Annual Rates.”

The TABLENAME= option specifies which table you want to retrieve the data from in the data set that you specify in the SETNAME= option, which in this sample code is the T10101 table in the NIPA data set.

The OUT= option specifies both the name of the resulting JSON file(s) and the name of the SAS data set.

The range of the retrieved data is determined by the YEAR= option. You specify each year in a quoted list in ‘YYYY’ format.

The JSON data that the BEA's website returns are placed in a file that is named by the OUT= option—in this case, *NIPGDP.json*. **NOTE:** The SASEBEA interface engine appends a numeral to the JSON file name, and the file extension (.json) is excluded from the file name that appears in the OUT= option (or OUTJSON= option). When the SET statement is executed, the JSON data are read (and merged) into a SAS data set named *NIPGDP.sas7bdat*, which resides in the location that is specified inside the string enclosed in double quotation marks in the LIBNAME statement.

The result is named in the DATA step in the SET statement and is shown in [Figure 22.1](#). **NOTE:** It is good practice to use the DATA step with the SET statement, followed by a separate proc print statement that references the output data set named in the DATA step. For more information, see “[SAS Output Data Set](#)” on page 1548.

For another example that uses more LIBNAME statement options, see the section “[Examples: SASEBEA Interface Engine](#)” on page 1553.

Syntax: SASEBEA Interface Engine

The SASEBEA interface engine uses standard engine syntax to read the observations or data values for one or more time series from BEA's economic statistics data website.

Functional Summary

Table 22.1 summarizes the options that the SASEBEA engine uses.

Table 22.1 Summary of SASEBEA Interface Engine Options

Option	Description
AFFILIATION=	Specifies the affiliation classification of the services transaction
AREAORCOUNTRY=	Specifies the counterparty area or country for which to select BEA time series data
CASLIB=	Specifies the name of the caslib where the in-memory CAS table containing the BEA data is stored
CASOUT=	Specifies the name of the in-memory CAS table, which contains the data that the SASEBEA interface engine returns
CLASSIFICATION=	Specifies the name of the classification by which the data are returned
COMPONENT=	Specifies either the position (Pos) or a component in the change of position (ChgPosTrans) from the previous period
COUNTRY=	Specifies the geographic area code of the selected data to retrieve
DEBUG=	Specifies whether to include diagnostic message logging in the SAS log window
DESCRIPTION=	Specifies whether to use a long or short label
DIRECTIONOFINVESTMENT=	Specifies the direction of investment for multinational enterprise, with respect to United States (inward or outward)

Table 22.1 *continued*

Option	Description
FOOTNOTES=	Specifies whether to include footnotes in the data to retrieve
FREQ=	Specifies the frequency of the data to retrieve
GEOFIPS=	Specifies a list of the federal information processing system (FIPS) codes for state, county, or MSA codes of the data to retrieve
GOCAS=	Specifies whether to generate an in-memory CAS table for the BEA data
INDICATOR=	Specifies a list of series indicators to retrieve
INDUSTRY=	Specifies a list of industries to retrieve
LINECODE=	Specifies the line code in the table to retrieve
NONBANKAFFILIATESONLY=	Specifies whether the selection of data is for nonbank affiliates only (1) or for both bank and nonbank affiliates (0)
OUT=	Specifies the name of the SAS data set and the JSON file, which contains the data that the SASEBEA interface engine returns
OWNERSHIPLEVEL=	Specifies the selection of data for all affiliates (OWNERSHIP=1), or for majority-owned affiliates (OWNERSHIP=0)
SERIESID=	Specifies the series identifier (integer) of the time series data to retrieve
SETNAME=	Specifies the name of the BEA data set from which to retrieve the time series data
STATE=	Specifies the two-digit FIPS code of the state to select the time series data to retrieve
TABLEID=	Specifies the table identifier of the data table to retrieve
TABlename=	Specifies the name of the data table to retrieve
TRADEDIRECTION=	Specifies the trade direction to retrieve data for
TYPEOFINVESTMENT=	Specifies the type of investment to retrieve data for
TYPEOFSERVICE=	Specifies the type of service to retrieve data for
USER=	Specifies the required BEA access key to authenticate the request for the retrieved data
YEAR=	Specifies a list of years to retrieve data for

The LIBNAME *libref* SASEBEA Statement

LIBNAME *libref* **SASEBEA** '*physical-name*' *options* ;

The LIBNAME statement assigns a SAS library reference (*libref*) to the physical path of the directory where the SASEBEA interface engine stores the BEA economic data. The required *physical-name* argument specifies the final location of the folder where your BEA data reside in a SAS data set that is named in the OUT= option. The *physical-name* should end with a backslash (for example, C:*physical_name*\) when you are in a Windows environment or a forward slash (/user/*physical_name*/) when you are in a UNIX environment.

You can specify the following *options*:

AFFILIATION=*bea_affiliation*

specifies the affiliation classification of the services transactions for which to select BEA time series data. See [Table 22.54](#) for a list of valid affiliation classifications.

AREAORCOUNTRY=*bea_areaorcountry*

specifies the counterparty area or country for which to select BEA time series data. The requested data are organized according to the specified counterparty area(s) or countries. See [Table 22.53](#) for a list of available counterparty area or countries for the IntlServTrade data.

CASLIB=*bea_caslib_name*

specifies the name of the CAS library (caslib) where the in-memory CAS table is stored when the JSON data from the BEA website are read into SAS. You can use this option to name your caslib where the in-memory CAS table is stored. The default value is the name of the active caslib. The GOCAS=ON option is required when you specify the CASLIB= option.

CASOUT=*libref.data-table***OUTCAS=***libref.data-table*

specifies the name of the in-memory CAS table that is created when the JSON data from the BEA are read into SAS. You can use this option to name your in-memory CAS table. The default value is the name that you specify in the OUT= option. The in-memory table is created only when you also specify the GOCAS=ON option. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1439.

CLASSIFICATION=*bea_classification***CLASS=***bea_classification*

specifies the name of the classification key (such as COUNTRY or INDUSTRY) with which to group BEA time series data. You can use this option to name one of the key classifications shown in [Table 22.58](#). The requested data are organized according to the specified classification.

COMPONENT=*bea_component*

specifies a position or a component in the change of position from the previous period. You can use this option to select a component or multiple components to retrieve BEA time series data. The requested data are organized according to the specified component(s). See [Table 22.51](#) for a list of available components and their descriptions.

COUNTRY=*bea_country***COUNTRIES=***bea_country*

specifies the geographic area code of the country with which to select BEA time series data. You can use this option to select a geographic area to retrieve BEA time series data from. The requested data are organized according to the specified geographic area code(s). See [Table 22.59](#) for a list of available country geographic area codes for MNE data, and see [Table 22.48](#) for International Transactions Accounts (ITA) data.

DEBUG=ON | OFF

specifies whether or not to include diagnostic message logging in the SAS log window. This information can be useful for troubleshooting a problem. By default, DEBUG=OFF.

DESCRIPTION=LONG | SHORT

For data from the International Trade in Services, specifies whether to use the short BEA time series indicator (using indicators whose names start with the prefix ‘TSI_Ist’) as the time series label, or whether to use the long BEA time series description as the time series label. By default, DESCRIPTION=SHORT. When printing the output data set, it is useful to use the LABEL option on the PROC PRINT statement so that each column heading matches the BEA time series indicator for each time series variable. When DESCRIPTION=LONG and the LABEL option is used on the PROC PRINT statement, each column heading matches the time series description of each time series variable.

DIRECTIONOFINVESTMENT=OUTWARD | INWARD | STATE | PARENT**DIRECT_OF_INVEST=OUTWARD | INWARD | STATE | PARENT**

For data from the Direct Investment (DI) Multinational Enterprise (MNE) data set, specifies whether the direction is outward, as in US direct investment abroad, or inward, as in foreign investment in the United States.

For data from the Activities of Multinational Enterprises (AMNE) data set, in addition to OUTWARD or INWARD, specify STATE when requesting the data on a state level, or specify PARENT for data on US parent enterprises.

The DIRECTIONOFINVESTMENT= option is important to the NONBANKAFFILIATESONLY= option; together these two options influence the range of years of data to be retrieved. When DIRECTIONOFINVESTMENT=OUTWARD and NONBANKAFFILIATESONLY=0, the data that are retrieved range from 2009 to the present. When DIRECTIONOFINVESTMENT=INWARD and NONBANKAFFILIATES=0, the data that are retrieved range from 2007 to the present. When DIRECTIONOFINVESTMENT=OUTWARD and NONBANKAFFILIATESONLY=1, the data that are retrieved are for AMNE “outward” data up to 2008. When DIRECTIONOFINVESTMENT=INWARD and NONBANKAFFILIATESONLY=1, the data that are retrieved are for AMNE “inward” data up to 2006.

FOOTNOTES=YES | NO

specifies whether or not to include footnotes in the retrieved data. By default, FOOTNOTES=NO.

FREQ=A | Q | QSA | QNSA | M**FREQUENCY=A | Q | QSA | QNSA | M****INTERVAL=A | Q | QSA | QNSA | M****PERIOD=A | Q | QSA | QNSA | M**

specifies the selection frequency for the time series. You can specify one of the following frequencies:

A specifies annual frequency.

Q specifies quarterly frequency.

QSA specifies seasonally adjusted quarterly frequency (ITA data set only).

QNSA specifies not seasonally adjusted quarterly frequency (ITA data set only).

M specifies monthly frequency.

GEOFIPS=*bea_geofips*

specifies a list of the federal information processing system (FIPS) codes for state, county, or metropolitan statistical area (MSA) or other codes of the data to retrieve. You can specify *bea_geofips* as a comma-delimited string enclosed in double quotes. Specify GEOFIPS=STATE to select all states, GEOFIPS=COUNTY to select all counties, GEOFIPS=MSA to select all metropolitan statistical areas, GEOFIPS=MIC to select all micropolitan statistical areas, GEOFIPS=DIV to select all metropolitan divisions, GEOFIPS=CSA to select all combined statistical areas, or GEOFIPS=PORT to select all metropolitan and nonmetropolitan portions. The list can contain ANSI state-county codes or metropolitan area codes, which are described at the following web page:

<https://transition.fcc.gov/oet/info/maps/census/fips/fips.txt>

In addition, a comprehensive list of MSAs and their component counties is given at the following web page:

<https://apps.bea.gov/regional/docs/msalist.cfm>

GOCAS=ON | OFF

specifies whether to create (ON) or not create (OFF) an in-memory CAS table of the BEA data (in addition to the SAS data set that is created). When GOCAS=ON, the SASEBEA engine assumes that there is an active CAS session running when it executes the LIBNAME statement. By default, GOCAS=OFF.

INDUSTRY=*bea_industries***INDUSTRIES=***bea_industries*

specifies a list of the desired industries for the time series data selection. You can specify *bea_industries* as a comma-delimited string enclosed in double quotes. You can specify INDUSTRY=ALL to select all available industries. See [Table 22.60](#) for a list of available industry codes.

LINECODE=*bea_linecode*

specifies the line that corresponds to the statistic in a table that is required for the time series data selection. You can specify only one line code. You must use only one GEOFIPS= specification when you specify LINECODE=ALL. GEOFIPS=STATE, COUNTY, MSA, MIC, DIV, CSA, or PORT are treated as multiple GEOFIPS codes so these cannot be used with LINECODE=ALL. When a multiple GEOFIPS code is used, specify only one LINECODE (for example, LINECODE=1). This option is required.

NONBANKAFFILIATESONLY=0 | 1**NONBANKONLY=0 | 1**

specifies whether to return data for nonbank affiliates only (1) or for both bank and nonbank affiliates (0). Specify NONBANKAFFILIATESONLY=0 for AMNE “outward” data from 2009 to present and for “inward” AMNE data from 2007 to present. Specify NONBANKAFFILIATESONLY=1 for AMNE “outward” data up to 2008 and for “inward” AMNE data up to 2006. This option is required when you specify the OWNERSHIPLEVEL= option.

OUT=*bea_jsonfile***OUTJSON=***bea_jsonfile***JSON=***bea_jsonfile*

specifies the name of the JSON file (downloaded) and the name of the SAS data set that is created when the JSON data are read into SAS. You can use the OUT= option to name the JSON data file. It is

stored in the SAS Work library. The SAS data set that is created (when the JSON data are read into SAS) is stored in the folder specified by *physical-name*. You can refer to it by using the myLib libref in the LIBNAME statement.

OWNERSHIPLEVEL=0 | 1

OWNERS=0 | 1

specifies whether to return data for all affiliates (1) or to return data for majority-owned affiliates only (0). This option is used only with AMNE statistics and is required. When DIRECTIONOFINVESTMENT=PARENT, the OWNERSHIPLEVEL= option must be set to 1. You must specify the OWNERSHIPLEVEL= option to retrieve AMNE data.

SERIESID='bea_seriesid'

SERIESIDS='bea_seriesid'

INDICATOR='bea_seriesid'

SERIESINDICATOR='bea_seriesid'

specifies a list of the BEA time series identifiers (or indicators) to retrieve, enclosed in quotes. You can specify *bea_seriesid* as a comma-delimited string enclosed in double quotes. For the ITA data set, you can specify INDICATOR=ALL to select all available indicators. See [Table 22.24](#) through [Table 22.47](#) for a list of available ITA indicator codes. For the MNE data set, you can specify SERIESID='0' to retrieve all the available series IDs whose criteria match the rest of the SASEBEA LIBNAME option specifications. [Table 22.57](#) shows the list of BEA series identifiers for MNE data.

SETNAME=bea_setname

DATASETNAME=bea_setname

DATASET=bea_setname

SETID=bea_setname

specifies the BEA data set name to retrieve the BEA data from. [Table 22.2](#) shows the list of BEA data set names.

STATE=bea_statecode

STATES=bea_statecode

specifies the unique two-digit state FIPS code to select which data are retrieved. [Table 22.61](#) shows the list of state FIPS codes with their corresponding state names. Only one FIPS code is allowed.

TABLEID=bea_tableids

TABLEIDS=bea_tableids

specifies the unique identifier of the table from which the data are retrieved. The available table IDs for the GDPbyIndustry data are listed in [Table 22.17](#). The available table IDs for the UnderlyingGDPbyIndustry data are listed in [Table 22.21](#). The available table IDs for the Input-Output Statistics data are listed in [Table 22.52](#).

TABLENAME=bea_table

TABLE=bea_table

specifies the name of the table from which the data are retrieved. [Table 22.14](#) and [Table 22.15](#) show the list of NIPA and Underlying NIPA table names. Fixed assets table names are shown in [Table 22.22](#). Regional table names are shown in [Table 22.62](#). This is a required option.

TRADEDIRECTION=*bea_tradedirection*

specifies the direction of trade of the data to be retrieved. [Table 22.55](#) shows the list of trade directions and their corresponding descriptions.

TYPEOFINVESTMENT=*bea_typeofinvestment*

specifies the type of investment data to be retrieved. [Table 22.50](#) shows the list of investment types and their corresponding descriptions.

TYPEOFSERVICE=*bea_typeofservice*

specifies the type of service data to be retrieved. [Table 22.56](#) shows the list of service types and their corresponding descriptions.

USER=*'bea_user'***ACCESSKEYID=***'bea_user'*

specifies the unique user access key, enclosed in quotes, that the BEA assigns to the user (subscriber) to allow access to the BEA economic statistics API data service.

YEAR=*bea_years***YEARS=***bea_years*

specifies a list of the desired years for the time series data selection. You can specify *bea_years* as a comma-delimited string enclosed in double quotes. If not specified, the default is set to “LAST5” (last 5 years). You can also specify “LAST10” to select the last ten years, or “ALL” to select all available years.

Details: SASEBEA Interface Engine

The SASEBEA interface engine enables SAS users to access time series data from the BEA data sets shown in [Table 22.2](#). To specify the BEA data set, use one of the supported data set names listed in the table. To access the data set, specify SETNAME=<data set name>, as shown in the SASEBEA LIBNAME statement in [Example 22.1](#). [Table 22.3](#) shows where to find a summary of each data set’s details.

Table 22.2 Supported BEA Data Set Names

Supported Data Set Name	Description and Example Reference
FIXEDASSETS	Fixed Assets; see Example 22.4
GDPBYINDUSTRY	Gross Domestic Product by Industry; see Example 22.2
IIP	International Investment Position (IIP); see Example 22.9

REGIONAL	Regional; see Example 22.12
UNDERLYINGGDPBYINDUSTRY	Underlying Gross Domestic Product by Industry; see Example 22.3

Table 22.3 gives a summary of supported options for each set name. See the Section “[Data Elements Reference: SASEBEA Interface Engine](#)” on page 1551 for sample code that shows how to update the information displayed in each option summary table.

Table 22.3 Supported Options Summary for Each BEA Data Set Name

Data Set Name	Option Summary Table
FIXEDASSETS	See Table 22.6
GDPBYINDUSTRY	See Table 22.5
IIP	International Investment Position (IIP); see Table 22.10
INPUTOUTPUT	Input-Output Statistics; see Table 22.11
INTLSERVTRADE	International Trade in Services; see Table 22.12
ITA	International Transactions Accounts (ITA); see Table 22.9
MNE (AMNE)	Activities of Multinational Enterprises (AMNE); see Table 22.8
MNE (DI)	Direct Investment (DI); see Table 22.7
NIPA	See Table 22.4
NIPAUNDERLYINGDETAIL	See Table 22.4
REGIONAL	Regional; see Table 22.13
UNDERLYINGGDPBYINDUSTRY	See Table 22.5

Table 22.4 shows the options specific to the NIPA and NIPAUnderlyingDetail data sets.

Table 22.4 Options for the NIPA and the NIPAUnderlyingDetail Data Sets

Option	Description
FREQ=	Specifies the frequency of the data to retrieve (M, monthly; Q, quarterly; or A, annual)
TABLENAME=	Specifies the name of the data table to retrieve (see Table 22.14 , and Table 22.15)
YEAR=	Specifies a list of years to retrieve data for (ALL for All)

Table 22.5 shows the options specific to the GDPbyIndustry and UnderlyingGDPbyIndustry data sets.

Table 22.5 Options for the GDPbyIndustry and the UnderlyingGDPbyIndustry Data Sets

Option	Description
FREQ=	Specifies the frequency of the data to retrieve (A, annual; or Q, quarterly)
INDUSTRY=	Specifies a list of the industries to retrieve data for (ALL for All) (see Table 22.18 , Table 22.19 , and Table 22.20)
TABLEID=	Specifies the table identifier of the data table to retrieve (ALL for All) (see Table 22.17 , and for underlying data see Table 22.21)
YEAR=	Specifies a list of years to retrieve data for (ALL for All)

Table 22.6 shows the options specific to the FixedAssets data set.

Table 22.6 Options for the FixedAssets Data Set

Option	Description
TABLENAME=	Specifies the name of the data table to retrieve (see Table 22.22)
YEAR=	Specifies a list of years to retrieve data for (ALL for All)

Table 22.7 shows the options specific to the Direct Investment Multinational Enterprises data set.

Table 22.7 Options for the DI Multinational Enterprises Data Set

Option	Description
CLASSIFICATION=	Specifies a data classification based on country and/or industry to retrieve See Table 22.58 for classification names
COUNTRY=	Specifies a list of geographic area codes based on country See Table 22.59 for country codes
DIRECTIONOFINVESTMENT=	Specify 'OUTWARD' for US direct investment abroad, or Specify 'INWARD' for foreign investment in the US

Table 22.7 *continued*

Option	Description
FOOTNOTES=	Specify 'YES' to include footnotes or 'NO' to exclude them
INDUSTRY=	Specifies a list of industry codes based on industry See Table 22.60 for industry codes
SERIESID=	Specifies a list of series IDs to retrieve; optional, 0 means ALL See Table 22.57 for available series IDs
YEAR=	Specifies a list of years to retrieve data for (ALL for All)

Table 22.8 shows the options specific to the Activities of Multinational Enterprises (AMNE) data set.

Table 22.8 Options for the Activities of Multinational Enterprises (AMNE) Data Set

Option	Description
CLASSIFICATION=	Specifies a data classification based on country and/or industry to retrieve. See Table 22.58 for classification names.
COUNTRY=	Specifies a list of geographic area codes based on country. See Table 22.59 for country codes.
DIRECTIONOFINVESTMENT=	Specify 'OUTWARD' for US direct investment abroad, or specify 'INWARD' for foreign investment in the US Specify 'PARENT' for US parent companies. Specify 'STATE' for US affiliates of foreign multinational companies at the state level.
FOOTNOTES=	Specify 'YES' to include footnotes or 'NO' to exclude them.
INDUSTRY=	Specifies a list of industry codes based on industry. See Table 22.60 for industry codes.
NONBANKAFFILIATESONLY=	Specify 0 for Both Bank and Nonbank Affiliates, or 1 for Nonbank Affiliates.
OWNERSHIPLEVEL=	Specify 0 for Majority-Owned Affiliates or 1 for All Affiliates.
SERIESID=	Specifies a list of series IDs to retrieve; optional; 0 means ALL. See Table 22.57 for available series IDs.
STATE=	Specifies a list of years to retrieve data for (ALL for All). See Table 22.61 for state codes.
YEAR=	Specifies a list of years to retrieve data for (ALL for All).

Table 22.9 shows the options specific to the International Transactions (ITA) data set.

Table 22.9 Options for the International Transactions Accounts (ITA) Data Set

Option	Description
INDICATOR=	Specifies the indicator code for the type of transaction requested. See the tables at the following URL: https://www.bea.gov/iTable/iTableHtml.cfm?reqid=62&step=2&isuri=1&6210=1
COUNTRY=	Specifies a list of the counterparty areas or countries of the transactions. See Table 22.48 for ITA country codes.
FREQ=	Specifies a frequency with which to select data (A, annual; QNSA, quarterly not seasonally adjusted; or QSA, quarterly seasonally adjusted).
YEAR=	Specifies a list of years to retrieve data for (ALL for All).

Table 22.10 shows the options specific to the International Investment Position (IIP) data set.

Table 22.10 Options for the International Investment Position (IIP) Data Set

Option	Description
COMPONENT=	Specifies the component or components requested (listed in Table 22.51)
FREQ=	Specifies a frequency at which to select data (A, annual; or QNSA, quarterly not seasonally adjusted). When quarterly data are requested, all available quarters of the specified years are returned.
TYPEOFINVESTMENT=	Specifies the type of investment requested (listed in Table 22.50). For more information, see the tables at the following URL: https://apps.bea.gov/iTable/iTable.cfm?0=1&isuri=1&reqid=62&step=2#0=1&isuri=1&reqid=62&step=2
YEAR=	More than one type of investment can be specified if only one year is specified. If more than one year is specified, only one type of investment can be specified. Specifies a list of years to retrieve data for (ALL for All) If more than one year is requested, then only one type of investment request is allowed.

Table 22.11 shows the options specific to the Input-Output Statistics data set.

Table 22.11 Options for the Input-Output Statistics Data Set

Option	Description
TABLEID=	Specifies the table ID (listed in Table 22.52). For more information, visit the web page at the following URL: https://www.bea.gov/data/industries/input-output-accounts-data
YEAR=	Specifies a list of years to retrieve data for (ALL for All)

Table 22.12 shows the options specific to the International Trade in Services (IntlServTrade) data set.

Table 22.12 Options for the International Trade in Services (IntlServTrade) Data Set

Option	Description
AFFILIATION=	Specifies the affiliation of the data to retrieve (listed in Table 22.54). By default, AFFILIATION=All.
AREAORCOUNTRY=	Specifies the area or country of the data to retrieve (listed in Table 22.53). By default, AREAORCOUNTRY=AllCountries. A list of countries can be specified only if a single type of service is specified.
DESCRIPTION=	Specifies whether to use the short or the long label. The short label matches the BEA time series indicator, and the long label matches the BEA time series description. By default, DESCRIPTION=SHORT.
TRADEDIRECTION=	Specifies the trade direction of the data to retrieve (listed in Table 22.55). By default, TRADEDIRECTION=All.
TYPEOFSERVICE=	Specifies the type of service of the data to retrieve (listed in Table 22.56). By default, TYPEOFSERVICE=All. More than one type of service can be specified only if a single area or country is specified.
YEAR=	Specifies a list of years to retrieve data for (ALL for All). By default, YEAR=All.

Table 22.13 shows the options specific to the Regional data set.

Table 22.13 Options for the Regional Data Set

Option	Description
GEOFIPS=	Specifies the state, county, MSA, or other code for selecting the data to retrieve. It can be a list of codes, separated by commas. “ALL” values can be one of the following: “STATE”, “COUNTY”, “MSA”, “MIC”, “PORT”, “DIV”, “CSA”, or “PO code”. GEOFIPS= is a required option.
LINECODE=	Specifies one line code to select a corresponding statistic of the Regional data to retrieve. LINECODE= is a required option.
TABlename=	Specifies a published table name from the regional accounts that designates the data to retrieve (listed in Table 22.62). TABlename= is a required option.
YEAR=	Specifies a list of years to retrieve data for, or can be one of the following: “ALL” for all available years, “LAST10” for last 10 years, or “LAST5” for last 5 years. By default, YEAR=LAST5. The YEAR= option is not required.

The National Income and Product Accounts

The table names available for the NIPA data set are listed in [Table 22.14](#) and [Table 22.15](#). Each table is identified by a unique string called the table name. The TABLENAME= option is a required option that specifies which table to retrieve. Historically, the NIPA tables were identified by a table ID, but this practice was discontinued in October 2018. For convenience, [Table 22.14](#) and [Table 22.15](#) show how table names correspond to table IDs.

Table 22.14 NIPA Table Names and Corresponding Table IDs

The Gross Domestic Product by Industry Data

The table names available for the GDPbyIndustry data set are listed in Table 22.17. Each table is identified by a unique table ID code.

Table 22.17 GDP Table IDs and Descriptions

TableId	Description
1	Value Added by Industry (A)(Q)
5	Value Added by Industry as a Percentage of Gross Domestic Product (A)(Q)
6	Components of Value Added by Industry (A)
7	Components of Value Added by Industry as a Percentage of Gross Domestic Product (A)
8	Chain-Type Quantity Indexes for Value Added by Industry (A)(Q)
9	Percent Changes in Chain-Type Quantity Indexes for Value Added by Industry (A)(Q)
10	Real Value Added by Industry (A)(Q)
11	Chain-Type Price Indexes for Value Added by Industry (A)(Q)
12	Percent Changes in Chain-Type Price Indexes for Value Added by Industry (A)(Q)
13	Contributions to Percent Change in Real Gross Domestic Product by Industry (A)(Q)
14	Contributions to Percent Change in the Chain-Type Price Indexes for Gross Domestic Product by Industry (A)(Q)
15	Gross Output by Industry (A)(Q)
16	Chain-Type Quantity Indexes for Gross Output by Industry (A)(Q)
17	Percent Changes in Chain-Type Quantity Indexes for Gross Output by Industry (A)(Q)
18	Chain-Type Price Indexes for Gross Output by Industry (A)(Q)
19	Percent Changes in Chain-Type Price Indexes for Gross Output by Industry (A)(Q)
20	Intermediate Inputs by Industry (A)(Q)
21	Chain-Type Quantity Indexes for Intermediate Inputs by Industry (A)(Q)
22	Percent Changes in Chain-Type Quantity Indexes for Intermediate Inputs by Industry (A)(Q)
23	Chain-Type Price Indexes for Intermediate Inputs by Industry (A)(Q)
24	Percent Changes in Chain-Type Price Indexes for Intermediate Inputs by Industry (A)(Q)
25	Composition of Gross Output by Industry (A)
26	Shares of Gross Output by Industry (A)
27	Cost per Unit of Real Gross Output by Industry Group (A)
29	Contributions to Percent Change in the Chain-Type Quantity Indexes for Gross Output by Industry Group(A)
30	Contributions to Percent Change in the Chain-Type Price Indexes for Gross Output by Industry Group(A)

Table 22.17 *continued*

TableId	Description
31	Chain-Type Quantity Indexes for Energy Inputs by Industry (A)
32	Contributions to Percent Change by Industry in the Chain-Type Quantity Index for All Industries Energy Inputs (A)
33	Chain-Type Price Indexes for Energy Inputs by Industry (A)
34	Contributions to Percent Change by Industry in the Chain-Type Price Index for All Industries Energy Inputs (A)
35	Chain-Type Quantity Indexes for Materials Inputs by Industry (A)
36	Contributions to Percent Change by Industry in the Chain-Type Quantity Index for All Industries Material Inputs (A)
37	Chain-Type Price Indexes for Materials Inputs by Industry (A)
38	Contributions to Percent Change by Industry in the Chain-Type Price Index for All Industries Material Inputs (A)
39	Chain-Type Quantity Indexes for Purchased Service Inputs by Industry (A)
40	Contributions to Percent Change by Industry in the Chain-Type Quantity Index for All Industries Purchased Service Inputs (A)
41	Chain-Type Price Indexes for Purchased Service Inputs by Industry (A)
42	Contributions to Percent Change by Industry in the Chain-Type Price Index for All Industries Purchased Service Inputs (A)
208	Real Gross Output by Industry (A)(Q)
209	Real Intermediate Inputs by Industry (A)(Q)

The industries available for the GDPbyIndustry data set are listed in [Table 22.18](#), [Table 22.19](#), and [Table 22.20](#). Each industry is identified by a unique industry code.

Table 22.18 GDP Industries and Descriptions

Industry Code	Description
GDP	Gross domestic product (A,Q)
II	All industries (A,Q)
PVT	Private industries (A,Q)
11	Agriculture, forestry, fishing, and hunting (A,Q)
111CA	Farms (A,Q)
113FF	Forestry, fishing, and related activities (A,Q)
21	Mining (A,Q)
211	Oil and gas extraction (A,Q)
212	Mining, except oil and gas (A,Q)
213	Support activities for mining (A,Q)
22	Utilities (A,Q)
23	Construction (A,Q)
31G	Manufacturing (A,Q)
33DG	Durable goods (A,Q)
321	Wood products (A,Q)
327	Nonmetallic mineral products (A,Q)

Table 22.18 *continued*

Industry Code	Description
331	Primary metals (A,Q)
332	Fabricated metal products (A,Q)
333	Machinery (A,Q)
334	Computer and electronic products (A,Q)
335	Electrical equipment, appliances, and components (A,Q)
3361MV	Motor vehicles, bodies and trailers, and parts (A,Q)
3364OT	Other transportation equipment (A,Q)
337	Furniture and related products (A,Q)
339	Miscellaneous manufacturing (A,Q)
31ND	Nondurable goods (A,Q)
311FT	Food and beverage and tobacco products (A,Q)
313TT	Textile mills and textile product mills (A,Q)
315AL	Apparel and leather and allied products (A,Q)
322	Paper products (A,Q)
323	Printing and related support activities (A,Q)
324	Petroleum and coal products (A,Q)
325	Chemical products (A,Q)
326	Plastics and rubber products (A,Q)
42	Wholesale trade (A,Q)
44RT	Retail trade (A,Q)
441	Motor vehicle and parts dealers (A,Q)
445	Food and beverage stores (A,Q)
452	General merchandise stores (A,Q)
4A0	Other retail (A,Q)
48TW	Transportation and warehousing (A,Q)
481	Air transportation (A,Q)
482	Rail transportation (A,Q)
483	Water transportation (A,Q)
484	Truck transportation (A,Q)

Table 22.19 GDP Industries and Descriptions

Industry Code	Description
485	Transit and ground passenger transportation (A,Q)
486	Pipeline transportation (A,Q)
487OS	Other transportation and support activities (A,Q)
493	Warehousing and storage (A,Q)
51	Information (A,Q)
511	Publishing industries, except internet (includes software) (A,Q)
512	Motion picture and sound recording industries (A,Q)
513	Broadcasting and telecommunications (A,Q)
514	Data processing, internet publishing, and other information services (A,Q)

Table 22.19 *continued*

Industry Code	Description
FIRE	Finance, insurance, real estate, rental, and leasing (A,Q)
52	Finance and insurance (A,Q)
521CI	Federal Reserve banks, credit intermediation, and related activities (A,Q)
523	Securities, commodity contracts, and investments (A,Q)
524	Insurance carriers and related activities (A,Q)
525	Funds, trusts, and other financial vehicles (A,Q)
53	Real estate and rental and leasing (A,Q)
531	Real estate (A,Q)
HS	Housing (A,Q)
ORE	Other real estate (A,Q)
532RL	Rental and leasing services and lessors of intangible assets (A,Q)
PROF	Professional and business services (A,Q)
54	Professional, scientific, and technical services (A,Q)
5411	Legal services (A,Q)
5415	Computer systems design and related services (A,Q)
5412OP	Miscellaneous professional, scientific, and technical services (A,Q)
55	Management of companies and enterprises (A,Q)
56	Administrative and waste management services (A,Q)
561	Administrative and support services (A,Q)
562	Waste management and remediation services (A,Q)
6	Educational services, health care, and social assistance (A,Q)
61	Educational services (A,Q)
62	Health care and social assistance (A,Q)
621	Ambulatory health care services (A,Q)
622	Hospitals (A,Q)
623	Nursing and residential care facilities (A,Q)
624	Social assistance (A,Q)
7	Arts, entertainment, recreation, accommodation, and food services (A,Q)
71	Arts, entertainment, and recreation (A,Q)

Table 22.20 GDP Industries and Descriptions

Industry Code	Description
711AS	Performing arts, spectator sports, museums, and related activities (A,Q)
713	Amusements, gambling, and recreation industries (A,Q)
72	Accommodation and food services (A,Q)
721	Accommodation (A,Q)
722	Food services and drinking places (A,Q)
81	Other services, except government (A,Q)
G	Government (A,Q)
GF	Federal (A,Q)
GFG	General government (A,Q)

Table 22.20 *continued*

Industry Code	Description
GFGD	National defense (A,Q)
GFGN	Nondefense (A,Q)
GFE	Government enterprises (A,Q)
GSL	State and local (A,Q)
GSLG	General government (A,Q)
GSLE	Government enterprises (A,Q)
NABI	Not allocated by industry [1] (A,Q)
PGOOD	Private goods-producing industries [2] (A,Q)
PSERV	Private services-producing industries [3] (A,Q)
ICT	Information-communications-technology-producing industries [4] (A)

The Underlying Gross Domestic Product by Industry Data

The table names available for the UnderlyingGDPbyIndustry data set are listed in [Table 22.21](#). Each table is identified by a unique table ID code.

Table 22.21 Underlying GDP Table IDs and Descriptions

TableId	Description
210	U.Value Added by Industry (A)
211	U.Value Added by Industry as a Percentage of Gross Domestic Product (A)
212	U.Chain-Type Quantity Indexes for Value Added by Industry (A)
213	U.Percent Changes in Chain-Type Quantity Indexes for Value Added by Industry (A)
214	U.Real Value Added by Industry (A)
215	U.Chain-Type Price Indexes for Value Added by Industry (A)
216	U.Percent Changes in Chain-Type Price Indexes for Value Added by Industry (A)
217	U.Contributions to Percent Change in Real Gross Domestic Product by Industry (A)
218	U.Contributions to Percent Change in the Chain-Type Price Index for GDP (A)
219	U.Gross Output by Industry (A)
221	U.Chain-Type Quantity Indexes for Gross Output by Industry (A)
223	U.Percent Changes in Chain-Type Quantity Indexes for Gross Output by Industry (A)
225	U.Chain-Type Price Indexes for Gross Output by Industry (A)
227	U.Percent Changes in Chain-Type Price Indexes for Gross Output by Industry (A)
229	U.Intermediate Inputs by Industry (A)
230	U.Chain-Type Quantity Indexes for Intermediate Inputs by Industry (A)
231	U.Percent Changes in Chain-Type Quantity Indexes for Intermediate Inputs by Industry (A)
232	U.Chain-Type Price Indexes for Intermediate Inputs by Industry (A)
233	U.Percent Changes in Chain-Type Price Indexes for Intermediate Inputs by Industry (A)
234	U.Real Gross Output by Industry (A)
236	U.Real Intermediate Inputs by Industry (A)

Fixed Assets Data

The table names available for the FixedAssets data set are listed in [Table 22.22](#). Each table is identified by a unique table name.

International Transactions Accounts Data

The indicators available for the International Transactions Accounts (ITA) data set can be found by using the lookup index found in [Table 22.23](#). Click the desired table reference in the lookup table to display a list of indicators. The selected indicator appears in alphabetical order in the list.

There is a one-to-many relationship between the indicator name and the time series names that make up the components of each indicator. Most time series names contain the indicator name and are made up of the following concatenations, in this order: 'TSI_Ita', indicator, area or country code, '_', and frequency code.

Table 22.34 ITA Series Indicators and Descriptions (*continued*)

Series Indicator	Description
ExpGds	Exports of goods
ExpGdsAgFoodsFeedsAndBevs	Exports of agricultural foods, feeds, and beverages
ExpGdsAgIsM	Exports of agricultural industrial supplies and materials
ExpGdsAppFootAndHouse	Exports of apparel, footwear, and household goods
ExpGdsAutoEngAndEngParts	Exports of automotive engines and engine parts
ExpGdsAutoVehPartsAndEngines	Exports of automotive vehicles, parts, and engines
ExpGdsBauxAndAlum	Exports of bauxite and aluminum
ExpGdsBopAdj	Exports of goods; balance of payments adjustments, net
ExpGdsBuildMatsExcMetals	Exports of building materials except metals
ExpGdsCapGoodsExclAuto	Exports of capital goods except automotive
ExpGdsCensus	Exports of goods, Census basis
ExpGdsChemsExcMeds	Exports of chemicals except medicinals
ExpGdsCivAir	Exports of civilian aircraft, complete, all types
ExpGdsCivAirEngAndParts	Exports of civilian aircraft, engines, and parts
ExpGdsCoalAndRelProds	Exports of coal and related products
ExpGdsComp	Exports of computers
ExpGdsCompAccPeriAndParts	Exports of computer accessories, peripherals, and parts
ExpGdsConsGoodsExcFoodAndAuto	Exports of consumer goods except food and automotive
ExpGdsCopper	Exports of copper
ExpGdsCorn	Exports of corn
ExpGdsCrudePet	Exports of crude petroleum
ExpGdsDistBevAndOthNonAgFoodsFeedsAndBevs	Exports of distilled beverages and other nonagricultural foods, feeds, and beverages
ExpGdsDurCons	Exports of durable consumer goods
ExpGdsElecGenMachElecAppAndParts	Exports of electric-generating machinery, electric apparatus, and parts
ExpGdsEnergyProd	Exports of energy products
ExpGdsEngAndPartsForCivAir	Exports of engines and parts for civilian aircraft
ExpGdsFertPestAndInsect	Exports of fertilizers, pesticides, and insecticides
ExpGdsFishShellfish	Exports of fish and shellfish
ExpGdsFoodsFeedsAndBevs	Exports of foods, feeds, and beverages
ExpGdsFuelOil	Exports of fuel oil
ExpGdsGdsProcPortsBopAdj	Exports of goods; balance of payments adjustments, net; goods procured in US ports by foreign carriers
ExpGdsGemDiamAndOthGem	Exports of gem diamonds and other gemstones
ExpGdsGenMerch	Exports of general merchandise
ExpGdsGrainsPreps	Exports of grains and preparations
ExpGdsHidesSkins	Exports of hides and skins, including fur skins

Table 22.34 *continued*

Series Indicator	Description
ExpGdsHouseAndKitchApp	Exports of household and kitchen appliances
ExpGdsHouseFurnAndRelProds	Exports of household furnishings and related products
ExpGdsHouseKitchAppAndOthHouse	Exports of household and kitchen appliances and other household goods
ExpGdsIndEngPumpsComps	Exports of industrial engines, pump, and compressors
ExpGdsIndInorgChems	Exports of industrial inorganic chemicals
ExpGdsIndOrgChems	Exports of industrial organic chemicals
ExpGdsIronAndSteelProds	Exports of iron and steel products
ExpGdsIsM	Exports of industrial supplies and materials
ExpGdsJewelryAndCollect	Exports of jewelry and collectibles
ExpGdsLiqPetGases	Exports of liquified petroleum gases
ExpGdsMachAndEquipExcCons	Exports of machinery and equipment except consumer-type
ExpGdsMachToolsMetalworkMach	Exports of machine tools and metalworking machinery
ExpGdsMeasTestControlInst	Exports of measuring, testing, and control instruments
ExpGdsMeatProdsPoultry	Exports of meat products and poultry
ExpGdsMedDentAndPharm	Exports of medicinal, dental, and pharmaceutical products
ExpGdsMerchantingBopAdj	Exports of goods; balance of payments adjustments, net; net exports of goods under merchanting
ExpGdsMerchantingNet	Net exports of goods under merchanting
ExpGdsMetalsAndNonmetProds	Exports of metals and nonmetallic products
ExpGdsNaturalGas	Exports of natural gas
ExpGdsNonAgFoodsFeedsAndBevs	Exports of nonagricultural foods, feeds, and beverages
ExpGdsNonAgIsM	Exports of nonagricultural industrial supplies and materials
ExpGdsNondurCons	Exports of nondurable consumer goods
ExpGdsNonferrousMetals	Exports of nonferrous metals
ExpGdsNonmonetaryGold	Exports of nonmonetary gold
ExpGdsNonmonGoldBopAdj	Exports of goods; balance of payments adjustments, net; nonmonetary gold

Table 22.35 ITA Series Indicators and Descriptions (*continued*)

Series Indicator	Description
ExpGdsNuclearFuelAndElecEnergy	Exports of nuclear fuel and electric energy
ExpGdsOilDrillMiningConstMach	Exports of oil-drilling, mining, and construction machinery
ExpGdsOthAgFoodsFeedsAndBevs	Exports of other agricultural foods, feeds, and beverages
ExpGdsOthAgIsm	Exports of other agricultural industrial supplies
ExpGdsOthAutoPartsAndAcc	Exports of other automotive parts and accessories
ExpGdsOthBopAdj	Exports of goods; balance of payments adjustments, net; other adjustments, net
ExpGdsOthChems	Exports of other chemicals
ExpGdsOthDurCons	Exports of other durable consumer goods
ExpGdsOthFeeds	Exports of other feeds
ExpGdsOthGenMerch	Exports of other general merchandise
ExpGdsOthHouseIncCellPhones	Exports of other household goods, including cell phones
ExpGdsOthIndMach	Exports of other industrial machinery
ExpGdsOthMetalsAndNonmetProds	Exports of other metals and nonmetallic products
ExpGdsOthNondurCons	Exports of other nondurable consumer goods
ExpGdsOthNonferrousMetals	Exports of other nonferrous metals
ExpGdsOthNonmetals	Exports of other nonmetals
ExpGdsOthOfficeAndBusMach	Exports of other office and business machines
ExpGdsOthPetProds	Exports of other petroleum products
ExpGdsOthServIndAndAgMach	Exports of other service-industry and agricultural machinery
ExpGdsOthTransEquip	Exports of other transportation equipment
ExpGdsPaperAndPaperBaseStocks	Exports of paper and paper-base stocks
ExpGdsPassCars	Exports of passenger cars, new and used
ExpGdsPetAndProds	Exports of petroleum and products
ExpGdsPlasticMaterials	Exports of plastic materials
ExpGdsPrecMetalsExcNonmonGold	Exports of precious metals except nonmonetary gold
ExpGdsPrivGiftParcelRemitBopAdj	Exports of goods; balance of payments adjustments, net; private gift parcel remittances
ExpGdsRadioAndStereoEquip	Exports of radio and stereo equipment, including recorded media
ExpGdsRawCotton	Exports of raw cotton
ExpGdsRepairEquipBopAdj	Exports of goods; balance of payments adjustments, net; repair of equipment
ExpGdsRiceOthFoodGrains	Exports of rice and other food grains
ExpGdsSciHospAndMedEquipAndParts	Exports of scientific, hospital, and medical equipment and parts
ExpGdsSemiconductors	Exports of semiconductors
ExpGdsServ	Exports of goods and services
ExpGdsServIncRec	Exports of goods and services and income receipts

Table 22.35 *continued*

Series Indicator	Description
	(credits)
ExpGdsSoybeans	Exports of soybeans
ExpGdsSteelmakingMats	Exports of steelmaking materials
ExpGdsTelecomEquip	Exports of telecommunications equipment
ExpGdsTextileSupAndRelMats	Exports of textile supplies and related materials
ExpGdsToilAndCosmet	Exports of toiletries and cosmetics
ExpGdsToysAndSport	Exports of toys and sporting goods, including bicycles
ExpGdsTrucksBusesSpecPurpVeh	Exports of trucks, buses, and special-purpose vehicles
ExpGdsTvsVidRecAndOthVidEquip	Exports of televisions, video receivers, and other video equipment
ExpGdsUnmanufTobacco	Exports of unmanufactured tobacco
ExpGdsUSMilAgencyBopAdj	Exports of goods; balance of payments adjustments, net; exports under US military agency sales contracts
ExpGdsVegFruitNutPreps	Exports of vegetables, fruits, nuts, and preparations
ExpGdsWheat	Exports of wheat
ExpGenMerch	Exports of general merchandise
ExpServ	Exports of services
ExpServArtisticRelated	Exports of artistic related services
ExpServAudVis	Exports of audiovisual services

Table 22.36 ITA Series Indicators and Descriptions (*continued*)

Series Indicator	Description
ExpServChargesForTheUseOfIpNie	Charges for the use of intellectual property, not included elsewhere (n.i.e.); exports
ExpServCipAudVisRelated	Charges for the use of intellectual property n.i.e.; exports; audiovisual and related products

ExpServCipTrademarkFranchiseFees	Charges for the use of intellectual property n.i.e.; exports; trademarks and franchise fees
ExpServComp	Exports of computer services
ExpServFinancial	Exports of financial services
ExpServFinCredCardOthCredRelated	Exports of credit card and other credit-related services
ExpServFinFinManFinAdvCust	Exports of financial management, financial advisory, and custody services
ExpServFinSecBrokUwRelated	Exports of securities brokerage, underwriting and related services
ExpServFinSecLendEftOth	Exports of securities lending, electronic funds transfer, and other services
ExpServGovtGoodsAndServicesNie	Exports of government goods and services n.i.e.
ExpServInfo	Exports of information services
ExpServInsurance	Exports of insurance services
ExpServInsuranceAuxIns	Exports of auxiliary insurance services
ExpServInsuranceDirect	Exports of direct insurance services
ExpServInsuranceReIns	Exports of reinsurance services
ExpServMaintenanceAndRepairNie	Exports of maintenance and repair services n.i.e.
ExpServOtherBusiness	Exports of other business services
ExpServProfMgmtConsult	Exports of professional and management consulting services
ExpServResearchAndDev	Exports of research and development services
ExpServTechTradeRelatedOth	Exports of technical, trade-related, and other business services
ExpServTelecom	Exports of telecommunications services
ExpServTelecomCompAndInfo	Exports of telecommunications, computer, and information services
ExpServTransport	Exports of transport services
ExpServTransportAir	Exports of air transport services
ExpServTransportAirFreight	Exports of air freight services
ExpServTransportAirPass	Exports of air passenger services
ExpServTransportAirPort	Exports of airport services
ExpServTransportOth	Exports of transport services; other modes of transport

Table 22.36 *continued*

Series Indicator	Description
ExpServTransportSea	Exports of sea transport services
ExpServTransportSeaFreight	Exports of sea freight services
ExpServTransportSeaPort	Exports of seaport services
ExpServTravel	Exports of travel services (for all purposes, including education)

Table 22.37 ITA Series Indicators and Descriptions (*continued*)

Series Indicator	Description
ExpServTravelBusiness	Exports of business travel services
ExpServTravelBusinessOth	Exports of other business travel services
ExpServTravelEducation	Exports of education-related services
ExpServTravelHealth	Exports of health-related services
ExpServTravelPersonal	Exports of personal travel services
ExpServTravelPersonalOth	Exports of other personal travel services
ExpServTravelShortTermWork	Expenditures in the US by border, seasonal, and other short-term workers
FinAssetsExclFinDeriv	Net US acquisition of financial assets, excluding financial derivatives
FinDeriv	Financial derivatives other than reserves, net transactions
FinDerivReserveAssets	Net US acquisition of reserve assets; other; financial derivatives
FinLiabsExclFinDeriv	Net US incurrence of liabilities, excluding financial derivatives
FinLiabsFoa	Net US incurrence of liabilities to foreign official agencies
GoldReserveAssets	Net US acquisition of reserve assets; monetary gold
ImfReserveAssets	Net US acquisition of reserve assets; reserve position in the International Monetary Fund
ImpGds	Imports of goods
ImpGdsAgFoodsFeedsAndBevs	Imports of agricultural foods, feeds, and beverages
ImpGdsAgIsm	Imports of agricultural industrial supplies and materials
ImpGdsAppFootAndHouse	Imports of apparel, footwear, and household goods
ImpGdsAutoEngAndEngParts	Imports of automotive engines and engine parts
ImpGdsAutoVehPartsAndEngines	Imports of automotive vehicles, parts, and engines
ImpGdsBauxAndAlum	Imports of bauxite and aluminum
ImpGdsBopAdj	Imports of goods; balance of payments adjustments, net
ImpGdsBuildMatsExcMetals	Imports of building materials except metals

Table 22.37 *continued*

Series Indicator	Description
ImpGdsCapGoodsExclAuto	Imports of capital goods except automotive
ImpGdsCensus	Imports of goods, Census basis
ImpGdsChemsExcMeds	Imports of chemicals except medicinals
ImpGdsCivAir	Imports of civilian aircraft, complete, all types
ImpGdsCivAirEngAndParts	Imports of civilian aircraft, complete, all types
ImpGdsCoalAndRelProds	Imports of coal and related products
ImpGdsCocoaAndSugar	Imports of cocoa beans and sugar
ImpGdsComp	Imports of computers
ImpGdsCompAccPeriAndParts	Imports of computer accessories, peripherals, and parts
ImpGdsConsGoodsExcFoodAndAuto	Imports of consumer goods except food and automotive
ImpGdsCrudePet	Imports of crude petroleum
ImpGdsDistBevAndOthNonAgFoodsFeedsAndBevs	Imports of distilled beverages and other nonagricultural foods, feeds, and beverages
ImpGdsDurCons	Imports of durable consumer goods
ImpGdsElecGenMachElecAppAndParts	Imports of electric-generating machinery, electric apparatus and parts
ImpGdsEnergyProds	Imports of energy products
ImpGdsEngAndPartsForCivAir	Imports of engines and parts for civilian aircraft
ImpGdsFertPestAndInsect	Imports of fertilizers, pesticides, and insecticides
ImpGdsFishShellfish	Imports of fish and shellfish
ImpGdsFoodsFeedsAndBevs	Imports of foods, feeds, and beverages
ImpGdsFuelOil	Imports of fuel oil
ImpGdsGdsProcPortsBopAdj	Imports of goods; balance of payments adjustments, net; goods procured in foreign ports
ImpGdsGemDiamAndOthGem	Imports of gem diamonds and other gemstones
ImpGdsGenMerch	Imports of general merchandise
ImpGdsGreenCoffee	Imports of green coffee
ImpGdsHouseAndKitchApp	Imports of household and kitchen appliances
ImpGdsHouseFurnAndRelProds	Imports of household furnishings and related product
ImpGdsHouseKitchAppAndOthHouse	Imports of household and kitchen appliances and other household goods
ImpGdsIndEngPumpsComps	Imports of industrial engines, pumps, and compressors
ImpGdsIndInorgChems	Imports of industrial inorganic chemicals
ImpGdsIndOrgChems	Imports of industrial organic chemicals
ImpGdsInlandFreightCanMexBopAdj	Imports of goods; balance of payments adjustments, net; inland freight in Canada and Mexico
ImpGdsIronAndSteelProds	Imports of iron and steel products
ImpGdsIsm	Imports of industrial supplies and materials
ImpGdsJewelryAndCollect	Imports of jewelry and collectibles

Table 22.38 ITA Series Indicators and Descriptions (*continued*)

Series Indicator	Description
ImpGdsLiqPetGases	Imports of liquified petroleum gases
ImpGdsLocoRailBopAdj	Imports of goods; balance of payments adjustments, net; locomotives and railcars
ImpGdsMachAndEquipExcCons	Imports of machinery and equipment except consumer-type
ImpGdsMachToolsMetalworkMach	Imports of machine tools and metalworking machinery
ImpGdsMeasTestControlInst	Imports of measuring, testing, and control instruments
ImpGdsMeatProdsPoultry	Imports of meat products and poultry
ImpGdsMedDentAndPharm	Imports of medicinal, dental, and pharmaceutical products
ImpGdsMetalsAndNonmetProds	Imports of metals and nonmetallic products
ImpGdsNaturalGas	Imports of natural gas
ImpGdsNonAgFoodsFeedsAndBevs	Imports of nonagricultural foods, feeds, and beverages
ImpGdsNonAgIsm	Imports of nonagricultural industrial supplies and materials
ImpGdsNondurCons	Imports of nondurable consumer goods
ImpGdsNonferrousMetals	Imports of nonferrous metals
ImpGdsNonmonetaryGold	Imports of nonmonetary gold
ImpGdsNonmonGoldBopAdj	Imports of goods; balance of payments adjustments, net; nonmonetary gold
ImpGdsNuclearFuelAndElecEnergy	Imports of nuclear fuel and electric energy
ImpGdsOilDrillMiningConstMach	Imports of oil-drilling, mining, and construction machinery
ImpGdsOthAgFoodsFeedsAndBevs	Imports of other agricultural foods, feeds, and beverages
ImpGdsOthAutoPartsAndAcc	Imports of other automotive parts and accessories
ImpGdsOthBopAdj	Imports of goods; balance of payments adjustments, net; other adjustments, net
ImpGdsOthChems	Imports of other chemicals
ImpGdsOthDurCons	Imports of other durable consumer goods
ImpGdsOthGenMerch	Imports of other general merchandise
ImpGdsOthHouseIncCellPhones	Imports of other household goods, including cell phones
ImpGdsOthIndMach	Imports of other industrial machinery
ImpGdsOthMetalsAndNonmetProds	Imports of other metals and nonmetallic products
ImpGdsOthNondurCons	Imports of other nondurable consumer goods
ImpGdsOthNonferrousMetals	Imports of other nonferrous metals
ImpGdsOthNonmetals	Imports of other nonmetals
ImpGdsOthOfficeAndBusMach	Imports of other office and business machines
ImpGdsOthPetProds	Imports of other petroleum products
ImpGdsOthServIndAndAgMach	Imports of other service-industry and agricultural

Table 22.38 *continued*

Series Indicator	Description
ImpGdsOthTransEquip	machinery Imports of other transportation equipment
ImpGdsPaperAndPaperBaseStocks	Imports of paper and paper-base stocks
ImpGdsPassCars	Imports of passenger cars, new and used
ImpGdsPetAndProds	Imports of petroleum and products
ImpGdsPlasticMaterials	Imports of plastic materials
ImpGdsPrecMetalsExcNonmonGold	Imports of precious metals except nonmonetary gold
ImpGdsRadioAndStereoEquip	Imports of radio and stereo equipment, including recorded media
ImpGdsRepairEquipBopAdj	Imports of goods; balance of payments adjustments, net; repair of equipment
ImpGdsSciHospAndMedEquipAndParts	Imports of scientific, hospital, and medical equipment and parts
ImpGdsSemiconductors	Imports of semiconductors
ImpGdsServ	Imports of goods and services
ImpGdsServIncPay	Imports of goods and services and income payments (debits)
ImpGdsSoftRevalBopAdj	Imports of goods; balance of payments adjustments, net; software revaluation
ImpGdsSteelmakingMats	Imports of steelmaking materials
ImpGdsTelecomEquip	Imports of telecommunications equipment
ImpGdsTextileSupAndRelMats	Imports of textile supplies and related materials
ImpGdsToilAndCosmet	Imports of toiletries and cosmetics
ImpGdsToysAndSport	Imports of toys and sporting goods, including bicycles
ImpGdsTrucksBusesSpecPurpVeh	Imports of trucks, buses, and special purpose vehicles
ImpGdsTvsVidRecAndOthVidEquip	Imports of televisions, video receivers, and other video equipment
ImpGdsUSMilAgencyBopAdj	Imports of goods; balance of payments adjustments, net; imports by US military agencies
ImpGdsVegFruitNutPreps	Imports of vegetables, fruits, nuts, and preparations
ImpGdsWineBeerRelProds	Imports of wine, beer, and related products
ImpServ	Imports of services
ImpServArtisticRelated	Imports of artistic related services
ImpServAudVis	Imports of audiovisual services

Table 22.39 ITA Series Indicators and Descriptions (*continued*)

Series Indicator	Description
ImpServChargesForTheUseOfIpNie	Charges for the use of intellectual property n.i.e.; imports
ImpServCipAudVisRelated	Charges for the use of intellectual property n.i.e.; imports; audiovisual and related property
ImpServCipCompSoft	Charges for the use of intellectual property n.i.e.; imports; computer software
ImpServCipIndProcess	Charges for the use of intellectual property n.i.e.; imports; industrial processes
ImpServCipLicensesAudVis	Charges for the use of intellectual property n.i.e.; imports; licenses to reproduce and/or distribute audiovisual products
ImpServCipLicensesCompSoftware	Charges for the use of intellectual property n.i.e.; imports; licenses to reproduce and/or distribute computer software
ImpServCipLicensesFranchisesTrademarks	Charges for the use of intellectual property n.i.e.; imports; franchises and trademarks licensing fee
ImpServCipLicensesOutcomesResearchAndDev	Charges for the use of intellectual property n.i.e.; imports; licenses for the use of outcomes of research and development
ImpServCipOth	Charges for the use of intellectual property n.i.e.; imports; other intellectual property
ImpServCipTrademarkFranchiseFees	Charges for the use of intellectual property n.i.e.; imports; trademarks and franchise fees
ImpServComp	Imports of computer services
ImpServFinancial	Imports of financial services
ImpServFinCredCardOthCredRelated	Imports of credit card and other credit-related services
ImpServFinFinManFinAdvCust	Imports of financial management, financial advisory, and custody services
ImpServFinSecBrokUwRelated	Imports of securities brokerage, underwriting, and related services
ImpServFinSecLendEftOth	Imports of securities lending, electronic funds transfer, and other services
ImpServGovtGoodsAndServicesNie	Imports of government goods and services n.i.e.
ImpServInfo	Imports of information services
ImpServInsurance	Imports of insurance services
ImpServInsuranceAuxIns	Imports of auxiliary insurance services
ImpServInsuranceDirect	Imports of direct insurance services
ImpServInsuranceReIns	Imports of reinsurance services
ImpServMaintenanceAndRepairNie	Imports of maintenance and repair services n.i.e.
ImpServOtherBusiness	Imports of other business services
ImpServProfMgmtConsult	Imports of professional and management consulting services
ImpServResearchAndDev	Imports of research and development services

Table 22.39 *continued*

Series Indicator	Description
ImpServTechTradeRelatedOth	Imports of technical, trade-related, and other business services
ImpServTelecom	Imports of telecommunications services
ImpServTelecomCompAndInfo	Imports of telecommunications, computer, and information services
ImpServTransport	Imports of transport services
ImpServTransportAir	Imports of air transport services
ImpServTransportAirFreight	Imports of air freight services
ImpServTransportAirPass	Imports of air passenger services
ImpServTransportAirPort	Imports of airport services
ImpServTransportOth	Imports of transport services; other modes of transport

Table 22.40 ITA Series Indicators and Descriptions (*continued*)

Series Indicator	Description
ImpServTransportSea	Imports of sea transport services
ImpServTransportSeaFreight	Imports of sea freight services
ImpServTransportSeaPort	Imports of seaport services
ImpServTravel	Imports of travel services (for all purposes including education)
ImpServTravelBusiness	Imports of business travel services
ImpServTravelBusinessOth	Imports of other business travel services
ImpServTravelEducation	Imports of education-related services
ImpServTravelHealth	Imports of health-related services
ImpServTravelPersonal	Imports of personal travel services
ImpServTravelPersonalOth	Imports of other personal travel services
ImpServTravelShortTermWork	Expenditures abroad by border, seasonal, and other short-term workers
InsLossesPaid	Insurance losses paid
InsLossesRecovered	Insurance losses recovered
InsPremiumsPaid	Insurance premiums paid
InsPremiumsReceived	Insurance premiums received
InsTechReservesAssets	Net US acquisition of other investment assets; insurance technical reserves
InsTechReservesAssetsOthFinNonFin	Net US acquisition of other investment assets; insurance technical reserves; held by non-deposit-taking institutions and nonfinancial institutions except general government
InsTechReservesLiabs	Net US incurrence of other investment liabilities; insurance technical reserves
InsTechReservesLiabsOthFinNonFin	Net US incurrence of other investment liabilities;

Table 22.40 *continued*

Series Indicator	Description
	insurance technical reserves; issued by non-deposit-taking institutions and nonfinancial institutions except general government
InvFundSharesAssets	Net US acquisition of portfolio investment assets; investment fund shares
InvFundSharesIncPay	Portfolio investment income payments; income attributable to investment fund shareholders
InvFundSharesIncRec	Portfolio investment income receipts; income attributable to investment fund shareholders
InvFundSharesLiabs	Net US incurrence of portfolio investment liabilities; investment fund shares
InvFundSharesLiabsFoa	Net US incurrence of portfolio investment liabilities to foreign official agencies; investment fund shares
InvIncPay	Investment income payments
InvIncRec	Investment income receipts
InvRaIncRec	Reserve asset income receipts
InvRaIntIncRec	Reserve asset income receipts; interest
LoansAssets	Net US acquisition of other investment assets; loans
LoansAssetsDepTaking	Net US acquisition of other investment assets; loans; held by deposit-taking institution

Table 22.40 *continued*

Series Indicator	Description
LoansAssetsGenGovt	Net US acquisition of other investment assets; loans; held by general government
LoansAssetsOthFinNonFin	Net US acquisition of other investment assets; loans; held by non-deposit-taking institutions

Direct Investment Data and Activities of Multinational Enterprise Data

The series IDs available for the Direct Investment (DI) Multinational Enterprise (MNE) data set and the Activities of Multinational Enterprise (AMNE) data set are listed in [Table 22.57](#). Each series is identified by a unique code, which is an integer enclosed in quotes. The time series names are made up of the following concatenations in this order: 'SeriesID_', series ID, 'ROW_', row position, 'COL_', and column code.

SeriesID="0" is the first entry in [Table 22.57](#) and is used to retrieve a list of series IDs whose data match the criteria that are set by the options specified in the SASEBEA LIBNAME statement. The remaining series IDs are used to request data by subject, and they have integer codes that must be enclosed in quotes. They are listed with their descriptions in [Table 22.57](#).

Table 22.57 MNE Series IDs and Descriptions

Series ID	Description
0	All
16	Balance Sheet - Balance sheet data present items typically found on corporate balance sheets, including assets and liabilities.
69	Balance Sheet of New Affiliates - Balance sheet data present items typically found on corporate balance sheets, including assets and liabilities.
3	Capital Expenditures - The expenditures made by a firm to acquire, to add to, or to improve property, plant, and equipment (PPE).
7	Compensation of Employees - The income received from an employer as remuneration for work.
26	Debt Instruments Inflows - Transactions in debt instruments (previously called intercompany debt flows) are the result of changes in net outstanding loans between foreign parent companies and their US affiliates, including loans by parents to affiliates and loans by affiliates to parents.
33	Debt Instruments Outflows - Transactions in debt instruments (previously called intercompany debt flows) are the result of changes in net outstanding loans between US parent companies and their foreign affiliates, including loans by parents to affiliates and loans by affiliates to parents.
27	Direct Investment Income Without Current-Cost Adjustment - Income is the return on the direct investment position. It consists of earnings, which include the parents' shares in the net income from the operations of their affiliates and net interest received by parents from affiliates from outstanding loans and trade accounts.
8	Employment - The number of full-time and part-time employees on the payroll at year end.
9	Employment - Manufacturing - Consists of the employees on the payrolls of manufacturing plants of affiliates. It includes employees of manufacturing plants of affiliates that are not classified in manufacturing, and it excludes employees of nonmanufacturing plants of affiliates that are classified in manufacturing.
64	Employment of New Affiliates - The number of full-time and part-time employees on the payroll at year end.
24	Equity Inflows Other than Reinvestment of Earnings - Equity investment other than reinvestment of earnings is the net of equity increases and decreases other than those due to reinvestment of earnings. Equity increases consist of payments by parents for the purchase of capital stock or other equity interests when they acquire an

Table 22.57 *continued*

Series ID	Description
	existing business, payments made by parents to acquire additional ownership interests in their affiliates, and capital contributions to their affiliates. Equity decreases are the funds parents receive when they reduce their equity interest in their affiliates.
32	Equity Outflows Other than Reinvestment of Earnings - Equity investment other than reinvestment of earnings is the net equity increases and decreases other than those due to reinvestment of earnings. Equity increases consist of payments by parents for the purchase of capital stock or other equity interests when they acquire an existing business, payments made by parents to acquire additional ownership interests in their affiliates, and capital contributions to their affiliates. Equity decreases are the funds parents receive when they reduce their equity interest in their affiliates.
23	Financial Inflow Transactions Without Current-Cost Adjustment - Direct investment financial inflow transactions (previously called financial flows) measure the funds that foreign parent companies provide to their US affiliates, net of funds that affiliates provide to their parents, in a given time period. Direct investment financial transactions consist of equity investment other than reinvestment of earnings, and transactions in debt instruments.
31	Financial Outflow Transactions Without Current-Cost Adjustment - Direct investment financial outflow transactions (previously called financial flows) measure the funds that US parent companies provide to their foreign affiliates, net of funds that affiliates provide to their parents, in a given time period. Direct investment financial transactions consist of equity investment other than reinvestment of earnings, reinvestment of earnings, and transactions in debt instruments.
22	Foreign Direct Investment Position in the United States on a Historical-Cost Basis - The foreign direct investment position in the United States is the value of foreign direct investors' equity in their US affiliates plus the value of net outstanding loans to their US affiliates. It may be viewed as the direct investors' net financial claims on their affiliates.
58	Goods Supplied - For most industries, goods supplied are generally defined as sales of outputs that are tangible. For wholesalers and retailers, goods supplied include only the value of goods resold; BEA estimates the value of the distributive services provided by selling or arranging for the sale of goods and includes it in services supplied.
2	Gross Property, Plant, and Equipment - Property, Plant, and Equipment (PPE) consists of land, mineral rights, buildings, structures, machinery, and equipment (production, office, and transportation equipment). This measure records the value of PPE before the deduction of accumulated depreciation and depletion.
62	Investment Expenditures - Investment Expenditures
20	Liabilities - The total debts or obligations of the firm.
5	Net Income - The profits that a firm earns in a given time period. It equals total sales or gross operating revenues and other income less total expenses. It is net of, that is, after deduction of, income taxes and includes income from equity investments.

Table 22.57 *continued*

Series ID	Description
68	Net Income of New Affiliates - The profits that a firm earns in a given time period. It equals total sales or gross operating revenues and other income less total expenses. It is net of, that is, after deduction of, income taxes and includes income from equity investments.
54	Net Property, Plant, and Equipment - Property, Plant, and Equipment (PPE) consists of land, mineral rights, buildings, structures, machinery, and equipment (production, office, and transportation equipment). This measure records the value of PPE after the deduction of accumulated depreciation and depletion.
44	Other Private Services, Net Payments - Other Private Services, Net Payments represent net payments between US affiliates and their foreign parents for services provided to one another. They consist of service charges, including management fees and allocated expenses and rentals for tangible property.
35	Other Private Services, US Parents' Receipts - Other Private Services, US Parents' Receipts - Other Private Services, US Parents' Receipts represent receipts by US parents from their foreign affiliates for services provided. They consist of service charges, including management fees and allocated expenses and rentals for tangible property.
29	Other Private Services, US Affiliates' Payments - Other Private Services, US Affiliates' Payments represent payments by US affiliates to their foreign parents for services provided. They consist of service charges, including management fees and allocated expenses and rentals for tangible property.
42	Other Private Services, US Affiliates' Receipts - Other Private Services, US Affiliates' Receipts represent receipts by US affiliates from their foreign parents for services provided. They consist of service charges, including management fees and allocated expenses and rentals for tangible property.
40	Other Private Services, US Parents' Payments - Other Private Services, US Parents' Payments represent payments by US parents to their foreign affiliates for services provided. They consist of service charges, including management fees and allocated expenses and rentals for tangible property.
21	Owners Equity - Total assets of the firm less total liabilities.
53	Property, Plant, and Equipment Expenditures - The expenditures made by a firm to acquire, to add to, or to improve property, plant, and equipment (PPE). PPE includes land, timber, mineral and like-rights owned; structures, machinery, equipment, special tools, and other depreciable property; construction in progress; and tangible and intangible exploration and development costs. It excludes the changes in PPE that are due to changes in the entity—such as mergers, acquisitions, and divestitures—or that are due to changes in accounting methods. The expenditures are measured on a gross basis; sales and other dispositions of fixed assets are not netted against them.
25	Reinvestment of Earnings Without Current-Cost Adjustment - Reinvestment of earnings (a component of direct investment financial transactions) are the parents' claim on the current period undistributed earnings of their affiliates.
14	Research and Development Expenditures - Includes expenditures for the following: the planned, systematic pursuit of new knowledge or understanding toward general application (basic research); the acquisition of knowledge or understanding to meet a specific, recognized need (applied research); and the application of knowledge or understanding

Table 22.57 *continued*

Series ID	Description
	toward the production or improvement of a product, service, process, or method (development). It excludes quality control, routine product testing, market research, sales promotion, sales service and other nontechnical activities; routine technical services; geological and geophysical exploration activities, and advertising programs to promote or demonstrate new products or processes. Also excluded are capital expenditures, expenditures for tests and evaluations once a prototype becomes a production model, patent expenses, and income taxes and interest.
43	Royalties and License Fees Net of Withholding Taxes, Net Payments - Royalties and License Fees Net of Withholding Taxes, Net Payments represent receipts and payments between US affiliates and their foreign parents for the use or sale of intangible property or rights (including patents, trademarks, and copyrights).
28	Royalties and License Fees Net of Withholding Taxes, US Affiliates' Payments - Royalties and License Fees Net of Withholding Taxes, US Affiliates' Payments represent payments by US affiliates from their foreign parents for the use or sale of intangible property or rights (including patents, trademarks, and copyrights).
41	Royalties and License Fees Net of Withholding Taxes, US Affiliates' Receipts - Royalties and License Fees Net of Withholding Taxes, US Affiliates' Receipts represent receipts by US affiliates from their foreign parents for the use or sale of intangible property or rights (including patents, trademarks, and copyrights).
39	Royalties and License Fees Net of Withholding Taxes, US Parents' Payments - Royalties and License Fees Net of Withholding Taxes, US Parents' Payments represent payments by US parents from their foreign affiliates for the use or sale of intangible property or rights (including patents, trademarks, and copyrights).
34	Royalties and License Fees Net of Withholding Taxes, US Parents' Receipts - Royalties and License Fees Net of Withholding Taxes, US Parents' Receipts represent receipts of US parents from their foreign affiliates for the use or sale of intangible property or rights (including patents, trademarks, and copyrights).
56	Sales of Goods - For purposes of disaggregating sales into goods, services, and investment income, sales of goods are defined as sales that are typical of establishments in any of the following six NAICS sectors: Agriculture, forestry, fishing and hunting (except support activities for agriculture and forestry); mining (except support activities); construction; manufacturing; wholesale trade; and retail trade. (A parent or affiliate need not be classified in any of these sectors to have sales of goods.) Sales of services are defined as sales that are typical of establishments in the 14 other NAICS sectors and the support activities for agriculture, forestry, fishing and hunting and for mining. (A parent or affiliate need not be classified in one of these sectors to have sales of services.)
55	Sales of Services - For purposes of disaggregating sales into goods, services, and investment income, sales of goods are defined as sales that are typical of establishments in any of the following six NAICS sectors: Agriculture, forestry, fishing and hunting (except support activities for agriculture and forestry); mining (except support activities); construction; manufacturing; wholesale trade; and retail trade. (A parent or affiliate need not be classified in any of these sectors to have sales of goods.) Sales of

Table 22.57 *continued*

Series ID	Description
	services are defined as sales that are typical of establishments in the 14 other NAICS sectors and the support activities for agriculture, forestry, fishing and hunting and for mining. (A parent or affiliate need not be classified in one of these sectors to have sales of services.)
60	Services Supplied - For most industries, services supplied generally are defined as sales of outputs that are intangible. For insurance, services supplied consists of BEA's estimate of the portion of premiums remaining after provision for expected or normal losses and a measure of premium supplements, which represent income earned on funds insurers hold on policyholders' behalf. For banks, it includes explicit fees and commissions and an estimate of the value of implicit services provided by banks. For wholesalers and retailers, services supplied includes an estimate of the distributive services provided by selling or arranging for the sales of goods.
61	Services Supplied to Foreigners - Services Supplied to Foreigners - Sales of outputs that are intangible to foreign persons. Sales may be to other foreign affiliates or unaffiliated foreigners, and the foreign persons may be local or in another foreign country.
1	Total Assets - Any owned physical object or intangible right having economic value to a firm. It includes items such as cash, inventories, receivables, and property, plant, and equipment. It also includes equity investments in unconsolidated domestic and foreign businesses.
52	Total Assets - Affiliates - Any owned physical object or intangible right
51	Total Assets - US Parent - Any owned physical object or intangible right
4	Total Sales - The value of goods and services sold and, for financial firms, also includes investment income. It is net of returns, allowances, and discounts and excludes sale or consumption taxes levied directly on the consumer and excise taxes levied on manufacturers, wholesalers, and retailers.
66	Total Sales of New Affiliates - The value of goods and services sold and, for financial firms, also includes investment income. It is net of returns, allowances, and discounts and excludes sale or consumption taxes levied directly on the consumer and excise taxes levied on manufacturers, wholesalers, and retailers.
30	US Direct Investment Position Abroad on a Historical-Cost Basis - The US direct investment position abroad is the value of US direct investors' equity in their foreign affiliates plus the value of net outstanding loans to their affiliates. It may be viewed as the direct investors' net financial claims on their affiliates
10	US Exports of Goods - Exports are valued on an f.a.s. (free alongside ship) basis; they exclude transit costs, such as the costs of shipping and insurance.
57	US Exports of Goods Shipped by US Parents to Foreign Affiliates - Exports are valued on an f.a.s. (free alongside ship) basis; they exclude transit costs, such as the costs of shipping and insurance.
46	US Exports of Goods Shipped by US Parents to Foreigners Other Than Foreign Affiliates - Exports are valued on an f.a.s. (free alongside ship) basis; they exclude transit costs, such as the costs of shipping and insurance.
11	US Exports of Goods to the Foreign Parent Group - US Exports of Goods to the Foreign Parent Group represents total exports of goods from US affiliates to their foreign parent groups
12	US Imports of Goods - Imports are valued on an f.a.s. (free alongside ship) basis; they exclude

Table 22.57 *continued*

Series ID	Description
	transit costs, such as the costs of shipping and insurance.
13	US Imports of Goods from the Foreign Parent Group - US Imports of Goods from the Foreign Parent Group represents total imports of goods by US parent enterprises from their foreign affiliates
47	US Imports of Goods Shipped to US Parents by Foreign Affiliates - Imports are valued on an f.a.s. (free alongside ship) basis; they exclude transit costs, such as the costs of shipping and insurance.
48	US Imports of Goods Shipped to US Parents by Foreigners Other Than Foreign Affiliates - Imports are valued on an f.a.s. (free alongside ship) basis; they exclude transit costs, such as the costs of shipping and insurance.
50	US Trade in Goods of Affiliates; US Trade in Goods of Affiliates represents US exports and imports of goods associated with a US affiliate or foreign affiliate
19	US Trade in Goods of Majority-Owned Affiliates - US Trade in Goods of Majority-Owned Affiliates represents US exports and imports of goods associated with a majority-owned US affiliate or majority-owned foreign affiliate
6	Value Added (Gross Product) - The portion of the goods and services sold or added to inventory or fixed investment by a firm that reflects the production of the firm itself. It represents the firm's contribution to a country's gross domestic product, which is the value of goods and services produced by labor and property located in the country. Compared to sales, value added is a preferable measure of production because it indicates the extent to which a firm's sales result from their own production rather than from production that originates elsewhere, whereas sales data do not distinguish between these two sources of production. Value added can be measured as gross output minus intermediate inputs; alternatively, it can be measured as the sum of the costs incurred (except for intermediate inputs) and the profits earned in production. The value-added estimates presented here were prepared by summing the costs and profits data.

The classification names available for the DirectInvestment (DI) Multinational Enterprise (MNE) data set and the Activities of Multinational Enterprise (AMNE) data set are listed in [Table 22.58](#). Each classification has a unique name.

Table 22.58 MNE Classifications and their Descriptions

Classification Name	Description
Country	Set the classification to country to obtain data for all countries for which data are available for the given series, ownership, and year
CountryByDestination	Country by destination returns values for country broken out by destination for goods supplied and services supplied.
CountryByIndustry	Country by industry provides data for a large set of countries broken down by major industry.
CountrybyType	Country by type of investment returns data on new

Table 22.58 *continued*

Classification Name	Description
	foreign direct investment in the United States broken out by country of ultimate beneficial owner (UBO) and the type of investment (acquisition, establishment, or expansion).
CountryofUBO	Presents data on foreign direct investment in the United States by the country of the ultimate beneficial owner (UBO). The ultimate beneficial owner (UBO) is the entity, proceeding up the foreign ownership chain, which is not more than 50 percent owned by another entity. The UBO is the entity that ultimately owns or controls an affiliate and thus ultimately derives the benefits and assumes the risks from owning or controlling an affiliate.
CountryofUBObyDestination	Presents data on services supplied by US affiliates of foreign MNEs, broken down by the country of ultimate beneficial owner (UBO) and the destination (US or foreign) of the service supplied
CountryofUBObyIndustry	Presents data on foreign direct investment in the United States broken down by the country of the ultimate beneficial owner (UBO) and the industry of the affiliate.
CountryofUBObyType	Country of UBO by type of investment returns data on new foreign direct investment in the United States broken out by the country of the ultimate beneficial owner (UBO) and the type of investment (acquisition, establishment, or expansion).
Industry	Set the classification equal to 'industry' to obtain data for all industries for which data are available for the given series, ownership, and year.
IndustryByCountry	Industry by country provides data for a large set of industries broken down by major country.
IndustrybyCountryofUBO	Presents foreign direct investment data broken down by industry of the US affiliate and the country of ultimate beneficial owner (UBO)
IndustryByDestination	Industry by destination returns values for industry broken out by destination for goods supplied and services supplied.
IndustrybyType	Industry by type of investment returns data on new foreign direct investment in the United States broken out by industry of US business and the type of investment (acquisition, establishment, or expansion).
IndustryofSales	Industry of sales provides data on employment and sales for majority-owned US affiliates of foreign MNEs. Each majority-owned US affiliate above a minimum size threshold was required to distribute its sales and its employment among the four-digit industry in which it had sales. These data approximate an establishment-based distribution.
IndustryofUSParent	Industry of US parent provides data for foreign affiliates of US

Table 22.58 *continued*

Classification Name	Description
IndustryofUSParentAllIndustries	parents, broken down by the industry of the US parent, which may differ from the industry of the affiliate. Industry of US parent, all industries, provides data for foreign affiliates of US parents, broken down by the most detailed industry of the US parent, which may differ from the industry of the affiliate.
IndustryofUSParentByCountry	Industry of US parent by country provides data for foreign affiliates of US parents, broken down by the industry of the US parent, which may differ from the industry of the affiliate, and broken and broken by major country.
StatebyCountryofUBO	Presents selected activities of multinational enterprises data on US affiliates, broken down by US state and country of UBO.
StatebyType	State by type of investment returns data on new foreign direct investment in the United States broken out by destination state and the type of investment (acquisition, establishment, or expansion).
TypeofExpenditure	Type of expenditure returns values on investment expenditure for new foreign direct investment in the United States, broken out by type of expenditure.

The geographic area codes available for the DirectInvestment (DI) Multinational Enterprise (MNE) data set and the Activities of Multinational Enterprise (AMNE) data set are listed in [Table 22.59](#). Each geographic area (or country) has a unique code.

Table 22.59 MNE Geographic Area Codes and Descriptions

Geographic Area Code	Country Name	Geographic Area Code	Country Name
all	All	316	Luxembourg

Regional Data

The table names available for the Regional data set are listed in [Table 22.62](#). Each table is identified by a unique table name.

Table 22.62 Regional Table Names and Descriptions

TableName	Description
CAEMP25N	Total Full-Time and Part-Time Employment by NAICS Industry (NAICS)
CAEMP25S	Total Full-Time and Part-Time Employment by SIC Industry (SIC)
CAGDP1	Gross Domestic Product (GDP) summary by county and metropolitan area (Non-Industry)
CAGDP11	Contributions to percent change in real GDP (NAICS)
CAGDP2	Gross domestic product (GDP) by county and metropolitan area (NAICS)
CAGDP8	Chain-type quantity indexes for real GDP by county and metropolitan area (2012=100.0) (NAICS)
CAGDP9	Real GDP by county and metropolitan area (NAICS)
CAINC1	Personal Income Summary: Personal Income, Population, Per Capita Personal Income (Non-Industry)
CAINC30	Economic Profile (Non-Industry)
CAINC35	Personal Current Transfer Receipts (Non-Industry)
CAINC4	Personal Income and Employment by Major Component (Non-Industry)
CAINC45	Farm Income and Expenses (Non-Industry)
CAINC5N	Personal Income by Major Component and Earnings by NAICS Industry (NAICS)
CAINC5S	Personal Income by Major Component and Earnings by SIC Industry (SIC)
CAINC6N	Compensation of Employees by NAICS Industry (NAICS)
CAINC6S	Compensation of Employees by SIC Industry (SIC)
CAINC91	Gross Flow of Earnings (Non-Industry)
MAIRPD	Implicit Regional Price Deflators by MSA (Non-Industry)
MARPI	Real Personal Income by MSA (Non-Industry)
MARPP	Regional Price Parities by MSA (Non-Industry)
PAIRPD	Implicit Regional Price Deflators by Portion (Non-Industry)
PARPI	Real Personal Income by Portion (Non-Industry)
PARPP	Regional Price Parities by Portion (Non-Industry)
SAACArtsComp	ACPSA compensation by ACPSA industry (NAICS)
SAACArtsEmp	ACPSA full-time and part-time employment by ACPSA industry (NAICS)
SAACArtsVA	ACPSA value added by ACPSA industry (NAICS)
SAACCompLQ	Arts Compensation Location Quotient (NAICS)
SAACCompRatio	Arts Compensation Ratio (NAICS)
SAACEmpLQ	Arts Employment Location Quotient (NAICS)
SAACEmpRatio	Arts Employment Ratio (NAICS)
SAACVALQ	Arts Value Added Location Quotient (NAICS)
SAACVARatio	Arts Value Added Ratio (NAICS)
SAEMP25N	Total Full-Time and Part-Time Employment by NAICS Industry (NAICS)
SAEMP25S	Total Full-Time and Part-Time Employment by SIC Industry (SIC)
SAEMP27N	Full-Time and Part-Time Wage and Salary Employment by NAICS Industry (NAICS)
SAEMP27S	Full-Time and Part-Time Wage and Salary Employment by SIC Industry (SIC)

Table 22.62 *continued*

TableName	Description
SAEXP1	Total personal consumption expenditures (PCE) by state (NAICS)
SAEXP2	Per capita personal consumption expenditures (PCE) by state (NAICS)
SAGDP1	Gross Domestic Product (GDP) summary, annual by state (Non-Industry)
SAGDP11N	Contributions to percent change in real GDP (NAICS)
SAGDP2N	Gross domestic product (GDP) by state (NAICS)
SAGDP2S	Gross domestic product (GDP) by state (SIC)
SAGDP3N	Taxes on production and imports less subsidies (NAICS)
SAGDP3S	Taxes on production and imports less subsidies (SIC)
SAGDP4N	Compensation of employees (NAICS)
SAGDP4S	Compensation of employees (SIC)
SAGDP5N	Subsidies (NAICS)
SAGDP5S	Subsidies (SIC)
SAGDP6N	Taxes on production and imports (NAICS)
SAGDP6S	Taxes on production and imports (SIC)
SAGDP7N	Gross operating surplus (NAICS)
SAGDP7S	Gross operating surplus (SIC)
SAGDP8N	Chain-type quantity indexes for real GDP by state (2012=100.0) (NAICS)
SAGDP8S	Chain-type quantity indexes for real GDP by state (1997=100.0) (SIC)
SAGDP9N	Real GDP by state (NAICS)
SAGDP9S	Real GDP by state (SIC)
SAINC1	Personal Income Summary: Personal Income, Population, Per Capita Personal Income (Non-Industry)
SAINC30	Economic Profile (Non-Industry)
SAINC35	Personal Current Transfer Receipts (Non-Industry)
SAINC4	Personal Income and Employment by Major Component (Non-Industry)
SAINC40	Property Income (Non-Industry)
SAINC45	Farm Income and Expenses (Non-Industry)
SAINC50	Personal Current Taxes (Non-Industry)
SAINC51	Disposable Personal Income Summary: Disposable Personal Income, Population, and Per Capita Personal Income (Non-Industry)
SAINC5H	Personal Income by Major Component and Earnings by Industry (Historical) (SIC)
SAINC5N	Personal Income by Major Component and Earnings by NAICS Industry (NAICS)
SAINC5S	Personal Income by Major Component and Earnings by SIC Industry (SIC)
SAINC6N	Compensation of Employees by NAICS Industry (NAICS)
SAINC6S	Compensation of Employees by SIC Industry (SIC)
SAINC7H	Wages and Salaries by Industry (Historical) (SIC)
SAINC7N	Wages and Salaries by NAICS Industry (NAICS)
SAINC7S	Wages and Salaries by SIC Industry (SIC)
SAINC91	Gross Flow of Earnings (Non-Industry)
SAIRPD	Implicit Regional Price Deflators by state (Non-Industry)
SARPI	Real Personal Income by state (Non-Industry)
SARPP	Regional Price Parities by state (Non-Industry)
SQGDP1	Gross Domestic Product (GDP) summary, quarterly by state (Non-Industry)
SQGDP11	Contributions to percent change in real GDP (NAICS)

Table 22.62 *continued*

TableName	Description
SQGDP2	Gross domestic product (GDP) by state (NAICS)
SQGDP8	Chain-type quantity indexes for real GDP by state (2012=100.0) (NAICS)
SQGDP9	Real GDP by state (NAICS)
SQINC1	Personal Income Summary: Personal Income, Population, Per Capita Personal Income (Non-Industry)
SQINC35	Personal Current Transfer Receipts (Non-Industry)
SQINC4	Personal Income by Major Component (Non-Industry)
SQINC5H	Personal Income by Major Component and Earnings by Industry (Historical) (SIC)
SQINC5N	Personal Income by Major Component and Earnings by NAICS Industry (NAICS)
SQINC5S	Personal Income by Major Component and Earnings by SIC Industry (SIC)

SQINC7H	Wages and Salaries by Industry (Historical) (SIC)
SQINC7N	Wages and Salaries by NAICS Industry (NAICS)
SQINC7S	Wages and Salaries by SIC Industry (SIC)

Two older data sets, `RegionalIncome` and `RegionalProduct`, are now deprecated by the BEA. The SASEBEA engine does not support the deprecated data sets. However, for compatibility, [Table 22.63](#) and [Table 22.64](#) show the crosswalk that gives the correct table name for the new Regional data set that replaces either the old component parameter in the `RegionalProduct` data set or the old table name parameter in the `RegionalIncome` data set.

Table 22.63 New Table Name to Old Component Parameter

There are also changes in the units of measurement for the new Regional tables. For more information about the new Regional data set changes to the units, see the section “Change in Units” at the following web page:

<https://apps.bea.gov/regional/docs/RegionalApi.cfm>

SAS Output Data Set

You can use a SAS DATA step to write the selected BEA time series data to a SAS data set. This enables you to use SAS software to easily analyze the data. If you specify the name of the output data set in the DATA statement, the SAS engine supervisor creates a SAS data set that has the specified name in the location specified by the SASEBEA engine libref’s *physical-name*.

The contents of the SAS data set include the date of each observation and the name of each time series that is read from the BEA website. Refer to the details of each BEA data set to find that data set’s naming convention for time series.

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure with your SASEBEA engine libref to create a custom view of your data.

Because each SASEBEA engine libref results in retrieving the requested data from the BEA's economic statistics data site, it is best to use a DATA step to store the data. You should avoid the inefficient use of the SASEBEA engine libref that follows:

```
proc print data=BEANIPA.NIPGDP;
```

Here the member name, NIPGDP, which is used in the PROC PRINT statement, invokes the BEANIPA libref to run the SASEBEA engine. It is more efficient to refer to the SAS data set myGDP repeatedly than to invoke the interface engine repeatedly. This use of the member name, NIPGDP, corresponds to specifying the OUT=NIPGDP option. Although using this statement might seem easier, it is much less efficient, because every time you use the SASEBEA engine libref, the SASEBEA engine reads the entire JSON file into SAS again.

Series Names for BEA SETNAME=NIPA and SETNAME=NIPAUNDERLYINGDETAIL

For the NIPA tables, the series names can be listed by using the CONTENTS procedure on the SAS output data set. The available table names are listed in [Table 22.14](#) and [Table 22.15](#). For the NIPA Underlying Detail tables, the series names can be listed by using the CONTENTS procedure on the SAS output data set. The table names are listed in [Table 22.16](#).

Series Names for BEA SETNAME=GDPBYINDUSTRY and SETNAME=UNDERLYINGGDPBYINDUSTRY

For the Gross Domestic Product data, the series names can be listed by using the CONTENTS procedure on the SAS output data set. Time series names begin with an underscore, followed by the industry code as a prefix, which is then joined to the description using an underscore ('_') and truncated to 24 bytes. Then the table ID is appended to the 24-byte name. The three parts of the time series names are joined together using underscores ('_'). The available table names for the GDPbyIndustry data are listed in [Table 22.17](#). The available table names for the UnderlyingGDPbyIndustry data are listed in [Table 22.21](#).

Series Names for BEA SETNAME=FIXEDASSETS

For the FixedAssets data, the series names can be listed by using the CONTENTS procedure on the SAS output data set. The SASEBEA engine forms each time series name by starting with the series code, followed by an underscore ('_'), and then the line number. The available table names for the FixedAssets data are listed in [Table 22.22](#).

Series Names for BEA SETNAME=MNE

For the Direct Investment Data and Activities of Multinational Enterprise data, the series names can be listed by using the CONTENTS procedure on the SAS output data set. Each time series name is made up of the following concatenations in this order: 'SeriesID_', seriesID, 'ROW_', row position, 'COL_', and column code. The available series IDs for the MNE data are listed in [Table 22.57](#).

Series Names for BEA SETNAME=ITA

For the International Transactions Accounts data, the series names can be listed by using the CONTENTS procedure on the SAS output data set. Each time series name is made up of the following concatenation, in this order: time series ID, area or country code (first 7 bytes or characters), ‘_’, and frequency code. For very long time series IDs, the engine uses only bytes 8–18 and the last 12 bytes as a prefix to the country code and frequency code.

You can generate a list of all series names for each indicator that is listed in [Table 22.24](#) through [Table 22.47](#). The ITA database can contain more or fewer indicators than are listed because it is updated periodically.

To generate a list of all the time series names for a particular indicator, specify one indicator by using the INDICATOR= option, and specify AREAORCOUNTRY=ALL. Then use the CONTENTS procedure on the SAS output data set to list all the series names for the specified indicator. See [Example 22.7](#) for an example.

Series Names for BEA SETNAME=IIP

For the International Investment Position data, the series names can be listed by using the CONTENTS procedure on the SAS output data set. Each time series name is made up of the following concatenation in this order: ‘TSI_Iip’, type of investment position, component, ‘_’, and frequency code. For very long time series IDs, the engine does not use the prefix ‘TSI_Iip’. Instead, the time series name is made up of the first 10 bytes of the type of investment, followed by the last 10 bytes of the type of investment, followed by ‘_’ and then the component. See [Example 22.9](#) for an example.

Series Names for BEA SETNAME=InputOutput

For the Input-Output statistics data, the series names can be listed by using the CONTENTS procedure on the SAS output data set. Each time series name is made up of the following concatenation, in this order: ‘Tab’, table ID, ‘_ROW_’, commodity code, ‘_COL_’, and industry code. See [Example 22.10](#) for an example.

Series Names for BEA SETNAME=IntIServTrade

For the international trade in services data, the series names can be listed by using the CONTENTS procedure on the SAS output data set. The engine renames the time series to ISTVAR1-ISTVARn, where n is the number of variables (number of time series). The label for each time series contains the BEA assigned time series ID. To use the longer time series description for the label, use the DESCRIPTION=LONG option. If column headings in the SAS output are preferred to match the label instead of the ISTVARn series name, use the LABEL option on the PROC PRINT statement. See [Example 22.11](#) for an example.

Series Names for BEA SETNAME=Regional

For the regional data, the series names can be listed by using the CONTENTS procedure on the SAS output data set. Each time series name is made up of the following concatenation, in this order: table name, ‘-’, line number, ‘_GeoFips’, and FIPS code. See [Example 22.12](#) for an example.

Data Elements Reference: SASEBEA Interface Engine

Table 22.3 lists the data set names and respective options for each data set. This table is not exhaustive because the BEA website is updated constantly. Visit the website for current BEA data set names, parameters, and valid parameter values. This section demonstrates how to retrieve an updated list of valid parameter values for each parameter of a specified BEA data set.

You can use the following sample code to obtain an updated list of valid data set names, as shown in Table 22.3:

```
/* First, read the data set names list using the Bureau of Economic
   Analysis API with the URL engine in the FILENAME statement */

filename trans url
  'https://apps.bea.gov/api/data/?&userid=XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
  &method=getdatasetlist&resultformat=xml';

filename fast 'U:\mytestfolder\fast2t.xml';
filename MyMap "U:\mytestfolder\fast2t.map";

data _NULL_;
  FILE fast;
  INFILE trans;
  INPUT;
  PUT _infile_;
RUN;

libname fast xmlv2 xmlmap=MyMap automap=REPLACE;

proc datasets
  lib=fast;
run;

/* Print the data set names and their descriptions */
proc print
  data=fast.Dataset;
run;
```

Available Options for Each BEA Data Set

Table 22.4 shows a list of options specific to the NIPA and NIPAUnderlyingDetail data sets. Because these options can change, you can run the following sample code to get an updated list of the allowed options for the NIPA data set:

```
/* First, retrieve an updated list of options for the NIPA data set */

filename fast 'U:\mytestfolder\fasttab.json';
filename MyMap "U:\mytestfolder\test\fasttab.map";

proc http
  url='https://apps.bea.gov/api/data/?&userid=XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
```

```

        &method=getparameterlist&datasetname=NIPA'
    method="GET"
    out=fast;
run;

libname posts JSON fileref=fast map=mymap automap=replace;;

proc datasets
    lib=posts;
run;

/* Print the available option names (parameters) and their descriptions */
proc print
    data=posts.results_parameter;
run;

```

You can run the preceding code for any of the BEA data sets by specifying the appropriate data set name in the HTTP procedure statement. This enables you to update the parameter (option) list available for the specified data set.

Available Values for Each Parameter of a Specified BEA Data Set

To retrieve an updated list of the available table names for the NIPA data set, you can run the following sample code:

```

/* First, get a list of the table names (to use in the TABLENAME= option)
   for the NIPA data set from Bureau of Economic Analysis API by using
   the HTTP procedure in the FILENAME statement */

filename fast 'U:\mytestfolder\fasttab.json';
filename MyMap "U:\mytestfolder\test\fasttab.map";

proc http
    url='https://apps.bea.gov/api/data/?&userid=XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
        &method=getparametervalues&datasetname=NIPA&ParameterName=TableName'
    method="GET"
    out=fast;
run;

libname posts JSON fileref=fast map=mymap automap=replace;;

proc datasets
    lib=posts;
run;

proc print
    data=posts.RESULTS_PARAMVALUE;
run;

```

You can repeat this code for the next option that you want to explore by naming the parameter you want (PARAMETERNAME=) in the HTTP procedure's URL= option. You can also specify a different data set name (in the DATASETNAME=) in the HTTP procedure's URL= option.

In this way, you can easily access the most updated version of each data set that is available on the BEA website. Each data set has its own specific list of parameters, and each parameter has its own specific list of available parameter values. The tables that describe the options and valid parameter values in this document are included for your convenience, but to ensure that you have a complete and updated list of parameter values with their corresponding parameters, it is recommended that you run the preceding sample code periodically for each data set.

The BEA publishes a release schedule at the following URL:

<https://www.bea.gov/news/schedule/full>

Examples: SASEBEA Interface Engine

The following examples use the VALIDVARNAME=ANY option. This option allows special characters to be used in the time series names (SAS variable names) that are generated for the BEA time series data.

Example 22.1: Retrieving Auto and Truck Unit Sales, Production, Inventories, Expenditures, and Price

This example requests auto and truck detail data from the NIPA Underlying Detail data set. The request is for monthly data for the years 2015 and 2016. The SETNAME= option specifies the data set NIUNDERLYINGDETAIL. The TABLENAME= option specifies the table U70205S (Truck and Auto Unit Sales, Production, Inventories, Expenditures, and Price) time series. The FREQ= option selects monthly time series, and the YEAR= option specifies the years 2015 and 2016 as the range of data. The SAS code is shown after the next paragraph. [Output 22.1.1](#) shows the output for the selected date range.

The SET statement reads observations from the input data set Beanip.NIPU, and the DATA step stores them in a SAS data set named myNIPAU. When all the data are retrieved, they are placed in a SAS data set that is named by the OUT= option and is located in the folder specified by the *physical-name* in the LIBNAME statement.

```
options validvarname=any;

title 'Request Truck Unit Sales, Production, Inventories, Expenditures, and Price,
      Monthly, for 2015 and 2016';
LIBNAME beanip sasebea "physical path to your folder for storing the BEA data"
      setname=NIUnderlyingDetail
      TableName="U70205S"
      user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
      freq=M
      outjson=NIPU
      year='2015,2016'
      format=json;

data myNIPAU;
      set beanip.NIPU;
run;
```

```
proc print data=myNIPAU; run;
```

Output 22.1.1 Auto and Truck Unit Sales, Production, Inventories, Expenditures, and Price, Monthly, for 2015 and 2016**Request Truck Unit Sales, Production, Inventories, Expenditures, and Price, Monthly, for 2015 and 2016**

Example 22.2: Retrieving Table IDs 6 and 25 for the Housing Industry

In this example, the BEA data set name is GDPbyIndustry as specified in the SETNAME= option. The TABLEID='6,25' specifies that the statistics for table ID 6 (Components of Value Added by Industry) and table ID 25 (Composition of Gross Output by Industry) are requested for the housing industry (INDUS-TRY='HS'). The YEARS=ALL option specifies the range of data is for all available years. The output is shown in [Output 22.2.1](#), which contains fourteen variables whose names are prefixed with the industry code (HS) followed by '_'. With the exception of the DATE variable, the variable names also have a suffix of '_' followed by the table ID. Between the prefix and suffix is the main part of the name, which is the truncated description of the time series. Together, the three parts, prefix, description and suffix, name each of the time series variables in the SAS output data set. The FREQ= option selects annual data and the OUTJSON= option specifies the name of the SAS output data set (which is also the name of the JSON data file that is retrieved from the BEA website and read into SAS. [Output 22.2.1](#) shows the output for all available years.

Example 22.3: Retrieving All Tables for GDP by Industry from the UnderlyingGDPbyIndustry Data Set

In this example, the BEA data set name is UnderlyingGDPbyIndustry, as specified in the SETNAME= option. The TABLEID=ALL specifies that the statistics for all table IDs are requested for the gross domestic product industry (INDUSTRY='GDP'). The YEAR=ALL option specifies that the range of data is for all available years. The output is shown in [Output 22.3.1](#), which contains nine variables, whose names are prefixed with the industry code (GDP) followed by '_'. With the exception of the DATE variable, the variable names also have a suffix of '_', followed by the table ID. Between the prefix and suffix is the main part of the name, which is the truncated description of the time series. Together, the three parts, prefix, description and suffix, name each of the time series variables in the SAS output data set. The FREQ= option selects annual data, and the OUTJSON= option specifies the name of the SAS output data set, which is also the name of the JSON data file that is retrieved from the BEA website and read into SAS. [Output 22.3.1](#) shows the output for all available years.

Example 22.4: Retrieving One Table from the FixedAssets Data Set

In this example, the BEA data set name is FixedAssets, as specified in the SETNAME= option. The TABLENAME="FAAt201" specifies that the statistics for one table, named FAAt201, is requested. The table contains current-cost net stock of private fixed assets, equipment, structures, and intellectual property products by type. The YEAR='2015,2016,2017,2018,2019' option specifies that the range of data is for five years, 2015 through 2019. The output is shown in [Output 22.4.1](#), which contains 106 variables whose names are given by the series code (with the exception of the DATE variable). The FREQ= option selects annual data, and the OUTJSON= option specifies the name of the SAS output data set, which is also the name of the JSON data file that is retrieved from the BEA website and read into SAS. [Output 22.4.1](#) shows the output for the last five years, ranging from 2015 to 2019.

```
options validvarname=any;

title 'Request Table FAAt201 Statistics from Fixed Assets, Annual Data';
LIBNAME beaFAAt sasebea "physical path to your folder for storing the BEA data"
    setname=FixedAssets
    TableName="FAAt201"
    user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
    outjson=MCOST
    year='2015,2016,2017,2018,2019'
    format=json;

data myMCOST;
    set beaFAAt.MCOST;
run;

proc print data=myMCOST; run;
```

Example 22.5: Retrieving US Direct Investment Position in Canada from the MNE Data Set

In this example, the BEA data set name is MNE, as specified in the SETNAME= option. The SERIESID="30" option specifies that the statistics for one series, US Direct Investment Position Abroad on a Historical-Cost Basis, is requested. This series contains the direct investors' net financial claims on their affiliates, which is defined as the value of US direct investors' equity in their foreign affiliates, plus the value of net outstanding loans to their affiliates. The YEAR= option specifies that the selected data are for five years, 2015 to 2019. The output is shown in [Output 22.5.1](#), which contains 19 variables, whose names are made up of the following concatenations in this order: 'SeriesID_', series ID, 'ROW_', row position, 'COL_', and industry code (column code). The OUTJSON= option specifies the name of the SAS output data set, which is also the name of the JSON data file that is retrieved from the BEA website and read into SAS. [Output 22.5.1](#) shows the output for 2015 to 2019. Note that the SASEBEA engine sorts the years in chronological order, even though they can be specified in any order. Also, the output value, "(D)", indicates that the data in the cell have been suppressed to avoid disclosure of data of individual companies.

Example 22.6: Net Income and Sales for Brazilian, Canadian, and UAE Affiliates of US Parent Enterprises

In this example, the BEA data set name is MNE, as specified in the SETNAME= option. The SERIESID="5,4" option specifies that the statistics for two series, Net Income and Total Sales, are requested. The COUNTRY="202,100,513" option specifies that Brazil, Canada, and the United Arab Emirates (UAE) are the three countries whose data are selected to be retrieved. The INDUSTRY=ALL option indicates that all industries are to be reported. The DIRECTIONOFINVESTMENT=OUTWARD option indicates that the United States is where the parent company is from. The CLASSIFICATION=CountryByIndustry option indicates that each country's data are to be retrieved by industry—in this case, all industries. The YEAR='2012,2011' option specifies that the selected data are for two years, 2012 and 2011. The output is shown in [Output 22.6.1](#), which contains 97 variables, whose names are made up of the following concatenations in this order: 'SeriesID_', series ID, 'ROW_', row position, 'COL_', and industry code (column code). The OUTJSON= option specifies the name of the SAS output data set, which is also the name of the JSON data file that is retrieved from the BEA website and read into SAS. [Output 22.6.1](#) shows the output for 2011 and 2012. Note that the SASEBEA engine sorts the years in chronological order, even though they can be specified in any order. Also, the output value, "(D)", indicates that the data in the cell have been suppressed to avoid disclosure of data of individual companies.

Example 22.7: Retrieving Available Time Series Names for a Specified Indicator from the ITA Data Set

In this example, the BEA data set name is ITA, as specified in the SETNAME= option. The INDICATOR="BalGds" option specifies that the request is for balance on goods time series, and AREAORCOUNTRY=ALL specifies this time series for all countries where it is available. The YEAR='2011,2012' option specifies that the selected data are for two years, 2011 and 2012. The output is shown in [Output 22.7.1](#), which contains 112 variables, whose names are listed by the CONTENTS procedure. The OUTJSON= option specifies the name of the SAS output data set, which is also the name of the JSON data file that is retrieved from the BEA website and read into SAS.

```
options validvarname=any;

title 'Request Balance on Goods Annual ITA Data for Years 2011 and 2012';
LIBNAME beaita sasebea "physical path to your folder for storing the BEA data"
    setname=ITA
    indicator="BalGds"
    areaOrCountry=All
    freq=A
    user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
    outjson=ITAB
    year='2011,2012'
    format=json;

data myITAB;
    set beaita.ITAB;
run;

proc contents data=myITAB; run;
```

Output 22.7.1 Balance on Goods in All Areas or Countries: From the ITA Data Set for 2011 and 2012

Request Balance on Goods Annual ITA Data for Years 2011 and 2012

Example 22.8: Retrieving Time Series for Two Specified Indicators in the ITA Data Set

In this example, the BEA data set name is ITA, as specified in the SETNAME= option. The INDICATOR="BALCURRACCT,BALGDS" option specifies that the request is for two indicators: balance on current account on goods, and balance of goods. Only one area or country may be specified when more than one indicator is specified. This example specifies AREAORCOUNTRY=CHINA so that only the time series for China are returned. The YEAR= ALL option specifies that the selected data are for all available years, and the FREQ= A option specifies annual data is selected. The output is shown in [Output 22.8.1](#), which contains 2 time series, TSI_ItaBalCurrAcctChina_A and TSI_ItaBalGdsChina_A. These data are available for the years 1999-2019. The OUTJSON= option specifies the name of the SAS output data set, which is also the name of the JSON data file that is retrieved from the BEA website and read into SAS.

[illegible]

```

format=json;

data myIFAB;
    set beaita.IFAB;
run;

proc contents data=myIFAB; run;
proc print data=myIFAB; run;

```

Example 22.9: Retrieving Quarterly Time Series for Two Types of Investments from the IIP Data Set

In this example, the BEA data set name is IIP, as specified in the SETNAME= option. The TYPEOFINVESTMENT= option specifies that the request is for two types of investments: US liabilities excluding financial derivatives and US liabilities to foreign official agencies. The COMPONENT= option requests the position statistics (POS) for the two specified investment types. The YEAR= option specifies that the selected data are for 2013, and the FREQ= option specifies the time period to be quarterly, not seasonally adjusted. The output is shown in [Output 22.9.1](#), which contains three variables: DATE, FinLiabsExclFinDerivPos_QNSA, and TSI_lipFinLiabsFoaPos_QNSA. The CONTENTS procedure shows the attributes for each variable, including the description (shown as the label). The OUTJSON= option specifies the name of the SAS output data set, which is also the name of the JSON data file that is retrieved from the BEA website and read into SAS. [Output 22.9.1](#) shows the output for the requested year, 2013.

Example 22.10: Retrieving Use of Commodities by Industries (Sector Level) from the InputOutput Data Set

In this example, the BEA data set name is InputOutput, as specified in the SETNAME= option. The TABLEID= option specifies that the request is for TableID 258, Use of Commodities by Industry. The YEAR= option specifies that the selected data are for two years, 2011 and 2012. The output is shown in [Output 22.10.1](#), which contains only the kept variables specified in the KEEP= option: DATE and the variables whose names start with 'Tab258_ROW_FIRE'. Because the row code in the kept variable names is 'FIRE', only the variables in the commodity FIRE (finance, insurance, real estate, rental, and leasing) are kept. The OUTJSON= option specifies the name of the SAS output data set, which is also the name of the JSON data file that is retrieved from the BEA website and read into SAS. [Output 22.10.1](#) shows the output for the requested years, 2011 and 2012.

Example 22.11: Retrieving Exports and Imports of Advertising Services from the IntlServTrade Data Set

In this example, the BEA data set name is IntlServTrade, as specified in the SETNAME= option. The TYPEOFSERVICE= option specifies that the request is for advertising services. The TRADEDIRECTION= option specifies that both imports and exports data are selected. The AFFILIATION= option specifies that all affiliations are selected. The YEAR= option specifies that the selected data are for all years. Because these data are available starting in 1999 and ending in 2019, only the data for those years are retrieved. The output is shown in [Output 22.11.1](#). Because DESCRIPTION=SHORT is the default, when the PROC PRINT statement uses the LABEL option, each column heading in the output lists the BEA time series indicator using the prefix 'TSI_Ist' for each indicator. If the PROC PRINT statement did not use the LABEL option, then the column headings in the output would have been ISTVAR1, ISTVAR2, ISTVAR3, and ISTVAR4, which are the actual variable names used by the engine. To see a list of all of the variables and their corresponding labels, use the PROC CONTENTS statement.

Example 22.12: Retrieving Per Capita Personal Income from the Regional Data Set

In this example, the BEA data set name is *Regional*, as specified in the `SETNAME=` option. The `TABLENAME='SAINC1'` option specifies that the request is for state annual income. The `LINECODE=3` option specifies that per capita personal income is selected. The `GEOFIPS=STATE` option specifies that all states are selected. The `YEAR=` option specifies that the selected data are for the years 2013 through 2017. The output is shown in [Output 22.11.1](#).

```
options validvarname=any;

title 'Request Per Capita Personal Income, for Every State';
LIBNAME bear sasebea "physical path to your folder for storing the BEA data"
  setname=Regional
  TableName="SAINC1"          /* state annual income */
  linecode=3
  geofips=STATE
  user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
  outjson=MSAIS
  year='2013,2014,2015,2016,2017'
  format=json;

data myMSAIS;
  set bear.MSAIS;
run;

proc print data=myMSAIS; run;
```

Example 22.13: Using the GOCAS= Option

To use the GOCAS= option, add the options shown in [Table 22.65](#) to your SASEBEA LIBNAME statement.

Table 22.65 Additional Options for SASEBEA Engine When CAS Is Used

Option Specification	Description of Option
CASLIB=	Names the CAS library reference for storing the in-memory tables created by the SASEBEA engine
CASOUT=	Names the in-memory table where the BEA data are stored
GOCAS=ON	Specifies that the CAS server is being used

The following code shows how to use CAS with [Example 22.12](#):

```
options validvarname=any;
title 'Request Per Capita Personal Income, for Every State';

LIBNAME bear sasebea "physical path to your folder for storing the BEA data"
    gocas=on
    caslib=casuserhdfs
    casout=M2MSAIS
    setname=Regional
    TableName="SAINC1"          /* state annual income */
    linecode=3
    geofips=STATE
    user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
    outjson=MSAIS
    year='2013,2014,2015,2016,2017'
    format=json;

data myMSAIS;
    set bear.MSAIS;
run;

proc print data=myMSAIS; run;
```

In the preceding code, you can reference the in-memory CAS table, M2MSAIS, later in the same CAS session to save the data in a SASHDAT file, but do not specify the SASHDAT extension in the file name:

```
proc casutil;
    save casdata="M2MSAIS" casout="<physical path and filename>" replace;
quit;
```

To list the tables in the active caslib, specify the following statements:

```
proc casutil; list; quit;
```

Overview: SASEBLS Interface Engine

The SASEBLS interface engine enables SAS users to retrieve economic data from the United States Bureau of Labor Statistics (BLS) website (www.bls.gov), which is hosted by the principal federal agency in the US Department of Labor that measures labor market activity, working conditions, and price changes in the economy. The BLS data focus on the US economy in the areas of employment and unemployment, consumer and producer prices, consumer expenditures, import and export prices, wages and other worker compensation, productivity and technological change, employment projections, and safety and health statistics. The economic time series on the BLS website contain observation or measurement periods that are associated with data values.

The SASEBLS interface engine uses the LIBNAME statement to enable you to specify how to subset your BLS data, select according to frequency of the data, and retrieve annual average time series at the specified frequency. You can then use a SAS DATA step to perform further subsetting, retrieve the data, and store the resulting time series in a SAS data set and in a CAS data table (if desired).

The SASEBLS interface engine supports 64-bit Windows and Linux X64 (LAX) platforms.

Note that the SASEBLS engine uses the BLS API, but it is not endorsed or certified by the Bureau of Labor Statistics, and that by using the SASEBLS interface, you are agreeing to comply with the BLS terms of use, which are described on the web page at the following URL: <https://www.bls.gov/developers/termsOfService.htm>.

To get started using the SASEBLS engine, see the section “[Getting Started: SASEBLS Interface Engine](#)” on page 1597, which shows how to view the time series data. The sample SAS code for accessing these data appears at the end of that section.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);  
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;  
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS statement and the LIBNAME statement, see *SAS Cloud Analytic Services: User's Guide*. For general information about CAS and CAS sessions, see *SAS Cloud Analytic Services: Fundamentals*.

Getting Started: SASEBLS Interface Engine

You can query the Bureau of Labor Statistics (BLS) databases to retrieve the observations or data values for a list of economic time series by specifying the series ID of each time series that you want to read into SAS and by specifying your unique BLS API key. To obtain your own unique API key, visit the BLS website at the following URL:

<https://data.bls.gov/registrationEngine/>

The BLS API key is a 32-character alphanumeric lowercase string, such as 'abcdefghijklmnopqrstu-vwxyz123456', and is represented by 'XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX' in the USER= option in the following example. In addition, the example URLs in this section and in the section “Details: SASEBLS Interface Engine” on page 1605 use the same BLS API key as the argument *your_bls_apikey*.

Now that you are informed about the terms of service of the BLS data, you can use your BLS API registration key to access the BLS data, as shown in the following example.

The following statements enable you to access the three different time series from the Consumer Price Index (CPI) database: 'CUUR0000SA0' from the CPI-U (Urban consumers, US city average, all items), 'CWUR0000SA0' from the CPI-W (Urban wage earners, US city average, all items), and 'SUUR0000SA0' from the C-CPI-U (Chained CPI, all urban consumers). These three time series are listed in the following SAS DATA step and shown in Figure 23.1:

```
options validvarname=any;

DATA inseries;
  length seriesid $ 17;                /* Allow up to 17 bytes for series names */
  seriesid = 'CUUR0000SA0'; output; /* CPI-U, Urban consumers, US city avg */
  seriesid = 'CWUR0000SA0'; output; /* CPI-W, Wage earners, US city avg */
  seriesid = 'SUUR0000SA0'; output; /* C-CPI-U, Chained CPI, all urban consumers*/
RUN;

title 'Retrieve Data for Three Consumer Price Index Time Series';
libname _all_ clear;
```

```

libname bls sasebls "%sysget(BLS) "
  USER='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
  SETNAME=CPI
  INSET=inseries
  PAYPATH="%sysget(BLS)payload"
  STARTYEAR='2020'
  ENDYEAR='2021'
  FREQ=month
  OUTJSON=cpigs
  FORMAT=json;

data cpi_gsa;
  set bls.cpigs ;
run;

proc contents data=cpi_gsa; run;
proc print data=cpi_gsa; run;

```

The JSON data that the BLS website returns are placed in a file named by the OUTJSON= option—in this case, *CPIGS.json*. Note that the JSON file extension is excluded from the file name that is specified in the OUTJSON= option. When the SET statement is executed, the JSON data are read into a SAS data set named *cpigs.sas7bdat*, which resides in the location that is specified inside the string enclosed in double quotation

marks in the SASEBLS LIBNAME statement. So, in the preceding example, if the BLS environment variable is set to `/sasusr/bls/test/`, then the SAS data set that is created from reading the downloaded JSON file is placed into the following file:

```
/sasusr/bls/test/cpigs.sas7bdat
```

An equivalent LIBNAME statement that does not use any environment variables could be as follows:

```
libname bls sasebls "/sasusr/bls/test/"
  USER='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
  SETNAME=CPI
  INSET=inseries
  PAYPATH="/sasusr/bls/test/payload"
  STARTYEAR='2020'
  ENDYEAR='2021'
  FREQ=month
  OUTJSON=cpigs
  FORMAT=json;
```

You could also use either a SAS macro variable or a system environment variable to store the value of your BLS API registration key so that the key does not appear explicitly in your SAS code. The SETNAME= option names the BLS data set that you are retrieving data from. The INSET= option specifies SAS input data set that contains the list of time series that you want to retrieve. This option accepts a string that names the SAS data set containing a list of one or more time series that you select (keep) in the resulting SAS data set. The SASEBLS interface engine creates a file named by the PAYPATH= option—in this case, `/sasusr/bls/test/payload.txt`. When you specify the pay path, do not add the .txt file extension; the SASEBLS engine automatically adds it. The result, CPI_GSA, is named in the DATA step and is shown in [Figure 23.1](#). It is more efficient to use the DATA step to store your BLS data in a SAS data set and then refer to the SAS data set directly in your PROC PRINT or PROC SGPLOT statement, but you can also refer to the SASEBLS libref directly, as in the following statements:

```
proc print data=bls.cpigs; run;
```

This statement uses the member name, CPIGS, in the PROC PRINT statement; this usage corresponds to specifying the OUTJSON=CPIGS option. Although using this code might seem easier, it is not as efficient, because every time you use the SASEBLS libref, the BLS interface reads the entire JSON file again into SAS. It is better to refer to the SAS data set repeatedly than to invoke the interface engine repeatedly. For another example that uses more SASEBLS LIBNAME statement options, see the section “[Details: SASEBLS Interface Engine](#)” on page 1605.

Syntax: SASEBLS Interface Engine

The SASEBLS interface engine uses standard engine syntax to read the observations or data values for one or more economic time series. [Table 23.1](#) summarizes the options that the SASEBLS engine uses. There are two required options: `USER='bls_apikey'` and `INSET='bls_input_dataset_name'`.

Table 23.1 Summary of LIBNAME *libref* SASEBLS Options

Option	Description
ASPECTS=	Specifies whether or not to retrieve the aspects data containing name-value pairs of variables associated with a given data point for a specified BLS series ID
CALCULATIONS=	Specifies whether or not to retrieve the net change and percentage change calculations available for 1, 2, 3, 6, or 12 months
CASLIB=	Specifies the name of the caslib where the in-memory CAS table containing the BLS data is stored
CASOUT=	Specifies the name of the in-memory CAS table, which contains the data that the SASEBLS interface engine returns
CATALOG=	Specifies whether or not to retrieve the series descriptive information for a BLS series ID
CONNECT=	Specifies whether or not to use the connect method for a secure connection via a proxy server. You must specify the <code>PROXY=</code> option when you use the <code>CONNECT=ON</code> option.
DEBUG=	Specifies whether or not to use diagnostic message logging in the SAS log window
ENDYEAR=	Specifies the ending year for the observation period ('YYYY' formatted string, optional)
FORMAT=	Specifies a file extension that indicates the type of file to retrieve. Only the JSON format is supported.
FREQ=	Specifies the reporting frequency of the selected data. For the complete list of frequencies, see Table 23.2 .
GOCAS=	Specifies whether to generate an in-memory CAS table for the BLS data
INSET=	Specifies a SAS input data set that contains a list of BLS time series IDs for retrieving BLS data
OUTJSON=	Specifies the name of the output SAS data set and the JSON file requested by the <code>INSET=</code> option
PAYPATH=	Specifies the fully qualified name of the location where the SASEBLS engine stores the payload text file that contains the IDs of the series to retrieve
PROXY=	Specifies the proxy server that you want to use (if you have trouble connecting without specifying a proxy). If you also need the connect method for a secure connection, use the <code>CONNECT=ON</code> option in addition to the <code>PROXY=</code> option. See the <code>CONNECT=</code> option.
SETNAME=	Specifies the data set name of the data you want to access
STARTYEAR=	Specifies the starting year for the observation period ('YYYY' formatted string, optional)
USER=	Specifies the required BLS registration key that enables you to access the data that the BLS website provides

The LIBNAME libref SASEBLS Statement

LIBNAME libref **SASEBLS** 'physical-name' options ;

The LIBNAME statement assigns a SAS library reference (libref) to the physical path of the directory where the SASEBLS interface engine stores the BLS economic data. The required *physical-name* argument specifies the final location of the folder where your BLS data reside in a SAS data set that is named in the OUT= option. The *physical-name* should end with a backslash (for example, C:\physical_name\) when you are in a Windows environment or a forward slash (for example, /user/physical_name/) when you are in a UNIX environment.

You can specify the following *options*:

ASPECTS=TRUE | FALSE

specifies whether or not to retrieve the aspects data that are associated with a given data point for a specified BLS series ID. For each observation, the associated aspects data consist of one or more name-value pairs of variables along with footnotes. When ASPECTS=TRUE and an aspect data file exists for the requested time series, the SASEBLS engine creates an auxiliary data set containing the aspects data. This auxiliary data set is named using the name specified in the OUTJSON= option, which is appended with “_data_aspects”. For example, if OUTJSON=MYCPI, then the aspects data set is named mycpi_data_aspects.sas7bdat.

TRUE specifies that the aspects data be retrieved.

FALSE specifies that no aspects data be retrieved.

By default, ASPECTS=FALSE.

CALCULATIONS=TRUE | FALSE

specifies whether to retrieve (TRUE) or not retrieve (FALSE) the net change and percentage change calculations available for 1, 2, 3, 6, or 12 months. Depending on the frequency of the data and the availability of the data, there might not be calculations

available for all intervals (1, 2, 3, 6, or 12 months).

TRUE retrieves the calculations.

FALSE does not retrieve the calculations.

By default, CALCULATIONS=FALSE. When CALCULATIONS=TRUE and a catalog is available for the requested time series, each calculation series is labeled appropriately. To see the labels, use the CONTENTS procedure with the output data set.

CASLIB=bls_caslib_name

specifies the name of the CAS library (caslib) where the in-memory CAS table is stored when the JSON data from the BLS website are read into SAS. You can use this option to name your caslib where the in-memory CAS table is stored. The default value is the name of the active caslib. The GOCAS=ON option is required when you specify the CASLIB= option.

CASOUT=*libref.data-table***OUTCAS=***libref.data-table*

specifies the name of the in-memory CAS table that is created when the JSON data from BLS are read into SAS. The default value is the name that you specify in the OUT= option. The in-memory table is created only when you also specify the GOCAS=ON option. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section “Using CAS Sessions and CAS Engine Librefs” on page 1596.

CATALOG=TRUE | FALSE

specifies whether or not to retrieve additional descriptive data about the requested time series. These catalog data include the series description (series title); the seasonality description; the survey name description; the survey abbreviation; and (where appropriate) descriptions such as measured data type, commerce industry, occupation, and regional area. When CATALOG=TRUE and a catalog is available for the requested time series, the SASEBLS engine creates an auxiliary data set that contains the catalog data. This auxiliary data set is named using the name specified in the OUTJSON= option, which is then appended with “_catalog”. For example, if OUTJSON=MYCPI, then the catalog data set is named mycpi_catalog.sas7bdat.

TRUE retrieves additional descriptive data about the requested time series.

FALSE does not retrieve additional descriptive data about the requested time series.

By default, CATALOG=FALSE.

CONNECT=ON | OFF

specifies whether to use (ON) or not use (OFF) the connect method along with the PROXY= option.

NOTE: To use the connect method, you must use the PROXY= option and specify your proxy server in addition to the CONNECT=ON option. For more information about a secure connection, see the [PROXY=](#) option.

DEBUG=ON | OFF

specifies whether or not to include diagnostic message logging in the SAS log window. This information can be useful for troubleshooting. Specify DEBUG=ON to see all the log messages (including debugging information) in the SAS log. By default, DEBUG=OFF.

ENDYEAR=*'bls_endyear'*

specifies the ending year of the time series in the format 'YYYY'.

FORMAT=*bls_jsonformat*

specifies the format of the file to be retrieved from the BLS website. Although BLS can report data in many formats, the SASEBLS engine supports only the JSON format (the default).

FREQ=*'bls_frequency_code'*

specifies the frequency of the data that you want to retrieve. You can specify the option values shown in the Frequency Code column in [Table 23.2](#). For an example that retrieves monthly data, see [Example 23.1](#).

Table 23.2 BLS Frequency Codes

Period	Period Description	Frequency Code	Description
M01–M12	Jan.–Dec.	M	Displays data on a monthly basis
M13	Annual average	M13	Displays annual averages of monthly data
M01–M12	Monthly	Mon	Displays data on a monthly basis
M01–M12	Monthly	Month	Displays data on a monthly basis
M01–M12	Monthly	Monthly	Displays data on a monthly basis
Q01–Q04	1st–4th quarter	Q	Displays data on a quarterly basis
Q05	Annual average	Q05	Displays annual averages of quarterly data
Q01–Q04	1st–4th quarter	QTR	Displays data on a quarterly basis
Q01–Q04	1st–4th quarter	Quarter	Displays data on a quarterly basis
Q01–Q04	1st–4th quarter	Quarterly	Displays data on a quarterly basis
S01–S02	1st–2nd half	S	Displays data on a semiannual basis
S03	Annual average	S03	Displays annual averages of semiannual data
S01–S02	1st–2nd half	Semiannual	Displays data on a semiannual basis
A01	Annual	A or A01	Displays data on an annual basis
A02	Annual average	A02	Displays annual averages of annual data
A02,S03,Q05,M13	Annual average	Annual_avg	Displays data for annual averages
A01	Annual	Year	Displays data on an annual basis
A01	Annual	Yearly	Displays data on an annual basis

GOCAS=ON | OFF

specifies whether to create (ON) or not create (OFF) an in-memory CAS table of the BLS data (in addition to the SAS data set that is created). When GOCAS=ON, the SASEBLS engine assumes that there is an active CAS session running when it executes the LIBNAME statement. By default, GOCAS=OFF.

INSET=bls_input_SAS_dataset_name

specifies the name of the input SAS data set that contains a list of time series to include in the output SAS data set. The list is in the following format:

```
DATA \Argument{bls\_input\_SAS\_dataset\_name};
    seriesid = \Argument{\Quotes{bls\_seriesid\_name1}}; output;
    seriesid = \Argument{\Quotes{bls\_seriesid\_name2}}; output;
    .
    .
    .
    seriesid = \Argument{\Quotes{bls\_seriesid\_nameN}}; output;
run;
```

The BLS API enables you to retrieve up to 50 series IDs in one request. To see a list of all series IDs for a particular survey, such as CU, visit the web page at the following URL: <https://download.bls.gov/pub/time.series/cu/cu.series>.

The CPI and PPI survey names are as follows: CU, CW, SU, AP, LI, MU, MW, ND, PC, PD, WP, and WD. You can replace the 'CU' with a different survey name to see a list of that survey's series IDs. For example, for the WD survey, use the following URL

: <https://download.bls.gov/pub/time.series/wd/wd.series>.

For examples that retrieve CPI and PPI data, see [Example 23.1](#) and [Example 23.2](#), respectively.

OUTJSON=*bls_json_file_name*

specifies the name of the JSON file (downloaded to the SAS Work library) and the name of the SAS data set that is created when the JSON data are read into SAS. The SAS data set is stored in the folder that is specified by *physical-name*.

PAYPATH='bls_payload_path_and_filename'

specifies the physical path and file name of the *payload.txt* file. Do not specify the .txt file extension, because the SASEBLS engine automatically adds .txt to the end of the *payload.txt* file name. The *payload.txt* file is

created by the engine and contains information from the INSET= option, as well as information from the following options: STARTYR=, ENDYR=, CATALOG=, and ASPECTS=.

PROXY='bls_proxyserver'

specifies which proxy server to use. This option is not required. The specified proxy server is used only when a connection-refused error or a connection-timed-out error occurs. For *bls_proxyserver*, specify the server's HTTP address followed by a colon and the port number, and enclose that string in double quotation marks; for example, PROXY="http://inetgw.unx.sas.com:8118". See also the [CONNECT=](#) option.

SETNAME=*bls_setname*

DATASETNAME=*bls_setname*

DATASET=*bls_setname*

SETID=*bls_setname*

specifies the name of the BLS data set to retrieve the BLS data from. [Table 23.3](#) shows the list of available BLS data set names. This release of SASEBLS supports the data set names shown in [Table 23.4](#). See [Example 23.1](#) for a CPI example, [Example 23.2](#) for a PPI example, and [Example 23.3](#) for an IPP example.

STARTYEAR='bls_startyear'

specifies the starting year of the time series in the format 'YYYY'.

USER='bls_user'

APIKEY='bls_user'

REGISTRATIONKEY='bls_user'

specifies the unique user registration key, enclosed in quotation marks, that the BLS assigns to the user (subscriber) to allow access to the data provided by the BLS website. The BLS access key is a 32-character alphanumeric lowercase string that you can request from the website at the following URL: <https://data.bls.gov/registrationEngine/>.

Details: SASEBLS Interface Engine

Table 23.3 shows all the data sets that BLS offers. Currently, the SASEBLS interface engine enables you to access only the time series data from the BLS data sets shown in Table 23.4. To specify a supported BLS data set, use one of the data set names in this table.

To access the data set, specify SETNAME=<data set name>, as shown in the SASEBLS LIBNAME statement in the section “Getting Started: SASEBLS Interface Engine” on page 1597.

Table 23.3 BLS Data Sets

Data Set	Long Name	Surveys	Subject Area
CPI	Consumer Price Index	CU CW SU AP LI MU MW	Inflation and Prices
PPI	Producer Price Index	ND PC PD WP WD	Inflation and Prices

Data Elements Reference: SASEBLS Interface Engine

Table 23.4 shows where to find a summary of each data set’s details. This table lists the supported data sets and gives useful links to information about each data set, such as included surveys and links to details about each survey in that data set. The table also has links to examples that show how to retrieve the data, including example code for each data set.

Table 23.4 Supported BLS Data Sets

Data Set	Survey Name	Series Details	Example
ATUS	TU	https://download.bls.gov/pub/time.series/tu/tu.txt	Example 23.12
BDM	BD	https://download.bls.gov/pub/time.series/bd/bd.txt	Example 23.10
	GG	https://download.bls.gov/pub/time.series/gg/gg.txt	
CES	CE	https://download.bls.gov/pub/time.series/ce/ce.txt	Example 23.5
	EE	https://download.bls.gov/pub/time.series/ee/ee.txt	
CEX	CX	https://download.bls.gov/pub/time.series/cx	Example 23.4
CPI	AP	https://download.bls.gov/pub/time.series/ap/ap.txt	Example 23.1

	PD	https://download.bls.gov/pub/time.series/pd/pd.txt	
	WD	https://download.bls.gov/pub/time.series/wd/wd.txt	
	WP	https://download.bls.gov/pub/time.series/wp/wp.txt	
QCEW	EN	https://data.bls.gov/PDQWeb/en https://data.bls.gov/cgi-bin/dsrv?en	Example 23.9
	EW	https://data.bls.gov/PDQWeb/ew https://data.bls.gov/cgi-bin/dsrv?ew	
SAE	SM	https://download.bls.gov/pub/time.series/sm/sm.txt	Example 23.6
WSP	WS	https://download.bls.gov/pub/time.series/ws/ws.txt	Example 23.16

You can learn how to retrieve data from these supported BLS data sets by using the sample code shown in the section “Examples: SASEBLS Interface Engine” on page 1610.

Useful Links for BLS Time Series Data

To obtain a list of all available surveys of BLS economic data, enter the following URL in your web browser:

`https://api.bls.gov/publicAPI/v2/surveys`

To obtain a list of the most popular BLS and survey-specific series, use the following URL:

`https://api.bls.gov/publicAPI/v2/timeseries/popular`

To obtain a list of the most popular survey-specific series, include the survey name:

`https://api.bls.gov/publicAPI/v2/timeseries/popular?survey=LA`

To obtain a list of the most recent data points for a given BLS series ID, such as series ID LAUCN040010000000005, use the following form of the URL:

`https://api.bls.gov/publicAPI/v2/timeseries/data/LAUCN040010000000005?latest=true`

For a complete list of the flat-file equivalent data for all BLS time series (from the LABSTAT data server), use the following URL. You can use this series list to see details about each series by clicking on the series ID that you are interested in.

`https://download.bls.gov/pub/time.series/`

To see an overview of the contents of the entire catalog, click on the file, *overview.txt*, located at the following URL:

`https://download.bls.gov/pub/time.series/overview.txt`

To see a list of the limitations of the BLS API (application interface), use the following URL:

`https://www.bls.gov/developers/api_faqs.htm#register1`

SAS Output Data Set

You can use the SAS DATA step to write the selected BLS data to a SAS data set. This enables you to use SAS software to easily analyze the data. If you specify the name of the output data set in the DATA statement, the engine supervisor creates a SAS data set that has the specified name in either the SAS Work library or, if specified, the User library. The SASEBLS engine also keeps a copy of the output data set in the location that is specified by the *physical-name* in the LIBNAME *libref* SASEBLS statement, which is described in the section “[The LIBNAME libref SASEBLS Statement](#)” on page 1601.

The contents of the SAS data set include the date of each observation and the series name of each series that is read from the BLS data source. When CALCULATIONS=TRUE and the calculations time series data exist, then all available calculations time series are included in the SAS output data set.

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure with your SASEBLS libref to create a custom view of your data.

SAS Output Auxiliary Data Set for Aspects Data

When ASPECTS=TRUE and the aspects data exist, then an auxiliary data set is created containing the aspects data. It is named using the name of the output data set and appended with “_data_aspects”. The aspects data set is placed in the location that is specified by the *physical-name* in the LIBNAME *libref* SASEBLS statement, which is described in the section “The LIBNAME *libref* SASEBLS Statement” on page 1601.

SAS Output Auxiliary Data Set for Catalog Data

When CATALOG=TRUE and the catalog data exist, then an auxiliary data set is created containing the catalog data. It is named using the name of the output data set and appended with “_catalog”. The catalog data set is placed in the location that is specified by the *physical-name* in the LIBNAME *libref* SASEBLS statement, which is described in the section “The LIBNAME *libref* SASEBLS Statement” on page 1601. See Output 23.5.2 for an example of the information contained in the CATALOG data set.

SAS OUTJSON File

The SAS JSON data (in JSON format) that the BLS website returns are placed in a file named by the OUTJSON= option. The SAS JSON data file is placed in the SAS Work directory, but the SAS data set that is created by reading the JSON data into SAS is placed in the location that is specified by the *physical-name* in the LIBNAME *libref* SASEBLS statement, which is described in the section “The LIBNAME *libref* SASEBLS Statement” on page 1601.

Examples: SASEBLS Interface Engine

Example 23.1: Retrieving Consumer Price Index (CPI) Data for Multiple Time Series

This example shows how to use multiple time series IDs to retrieve Average Price (AP) data, all Urban Consumers (SU) chained Consumer Price Index (CPI) data, Urban Wage Earners and Clerical Workers (CW) current series data, and all Urban Consumers (CU) current series data from the CPI databases. You can view these data at the following URL:

<https://www.bls.gov/cpi/data.htm>

INSERIES is an input SAS data set that lists the IDs of the time series that you want to retrieve from the CPI database. In this example, this input SAS data set is named in the INSET=INSERIES option. To create the INSERIES data set, use the DATA step. In the DATA statement, specify the name of the input data set as ‘INSERIES’. Next, the length of the series ID is specified as 17 bytes prior to listing the ID of each series to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical

path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= name and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERIES for the list of series to be retrieved using their IDs. The date range of the data starts with 2019, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year to include in the range of data to be retrieved. FREQ=MONTH specifies the selection of only the monthly data, and the FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.1.1](#) shows the CPI data that are retrieved.

```
options validvarname=any;

DATA inseries;
  length seriesid $ 17;
  seriesid = 'CUUR0000SA0'; output; /* CPI-U, US city avg, all items */
  seriesid = 'APU0000704111'; output; /* AP, CPI average price data */
  seriesid = 'APU0000711211'; output; /* bananas */

Example 23.2: Retrieving Producer Price Index (PPI) Data for Multiple Time Series

This example shows how to use multiple time series IDs to retrieve Producer Price Index Revision–Current (PC) series data and Producer Price Index–Current Commodity (WP) series data. You can view these data at the following URL:

<https://www.bls.gov/ppi/data.htm>

INSERTIES is an input SAS data set that lists the IDs of the time series to be retrieved from the Producer Price Index (PPI) database. In this example, the input SAS data set is named in the INSET=INSERTIES option. To create the INSERTIES data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERTIES'. Next, the length of the series ID is specified as 17 bytes prior

to listing the ID of each series to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSET= option specifies the list of series to retrieve using their IDs. The date range of the data starts with 1985, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year to include in the range of data to retrieve. FREQ=M13 specifies the selection of only the annual averaged monthly data, and the FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.2.1](#) shows the PPI data that are retrieved.

```

Example 23.3: Retrieving Import/Export Price Index (EI) Data for Multiple Time Series

This example shows how to use multiple time series IDs to retrieve data from the Import/Export Price Index. You can view these data by using the following URL:

<https://www.bls.gov/mxp/data.htm>

INSERTS is an input SAS data set that lists the IDs of the time series to be retrieved from the Import/Export Price Index (EI) database. In this example, the input SAS data set is named in the INSET=INSERTS option. To create the INSERTS data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERTS'. Next, the length of the series ID is specified as 32 bytes prior to listing the ID of each series to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERTS data set for the list of series to retrieve using their IDs. The date range of the data starts with 2019, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year to include in the range of data to retrieve. The FREQ=MONTH option specifies the selection of only the monthly data (M1–M12) in the output data set. The FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.3.1](#) shows the EI data that are retrieved.

Example 23.4: Retrieving Consumer Expenditure Survey (CX) Data

This example shows how to retrieve data from the Consumer Expenditure Survey. You can view these data by using the following URL:

<https://www.bls.gov/cex/data.htm>

INSERTIES is an input SAS data set that lists the IDs of the time series to be retrieved from the Consumer Expenditure (CX) database. In this example, the input SAS data set is named in the INSET=INSERTIES option. To create the INSERTIES data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERTIES'. Next, the length of the series ID is specified as 32 bytes prior to listing the ID of each series to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement.

The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSET= data set for the list of series to retrieve using their IDs. In this example, only one time series, CXUCHGASLILB0101M, is requested. The date range of the data starts with 2010, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year, 2020, to include in the range of data to retrieve. The FREQ=ANNUAL option specifies the selection of yearly data, but because the CALCULATIONS=TRUE option is specified, the retrieved data also include the net change and percentage change calculation statistics. In this example, only the 12-month net change, CXUCHGASLILB0101M_12, and the 12-month percentage change, CXUCHGASLILB0101M%12, statistics are available. The 1-month net change, 3-month net change, and 6-month net change are missing (not available). In addition, the 1-month percentage change, 3-month percentage change, and 6-month percentage change are also missing (not available). The FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.4.1](#) shows the data that are retrieved.

Example 23.5: Retrieving Current Employment Statistics National Survey (CE) Data

This example shows how to retrieve data from the Current Employment Statistics Survey (CE). You can view these data by using the following URL:

<https://www.bls.gov/ces/data/>

INSERIES is an input SAS data set that lists the IDs of the time series to be retrieved from the Current Employment Statistics (CES) database. In this example, the input SAS data set is named in the INSET=INSERIES option. To create the INSERIES data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERIES'. Next, the length of the series ID is specified as 32 bytes prior to listing the ID of each series to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERIES data set for the list of series to retrieve using their IDs. In this example, two time series, CES0000000001 and CEU0500000001, are requested, along with any calculations. Both time series have 1-month, 3-month, 6-month, and 12-month net and percentage changes.

The date range of the data starts with 2003, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year, 2004, to include in the range of data to retrieve. The FREQ=MONTH option specifies the selection of monthly data, but because the CALCULATIONS=TRUE option is specified, the retrieved data also include the net change calculation and percentage change calculation statistics. The FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.5.1](#) shows the data that are retrieved. [Output 23.5.2](#) shows the catalog information for the retrieved data.

Example 23.6: Retrieving State and Metro Area Current Employment (SM) Data

This example shows how to retrieve data from the State and Metro Area Current Employment Survey (SM). You can view these data by using the following URL:

<https://www.bls.gov/sae/data/>

INSERIES is an input SAS data set that lists the IDs of the time series to be retrieved from the State and Metro Area Current Employment Statistics (SAE) database. In this example, the input SAS data set is named in the INSET=INSERIES option. To create the INSERIES data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERIES'. Next, the length of the series ID is specified as 32 bytes prior to listing the ID of each series to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERIES data set for the list of series to retrieve using their IDs. In this example, two time series, SMU78000009092000001 and SMS39496600000000001, are requested, along with any calculations. Both time series have 1-month, 3-month, 6-month, and 12-month net and percentage changes.

The date range of the data starts with 2021, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year, 2022, to include in the range of data to retrieve. The FREQ=MONTH option specifies the selection of monthly data, but because the CALCULATIONS=TRUE option is specified, the retrieved data also include the net change calculation and percentage change calculation statistics. The FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.6.1](#) shows the first seven observations of data that are retrieved. [Output 23.6.2](#) shows the catalog information for the retrieved data.

Example 23.7: Retrieving Labor Force Current Population Statistics (CPS) Data

This example shows how to retrieve data from the Weekly Hours and Earnings Survey, LE, and the Labor Force Statistics Survey (includes the national unemployment rate), LN, both from the Current Population Statistics program data. You can view these data by using the following URL:

<https://www.bls.gov/cps/>

INSERIES is an input SAS data set that lists the IDs of the time series to be retrieved from the Current Population Statistics database. In this example, the input SAS data set is named in the INSET=INSERIES option. To create the INSERIES data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERIES'. Next, the length of the series ID is specified as 32 bytes prior to listing the ID of each series to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option

and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERIES data set for the list of series to retrieve using their IDs. In this example, four time series are requested, along with any calculations.

The date range of the data starts with 2021, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year, 2022, to include in the range of data to retrieve. The FREQ=QUARTERLY option specifies the selection of quarterly data, but because the CALCULATIONS=TRUE option is specified, the retrieved data also include the net change calculation and percentage change calculation statistics. The FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.7.1](#) shows the data that are retrieved. [Output 23.7.2](#) shows the catalog information for the retrieved data.

Example 23.8: Retrieving Job Openings and Labor Turnover Statistics (JOLT) Data

This example shows how to retrieve data from the Job Openings and Labor Turnover Surveys, JT and JL. You can view these data by using the following URL:

<https://www.bls.gov/jlt>

INSERTS is an input SAS data set that lists the IDs of the time series to be retrieved from the Job Openings and Labor Turnover Statistics database. In this example, the input SAS data set is named in the INSET=INSERTS option. To create the INSERTS data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERTS'. Next, the length of the series ID is specified as 32 bytes prior to listing the ID of each series to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON=

option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERIES data set for the list of series to retrieve using their IDs. In this example, four time series are requested, along with any calculations.

The date range of the data starts with 2002, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year, 2003, to include in the range of data to retrieve. The FREQ=MONTH option specifies the selection of monthly data, but because the CALCULATIONS=TRUE option is specified, the retrieved data also include the net change calculation and percentage change calculation statistics. There is no catalog for the JOLT data set, so the description of each statistical time series can be obtained by the seriesid format described at the following URL:

<https://www.bls.gov/help/hlpforma.htm#jt>

These descriptions can be placed in the label for each time series as shown in the label statements of the myJOLT DATA STEP.

The FORMAT= option specifies that the data are to be retrieved using the JSON format. For brevity, only the first four observations are shown in [Output 23.8.1](#).

Example 23.9: Retrieving Quarterly Census of Employment and Wages (QCEW) Data

This example shows how to retrieve data from the Quarterly Census of Employment and Wages surveys. You can view these data by using the following URL:

<https://www.bls.gov/cew/data-overview.htm>

INSERIES is an input SAS data set that lists the IDs of the time series to be retrieved from the Quarterly Census of Employment and Wages (QCEW) database. In this example, the input SAS data set is named in the INSET=INSERIES option. To create the INSERIES data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERIES'. Next, the length of the series ID is specified as 32 bytes prior to listing the ID of each series to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERIES data set for the list of series to retrieve using their IDs. In this example, four time series are requested, along with any calculations.

The date range of the data starts with 2019, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year, 2020, to include in the range of data to retrieve. The FREQ=MONTH option specifies the selection of monthly data, but because the CALCULATIONS=TRUE option is specified, the retrieved data also include the net change calculation and percentage change calculation statistics. No catalog is available for the selected QCEW data in this example, so the description of each time series can be obtained by using the series ID format described at the following URL:

<https://www.bls.gov/help/hlpforma.htm#EN>

These descriptions can be placed in the label for each time series, as shown in the LABEL statements in the myQCEW DATA step.

The FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.9.1](#) shows the data that are retrieved.

Example 23.10: Retrieving Business Employment Dynamics Statistics (BDM) Data

This example shows how to retrieve data from the Business Employment Dynamics Statistics survey. You can view these data by using the following URL:

<https://www.bls.gov/bdm/data.htm>

INSERIES is an input SAS data set that lists the IDs of the time series to be retrieved from the Business Employment Dynamics Statistics (BDM) database. In this example, the input SAS data set is named in the INSET=INSERIES option. To create the INSERIES data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERIES'. Next, the length of the series ID is specified as 32 bytes prior to listing the ID of each series to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERIES data set for the list of series to retrieve using their IDs. In this example, four time series are requested, along with any calculations.

The date range of the data starts with 2019, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year, 2020, to include in the range of data to retrieve. The FREQ=QUARTERLY (or FREQ=Q) option specifies the selection of quarterly data, but because the CALCULATIONS=TRUE option is specified, the retrieved data also include the net change calculation and percentage change calculation statistics. The FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.10.1](#) shows the data that are retrieved. [Output 23.10.2](#) shows the catalog information for the retrieved data.

```
options validvarname=any;
libname blscat "%sysget(BLS)";      /* for Catalog data set*/

Example 23.11: Retrieving Occupational Employment and Wage Statistics (OEWS) Data

This example shows how to retrieve Occupational Employment and Wage Statistics (OEWS) data. You can view these data by using the following URL:

<https://www.bls.gov/oes/data.htm>

INSERIES is an input SAS data set that lists the IDs of the time series to be read from the OEWS database. In this example, the input SAS data set is named in the INSET=INSERIES option. To create the INSERIES data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERIES'. Next, the length of the series ID is specified as 32 bytes prior to listing the ID of each series to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERIES data set for the list of series to retrieve using their IDs. In this example, one time series is requested, along with any calculations.

The date range of the data starts with 2011, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year, 2021, to include in the range of data to retrieve. The FREQ=ANNUAL (or FREQ=A) option specifies the selection of annual data. The CALCULATIONS=TRUE option is specified, but the data that are returned do not contain any net change calculation or percentage change calculation statistics, so no calculations exist in the SAS Output data set. The FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.11.1](#) shows the data that are retrieved. [Output 23.11.2](#) shows the catalog information for the retrieved data.

Example 23.12: Retrieving American Time Use Survey (ATUS) Data

This example shows how to retrieve American Time Use Survey (ATUS) data. You can view these data by using the following URL:

<https://www.bls.gov/tus/database.htm>

INSERIES is an input SAS data set that lists the IDs of the time series to be read from the ATUS database. In this example, the input SAS data set is named in the INSET=INSERIES option. To create the INSERIES data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERIES'. Next, the length of the series ID is specified as 32 bytes prior to listing each series ID to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERIES data set for the list of series to retrieve using their IDs. In this example, four time series are requested.

The date range of the data starts with 2009, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year, 2019, to include in the range of data to retrieve. The FREQ=ANNUAL (or FREQ=A) option specifies the selection of annual data. The ASPECTS=TRUE option is specified, and the data that are retrieved show the standard error, name_aspects, and the value, value_aspects, that are associated with each observation of each time series. The FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.12.1](#) shows the data that are retrieved. [Output 23.12.2](#) shows the catalog information for the retrieved data. [Output 23.12.3](#) shows the aspects information for the retrieved data.

Example 23.13: Retrieving Employment Projections (EPP) Data

This example shows how to retrieve Employment Projections (EPP) data. You can view these data by using the following URL:

<https://www.bls.gov/emp/data.htm>

INSERTIES is an input SAS data set that lists the IDs of the time series to be read from the EP database. In this example, the input SAS data set is named in the INSET=INSERTIES option. To create the INSERTIES data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERTIES'. Next, the length of the series ID is specified as 32 bytes prior to listing each series ID to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERTIES data set for the list of series to retrieve using their IDs. In this example, four time series are requested, along with any calculations. Employment Projections data are available for only one year, so the date range is specified for that year. The date range of the data starts with 2021, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year, 2021, to include in the range of data to retrieve. The FREQ=ANNUAL (or FREQ=A) option specifies the selection of annual data. There is no catalog for the EPP data set, so the description of each time series can be obtained from the series_title column at the following URL:

<https://download.bls.gov/pub/time.series/ep/ep.series>

You can place these descriptions in the label for each time series, as shown in the LABEL statements of the myEPP DATA step.

The FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.13.1](#) shows the data that are retrieved.

Example 23.14: Retrieving International Labor Comparisons (ILC) Data

This example shows how to retrieve International Labor Comparisons (ILC) data. You can view these data by using the following URL:

`https://www.bls.gov/fls/data.htm`

INSERIES is an input SAS data set that lists the time series IDs to be retrieved from the IN database. In this example, the input SAS data set is named in the INSET=INSERIES option. To create the INSERIES data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERIES'. Next, the length of the series ID is specified as 32 bytes prior to listing each series ID to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The SASEBLS LIBNAME statement in the code that follows specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERIES data set for the list of series IDs to retrieve. In this example, three time series are requested, along with any calculations.

The date range of the data starts with 2013, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year, 2013, to include in the range of data to retrieve. The FREQ=MONTHLY option specifies the selection of monthly data, but because the CALCULATIONS=TRUE option is specified, the retrieved data also include the net change calculation and percentage change calculation statistics. There is no catalog for the IN data set, so the description of each time series can be obtained by using the BLS series report tool at the following URL:

`https://data.bls.gov/cgi-bin/srgate`

These descriptions can be placed in the label for each time series as shown in the LABEL statements of the myINS DATA step.

The FORMAT= option specifies that the data are to be retrieved using the JSON format. [Output 23.14.1](#) shows the data that are retrieved.

Example 23.17: Retrieving Local Area Unemployment Statistics (LAUS) Data

This example shows how to retrieve data from the Local Area Unemployment Statistics (LAUS) program. You can view these data by using the following URL:

`https://www.bls.gov/lau/data.htm`

INSERIES is an input SAS data set that lists the time series IDs to be read from the Local Area Unemployment Statistics (LAUS) program database. In this example, the input SAS data set is named in the INSET=INSERIES option. To create the INSERIES data set, use the DATA step. In the DATA statement, the name of the input data set is specified as 'INSERIES'. Next, the length of the series ID is specified as 32 bytes prior to listing each series ID to be accessed. Each time series is listed on its own line, along with the OUTPUT statement. When the series IDs have been listed, the DATA step is ended with a RUN statement. The following SASEBLS LIBNAME statement specifies the libref (BLS), followed by the engine name (SASEBLS) and the physical path where the retrieved BLS data are to be stored. The OUTJSON= option names the file where the JSON data are stored. The output data set is created using the OUTJSON= option and placed in the folder that is specified in the SASEBLS LIBNAME statement. The INSET= option specifies the INSERIES data set for the list of series IDs to retrieve. In this example, three time series are requested, along with the catalog (CATALOG=TRUE option).

The date range of the data starts with 2022, as specified by the STARTYEAR= option. The ENDYEAR= option specifies the last year, 2023, to include in the range of data to retrieve. The FREQ=MONTHLY option specifies the selection of monthly data, and because the CATALOG=TRUE option is specified, the retrieved data also include available catalog information.

The `FORMAT=` option specifies that the data are to be retrieved using the JSON format. [Output 23.17.1](#) shows the selected monthly data that are retrieved. [Output 23.17.2](#) shows the catalog information for the retrieved data. The data from the three retrieved time series come from three different metropolitan statistical areas (MSAs).

Overview: SASEMOOD Interface Engine

The SASEMOOD interface engine enables SAS users to retrieve time series data from the Moody's Analytics Data Buffet (Economy.com) website. This website offers access to over 600 sources of global historical statistical data at the regional, national, and subnational level, in addition to 40 forecast database offerings. Over 220 million time series are updated promptly after release, on topics such as housing, labor, demographics, finance, industry, housing prices, and consumer credit performance forecasts. Time series are offered in yearly, semiannual, quarterly, monthly, semimonthly, biweekly, weekly, workday (business), daily, and indexed frequencies.

The SASEMOOD interface engine uses the LIBNAME statement to enable you to download Moody's online economic data by using the Data Buffet API described at the following URL:

<https://www.economy.com/products/tools/api>

It also enables you to specify which time series you want to retrieve, by using the mnemonic code that corresponds to the data set that you select. You choose the time range of the retrieved data by specifying a start date and an end date. You can then use the SAS DATA step to perform further subsetting, retrieve the data, and store the resulting time series in a SAS data set and in a CAS table (if desired).

You can view the catalog of available Moody's databases on the web page at the following URL:

<https://www.economy.com/databuffet/>

The SASEMOOD interface engine supports Linux X64 (LAX) and Windows.

Although the SASEMOOD engine uses Moody's Analytics Data Buffet online API, it is not endorsed or certified by Moody's Analytics. By using the SASEMOOD interface engine, you are agreeing to comply with the terms of use, which are described on the web page at the following URL:

<https://www.economy.com/about/terms-of-use>

For more information see the Moody's Analytics (2019) Data Buffet API User Guide.

To get started using the SASEMOOD engine, follow the steps in the section “[Getting Started: SASEMOOD Interface Engine](#)” on page 1673, which enable you to view the GDP\$ (Gross Domestic Product in the National Income and Product Accounts) database to retrieve the GDP\$ time series. The sample SAS code for accessing the Moody's GDP\$ time series appears at the end of the section.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the `mylib` CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “[Introduction to Shared Concepts](#)” on page 54 in Chapter 4, “[Shared Concepts](#).” For more information about how to store your Moody’s data in a CAS table, see [Example 24.9](#) in this chapter.

Getting Started: SASEMOOD Interface Engine

You need a subscription to use Moody’s Analytics Data Buffet web service, and you must have the proper credentials to access this service. For more information, see “Using Data Buffet: Data Buffet API v1.0” (Thorne 2019b). After you log on, you will see your access key and encryption key in your account information at the following URL:

<https://www.economy.com/myeconomy/api-key-info>

For more information about getting started using Data Buffet, see “Using Data Buffet: Which Series Can You Download?” (Thorne 2019f).

The web page at the following URL describes how to use the Moody’s Analytics Data Buffet API (Moody’s Analytics 2019):

<https://github.com/moodysanalytics/databuffet.api.codesamples/blob/master/databuffet-api-userguide.pdf>

The statements at the end of this section enable you to access the mnemonic GDP\$.IUSA, which is described as “Gross domestic product, (Mil. Ch 2012 USD, SAAR) for United States.”

The MNEMONIC= option specifies the time series mnemonic code(s) that you need in order to retrieve the data from Moody’s Analytics Data Buffet. GDP\$.IUSA is the time series mnemonic code in the sample code shown at the end of this section.

The OUT= option specifies both the name of the resulting JSON file(s) and the name of the SAS data set.

The range of the retrieved data is determined by the START= and END= options. You specify the start and end dates in ‘YYYY-MM-DD’ format.

The JSON data that the Moody's Analytics Data Buffet website returns are placed in a file that is named by the OUT= option—in this case, *GDP1.json*. **NOTE:** The SASEMOOD engine appends a numeral to the JSON file name, and the file extension (.json) is excluded from the file name that appears in the OUT= option. When the SET statement is executed, the JSON data are read (and merged) into a SAS data set named GDP.sas7bdat, which resides in the location that is specified inside the string enclosed in double quotation marks in the LIBNAME statement.

The result is named in the DATA step in the SET statement and is shown in [Output 24.1](#).

For another example that uses more LIBNAME statement options, see the section “[Examples: SASEMOOD Interface Engine](#)” on page 1682.

```
options validvarname=any;

Syntax: SASEMOOD Interface Engine

The SASEMOOD interface engine uses standard engine syntax to read the observations or data values for one or more time series from Moody's Analytics Data Buffet.

Table 24.1 summarizes the options that the SASEMOOD engine uses.

Table 24.1 Summary of SASEMOOD Interface Engine Options

Option	Description
CASLIB=	Specifies the name of the CASLIB where the in-memory CAS table containing the MOODY's data is stored
CASOUT=	Specifies the name of the in-memory CAS table, which contains the data that the SASEMOOD interface engine returns
CONV=	Specifies the method to aggregate (or disaggregate) the frequency to
DEBUG=	Specifies whether to include diagnostic message logging in the SAS log window
END=	Specifies the end date of the retrieved data
FREQ=	Specifies the frequency to convert the time series to (if a conversion is necessary)
GOCAS=	Specifies whether to generate an in-memory CAS table for the Moody's data
MNEMONIC=	Specifies the required Moody's data set mnemonic code (concept code and geography code) that enables you to specify which data to select from Moody's Analytics Data Buffet
OUT=	Specifies the name of the SAS data set and the JSON file, which contains the data that the SASEMOOD interface engine returns
PASS=	Specifies the required Moody's encryption key that enables you to access Moody's Analytics Data Buffet
START=	Specifies the start date of the retrieved data
TRANS=	Specifies the transformation function to be applied to the selected data sets
USER=	Specifies the required Moody's access key to authenticate the request for the retrieved data

The LIBNAME libref SASEMOOD Statement

LIBNAME libref **SASEMOOD** '*physical-name*' options ;

The LIBNAME statement assigns a SAS library reference (libref) to the physical path of the directory where the SASEMOOD interface engine stores the Moody's data. The required *physical-name* argument specifies the final location of the folder where your Moody's data reside in a SAS data set named by the OUT= option. The *physical-name* should end with a backslash if you are in a Windows environment or a forward slash if you are in a UNIX environment.

You can specify the following *options*:

CASLIB=*mood_caslib_name*

specifies the name of the CAS library (caslib) where the in-memory CAS table is stored when the JSON data from Moody's Analytics Data Buffet are read into SAS. You can use this option to name your caslib where the in-memory CAS table is stored. The default for this option is the active caslib. The GOCAS=ON option is required when you specify the CASLIB= option.

CASOUT=*mood_castable_name***OUTCAS=***mood_castable_name*

specifies the name of the in-memory CAS table that is created when the JSON data from Moody's Analytics Data Buffet are read into SAS. You can use this option to name your in-memory CAS table. The default for this option is the same name that you specify in the OUT= option. The in-memory table is created only when you also specify the GOCAS=ON option.

CONV=CONSTANT | CUBIC | DISCRETE | LINEAR**CONVERSION=CONSTANT | CUBIC | DISCRETE | LINEAR**

specifies the technique to use to convert the native frequency to the desired frequency. You can specify the following values:

CONSTANT (or **0**) converts the native frequency to a cubic frequency.

CUBIC (or **2**) converts the native frequency to a constant frequency.

DISCRETE (or **3**) converts the native frequency to a discrete frequency.

LINEAR (or **1**) converts the native frequency to a linear frequency.

By default, CONV=CUBIC. For more about native frequency and frequency conversion, see "Using Data Buffet: The Convert Function" (Thorne 2019d).

For more information about frequency conversion, see "Using Data Buffet: How Frequency Conversion Works" (Zandi 2019) on the web page at the following URL:

<https://www.economy.com/support/blog/buffet.aspx?did=FE8BEE0D-53E5-4F6A-AF55-8A9E765DCE68>

DEBUG=ON | OFF

specifies whether or not to include diagnostic message logging in the SAS log window. This information can be useful for troubleshooting a problem.

END=*mood_endDate***ENDDATE=***mood_endDate***ENDATE=***mood_endDate***END_TIME=***mood_endDate***ENDTIME=***mood_endDate***OBSERVATION_END=***mood_endDate*

specifies the end date of the Moody's data that you request. Specify the *mood_endDate* in 'YYYY-MM-DD' format. The valid data range of available data varies with each Moody's data set.

FREQ=*mood_frequency***FREQUENCY**=*mood_frequency***INTERVAL**=*mood_frequency***PERIOD**=*mood_frequency*

specifies the desired frequency for the time series that are listed in the MNEMONIC= option. You can specify the *mood_frequency* as annual, quarterly, monthly, weekly, daily, and so on. Native is the default frequency when the FREQ= option is not specified. For more information about frequency conversion, see “Using Data Buffet: Caveats When Converting Low Frequencies” (Thorne 2019a). For a complete list of frequencies and their frequency codes, see [Table 24.2](#).

Table 24.2 Frequency Codes for Moody’s Analytics Data and the FREQ= Option

Interval or Frequency	Moody’s Frequency Code	Description
Yearly, year, annual, ann, anndec	204	Annual, year ending in December

Daily, day	49	Daily
Index	16	INDEX
Default	0	Native

GOCAS=ON | OFF

specifies whether to create (ON) or not create (OFF) an in-memory CAS table of the Moody's data (in addition to the SAS data set that is created). When GOCAS=ON, the SASEMOOD engine assumes that there is an active CAS session running when it executes the LIBNAME statement. By default, GOCAS=OFF.

MNEMONIC='mood_mnemonic_list'

ID='mood_mnemonic_list'

IDS='mood_mnemonic_list'

specifies the Moody's mnemonic code (or codes) that enables you to access the data set that corresponds to that code. Each mnemonic code consists of a concept code and a geography code, separated by a period (.). When you want more than one mnemonic code, specify the mnemonic codes in a list, separated by semicolons. There are too many codes to list here; you can view the catalog of the available list by visiting the web page at the following URL:

<https://www.economy.com/databuffet/>

OUT=mood_jsonfile

OUTJSON=mood_jsonfile

JSON=mood_jsonfile

specifies the name of both the JSON file (downloaded) and the SAS data set that is created when the JSON data are read into SAS. You can use the OUT= option to name your JSON data file. It is stored in the SAS Work library. The SAS data set that is created (when the JSON data are read into SAS) is stored in the folder specified by *physical-name*, and you can refer to it by using the myLib libref in your LIBNAME statement.

PASS='mood_password'

ENCRYPTKEY='mood_password'

specifies the unique PASS (password) encryption key that Moody's Analytics assigns to the user (subscriber) to provide security for accessing the Moody's Analytics Data Buffet online data.

USER='mood_user'

ACCESSKEYID='mood_user'

specifies the unique USER access key that Moody's Analytics assigns to the user (subscriber) to allow access to the Moody's Analytics Data Buffet API service.

START=mood_start

STARTDATE=mood_start

STDATE=mood_start

START_TIME=mood_start

STARTTIME=mood_start

BEGIN=mood_start

OBSERVATION_START=mood_start

specifies the start date for the Moody's data that you request. Specify the data in 'YYYY-MM-DD' format. The valid date range for available data varies with each Moody's data set.

TRANS=0 | 1 | 2 | 3 | 4 | 8

TRANSFORMATION=0 | 1 | 2 | 3 | 4 | 8

specifies the transformation function to be performed on the selected series. You can specify the following values:

0 indicates none.

1 indicates year-over-year percentage change.

2 indicates simple difference.

3 indicates annualized growth.

4 indicates percentage change.

8 indicates year-over-year difference.

By default, TRANS=0 (no transformation). For more information about Moody's transformations, see "Using Data Buffet: Transformations" (Thorne 2019e) at the following URL:

<https://www.economy.com/support/blog/buffet.aspx?did=783658E9-93DA-4F85-A206-9D14FC44904F>

Details: SASEMOOD Interface Engine

The SASEMOOD interface engine enables SAS users to access time series data that are stored in Moody's Analytics Data Buffet data sets. Each Moody's time series is identified by a unique mnemonic code. The mnemonic code consists of a concept code and a geography code. For more information about mnemonic codes, see "Using Data Buffet: Mnemonic, concept code and geo code" (Thorne 2019c) on the web page at the following URL:

<https://www.economy.com/support/blog/buffet.aspx?did=FC5702E3-32B7-4068-AC3B-5D18D3400416>

SAS Output Data Set

You can use a SAS DATA step to write the selected Moody's time series data to a SAS data set. This enables you to use SAS software to easily analyze the data. If you specify the name of the output data set in the DATA statement, the SAS engine supervisor creates a SAS data set that has the specified name in the location specified by the SASEMOOD engine libref's *physical-name*.

The contents of the SAS data set include the date of each observation and the name of each time series that is read from the Moody's website.

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure with your SASEMOOD engine libref to create a custom view of your data.

Because each SASEMOOD engine libref results in retrieving the requested data from the Moody's Analytics Data Buffet website, it is best to use a DATA step to store the data. You should avoid the inefficient use of the SASEMOOD engine libref that follows:

```
proc print data=moody.GDP; run;
```

Here the member name, GDP, is used in the PROC PRINT statement that invokes the Moody libref to run the SASEMOOD engine. It is more efficient to refer to the SAS data set myGDP repeatedly than to invoke the interface engine repeatedly. This use of the member name, GDP, corresponds to specifying the OUT=GDP option. Although using this statement might seem easier, it is not as efficient, because every time you use the SASEMOOD engine libref, the SASEMOOD engine reads the entire JSON file into SAS again.

Examples: SASEMOOD Interface Engine

Example 24.1: Retrieving Consumer Price Index Data from Moody's Analytics Data Buffet

This example requests Consumer Price Index data (all items, total for United States) from the OECD Main Economic Indicators database. The MNEMONIC= option specifies the Moody's data to retrieve, which in this example is OCMCPALTT01IXOBAM.IUSA. The FREQ= option requests monthly data. The range is specified using the START= and END= options. The OUTJSON= option names the JSON file and the SAS output data set that contains the time series data from the downloaded JSON file. The CONV= option specifies cubic conversion to the desired frequency. The SAS system option VALIDVARNAME=ANY allows for the special character '.' in the mnemonic code; the same mnemonic code is used to name the SAS variable's series name in the SAS output data set.

The SAS code is shown after the next paragraph, and it is followed by the output, shown in [Output 24.1.1](#), for the selected date range.

The SET statement reads observations from the input data set Moody.monCPI, and the DATA step stores them in a SAS data set named myMONCPI. When all the data are retrieved, they are placed in a SAS data set that is named by the OUT= option and that is located in the folder specified by the *physical-name* in the LIBNAME statement.

```
options validvarname=any;

title 'Request Consumer Price Index (Total - All Items - Index 2015-100)';
LIBNAME moody sasemood "%sysget(MOOD_DATA)"
    mnemonic="OCMCPALTT01IXOBAM.IUSA"
    user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
    pass='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
    freq=monthly
    conv=2
    outjson=moncpi
    start='2017-01-01'
    end='2018-05-01'
    format=json;

data myMONCPI;
    set moody.moncpi;
run;

proc print data=myMONCPI; run;
```

Example 24.2: Retrieving Quarterly Gross Domestic Product Data by Industry from the Bureau of Economic Analysis (BEA)

This example shows how to retrieve gross domestic product data by industry, starting in the second quarter of 2016 and ending in the third quarter of 2018. The output, which is shown in [Output 24.2.1](#), contains two variables, Date and PDPGPOD1Q.IUSA. The SAS system option VALIDVARNAME=ANY allows for the special character ‘.’ in the mnemonic code; the same mnemonic code is used to name the SAS variable’s series name in the SAS output data set.

The MNEMONIC= option specifies the Moody’s time series data to retrieve, which in this example is PDPGPOD1Q.IUSA. The FREQ= option selects the quarterly frequency, and the START= and END= options define the date range of the retrieved data.

```
options validvarname=any;

Example 24.5: Retrieving GDP by Industry: Chain-Type Price Index for Value Added for the United States

This example shows how to retrieve multiple time series for GDP by industry—utilities, manufacturing, finance, and all industries—starting January 1, 2016, and ending June 1, 2018. The MNEMONIC= option specifies the Moody's data to retrieve. This example lists four mnemonic codes, separated by semicolons. The FREQ= option specifies quarterly data intervals, and the START= and END= options define the date range of the data. The output is shown in [Output 24.5.1](#), which contains five variables: Date, PDPGPOD1Q.IUSA, PDPGPO22D1Q.IUSA, PDPGPOMFD1Q.IUSA, and PDPGPOFID1Q.IUSA. The SAS system option VALIDVARNAME=ANY allows for the special character '.' in the mnemonic name list; this list is used to name the SAS variables (time series) in the SAS output data set.

```
options validvarname=any;

title 'Request Gross Domestic Product by Industry for Multiple Time Series';
LIBNAME moody sasemood "%sysget(MOOD_DATA)"
  mnemonic="PDPGPOD1Q.IUSA;PDPGPO22D1Q.IUSA;PDPGPOMFD1Q.IUSA;PDPGPOFID1Q.IUSA"
  user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'

Example 24.6: Retrieving Unemployment Rate Data for the United States

This example shows how to retrieve unemployment rate data for United States (total), starting in January 1973 and ending in January 2019. The output is shown in [Output 24.6.1](#). The MNEMONIC= option specifies the Moody's data set to retrieve the data from; its mnemonic code is LBR.IUSA. The SAS system option VALIDVARNAME=ANY allows for the special character '.' in the mnemonic code; the same mnemonic code is used to name the SAS variable's series name in the SAS output data set. The START= and END= options define the date range. Although the native frequency of this series is monthly, the request is for an annual frequency, using the cubic conversion in the CONV= option.

```
options validvarname=any;

title 'Request Unemployment Data, Annual Frequency Using Cubic Conversion';
LIBNAME moody sasemood "%sysget(MOOD_DATA) "
    mnemonic="LBR.IUSA"
    user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
    pass='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
    freq=annual      /* Convert from monthly to annual frequency */
    conv=cubic
    outjson=labor
    start='1973-01-01'
    end='2019-01-01'
    format=json
    ;

data myLabor;
    set moody.labor;
run;

proc print data=work.myLabor; run;
```

Example 24.8: Retrieving Unemployment Data and Household Debt to Personal Disposable Income Ratio for the United States

This example shows how to retrieve unemployment data and household debt data for the United States, starting in January 2009 and ending in January 2019. The `FREQ=` option specifies quarterly frequency conversion, using the cubic conversion in the `CONV=` option.

The output is shown in [Output 24.8.1](#). The `MNEMONIC=` option specifies the Moody's data sets to retrieve the data from; their mnemonic codes are `LBR.IUSA` and `DM%CHHDPIAQ.IUSA`. The SAS system option `VALIDVARNAME=ANY` allows for the special character '.' in the mnemonic code; the same mnemonic code is used to name the SAS variable's series name in the SAS output data set. The `START=` and `END=` options define the date range.

```
options validvarname=any;

title 'Request Unemployment Data and Household Debt to Personal Disposable Income Ratio';
LIBNAME moody sasemood "%sysget(MOOD_DATA) "
  mnemonic="LBR.IUSA;DM%CHHDPIAQ.IUSA"
  user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
  pass='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
  freq=quarterly
  conv=2
  outjson=labdebt
  start='2009-01-01'
  end='2019-01-01'
  format=json
  ;

data myLabD;
  set moody.labdebt;
run;

proc print data=work.myLabD; run;
```

Output 24.8.1 US Unemployment Data and Household Debt to Personal Disposable Income Ratio

Request Unemployment Data and Household Debt to Personal Disposable Income Ratio

Example 24.9: Retrieving National Income and Product Account Data

This example shows how to retrieve the National Income and Product Account (NIPA) data for two time series—exports of goods data and NIPA exports of goods and services data—starting January 1, 2017, and ending December 1, 2017. The data are quarterly, because each mnemonic code ends in “Q.IUSA”.

The output is shown in [Output 24.9.1](#). The MNEMONIC= option specifies the Moody’s data sets to retrieve the data from; their mnemonic codes are NCU18_B020RCQ.IUSA and NCU18_A253RCQ.IUSA. The SAS system option VALIDVARNAME=ANY allows for the special character ‘.’ in the mnemonic code; the same mnemonic code is used to name the SAS variable’s series name in the SAS output data set. The START= and END= options define the date range. The GOCAS=ON option specifies the data to be stored in a CAS in-memory table, which is named M2MNIPA in the CASOUT= option. The CASLIB= option specifies the CAS library name where the in-memory table, M2MNIPA, is stored.

```
options validvarname=any;

title 'Request NIPA Data';
LIBNAME moody sasemood "%sysget(MOOD_DATA) "
  gocas=on
  caslib=casuserhdfs /* CAS library for MOODY's data */
  mnemonic="NCU18_B020RCQ.IUSA;NCU18_A253RCQ.IUSA"
  user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
  pass='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
  freq=0
  conv=2
  outjson=YNIPA /* SAS data set name for the incoming NIPA data */
  casout=M2MNIPA /* in-memory CAS table name for requested NIPA data */
  start='2017-01-01'
  end='2017-12-01'
  format=json
;

data myYNIPA;
  set moody.ynipa;
run;

proc print data=work.myYNIPA; run;
```

Output 24.9.1 US Exports of Goods and Exports of Goods and Services

Request NIPA Data

Obs	date	NCU18_B020RCQ.IUSA	NCU18_A253RCQ.IUSA
1	2017-03-31	2303282	1503009
2	2017-06-30	2313183	1508669
3	2017-09-30	2360093	1535383
4	2017-12-31	2450348	1606363

In the preceding code, you can reference the in-memory CAS table, M2MNIPA, later in the same CAS session to save the data in a SASHDAT file, but do not specify the SASHDAT extension in the file name:

```
proc casutil;
    save casdata="M2MNIPA" casout="<physical path and filename>" replace;
quit;
```

To list the tables in the active caslib, specify the following statements:

```
proc casutil; list; quit;
```

Overview: SASEUSCB Interface Engine

The SASEUSCB interface engine enables SAS users to retrieve economic data from the United States Census Bureau (USCB) website (www.census.gov), which is hosted by the principal agency in the US Department of Commerce that measures demographic, economic, and population data. The economic time series on the USCB website contain observation or measurement periods that are associated with data values.

The SASEUSCB interface engine uses the LIBNAME statement to enable you to specify how to subset your USCB data and select data according to their frequency and range. You can then use a SAS DATA step to perform further subsetting, retrieve the data, and store the resulting time series in a SAS data set and in a CAS data table (if desired).

The SASEUSCB interface engine supports 64-bit Windows and Linux X64 (LAX) platforms.

Note that the SASEUSCB engine uses the US Census Bureau API, but it is not endorsed or certified by the US Census Bureau, and that by using the SASEUSCB interface, you are agreeing to comply with the USCB terms of use. They are found on the web page at the following URL: <https://www.census.gov/data/developers/about/terms-of-service.html>.

To get started using the SASEUSCB engine, see the section “Getting Started: SASEUSCB Interface Engine” on page 1699, which shows how to view the time series data. The sample SAS code for accessing these data appears at the end of that section.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);  
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;  
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the `mylib` CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the `CASHOST` and `CASPORT` of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the `TERMINATE` option in the `CAS` statement as follows:

```
cas mysess terminate;
```

For more information about the `CAS` statement and the `LIBNAME` statement, see *SAS Cloud Analytic Services: User's Guide*. For general information about `CAS` and `CAS` sessions, see *SAS Cloud Analytic Services: Fundamentals*.

Getting Started: SASEUSCB Interface Engine

You can query the US Census Bureau (USCB) databases to retrieve the observations or data values for a list of economic time series by specifying the series ID of each time series that you want to read into SAS and by specifying your unique USCB API key. To obtain your own unique API key, start by visiting the USCB website:

<https://www.census.gov/data/developers.html>

Then click on the **Request a Key** box at the lower left of that page. Alternatively, you can go directly to the following site:

https://api.census.gov/data/key_signup.html

The USCB API key is a 40-character alphanumeric lowercase string, such as 'abcdefghijklmnopqrstuvwxyz12345612345678', and is represented by 'XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX' in the `USER=` option in the following example. In addition, the example URLs in this section and in the section “[Details: SASEUSCB Interface Engine](#)” on page 1706 use the same USCB API key as the argument `your_uscb_apikey`.

Now that you are informed about the terms of service of the USCB data, you can use your USCB API registration key to access the USCB data, as shown in the example that follows.

The following statements enable you to access monthly time series from the EITS (Economic Indicator Time Series) ADVDM3 (Advanced Report on Durable Goods) database. The time series for defense aircraft and parts (`CATEGORY=DAP`) that are selected from the time period starting September 2012 (`STARTDATE='2012-09'`) and ending April 2013 (`ENDDATE='2013-04'`) are retrieved by using the following SAS DATA step and shown in [Figure 25.1](#):

```
options validvarname=any;

title 'Retrieve Monthly Data from EITS ADVDM3 (Advanced Report on Durable Goods)';
libname _all_ clear;

libname uscb saseuscb "%sysget(USCB) "
    user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
    setname=eits_advdm3
    for='us:*'
    category=DAP
    startdate='2012-09'
    enddate='2013-04'
```

```

outjson=ADVM3
format=json;

data my_gsa;
  set uscb.ADVM3 ;
run;

proc contents data=my_gsa; run;
proc print data=my_gsa; run;

```

Figure 25.1 Advanced Report on Durable Goods Time Series: my_gsa

8	3629	12861	73980	4196

The JSON data that the USCB website returns are placed in a file that is named by the OUTJSON= option—in this case, *ADVM3.json*. Note that the JSON file extension is excluded from the file name that is specified in the OUTJSON= option. When the SET statement is executed, the JSON data are read into a SAS data set named *ADVM3.sas7bdat*, which resides in the location that is specified inside the string enclosed in double quotation marks in the SASEUSCB LIBNAME statement. So, in the preceding example, if the USCB environment variable is set to */sasusr/uscb/test/*, then the SAS data set that is created by reading the downloaded JSON file is placed in the following file: */sasusr/uscb/test/ADVM3.sas7bdat*.

An equivalent LIBNAME statement that does not use any environment variables could be as follows:

```
libname uscb saseuscb "/sasusr/uscb/test/"
  user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
  setname=eits_advm3
  for='us:*'
  category=DAP
  startdate='2012-09'
  enddate='2013-04'
  outjson=ADVM3
  format=json;
```

You could also use either a SAS macro variable or a system environment variable to store the value of your USCB API registration key so that the key does not appear explicitly in your SAS code. The SETNAME= option names the USCB data set that you are retrieving data from.

The result, MY_GSA, is named in the DATA step and shown in [Figure 25.1](#). It is more efficient to use the DATA step to store your USCB data in a SAS data set and then refer to the SAS data set directly in your PROC PRINT or PROC SGLOT statement, but you can also refer to the SASEUSCB libref directly, as in the following statement:

```
proc print data=uscb.ADVM3; run;
```

The PROC PRINT statement uses the member name, ADVM3; this usage corresponds to specifying the OUTJSON=ADVM3 option. Although using this statement might seem easier, it is not as efficient, because every time you use the SASEUSCB libref, the USCB interface engine reads the entire JSON file into SAS again. It is better to refer to the SAS data set repeatedly than to invoke the interface engine repeatedly. For another example that uses more SASEUSCB LIBNAME statement options, see the section “[Details: SASEUSCB Interface Engine](#)” on page 1706.

The variable name for each ADVM3 time series is made up of three parts, separated by underscores ('_'): the category code, the data type code, and an 'S' for seasonal data or a 'U' for nonseasonal data. See [Table 25.7](#) and [Table 25.8](#) for the complete list of categories and data type codes, respectively, in the ADVM3 data set.

Syntax: SASEUSCB Interface Engine

The SASEUSCB interface engine uses standard engine syntax to read the observations or data values for one or more economic time series. [Table 25.1](#) summarizes the options that the interface engine uses. Two options are required: USER='uscb_apikey' and SETNAME='uscb_input_dataset_name'.

Table 25.1 Summary of LIBNAME libref SASEUSCB Options

Option	Description
CASLIB=	Specifies the name of the caslib where the in-memory CAS table containing the USCB data is stored
CASOUT=	Specifies the name of the in-memory CAS table, which contains the data that the SASEUSCB interface engine retrieves
CATEGORY=	Specifies the name of a category which is used to keep or select the desired variables based on their category

Table 25.1 *continued*

Option	Description
CONNECT=	Specifies whether or not to use the connect method for a secure connection via a proxy server. You must specify the PROXY= option when you use the CONNECT=ON option.
DATATYPE=	Specifies the name of the data type of the variables to keep
DEBUG=	Specifies whether or not to use diagnostic message logging in the SAS log window
ENDDATE=	Specifies the ending date for the observation period
FOR=	Specifies the demographic category that you want to retrieve data for
FORMAT=	Specifies a file extension that indicates the type of file to retrieve. Only the JSON format is supported.
GEO=	Specifies the geographic region (or geo-level) of the data that you want to retrieve: ‘US’ for United States, ‘NE’ for Northeast, ‘MW’ for Midwest, ‘SO’ for South, ‘WE’ for West. For US states, some data sets let you use the standard two-letter postal codes, such as AL for Alabama. For the complete list of geo-level codes, see Table 25.2 .
GOCAS=	Specifies whether to generate an in-memory CAS table for the USCB data
OUTJSON=	Specifies the name of the output SAS data set and the JSON file for the retrieved data
PROXY=	Specifies the proxy server that you want to use (if you have trouble connecting without specifying a proxy). If you also need the connect method for a secure connection, specify the CONNECT=ON option in addition to the PROXY= option. (See the CONNECT= option.)
SETNAME=	Specifies the name of the data set that you want to access; see Table 25.3 .
STARTDATE=	Specifies the starting date for the observation period
USER=	Specifies the required USCB registration key that enables you to access data on the USCB website

The LIBNAME *libref* SASEUSCB Statement

LIBNAME *libref* **SASEUSCB** '*physical-name*' *options* ;

The LIBNAME statement assigns a SAS library reference (*libref*) to the physical path of the directory where the SASEUSCB interface engine stores the USCB economic data. The required *physical-name* argument specifies the final location of the folder where your USCB data reside in a SAS data set that is named in the OUT= option. The *physical-name* should end with a backslash (for example, C:*physical_name*\) when you are in a Windows environment or a forward slash (for example, /*user/physical_name*/) when you are in a UNIX environment.

You can specify the following *options*:

CASLIB=*uscb_caslib_name*

specifies the name of the CAS library (caslib) where the in-memory CAS table is stored when the JSON data from the USCB website are read into SAS. The default value is the name of the active caslib. When you specify this option, you must also specify the GOCAS=ON option.

CASOUT=*libref.data-table***OUTCAS=***libref.data-table*

specifies the name of the in-memory CAS table that is created when the JSON data from USCB are read into SAS. The default value is the name that you specify in the OUT= option. The in-memory table is created only when you also specify the GOCAS=ON option. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section “Using CAS Sessions and CAS Engine Librefs” on page 1698.

CATEGORY=*uscb_category_code*

specifies the category of time series variables to keep. All categories are kept when the CATEGORY= option is omitted. See Table 25.6 for more information about categories.

CONNECT=ON | OFF

specifies whether to use (ON) or not use (OFF) the connect method along with the PROXY= option. **NOTE:** To use the connect method, you must use the PROXY= option and specify your proxy server in addition to the CONNECT=ON option. For more information about a secure connection, see the PROXY= option.

DATATYPE=*uscb_datatype_code*

specifies the data type of time series variables to keep. All data types are kept when the DATATYPE= option is omitted. See Table 25.6 for more information about data types.

DEBUG=ON | OFF

specifies whether or not to include diagnostic message logging in the SAS log window. This information can be useful for troubleshooting. Specify DEBUG=ON to see all the log messages (including debugging information) in the SAS log. By default, DEBUG=OFF.

ENDDATE=*'uscb_enddate'*

specifies the ending year of the time series in the format 'YYYY', the ending quarter and year for quarterly data in the format 'YYYY-Qx' (where x = 1, 2, 3, or 4), or the ending month and year for monthly data in the format 'YYYY-nn' (where nn = 01, 02, ..., 10, 11, or 12).

FOR=*uscb_for_param*

specifies the demographic category that you want to retrieve data for. The Advanced Report on Durable Goods, Manufacturers' Shipments, Inventories, and Orders (ADVM3) data set, which is the only data set supported in this release, requires this option. By

default, FOR=US (United States).

See the following web page for more information: <https://www.census.gov/data/developers/guidance/api-user-guide/core-concepts.html>.

FORMAT=uscb_jsonformat

specifies the format of the file to be retrieved from the USCB website. Although USCB can report data in many formats, the SASEUSCB engine supports only the JSON format (the default).

GEO='uscb_geo_level'

specifies the geographic region (or geo-level) that you want to retrieve data for. See [Table 25.2](#) for a complete list of geo-level codes, which identify the regions. By default, GEO=US (United States Total). Note that geo-level codes for US states are usually the same as the standard two-letter postal codes, such as AL for Alabama.

GOCAS=ON | OFF

specifies whether to create (ON) or not create (OFF) an in-memory CAS table of the USCB data (in addition to the SAS data set that is created). When GOCAS=ON, the SASEUSCB engine assumes that there is an active CAS session running when it executes the LIBNAME statement. By default, GOCAS=OFF.

OUTJSON=uscb_json_file_name

specifies the name of the JSON file (which is downloaded to the SAS Work library) and the name of the SAS data set that is created when the JSON data are read into SAS. The SAS data set is stored in the folder that is specified by *physical-name*.

PROXY='uscb_proxyserver'

specifies which proxy server to use. This option is not required. The specified proxy server is used only when a connection-refused or connection-timed-out error occurs. For *uscb_proxyserver*, specify the server's HTTP address, followed by a colon and the port number, and enclose that string in double quotation marks; for example, PROXY="http://inetgw.unx.sas.com:8118". (See also the [CONNECT=](#) option.)

SETNAME=uscb_setname**DATASETNAME=uscb_setname****DATASET=uscb_setname****SETID=uscb_setname**

specifies the name of the USCB data set to retrieve data from. [Table 25.3](#) shows the list of available USCB data sets. **NOTE:** This version of the SASEUSCB interface engine supports only the data set that is shown in the first row of [Table 25.3](#) (EITS_ADVM3).

STARTDATE='uscb_startdate'

specifies the starting date of the time series in the format 'YYYY', the ending quarter and year for quarterly data in the format 'YYYY-Qx' (where x = 1, 2, 3, or 4), or the ending month and year for monthly data in the format 'YYYY-nn' (where nn = 01, 02, ..., 10, 11, or 12).

USER='uscb_user'**APIKEY='uscb_user'****REGISTRATIONKEY='uscb_user'**

specifies the unique user registration key, enclosed in quotation marks, that the USCB assigns to the user (subscriber) to allow access to the data on the USCB website. The USCB access key is a 40-character alphanumeric lowercase string that you can request. To obtain your own unique API key, visit the USCB website at the following URL: <https://www.census.gov/data/developers.html>. Then click on the **Request a Key** box at the lower left of that page. Alternatively, you can go directly to the following site: https://api.census.gov/data/key_signup.html.

Table 25.2 USCB Geo-level Region Codes

Geo-level Code	Description	Geo-level Code	Description
US	United States Total	MO	Missouri
NO	Northeast	MT	Montana

Details: SASEUSCB Interface Engine

The SASEUSCB interface engine enables you to access time series data from the USCB data sets shown in Table 25.3. To specify a USCB data set, use one of the supported data set names that are listed in the table.

NOTE: This version of the SASEUSCB engine supports only the ADVDM3 data set, the BFS data set, and the FTD data set. The Advance Report on Durable Goods, Manufacturers' Shipments, Inventories, and Orders (ADVDM3) data set is listed in the first row of the table. The Business Formation Statistics (BFS) data set is listed in the fourth row of the table. The International Trade in Goods and Services (FTD) data set is listed in the fifth row of the table.

To access the data set (the data set name is EITS_ADVM3), specify SETNAME=<data set name>, as shown in the SASEUSCB LIBNAME statement in the section “Getting Started: SASEUSCB Interface Engine” on page 1699.

Table 25.3 USCB Data Sets

Data Set	Starting Date	Long Name
EITS_ADVM3	1992	Advance Report on Durable Goods, Manufacturers' Shipments, Inventories, and Orders
EITS_ADVMRTS	1992	Advance Retail Inventories
EITS_ADVMWTS	1992	Advance Wholesale Inventories
EITS_BFS	2004	Business Formation Statistics
EITS_FTD	1992	International Trade in Goods and Services
EITS_HV	1956	Housing Vacancies and Homeownership
EITS_M3	1992	Manufacturers' Shipments, Inventories, and Orders
EITS_MARTS	1992	Advance Monthly Sales for Retail and Food Service
EITS_MHS	1959	Manufactured Homes Survey
EITS_MHS2	1959	Manufactured Housing Survey
EITS_MRTS	1992	Monthly Retail Trade and Food Services
EITS_MTIS	1992	Manufacturing and Trade Inventories and Services
EITS_MWTS	1992	Monthly Wholesale Trade: Sales and Inventories
EITS_QFR	2000	Quarterly Financial Report Survey
EITS_QPR	1968	Quarterly Survey of Public Pensions
EITS_QSS	2003	Quarterly Services Survey
EITS_QTAX	1992	Quarterly Summary of State and Local Taxes
EITS_RESCONST	1959	New Residential Construction
EITS_RESSALES	1963	New Home Sales
EITS_VIP	2002	Construction Spending

Data Elements Reference: SASEUSCB Interface Engine

Table 25.4 gives useful information about the supported data set: reporting frequency and allowed parameter values for required options. The default geo-level code, which identifies the geographic region that the data apply to, is US (United States Total). **NOTE:** This version of the SASEUSCB engine supports only the ADVM3 data set, the BFS data set, and the FTD data set.

Table 25.4 Supported USCB Data Sets

Data Set	Reporting Frequency	Required Options
ADVM3	Monthly	FOR=US; START= and END= <YYYYnn>
BFS	Quarterly	FOR=US; START= and END= <YYYYQn>
FTD	Monthly	START= and END= <YYYYnn>

Table 25.5 shows where you can find a summary of USCB data set details. To obtain a list of the queries that you can use for a data set, see the tables for that data set in the second column. Each USCB data set has its own list of allowed queries.

Table 25.5 USCB Data Set Details

Data Set	Where to Find Details for Specifying Options
ADVM3	Table 25.7 and Table 25.8
BFS	Table 25.9 , Table 25.10 , and Table 25.11
FTD	Table 25.12 and Table 25.13

The CATEGORY=, DATATYPE=, and GEO= options enable you to select the data to keep in your SAS output data set. Table 25.6 shows the available options for the supported data set and where to find the allowed values for each option. The GEO= option is not allowed for the ADVM3 data set or the FTD data set. **NOTE:** This version of the SASEUSCB engine supports only the ADVM3 data set, the BFS data set, and the FTD data set.

Table 25.6 Values for USCB Data Set Options

Data Set	Option	Option Value Table
ADVM3	CATEGORY=	Table 25.7
	DATATYPE=	Table 25.8
BFS	CATEGORY=	Table 25.9
	DATATYPE=	Table 25.10
	GEO=	Table 25.11
FTD	CATEGORY=	Table 25.12
	DATATYPE=	Table 25.13

ADVM3 Data Set: Advance Report on Durable Goods, Manufacturers' Shipments, Inventories, and Orders

Table 25.7 lists the codes for the supported categories in the ADVM3 data set and the description of each category.

Table 25.7 ADVM3 Data Set Categories

Category Code	Description
MDM	Durable Goods
DXT	Durable Goods Excluding Transportation
DXD	Durable Goods Excluding Defense
MTU	Manufacturing with Unfilled Orders
31S	Primary Metals
32S	Fabricated Metal Products
33S	Machinery
34S	Computers and Electronic Products
CRP	Computers and Related Products
34X	Communications Equipment
35S	Electrical Equipment, Appliances, and Components
36S	Transportation Equipment
MVP	Motor Vehicles and Parts
NAP	Nondefense Aircraft and Parts
DAP	Defense Aircraft and Parts
ODG	All Other Durable Goods
TCG	Capital Goods
NDE	Nondefense Capital Goods
NXA	Nondefense Capital Goods Excluding Aircraft
DEF	Defense Capital Goods

Table 25.8 lists the codes for the supported data types in the ADVM3 data set and the description of each data type. The description includes the unit of measurement in millions of dollars (MLN\$) or percentage change monthly (PCT).

Table 25.8 ADVM3 Data Set Data Types

Data Type Code	Description
VS	Value of Shipments (MLN\$)
NO	New Orders (MLN\$)
UO	Unfilled Orders (MLN\$)
TI	Total Inventories (MLN\$)
MPCVS	Value of Shipments Percent Change Monthly (PCT)
MPCNO	New Orders Percent Change Monthly (PCT)
MPCUO	Unfilled Orders Percent Change Monthly (PCT)
MPCTI	Total Inventories Percent Change Monthly (PCT)

BFS Data Set: Business Formation Statistics

Table 25.9 lists the codes for the supported categories in the BFS data set and the description of each category.

Table 25.9 BFS Data Set Categories

Category Code	Description
TOTAL	Total for All NAICS
NAICS11	Agriculture
NAICS21	Mining
NAICS22	Utilities
NAICS23	Construction
NAICSMNF	Manufacturing
NAICS42	Wholesale Trade
NAICSRET	Retail Trade
NAICSTW	Transportation and Warehousing
NAICS51	Information
NAICS52	Finance and Insurance
NAICS53	Real Estate
NAICS54	Professional Services
NAICS55	Management of Companies
NAICS56	Administrative and Support
NAICS61	Educational Services
NAICS62	Health Care and Social Assistance
NAICS71	Arts and Entertainment
NAICS72	Accommodation and Food Services
NAICS81	Other Services
NAICS92	Public Administration
NONAICS	No NAICS Assigned

Table 25.10 lists the codes for the supported data types in the BFS data set and the description of each data type. The description includes the unit of measurement in number of units (UNITS).

Table 25.10 BFS Data Set Data Types

Data Type Code	Description
BA_BA	Business Applications (UNITS)
BA_CBA	Business Applications from Corporations (UNITS)
BA_HBA	High-Propensity Business Applications (UNITS)
BA_WBA	Business Applications with Planned Wages (UNITS)
BF_BF4Q	Business Formations within Four Quarters (UNITS)
BF_BF8Q	Business Formations within Eight Quarters (UNITS)
BF_PBF4Q	Projected Business Formations within Four Quarters (UNITS)
BF_PBF8Q	Projected Business Formations within Eight Quarters (UNITS)
BF_SBF4Q	Spliced Business Formations within Four Quarters (UNITS)
BF_SBF8Q	Spliced Business Formations within Eight Quarters (UNITS)

Table 25.10 *continued*

Data Type Code	Description
BF_DUR4Q	Average Duration (in Quarters) from Business Application to Formation within Four Quarters (UNITS)
BF_DUR8Q	Average Duration (in Quarters) from Business Application to Formation within Eight Quarters (UNITS)

Table 25.11 lists the supported geographic regions (using geo-level codes) for the BFS data set and the description of each region. Note that for states, the geo-level codes are the same as the standard two-letter postal codes, such as AL for Alabama.

Table 25.11 BFS Data Set Geo-level Codes

Geo-level Code	Description	Geo-level Code	Description
US	United States Total	MN	Minnesota
*	All Geographies	MS	Mississippi
NO	Northeast	MO	Missouri
MW	Midwest	MT	Montana
SO	South	NE	Nebraska
WE	West	NV	Nevada
AK	Alaska	NH	New Hampshire
AL	Alabama	NJ	New Jersey

MI	Michigan		

FTD Data Set: International Trade in Goods and Services

Table 25.12 lists the codes for the supported categories in the FTD data set and the description of each category.

Table 25.12 FTD Data Set Categories

Category Code	Description
BOPG	Balance of Payment, Goods
BOPGS	Balance of Payment, Goods and Services

Table 25.13 lists the codes for the supported data types in the FTD data set and the description of each data type. The description includes the unit of measurement in millions of dollars (MLN\$).

Table 25.13 FTD Data Set Data Types

Data Type Code	Description
BAL	Balance (MLN\$)
EXP	Exports (MLN\$)
IMP	Imports (MLN\$)

SAS Output Data Set

You can use the SAS DATA step to write the selected USCB data to a SAS data set. This enables you to use SAS software to easily analyze the data. If you specify the name of the output data set in the DATA statement, the engine supervisor creates a SAS data set that has the specified name in either the SAS Work library or, if specified, the SAS User library. The SASEUSCB engine also keeps a copy of the output data set in the location that is specified by the *physical-name* in the LIBNAME *libref* SASEUSCB statement, which is described in the section “[The LIBNAME libref SASEUSCB Statement](#)” on page 1702.

The contents of the SAS data set include the date of each observation and the name of each series that is read from the USCB data source. The series names for each Economic Indicator Time Series (EITS) data set are made up of four parts, separated by underscores (‘_’): the category code, the data type code, the geo-level code, and an ‘S’ for seasonal data or a ‘U’ for nonseasonal data. When there is only one geo-level code, the series name might not include the geo-level code in the series name. The default geographic region for a time series name that does not include the geo-level code is the United States. For example, NXA_TI_S is a series name that has the following meaning: a seasonal time series in the category NXA, with the data type TI, for the United States. (See [Table 25.7](#) and [Table 25.8](#) for a list of the currently supported USCB data set’s categories and data types.)

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the chosen output data set in a SAS Explorer window. You can also use the SQL procedure with your SASEUSCB libref to create a custom view of the data.

SAS OUTJSON File

The SAS JSON data (in JSON format) that the USCB website retrieves are placed in a file that you name in the OUTJSON= option. The SAS JSON data file is placed in the SAS Work directory. But the SAS data set that is created by reading the JSON data into SAS is placed in the location that is specified by the *physical-name* in the LIBNAME *libref* SASEUSCB statement, which is described in the section “Data Elements Reference: SASEUSCB Interface Engine” on page 1707.

Examples: SASEUSCB Interface Engine

Example 25.1: Retrieving (ADVM3) Data for Category MDM (Durable Goods)

This example shows how to retrieve data from the Advance Report on Durable Goods Manufacturers’ Shipments, Inventories, and Orders data set from the US Census Bureau website. You can view these data at the following web page:

[https://www.census.gov/econ/currentdata/dbsearch?programCode=M3ADV&startYear=2020&endYear=2022&categories\[\]=MDM&dataType=NO&geoLevel=US&adjusted=1¬Adjusted=1&errorData=0](https://www.census.gov/econ/currentdata/dbsearch?programCode=M3ADV&startYear=2020&endYear=2022&categories[]=MDM&dataType=NO&geoLevel=US&adjusted=1¬Adjusted=1&errorData=0)

The following SASEUSCB LIBNAME statement specifies the libref (USCB), followed by the engine name (SASEUSCB) and the physical path where the retrieved USCB data are to be stored. The SETNAME= option specifies the name of the data set to retrieve data from. In this example, SETNAME=EITS_ADVM3 retrieves data from the Advance Report on Durable Goods Manufacturers’ Shipments, Inventories, and Orders data set. The CATEGORY=MDM option selects the time series for the durable goods category (MDM). See Table 25.7 for a list of available categories and Table 25.8 for a list of available data types in this data set. Each Census Bureau data set has its own specific list of categories and data types to choose from. If the CATEGORY= option is omitted, then all the categories of data are selected for retrieval. The USER= option specifies your unique USCB API key. Without a user API key (which you can obtain free of charge), you cannot retrieve data from the US Census Bureau. The OUTJSON= option names the file where the JSON data are stored. The output data set is created by using the OUTJSON= option and placed in the folder that you specify in the SASEUSCB LIBNAME statement. The date range of the data starts with 2004-09, as specified by the STARTDATE= option. The ENDDATE= option specifies the last period (2005-04) to include in the range of data to retrieve. The FORMAT= option specifies that the data are to be retrieved in the JSON format. Output 25.1.1 shows the data that are retrieved; only the time series in the durable goods category (MDM) are shown.

```
options validvarname=any;

title 'Retrieve ADVM3 Advance Report for Durable Goods Category Statistics';
libname uscb saseuscb "%sysget(USCB)"
    user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
    setname=EITS_ADVM3
    for='US:*'
    category=MDM
```

```

outjson=uscbex01
startdate='2004-09'
enddate='2005-04'
format=json;

data myAM3;
  set uscb.uscbex01;
run;

proc contents data=myAM3; run;
proc print data=myAM3; run;

```

Output 25.1.1 Durable Goods (CATEGORY=MDM) in the ADVM3 Economic Indicators Data Set

Retrieve ADVM3 Advance Report for Durable Goods Category Statistics

Example 25.2: Retrieving Business Formation Statistics (BFS) Data for Business Applications (BA_BA) Data Type

This example shows how to retrieve Business Formation Statistics (BFS) data from the US Census Bureau website. You can view these data at the following web page:

https://www.census.gov/econ/currentdata/dbsearch?program=BFS&startYear=2004&endYear=2022&categories=TOTAL&dataType=BA_BA&geoLevel=US&adjusted=1¬Adjusted=1&errorData=0

The following SASEUSCB LIBNAME statement specifies the libref (USCB), followed by the engine name (SASEUSCB) and the physical path where the retrieved USCB data are to be stored. The SETNAME= option specifies the name of the data set to retrieve data from. In this example, SETNAME=EITS_BFS requests data from the Business Formation Statistics data set. The USER= option specifies your unique USCB API key. Without a user API key (which you can obtain free of charge), you cannot retrieve data from the US Census Bureau. The FOR='US:*' option requests data for all the US states, and the GEO='*' option specifies all geographic levels. The DATATYPE=BA_BA option specifies the business applications data type. If you want to include all data types, omit this option. See Table 25.10 for available data types to use when you specify the DATATYPE= option for the BFS data set. See Table 25.9 for a complete list of available categories. The OUTJSON= BFSTX option names the file where the JSON data are stored. The output data set is created by using the name that is specified in the OUTJSON= option and placed in the folder that is specified in the SASEUSCB LIBNAME statement. The date range of the data starts with September 2007, as specified by the STARTDATE='2007-09' option. The ENDDATE='2008-04' option specifies the last month to include in the range of data to retrieve (April 2008). The FORMAT=JSON option specifies that the data are to be retrieved in the JSON format. Output 25.2.1 shows the BFS data that are retrieved. Time series whose names end in '_S' contain seasonal data, and time series whose names end in '_U' contain nonseasonal data.

```
options validvarname=any;

title 'Retrieve Business Formation Statistics for Business Applications,
      DATATYPE=BA_BA';
libname uscb saseuscb "%sysget(USCB)"
      user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
      setname=EITS_BFS
      for='US:*'
      geo='*'
      datatype=BA_BA
      startdate='2007-09'
      enddate='2008-04'
      outjson=uscbex02
      format=json;

data myBFS;
  set uscb.uscbex02 ;
run;

proc contents data=myBFS; run;
proc print data=myBFS; run;
```

Output 25.2.1 Retrieve Business Formation Statistics (BFS) Economic Indicator Time Series Data for Business Applications

You can subset your results by adding a KEEP= or DROP= option to your DATA statement as follows:

```
data myBFS( keep= date TOTAL:);
  set uscb.uscbex02 ;
run;
```

The results from the KEEP= option in the DATA statement return two time series, 'TOTAL_BA_BA_S.US'n and 'TOTAL_BA_BA_U.US'n, along with the date of each observation. Each time series is named by concatenating the category code, the data type code, and the seasonality code, using the underscore as the concatenation character, followed by the suffix '.US' (for United States).

Example 25.3: Retrieving International Trade in Goods and Services (FTD) Data for All Data Types

This example shows how to retrieve International Trade in Goods and Services (FTD) data from the US Census Bureau website. You can view these data at the following web page:

<https://www.census.gov/econ/currentdata/dbsearch?programCode=FTD>

The following SASEUSCB LIBNAME statement specifies the libref (USCB), followed by the engine name (SASEUSCB) and the physical path where the retrieved USCB data are to be stored. The SETNAME= option specifies the name of the data set to retrieve data from. In this example, SETNAME=EITS_FTD requests data from the International Trade in Goods and Services data set. The USER= option specifies your unique USCB API key. Without a user API key (which you can obtain free of charge), you cannot retrieve data from the US Census Bureau. The FOR='US:*' option requests data for all of the United States. The DATATYPE= option is omitted because the example includes all data types in the retrieved data. The CATEGORY= option is also omitted because the example includes all categories in the retrieved data. See [Table 25.12](#) for a complete list of available categories, and see [Table 25.13](#) for a complete list of available data types. The OUTJSON=USCBEX03 option names the file where the JSON data are stored. The output data set is created by using the name that is specified in the OUTJSON= option and placed in the folder that is specified in the SASEUSCB LIBNAME statement. The date range of the data starts with September 2021, as specified by the STARTDATE='2021-09' option. The ENDDATE='2022-04' option specifies the last month to include in the range of data to retrieve (April 2022). The FORMAT=JSON option specifies that the data are to be retrieved in the JSON format. [Output 25.3.1](#) shows the FTD data that are retrieved. Time series whose names end in '_S' contain seasonal data, and time series whose names end in '_U' contain nonseasonal data.

```
options validvarname=any;

title 'Retrieve International Trade in Goods and Services Data';
libname uscb saseuscb "%sysget(USCB) "
  user='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
  setname=EITS_FTD
  for='US:*'
  startdate='2021-09'
  enddate='2022-04'
  outjson=uscbex03
  format=json;

data myFT2D;
```

```

set uscb.uscbex03 ;
run;

proc contents data=myFT2D; run;
proc print data=myFT2D; run;

```

Output 25.3.1 Retrieve International Trade in Goods and Services (FTD) Data

Retrieve International Trade in Goods and Services Data

Overview: SEVSELECT Procedure

The SEVSELECT procedure estimates parameters of any arbitrary continuous probability distribution that is used to model the magnitude (severity) of a continuous-valued event of interest. Examples of such events include loss amounts paid by an insurance company and demand of a product as depicted by its sales. PROC SEVSELECT is especially useful when the severity of an event does not follow typical distributions (such as the normal distribution) that are often assumed by standard statistical methods.

PROC SEVSELECT provides a default set of probability distribution models that includes the Burr, exponential, gamma, generalized Pareto, inverse Gaussian (Wald), lognormal, Pareto, Tweedie, and Weibull distributions. In the simplest form, you can estimate the parameters of any of these distributions by using a list of severity values that are recorded in a data table. You can optionally group the values by a set of BY variables. PROC SEVSELECT computes the estimates of the model parameters, their standard errors, and their covariance structure by using the maximum likelihood method for each of the BY groups.

PROC SEVSELECT can fit multiple distributions at the same time and choose the best distribution according to a selection criterion that you specify. You can use seven different statistics of fit as selection criteria. They are log likelihood, Akaike's information criterion (AIC), corrected Akaike's information criterion (AICC), Schwarz Bayesian information criterion (SBC), Kolmogorov-Smirnov statistic (KS), Anderson-Darling statistic (AD), and Cramér–von Mises statistic (CvM).

You can request that the procedure output different types of diagnostic and inferential results, including the summary statistics of analysis variables, progress and status of the nonlinear estimation process, parameter estimates and their standard errors, estimated covariance structure of the parameters, and statistics of fit.

The following key features make PROC SEVSELECT unique among SAS procedures that can estimate continuous probability distributions:

- It enables you to fit a distribution model when the severity values are truncated, censored, or both. You can specify any combination of the following types of censoring and truncation effects: left-censoring,

right-censoring, left-truncation, or right-truncation. This is especially useful in applications with an insurance-type model, where a severity (loss) is reported and recorded only if it is greater than the deductible amount (left-truncation) and where a severity value greater than or equal to the policy limit is recorded at the limit (right-censoring). Another useful application is that of interval-censored data, where you know both the lower limit (right-censoring) and upper limit (left-censoring) on the severity, but you do not know the exact value.

PROC SEVSELECT also enables you to specify a *probability of observability* for the left-truncated data, which is a probability of observing values greater than the left-truncation threshold. This additional information can be useful in certain applications to more correctly model the distribution of the severity of events.

- It uses an appropriate estimator of the empirical distribution function (EDF). EDF is required to compute the KS, AD, and CvM statistics of fit. The procedure also provides the EDF estimates to your custom parameter initialization method. When you specify truncation or censoring, the EDF is estimated by using either Kaplan-Meier's product-limit estimator or Turnbull's estimator. The former is used by default when you specify only one form of censoring effect (right-censoring or left-censoring), and the latter is used by default when you specify both left-censoring and right-censoring effects.
- It enables you to define any arbitrary continuous parametric distribution model and to estimate its parameters. You just need to define the key components of the distribution, such as its probability density function (PDF) and cumulative distribution function (CDF), as a set of functions and subroutines written with the FCMP procedure, which is part of Base SAS software. As long as the functions and subroutines follow certain rules, the SEVSELECT procedure can fit the distribution model defined by them.
- It can model the influence of exogenous or regressor variables on a probability distribution, as long as the distribution has a scale parameter. A linear combination of regression effects is assumed to affect the scale parameter via an exponential link function. This type of model is referred to as the scale regression model.

If a distribution does not have a scale parameter, then either it needs to have another parameter that can be derived from a scale parameter by using a supported transformation or it needs to be reparameterized to have a scale parameter. If neither of these is possible, then regression effects cannot be modeled.

You can easily specify many types of regression effects by using various operators on a set of classification and continuous variables. You can specify classification variables in the CLASS statement. You can also construct the following special effects by using the EFFECT statement: collection effects, multimember effects, polynomial effects, and spline effects.

If you specify a large number of regression effects, then you can use the SELECTION statement to tell PROC SEVSELECT to perform scale regression model selection.

- It enables you to specify your own objective function to be optimized for estimating the parameters of a model. You can write SAS programming statements to specify the contribution of each observation to the objective function. You can use keyword functions such as `_PDF_` and `_CDF_` to generalize the objective function to any distribution. If you do not specify your own objective function, then PROC SEVSELECT estimates the parameters of a model by maximizing the likelihood function of the data.
- It enables you to create scoring functions that offer a convenient way to evaluate any distribution function, such as PDF, CDF, QUANTILE, or your custom distribution function, for a fitted model on new observations.

PROC SEVSELECT is the next-generation version of PROC HPSEVERITY. It can run on SAS Cloud Analytic Services (CAS). Because PROC SEVSELECT is a next-generation high-performance analytical procedure, it also does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- exploits all the available cores and concurrent threads

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the `mylib` CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section [“Introduction to Shared Concepts”](#) on page 54 in Chapter 4, [“Shared Concepts.”](#)

Getting Started: SEVSELECT Procedure

This section outlines the use of the SEVSELECT procedure to fit continuous probability distribution models. Three examples illustrate different features of the procedure.

A Simple Example of Fitting Predefined Distributions

The simplest way to use PROC SEVSELECT is to fit all the predefined distributions to a set of values and let the procedure identify the best-fitting distribution.

Consider a lognormal distribution, whose probability density function (PDF) f and cumulative distribution function (CDF) F are as follows, respectively, where Φ denotes the CDF of the standard normal distribution:

$$f(x; \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\log(x)-\mu}{\sigma}\right)^2} \quad \text{and} \quad F(x; \mu, \sigma) = \Phi\left(\frac{\log(x)-\mu}{\sigma}\right)$$

The following DATA step statements simulate a sample from a lognormal distribution with population parameters $\mu = 1.5$ and $\sigma = 0.25$, and store the sample in the variable Y of a data set Work.Test_sev1:

```
/*----- Simple Lognormal Example -----*/
data test_sev1(keep=y label='Simple Lognormal Sample');
  call streaminit(45678);
  label y='Response Variable';
  Mu = 1.5;
  Sigma = 0.25;
  do n = 1 to 100;
    y = exp(Mu) * rand('LOGNORMAL')**Sigma;
    output;
  end;
run;
```

NOTE: Input data must be in a CAS table that is accessible in your CAS session. You must refer to this table by using a two-level name. The first level must be a CAS engine libref, and the second level must be the table name. For more information, see the sections “[Using CAS Sessions and CAS Engine Librefs](#)” on page 54 and “[Loading a SAS Data Set onto a CAS Server](#)” on page 55 in Chapter 4, “[Shared Concepts](#).”

You can use a DATA step as follows to load the data set Work.Test_sev1 into a data table in your session that is associated with the mylib libref. The DATA step assumes that your libref is named mylib, but you can substitute any appropriately defined libref.

```
data mylib.test_sev1;
  set test_sev1;
run;
```

These statements assume that your libref is named mylib, as in the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1724, but you can substitute any appropriately defined libref.

The following statements fit all the predefined distribution models to the values of Y and identify the best distribution according to the corrected Akaike’s information criterion (AICC):

```
proc sevselect data=mylib.test_sev1 crit=aicc
              plots(histogram kernel)=all; /*(cdf pdf);*/
  loss y;
  dist _predefined_;
run;
```

The PROC SEVSELECT statement specifies the input data table along with the model selection criterion. The PLOTS= option displays comparative plots of the probability density function (PDF) and the cumulative distribution function (CDF) for all candidate distributions. The HISTOGRAM and KERNEL options request that the PDF plot contain histogram and kernel density estimates, respectively, which are nonparametric estimates of the density function. The LOSS statement specifies the variable to be modeled, and the DIST statement with the _PREDEFINED_ keyword specifies that all the predefined distribution models be fitted.

Some of the default output that is displayed by this step is shown in Figure 26.1 through Figure 26.5. First the “Model Selection” table is displayed, as shown in Figure 26.1. The model selection table displays the convergence status, the value of the selection criterion, and the selection status for each of the candidate models. The Converged column indicates whether the estimation process for a particular distribution model has converged, might have converged, or failed. The Selected column indicates whether a particular distribution has the best fit for the data according to the selection criterion. For this example, the lognormal distribution model is selected, because it has the lowest value for the selection criterion.

Figure 26.1 Model Selection Table

Model Selection			
Distribution	Converged	AICC	Selected
Burr	Yes	322.50845	No
Exp	Yes	508.12287	No
Gamma	Yes	320.50264	No
lgauss	Yes	319.61652	No
Logn	Yes	319.56579	Yes
Pareto	Yes	510.28172	No
Gpd	Yes	510.20576	No
Weibull	Yes	334.82373	No

Next, two comparative plots are prepared. These plots enable you to visually verify how the models differ from each other and from the nonparametric estimates. The plot in Figure 26.2 displays the CDF estimates of all the models and the estimates of the empirical distribution function (EDF). The CDF plot indicates that the Exp (exponential), Pareto, and Gpd (generalized Pareto) distributions are a poor fit as compared to the EDF estimate. The Weibull distribution is also a poor fit, although not as poor as exponential, Pareto, and generalized Pareto. The other four distributions seem to be quite close to each other and to the EDF estimate.

Figure 26.2 Comparison of EDF and CDF Estimates of the Fitted Models

The plot in [Figure 26.3](#) displays the PDF estimates of all the models and the nonparametric kernel and histogram estimates. The PDF plot enables better visual comparison between the Burr, gamma, Igauss (inverse Gaussian), and Logn (lognormal) models. The Burr and gamma models differ significantly from the Igauss and Logn models in the central portion of the range of Y values, whereas the latter two models fit the data almost identically. This provides a visual confirmation of the information in the “Model Selection” table in [Figure 26.1](#), which indicates that the AICC values of the Igauss and Logn models are very close.

Figure 26.3 Comparison of PDF Estimates of the Fitted Models

NOTE: When you request plots in a PROC SEVSELECT step that uses more than one worker node, the plots are approximate. PROC SEVSELECT creates these plots by using the sample that it uses to compute EDF-based fit statistics. It first computes the empirical quantiles on each worker node, then merges them to create the final plot. For more accurate visualization, it is recommended that you request plots only when you run PROC SEVSELECT in a CAS session that uses no more than one worker node.

The comparative plots are followed by the estimation information for each of the candidate models. The information for the lognormal model, which is the best-fitting model, is shown in Figure 26.4. The first table displays a summary of the distribution. The second table displays the convergence status. This is followed by a summary of the optimization process that indicates the technique used, the number of iterations, the number of times the objective function was evaluated, and the log likelihood that is obtained at the end of the optimization. Because the model with lognormal distribution has converged, PROC SEVSELECT displays its statistics of fit and parameter estimates. The estimates of $\mu=1.49605$ and $\sigma=0.26243$ are quite close to the population parameters of $\mu=1.5$ and $\sigma=0.25$ from which the sample was generated. The p -value for each estimate indicates the rejection of the null hypothesis that the estimate is 0, implying that both the estimates are significantly different from 0.

An Example with Left-Truncation and Right-Censoring

PROC SEVSELECT enables you to specify that the response variable values are left-truncated or right-censored. The following DATA step expands the data table of the previous example to simulate a scenario that is typically encountered by an automobile insurance company. The values of the variable Y represent the loss values on claims that are reported to an auto insurance company. The variable THRESHOLD records the deductible on the insurance policy. If the actual value of Y is less than or equal to the deductible, then it is unobservable and does not get recorded. In other words, THRESHOLD specifies the left-truncation of Y. LIMIT records the policy limit. If the value of Y is equal to or greater than the recorded value, then the observation is right-censored.

```
/*----- Lognormal Model with left-truncation and censoring -----*/
data test_sev2(keep=y threshold limit
               label='A Lognormal Sample With Censoring and Truncation');
  set test_sev1;
  label y='Censored & Truncated Response';
  if _n_ = 1 then call streaminit(45679);

  /* make about 20% of the observations left-truncated */
  if (rand('UNIFORM') < 0.2) then
    threshold = y * (1 - rand('UNIFORM'));
  else
    threshold = .;
  /* make about 15% of the observations right-censored */
  iscens = (rand('UNIFORM') < 0.15);
  if (iscens) then
    limit = y;
  else
    limit = .;
run;
```

You can use a DATA step as follows to load the data set Work.Test_sev2 into a data table in your session that is associated with the mylib libref. The DATA step assumes that your libref is named mylib, but you can substitute any appropriately defined libref.

```
data mylib.test_sev2;
  set test_sev2;
run;
```

The following statements fit four predefined distributions (lognormal, Burr, gamma, and Weibull) and use the AICC to identify the distribution that best fits the data:

```
proc sevselect data=mylib.test_sev2 crit=aicc
               print=all plots=all;
  loss y / lt=threshold rc=limit;

  dist logn burr gamma weibull;
run;
```

The LOSS statement specifies the left-truncation and right-censoring variables. The DIST statement specifies the candidate distributions. The PRINT= option in the PROC SEVSELECT statement requests that all the

displayed output be prepared. The PLOTS= option in the PROC SEVSELECT statement requests that all available plots be prepared.

Some of the key results that PROC SEVSELECT prepares are shown in Figure 26.6 through Figure 26.13. In addition to the estimates of the range, mean, and standard deviation of Y, the “Descriptive Statistics for y” table shown in Figure 26.6 also indicates the number of observations that are left-truncated or right-censored. The “Model Selection” table in Figure 26.6 shows that models with all the candidate distributions have converged and that the Logn (lognormal) model has the best fit for the data according to the AICC criterion.

Figure 26.6 Summary Results for the Truncated and Censored Data

Descriptive Statistics for y			
Observations			100
Observations Used for Estimation			100
Minimum			2.30264
Maximum			8.34116
Mean			4.62007
Standard Deviation			1.23627
Left Truncated Observations			23
Right Censored Observations			14

Model Selection			
Distribution	Converged	AICC	Selected
Logn	Yes	298.92672	Yes
Burr	Yes	302.66229	No
Gamma	Yes	299.45293	No
Weibull	Yes	309.26779	No

PROC SEVSELECT also prepares a table that shows all the fit statistics for all the candidate models. It is useful to see which model would be the best fit according to each of the criteria. The “All Fit Statistics” table prepared for this example is shown in Figure 26.7. It indicates that the lognormal model is chosen by all the criteria.

Figure 26.7 Comparing All Statistics of Fit for the Truncated and Censored Data

All Fit Statistics							
Distribution	-2 Log Likelihood	AIC	AICC	SBC	KS	AD	CvM
Logn	294.80301*	298.80301*	298.92672*	304.01335*	0.51824*	0.34736*	0.05159*
Burr	296.41229	302.41229	302.66229	310.22780	0.66984	0.36712	0.05726
Gamma	295.32921	299.32921	299.45293	304.53955	0.62511	0.42921	0.05526
Weibull	305.14408	309.14408	309.26779	314.35442	0.93307	1.40699	0.17465

Asterisk (*) denotes the best model in the column.

The plot that compares EDF and CDF estimates is shown in Figure 26.8. When you specify left-truncation, both the EDF and CDF estimates are conditional on the response variable being greater than the smallest left-truncation threshold in the sample.

Figure 26.8 EDF and CDF Estimates for the Truncated and Censored Data

When you specify the `PLOTS=CDFPERDIST` option, PROC SEVSELECT prepares a plot that compares the nonparametric EDF estimates with the parametric CDF estimates for each distribution. These plots for lognormal and Weibull distributions are shown in Figure 26.9. These plots also contain the lower and upper confidence limits of EDF for the specified confidence level. Because no confidence level is specified in the `EDFALPHA=` option in the PROC SEVSELECT statement, a default confidence level of 95% is used; this is equivalent to specifying `EDFALPHA=0.05`. If the CDF estimates lie entirely within the EDF confidence interval, then you can be 95% confident that the parametric and nonparametric estimates are in agreement.

Figure 26.9 Comparing EDF and CDF Estimates for Lognormal and Weibull Models Fitted to Truncated and Censored Data

There are two additional ways to compare nonparametric (empirical) and parametric estimates for each model that has not failed to converge:

- A P-P plot is a scatter plot of the EDF and CDF estimates. The model for which the points are scattered closer to the unit-slope reference line is a better fit. The P-P plot for the lognormal distribution is shown in Figure 26.10. It indicates that the EDF matches the CDF very closely. In contrast, the P-P plot for the Weibull distribution, also shown in Figure 26.10, indicates a poor fit.

Figure 26.10 P-P Plots for Lognormal and Weibull Models Fitted to Truncated and Censored Data

- A Q-Q plot is a scatter plot of empirical quantiles and the quantiles of a parametric distribution. As in the P-P plot, points that are scattered closer to the unit-slope reference line indicate a better fit. The Q-Q plots of lognormal and Weibull distributions are shown in Figure 26.11; these plots confirm the conclusions that are arrived at by comparing the P-P plots.

Figure 26.11 Q-Q Plots for Lognormal and Weibull Models Fitted to Truncated and Censored Data

Specifying Initial Values for Parameters

All the predefined distributions have parameter initialization functions built into them. For the current example, Figure 26.12 shows the initial values that are obtained by the predefined method for the Burr distribution. It also shows the summary of the optimization process and the final parameter estimates.

Figure 26.12 Burr Model Summary for the Truncated and Censored Data

Initial Parameter Values and Bounds					
Parameter	Initial Value	Lower Bound	Upper Bound		
Theta	4.78102	1.05367E-8	Infy		
Alpha	2.00000	1.05367E-8	Infy		
Gamma	2.00000	1.05367E-8	Infy		
Optimization Summary					
Optimization Technique		Trust Region			
Iterations		8			
Function Calls		23			
Log Likelihood		-148.2061441			
Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Theta	1	4.76980	0.62492	7.63	<.0001
Alpha	1	1.16363	0.58859	1.98	0.0509
Gamma	1	5.94081	1.05004	5.66	<.0001

You can specify a different set of initial values if estimates are available from fitting the distribution to similar

data. For this example, the parameters of the Burr distribution can be initialized with the final parameter estimates of the Burr distribution that were obtained in the first example (shown in Figure 26.5). One of the ways in which you can specify the initial values is as follows:

```
/*----- Specifying initial values using INIT= option -----*/
proc sevselect data=mylib.test_sev2 crit=aicc print=all;
  loss y / lt=threshold rc=limit;

  dist burr(init=(theta=4.62348 alpha=1.15706 gamma=6.41227));
run;
```

The names of the parameters that are specified in the INIT option must match the parameter names in the definition of the distribution. The results obtained with these initial values are shown in Figure 26.13. These results indicate that new set of initial values causes the optimizer to reach the same solution with fewer iterations and function evaluations as compared to the default initialization.

Gamma	1	5.94081	1.05004	5.66	<.0001

An Example of Modeling Regression Effects

Consider a scenario in which the magnitude of the response variable might be affected by some regressor (exogenous or independent) variables. The SEVSELECT procedure enables you to model the effect of such variables on the distribution of the response variable via an exponential link function. In particular, if you have k random regressor variables denoted by x_j ($j = 1, \dots, k$), then the distribution of the response variable Y is assumed to have the form

$$Y \sim \exp\left(\sum_{j=1}^k \beta_j x_j\right) \cdot \mathcal{F}(\Theta)$$

where $\mathcal{F}$ denotes the distribution of Y with parameters Θ and β_j ($j = 1, \dots, k$) denote the regression parameters (coefficients).

For the effective distribution of Y to be a valid distribution from the same parametric family as $\mathcal{F}$, it is necessary for $\mathcal{F}$ to have a scale parameter. The effective distribution of Y can be written as

$$Y \sim \mathcal{F}(\theta, \Omega)$$

where θ denotes the scale parameter and Ω denotes the set of nonscale parameters. The scale θ is affected by the regressors as

$$\theta = \theta_0 \cdot \exp\left(\sum_{j=1}^k \beta_j x_j\right)$$

where θ_0 denotes a *base* value of the scale parameter.

Given this form of the model, PROC SEVSELECT allows a distribution to be a candidate for modeling regression effects only if it has an untransformed or a log-transformed scale parameter.

All the predefined distributions, except the lognormal distribution, have a direct scale parameter (that is, a parameter that is a scale parameter without any transformation). For the lognormal distribution, the parameter μ is a log-transformed scale parameter. This can be verified by replacing μ with a parameter $\theta = e^\mu$, which results in the following expressions for the PDF f and the CDF F in terms of θ and σ , respectively, where Φ denotes the CDF of the standard normal distribution:

$$f(x; \theta, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\log(x) - \log(\theta)}{\sigma}\right)^2} \quad \text{and} \quad F(x; \theta, \sigma) = \Phi\left(\frac{\log(x) - \log(\theta)}{\sigma}\right)$$

With this parameterization, the PDF satisfies the $f(x; \theta, \sigma) = \frac{1}{\theta} f\left(\frac{x}{\theta}; 1, \sigma\right)$ condition and the CDF satisfies the $F(x; \theta, \sigma) = F\left(\frac{x}{\theta}; 1, \sigma\right)$ condition. This makes θ a scale parameter. Hence, $\mu = \log(\theta)$ is a log-transformed scale parameter and the lognormal distribution is eligible for modeling regression effects.

The following DATA step simulates a lognormal sample whose scale is decided by the values of the three regressors X1, X2, and X3 as follows:

$$\mu = \log(\theta) = 1 + 0.75 X1 - X2 + 0.25 X3$$

```
/*----- Lognormal Model with Regressors -----*/
data test_sev3(keep=y x1-x3
                label='A Lognormal Sample Affected by Regressors');
    array x{*} x1-x3;
    array b{4} _TEMPORARY_ (1 0.75 -1 0.25);
    call streaminit(45678);
    label y='Response Influenced by Regressors';
    Sigma = 0.25;
    do n = 1 to 100;
        Mu = b(1); /* log of base value of scale */
        do i = 1 to dim(x);
            x(i) = rand('UNIFORM');
            Mu = Mu + b(i+1) * x(i);
        end;
        y = exp(Mu) * rand('LOGNORMAL')**Sigma;
        output;
    end;
run;
```

You can use a DATA step as follows to load the data set `Work.Test_sev3` into a data table in your session that is associated with the `mylib` libref. The DATA step assumes that your libref is named `mylib`, but you can substitute any appropriately defined libref.

```
data mylib.test_sev3;
    set test_sev3;
run;
```

The following PROC SEVSELECT step fits the lognormal, Burr, and gamma distribution models to these data. The regressors are specified in the SCALEMODEL statement.

```
proc sevselect data=mylib.test_sev3 crit=aicc print=all;
    loss y;
    scalemodel x1-x3;

    dist logn burr gamma;
run;
```

Some of the key results that PROC SEVSELECT prepares are shown in [Figure 26.14](#) through [Figure 26.18](#). The descriptive statistics of all the variables are shown in [Figure 26.14](#).

Figure 26.14 Summary Results for the Regression Example

The SEVSELECT Procedure

Descriptive Statistics for y					
Observations					100
Observations Used for Estimation					100
Minimum					1.17863
Maximum					6.65269
Mean					2.99859
Standard Deviation					1.12845

Descriptive Statistics for Regressors					
Variable	N	Minimum	Maximum	Mean	Standard Deviation
x1	100	0.0005115	0.97971	0.51689	0.28206
x2	100	0.01883	0.99937	0.47345	0.28885
x3	100	0.00255	0.97558	0.48301	0.29709

The comparison of the fit statistics of all the models is shown in [Figure 26.15](#). It indicates that the lognormal model is the best model according to each of the likelihood-based statistics, whereas the gamma model is the best model according to two of the three EDF-based statistics.

Asterisk (*) denotes the best model in the column.

The model information and the convergence results of the lognormal model are shown in Figure 26.16. The iteration history gives you a summary of how the optimizer is traversing the surface of the log-likelihood function in its attempt to reach the optimum. Both the change in the log likelihood and the maximum gradient of the objective function with respect to any of the parameters typically approach 0 if the optimizer converges.

The final parameter estimates of the lognormal model are shown in Figure 26.17. All the estimates are significantly different from 0. The estimate that is reported for the parameter MU is the base value for the log-transformed scale parameter μ . Let x_i ($1 \leq i \leq 3$) denote the observed value for regressor X_i . If the lognormal distribution is chosen to model Y , then the effective value of the parameter μ varies with the observed values of regressors as

$$\mu = 1.04047 + 0.65221 x_1 - 0.91116 x_2 + 0.16243 x_3$$

These estimated coefficients are reasonably close to the population parameters (that is, within one or two standard errors).

Figure 26.17 Parameter Estimates for the Lognormal Model with Regressors

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Mu	1	1.04047	0.07614	13.66	<.0001
Sigma	1	0.22177	0.01609	13.78	<.0001
x1	1	0.65221	0.08167	7.99	<.0001
x2	1	-0.91116	0.07946	-11.47	<.0001
x3	1	0.16243	0.07782	2.09	0.0395

The estimates of the gamma distribution model, which is the best model according to a majority of the EDF-based statistics, are shown in [Figure 26.18](#). The estimate that is reported for the parameter *Theta* is the base value for the scale parameter θ . If the gamma distribution is chosen to model Y , then the effective value of the scale parameter is $\theta = 0.14293 \exp(0.64562 x_1 - 0.89831 x_2 + 0.14901 x_3)$.

Figure 26.18 Parameter Estimates for the Gamma Model with Regressors

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Theta	1	0.14293	0.02329	6.14	<.0001
Alpha	1	20.37726	2.93277	6.95	<.0001
x1	1	0.64562	0.08224	7.85	<.0001
x2	1	-0.89831	0.07962	-11.28	<.0001
x3	1	0.14901	0.07870	1.89	0.0613

Syntax: SEVSELECT Procedure

The following statements are available in the SEVSELECT procedure:

```

PROC SEVSELECT options ;
  BY variable-list ;
  LOSS < response-variable > < / censoring-truncation-options > ;
  WEIGHT weight-variable ;
  DIST distribution-name-or-keyword < (distribution-option) < distribution-name-or-keyword
    < (distribution-option) > > ... > < / options > ;
  CLASS variable < (options) > ... < variable < (options) > > < / global-options > ;
  EFFECT name=effect-type(variables < / options >) ;
  SCALEMODEL regression-effect-list < / scalemodel-options > ;
  SELECTION < METHOD=method < (method-options) > >< options > ;
  DISPLAY < table-list > < / options > ;
  DISPLAYOUT table-spec-list < / options > ;
  RESTRICT restriction1 [, restriction2 ...] ;
  OUTPUT < OUT=libref.data-table > output-options ;
  OUTSCORELIB < OUTLIB=> fcmp-library-name options ;
  NLOPTIONS options ;
  Programming statements ;

```

Functional Summary

Table 26.1 summarizes the statements and options that control the SEVSELECT procedure.

Table 26.1 Functional Summary

Description	Statement	Option
Statements		
Specifies BY-group processing	BY	
Specifies the response variable to model along with censoring and truncation effects	LOSS	
Specifies the weight variable	WEIGHT	
Specifies distributions to fit	DIST	
Specifies the classification variables	CLASS	
Specifies the constructed regression effects	EFFECT	
Specifies the regression effects to model	SCALEMODEL	
Specifies the options for selecting the best subset of regression effects	SELECTION	
Specifies the ODS tables to display (an alternative to the PRINT= option)	DISPLAY	
Specifies the ODS tables to save as output data tables	DISPLAYOUT	
Specifies linear restrictions on parameters	RESTRICT	
Specifies the scoring functions and quantiles to write	OUTPUT	
Specifies the library to write scoring functions to	OUTSCORELIB	
Specifies the optimization options	NLOPTIONS	
Specifies programming statements that define an objective function	Programming statements	

Table 26.1 *continued*

Description	Statement	Option
Input and Output Options		
Specifies the input data table	PROC SEVSELECT	DATA=
Specifies the input data table for parameter estimates	PROC SEVSELECT	INEST=
Specifies the output data table for estimates of scoring functions and quantiles	OUTPUT	OUT=
Specifies the output data table for parameter estimates	PROC SEVSELECT	OUTEST=
Specifies the output data table for model information	PROC SEVSELECT	OUTMODELINFO=
Specifies the output data table for statistics of fit	PROC SEVSELECT	OUTSTAT=
Specifies the output item store for context and estimation results	PROC SEVSELECT	OUTSTORE=
Data Interpretation Options		
Specifies left-censoring	LOSS	LEFTCENSORED=
Specifies left-truncation	LOSS	LEFTTRUNCATED=
Specifies the probability of observability	LOSS	PROBOBSERVED=
Specifies right-censoring	LOSS	RIGHTCENSORED=
Specifies right-truncation	LOSS	RIGHTTRUNCATED=
Distribution Processing Options		
Specifies the input data table to read the distribution definitions from	DIST	INFUNCDEF=
Specifies that distributions be listed in the log without estimating any models that use them	DIST	LISTONLY
Specifies the input data table to write the distribution definitions to	DIST	OUTFUNCDEF=
Specifies that distributions be validated without estimating any models that use them	DIST	VALIDATEONLY
Model Estimation Options		
Specifies the method for computing mixture distribution	SCALEMODEL	DFMIXTURE=
Specifies that informative missingness be used to model missing values of regressors	SCALEMODEL	INFORMATIVE
Specifies initial values for model parameters	DIST	INIT=
Specifies the sample to be used for computing initial parameter estimates	PROC SEVSELECT	INITSAMPLE
Specifies that observations do not need to be balanced among threads of computation	PROC SEVSELECT	NOBALANCETHREADS
Specifies role of constant distribution parameters in fit statistic calculations	PROC SEVSELECT	NOCONSTFITSTATS

Table 26.1 *continued*

Description	Statement	Option
Specifies the objective function symbol	PROC SEVSELECT	OBJECTIVE=
Specifies the offset variable in the scale regression model	SCALEMODEL	OFFSET=
Specifies the denominator for computing covariance estimates	PROC SEVSELECT	VARDEF=
Regression Effect Selection Options		
Specifies whether and how the model hierarchy requirement is applied	SELECTION	HIERARCHY=
Specifies the set of regression effects to be forced in all models	SCALEMODEL	INCLUDE=
Specifies the selection method	SELECTION	METHOD=
Specifies the selection order for displaying effects in the selected model	SELECTION	ORDERSELECT
Specifies the optimization technique to use for the intermediate selection steps	PROC SEVSELECT	SELECTNLOTECH=
Specifies the set of regression effects to begin the selection process	SCALEMODEL	START=
Specifies how to apply the STOP= criterion	SELECTION	STOPHORIZON=
Regression Effect Selection Method Options		
Specifies a criterion for choosing the best model at each step	SELECTION	CHOOSE=
Specifies that the competitive form of the stepwise selection method be used	SELECTION	COMPETITIVE
Specifies the maximum number of effects in the model	SELECTION	MAXEFFECTS=
Specifies the maximum number of selection steps	SELECTION	MAXSTEPS=
Specifies the minimum number of effects in the model	SELECTION	MINEFFECTS=
Specifies a criterion to decide which effects enter or leave the model at each step	SELECTION	SELECT=
Specifies a criterion for stopping the selection process	SELECTION	STOP=
Empirical Distribution Function (EDF) Estimation Options		
Specifies the nonparametric method of CDF estimation	PROC SEVSELECT	EMPIRICALCDF=
EMPIRICALCDF=MODIFIEDKLM Options		
Specifies the α value for the lower bound on risk set size	PROC SEVSELECT	ALPHA=
Specifies the c value for the lower bound on risk set size	PROC SEVSELECT	C=

Table 26.1 *continued*

Description	Statement	Option
Specifies the absolute lower bound on risk set size	PROC SEVSELECT	RSLB=
EMPIRICALCDF=TURNBULL Options		
Specifies that the final EDF estimates be maximum likelihood estimates	PROC SEVSELECT	ENSUREMLE
Specifies the relative convergence criterion	PROC SEVSELECT	EPS=
Specifies the maximum number of iterations	PROC SEVSELECT	MAXITER=
Specifies the threshold below which an EDF estimate is deemed to be 0	PROC SEVSELECT	ZEROPROB=
OUT= Data Table Generation Options		
Specifies the variables to copy from the DATA= data table to the OUT= data table	OUTPUT	COPYVARS=
Specifies the scoring functions to estimate	OUTPUT	FUNCTIONS=
Specifies the quantiles to estimate	OUTPUT	QUANTILES=
OUTEST= Data Table Generation Options		
Specifies that the OUTEST= data table contain covariance estimates	PROC SEVSELECT	COVOUT
Specifies that only the selected regression parameters be written	PROC SEVSELECT	SELECTOUT
Specifies that estimates of parameters not in the final model be 0	PROC SEVSELECT	ZEROEST
Scoring Function Generation Options		
Writes scoring functions of all models to one package	OUTSCORELIB	COMMONPACKAGE
Specifies the output data table for BY-group identifiers	OUTSCORELIB	OUTBYID=
Specifies the output library for scoring functions	OUTSCORELIB	OUTLIB=
Displayed Output Options		
Specifies the criterion to report in the model selection table	PROC SEVSELECT	CRITERION=
Specifies the level of detail to be produced about the selection process	SELECTION	DETAILS=
Specifies the confidence level for reporting the confidence interval for EDF estimates	PROC SEVSELECT	EDFALPHA=
Limits or suppresses the display of class levels	PROC SEVSELECT	NOCLPRINT
Suppresses all displayed and graphical output	PROC SEVSELECT	NOPRINT
Specifies which graphical output to prepare	PROC SEVSELECT	PLOTS=
Specifies which graphical output to prepare about the selection process	SELECTION	PLOTS=
Specifies which output to display	PROC SEVSELECT	PRINT=

Table 26.1 *continued*

Description	Statement	Option
Prints internal names assigned to parameters	PROC SEVSELECT	PRINTINTERNALNAMES

PROC SEVSELECT Statement

PROC SEVSELECT *options* ;

The PROC SEVSELECT statement invokes the procedure. You can specify two types of *options* in the PROC SEVSELECT statement. One set of *options* controls input and output. The other set of *options* controls the model estimation and selection process.

The following *options* control the input data tables used by PROC SEVSELECT and various forms of output generated by PROC SEVSELECT. The *options* are listed in alphabetical order.

COVOUT

specifies that the OUTEST= data table contain the estimate of the covariance structure of the parameters. This option has no effect if you do not specify the OUTEST= option. For more information about how the covariance is reported in the OUTEST= data table, see the section “OUTEST= Data Table” on page 1840.

CRITERION=*criterion-option*

CRITERIA=*criterion-option*

CRIT=*criterion-option*

specifies the criterion to report in the model selection table.

If you specify two or more candidate models for estimation, then the one that has the best value for the specified criterion is marked as the best model in the model selection table that is displayed by default or when you specify the PRINT=SELECTION option. If you specify the OUTSTAT= data table, then the observation for the model that has the best value for the specified criterion has a value of 1 for the variable `_SELECTED_`.

You can specify one of the following *criterion-options*:

AD	specifies the Anderson-Darling (AD) statistic value, which is computed by using the empirical distribution function (EDF) estimate, as the selection criterion. A lower value is deemed better.
AIC	specifies Akaike's information criterion (AIC) as the selection criterion. A lower value is deemed better.
AICC	specifies the finite-sample corrected Akaike's information criterion (AICC) as the selection criterion. A lower value is deemed better.
CUSTOM	specifies the custom objective function as the selection criterion. You can specify this criterion only if you also specify the OBJECTIVE= option. A lower value is deemed better.

CVM	specifies the Cramér–von Mises (CvM) statistic value, which is computed by using the empirical distribution function (EDF) estimate, as the selection criterion. A lower value is deemed better.
KS	specifies the Kolmogorov-Smirnov (KS) statistic value, which is computed by using the empirical distribution function (EDF) estimate, as the selection criterion. A lower value is deemed better.
LOGLIKELIHOOD LL	specifies $-2 * \log(L)$ as the selection criterion, where L is the likelihood of the data. A lower value is deemed better.
SBC BIC	specifies the Schwarz Bayesian information criterion (SBC) as the selection criterion. A lower value is deemed better.

If you do not specify the **CRITERION=** option, then by default, the procedure uses **CRITERION=CUSTOM** if you specify the **OBJECTIVE=** option, or **CRITERION=LOGLIKELIHOOD** if you do not specify the **OBJECTIVE=** option.

For more information about these *criterion-options*, see the section “Statistics of Fit” on page 1806.

DATA=*libref.data-table*

names the input data table for PROC SEVSELECT to use. *libref.data-table* is a two-level name, where

<i>libref</i>	refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about <i>libref</i> , see the section “Using CAS Sessions and CAS Engine Librefs” on page 1724.
<i>data-table</i>	specifies the name of the input data table.

EDFALPHA=*confidence-level*

specifies the confidence level in the range (0,1) to use for computing the confidence intervals for the EDF estimates. The lower and upper confidence limits that correspond to this level are displayed in the plot that is created when you specify the **PLOTS=CDFPERDIST** option.

If you do not specify the **EDFALPHA=** option, then PROC SEVSELECT uses a default value of 0.05.

INEST=*libref.data-table*

names the input data table that contains the initial values of the parameter estimates to start the optimization process.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1724. The *libref* must be identical to the *libref* that you specify in the **DATA=** option.

The initial values that you specify in the **INIT=** option in the **DIST** statement take precedence over any initial values that you specify in the **INEST=** data table. For more information about the variables in this data table, see the section “**INEST= Data Table**” on page 1839.

NOCLPRINT*<=number>*

suppresses the display of the “Class Level Information” table if you do not specify *number*. If you specify *number*, the values of the classification variables are displayed for only those variables whose number of levels is less than *number*. Specifying a *number* helps reduce the size of the “Class Level Information” table if some classification variables have a large number of levels. This option has no effect if you do not specify the CLASS statement.

NOPRINT

turns off all displayed and graphical output. If you specify this option, then any value that you specify for the PRINT= option is ignored.

OUTEST*=libref.data-table*

names the output data table to contain estimates of the parameter values and their standard errors for each model whose parameter estimation process converges.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1724. The *libref* must be identical to the *libref* that you specify in the DATA= option.

For more information about the variables in this data table, see the section “[OUTEST= Data Table](#)” on page 1840.

OUTMODELINFO*=libref.data-table*

names the output data table to contain the information about each candidate distribution.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1724. The *libref* must be identical to the *libref* that you specify in the DATA= option.

For more information about the variables in this data table, see the section “[OUTMODELINFO= Data Table](#)” on page 1843.

OUTSTAT*=libref.data-table*

names the output data table to contain the values of statistics of fit for each model whose parameter estimation process converges.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1724. The *libref* must be identical to the *libref* that you specify in the DATA= option.

For more information about the variables in this data table, see the section “[OUTSTAT= Data Table](#)” on page 1843.

OUTSTORE*=libref.data-table*

names the output data table to contain the context and results of the severity model estimation process in the form of an item store, which has a binary format that cannot be modified. You can specify this item store data table in a subsequent PROC CCDM step by using the SEVERITYSTORE= option.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option

and the section “Using CAS Sessions and CAS Engine Librefs” on page 1724. The *libref* must be identical to the *libref* that you specify in the DATA= option.

PLOTS <(global-plot-options)> <=plot-request-option>

PLOTS <(global-plot-options)> <=(plot-request-option ... plot-request-option)>

specifies which graphical output to create. If you specify more than one *global-plot-option*, then separate them with spaces and enclose them in parentheses. If you specify more than one *plot-request-option*, then separate them with spaces and enclose them in parentheses.

When the active CAS session contains more than one worker node, PROC SEVSELECT prepares the plots by using an aggregation algorithm that merges the plot data from individual worker nodes. Each worker node in turn prepares its plot data by using a sample of the local data to compute the empirical quantiles for a uniform grid of points along the empirical distribution function (EDF) axis; this data sample is the same sample that it uses to compute the EDF-based fit statistics. So the plots are approximate. You can still use them to compare the fits of different distributions visually. However, to get a more accurate visual comparison, it is recommended that you request plots only when you run the PROC SEVSELECT step in a CAS session that uses no more than one worker node.

You can specify the following *global-plot-options*:

HISTOGRAM

plots the histogram of the response variable on the probability density function (PDF) plots.

KERNEL

plots the kernel estimate of the probability density of the response variable on the PDF plots.

You can specify the following *plot-request-options*:

ALL

creates all the graphical output.

CDF

creates a plot that compares the cumulative distribution function (CDF) estimates of all the candidate distribution models to the empirical distribution function (EDF) estimate. The plot does not contain CDF estimates for models whose parameter estimation process does not converge.

CDFPERDIST

creates a plot of the CDF estimates of each candidate distribution model. A plot is not created for models whose parameter estimation process does not converge.

CONDITIONALPDF <(cpdf-options)>

CONDPDF <(cpdf-options)>

creates a plot that compares the conditional probability density function (PDF) estimates of all the candidate distribution models. The plot does not contain conditional PDF estimates for models whose parameter estimation process does not converge.

A conditional PDF of a loss random variable Y in an interval $(Y_l, Y_r]$ is the probability that a specific loss value is observed, given that the loss values belong to that interval. Formally, the conditional PDF of y , denoted by $f^c(y)$, for the $(Y_l, Y_r]$ interval is defined as $f^c(y) = \Pr[Y = y | Y_l < Y \leq Y_r]$. If $f(y)$ and $F(y)$ denote the PDF and CDF, respectively, at loss value y , then $f^c(y)$ for the $(Y_l, Y_r]$ interval is computed as $f^c(y) = f(y)/(F(Y_r) - F(Y_l))$. The scaling

factor of $1/(F(Y_r) - F(Y_l))$ ensures that the conditional PDF is a true PDF that integrates to 1 in the $(Y_l, Y_r]$ interval.

The conditional PDF comparison plot contains at most three regions (intervals) of mutually exclusive ranges of the loss variable's value,

- left-tail: $(y_{\min} - \epsilon, L]$
- center: $(L, R]$
- right-tail: $(R, y_{\max}]$

where $y_{\min}$ and $y_{\max}$ denote the smallest and largest values, respectively, of the loss variable in the DATA= data table and ϵ denotes a small machine-precision constant for a double-precision value.

You can specify the following *cpdf-options* to control how the values of L and R are computed and which regions are displayed:

LEFTQ=*number*

LEFT=*number*

L=*number*

specifies a *number*, which must be between 0 and 1, that sets the CDF value at the end of the left-tail region. The left-tail region always starts at the minimum loss variable value in the DATA= data table. If *number* is p_l , then PROC SEVSELECT sets L (the end of the left-tail region) equal to the $100p_l$ th percentile, which is an empirical estimate of $Q(p_l)$, where Q denotes the quantile function.

RIGHTQ=*number*

RIGHT=*number*

R=*number*

specifies a *number*, which must be between 0 and 1, that sets the CDF value at the start of the right-tail region. The right-tail region always ends at the maximum loss variable value in the DATA= data table. If *number* is p_r , then PROC SEVSELECT sets R (the start of the right-tail region) equal to the $100p_r$ th percentile, which is an empirical estimate of $Q(p_r)$, where Q denotes the quantile function.

SHOWREGION=(*region-options*)

SHOW=(*region-options*)

specifies one or more regions to display in the plot. You can specify any combination of the following *region-options*. If you specify more than one *region-option*, you must enclose the *region-options* in parentheses.

- | | |
|-------------------|---|
| CENTER C | displays the center region of the plot, which is the region between the end of the left-tail region and the beginning of the right-tail region. If you specify this option, you must also specify valid values for both the LEFTQ= and RIGHTQ= options. |
| LEFT L | displays the left-tail region of the plot. If you specify this option, you must also specify a valid value for the LEFTQ= option. |
| RIGHT R | displays the right-tail region of the plot. If you specify this option, you must also specify a valid value for the RIGHTQ= option. |

If you do not specify the `SHOWREGION` option, then PROC SEVSELECT determines the default displayed regions as follows:

- If you do not specify either the `LEFTQ=` or `RIGHTQ=` option, then this is equivalent to specifying (`LEFTQ=0.25 RIGHTQ=0.75`), and PROC SEVSELECT displays all three regions (left-tail, center, and right-tail).
- If you specify valid values for both the `LEFTQ=` and `RIGHTQ=` options, then PROC SEVSELECT displays all three regions (left-tail, center, and right-tail).
- If you specify a valid value for the `LEFTQ=` option but do not specify the `RIGHTQ=` option, then PROC SEVSELECT displays two regions: the left-tail region and the remaining region that combines the center and right-tail regions.
- If you specify a valid value for the `RIGHTQ=` option but do not specify the `LEFTQ=` option, then PROC SEVSELECT displays two regions: the right-tail region and the remaining region that combines the center and left-tail regions.

NOTE: PROC SEVSELECT computes the percentile estimates, which serve as region boundaries L and R , by using the EDF estimates that it computes by using the EDF estimation process as described in the section “[Empirical Distribution Function Estimation Methods](#)” on page 1799. For large input data tables or distributed mode of execution, the EDF estimates are approximate; therefore, the percentile estimates are also approximate—that is, they are not the same as the percentile estimates that would have been computed if the entire input data table were used.

CONDITIONALPDFPERDIST <(cpdf-options)>

CONDDPDFDIST <(cpdf-options)>

creates a plot of the conditional PDF estimates of each candidate distribution model. A plot is not created for models whose parameter estimation process does not converge.

The *cpdf-options* are identical to those listed for the [CONDITIONALPDF](#) plot option, except that they are interpreted in the context of each candidate distribution individually. You can specify a different set of values for the *cpdf-options* in the `CONDITIONALPDFPERDIST` option than you specify in the `CONDITIONALPDF` option.

NONE

creates none of the graphical output. If you specify this option, then it overrides all the other *plot-request-options*. The default graphical output is also suppressed.

PDF

creates a plot that compares the probability density function (PDF) estimates of all the candidate distribution models. The plot does not contain PDF estimates for models whose parameter estimation process does not converge.

PDFPERDIST

creates a plot of the PDF estimates of each candidate distribution model. A plot is not created for models whose parameter estimation process does not converge.

PP

creates the probability-probability plot (known as the P-P plot), which compares the CDF estimate of each candidate distribution model to the empirical distribution function (EDF). The data that are shown in this plot are used for computing the EDF-based statistics of fit.

QQ

creates the quantile-quantile plot (known as the Q-Q plot), which compares the empirical quantiles to the quantiles of each candidate distribution model.

PRINT *<(global-display-options) > <=display-option>*

PRINT *<(global-display-options) > <= (display-option ... display-option) >*

specifies which output to display. If you specify more than one *display-option*, then separate them with spaces and enclose them in parentheses.

You can specify the following *global-display-options*:

ONLY

turns off the default displayed output and displays only the requested output.

SYMMETRIC=*< symmetric-matrix-print-options >*

SYMM=*< symmetric-matrix-print-options >*

controls the contents of tables that display a symmetric matrix. You can specify the following *symmetric-matrix-print-options*:

SHAPE=*shape*

specifies the shape of the symmetric matrix. You can specify one of the following *shape* values:

FULL | F displays the full matrix.

LOWER | L displays the lower triangular matrix.

UPPER | U displays the upper triangular matrix.

By default, SHAPE=FULL.

NOUNITDIAG | ND

turns off the display of the diagonal for symmetric matrices that have a unit diagonal. By default, PROC SEVSELECT displays the unit diagonal.

If you do not specify the SYMMETRIC= option, then the procedure uses SYMMETRIC=(SHAPE=FULL) by default.

You can specify the following *display-options*:

ALL

displays all the output.

ALLFITSTATS

displays the comparison of all the statistics of fit for all the models in one table. The table does not include the models whose parameter estimation process does not converge.

CONVSTATUS

displays the convergence status of the parameter estimation process.

CORRB**CORR**

displays the estimated correlation matrix of parameters. You can control the display of this matrix by specifying the SHAPE= and NUNITDIAG suboptions of the SYMMETRIC= *global-display-option*.

COVB**COV**

displays the estimated variance-covariance matrix of parameters. You can control the display of this matrix by specifying the SHAPE= suboption of the SYMMETRIC= *global-display-option*.

DESCSTATS

displays the descriptive statistics for the response variable. If you specify the SCALEMODEL statement, then this option also displays the descriptive statistics for the regression effects that do not contain a CLASS variable.

DISTINFO

displays the information about each specified distribution. For each distribution, the information includes the name, description, validity status, and number of distribution parameters.

ESTIMATES**PARMEST**

displays the final estimates of parameters. The estimates are not displayed for models whose parameter estimation process does not converge.

ESTIMATIONDETAILS

displays the details of the estimation process for all the models in one table.

INITIALVALUES

displays the initial values and bounds used for estimating each model.

NLOHISTORY

displays the iteration history of the nonlinear optimization process used for estimating the parameters.

NLOSUMMARY

displays the summary of the nonlinear optimization process used for estimating the parameters.

NONE

displays none of the output. If you specify this option, then it overrides all other display options. The default displayed output is also suppressed.

SELECTION**SELECT**

displays the model selection table.

STATISTICS**FITSTATS**

displays the statistics of fit for each model. The statistics of fit are not displayed for models whose parameter estimation process does not converge.

If you do not specify the PRINT= option or if you do not specify the ONLY *global-display-option*, then the default displayed output is equivalent to specifying PRINT=(SELECTION CONVSTATUS NLOSUMMARY STATISTICS ESTIMATES).

PRINTINTERNALNAMES

prints internal names that are assigned to parameters.

SELECTOUT

specifies that only the regression parameters that correspond to the selected effects be written to the OUTEST= data table. If you omit this option, then the special missing value .N is written for such regression parameters. For more information, see the section “[OUTEST= Data Table](#)” on page 1840.

This option has no effect if you do not specify the SCALEMODEL and SELECTION statements.

VARDEF=DF | N

specifies the denominator to use for computing the covariance estimates. You can specify one of the following values:

DF specifies that the number of nonmissing observations minus the model degrees of freedom (number of parameters) be used.

N specifies that the number of nonmissing observations be used.

For more information about the covariance estimation, see the section “[Estimating Covariance and Standard Errors](#)” on page 1792.

ZEROEST

specifies that zero be written to the OUTEST= data table as an estimate of the regression parameter that is not in the final model (because it is either collinear or not selected). If you omit this option, then the special missing value .R or .N is written for such regression parameters. For more information, see the section “[OUTEST= Data Table](#)” on page 1840.

This option has no effect if you do not specify the SCALEMODEL statement.

The following *options* control the model estimation and selection process:

EMPIRICALCDF=method**EDF=method**

specifies the method to use for computing the nonparametric or empirical estimate of the cumulative distribution function of the data. You can specify one of the following values for *method*:

AUTOMATIC | AUTO

specifies that the method be chosen automatically based on the data specification.

If you do not specify any censoring or truncation, then the standard empirical estimation method (STANDARD) is chosen. If you specify both right-censoring and left-censoring, then Turnbull's estimation method (TURNBULL) is chosen. For all other combinations of censoring and truncation, the Kaplan-Meier method (KAPLANMEIER) is chosen.

KAPLANMEIER | KM

specifies that the product limit estimator proposed by Kaplan and Meier (1958) be used. Specification of this method has no effect when you specify both right-censoring and left-censoring.

MODIFIEDKM | MKM <(options)>

specifies that the modified product limit estimator be used. Specification of this method has no effect when you specify both right-censoring and left-censoring.

This method allows Kaplan-Meier's product limit estimates to be more robust by ignoring the contributions to the estimate due to small risk-set sizes. The risk set is the set of observations at the risk of failing, where an observation is said to fail if it has not been processed yet and might experience censoring or truncation. You can specify the minimum risk-set size that makes it eligible to be included in the estimation either as an absolute lower bound on the size (RSLB= option) or a relative lower bound determined by the formula cn^α proposed by Lai and Ying (1991). You can specify the values of c and α by using the C= and ALPHA= options, respectively. By default, the relative lower bound is used with values of $c = 1$ and $\alpha = 0.5$. However, you can modify the default by using the following *options*:

ALPHA | A=number

specifies the value to use for α when the lower bound on the risk set size is defined as cn^α . This value must satisfy $0 < \alpha < 1$.

C=number

specifies the value to use for c when the lower bound on the risk set size is defined as cn^α . This value must satisfy $c > 0$.

RSLB=number

specifies the absolute lower bound on the risk set size to be included in the estimate.

NOTURNBULL

specifies that the method be chosen automatically based on the data specification and that Turnbull's method not be used. This option is the default.

This method first replaces each left-censored or interval-censored observation with an uncensored observation. If the resulting set of observations has any truncated or right-censored observations, then the Kaplan-Meier method (KAPLANMEIER) is chosen. Otherwise, the standard empirical estimation method (STANDARD) is chosen. The observations are modified only for the purpose of computing the EDF estimates; the modification does not affect the parameter estimation process.

STANDARD | STD

specifies that the standard empirical estimation method be used. If you specify both right-censoring and left-censoring, then the specification of this method has no effect. If you specify any other combination of censoring or truncation effects, then this method ignores such effects, and can thus result in estimates that are more biased than those obtained with other methods that are more suitable for censored or truncated data.

TURNBULL | EM <(options)>

specifies that the Turnbull's method be used. This method is used when you specify both right-censoring and left-censoring. An iterative expectation-maximization (EM) algorithm proposed by Turnbull (1976) is used to compute the empirical estimates. If you also specify truncation, then the modification suggested by Frydman (1994) is used.

This method is used if you specify both right-censoring and left-censoring and if you explicitly specify the `EMPIRICALCDF=TURNBULL` option.

You can modify the default behavior of the EM algorithm by using the following *options*:

ENSUREMLE

specifies that the final EDF estimates be maximum likelihood estimates. The Kuhn-Tucker conditions are computed for the likelihood maximization problem and checked to ensure that EM algorithm converges to maximum likelihood estimates. The method generalizes the method proposed by Gentleman and Geyer (1994) by taking into account any truncation information that you might specify.

EPS=number

specifies the maximum relative error to be allowed between estimates of two consecutive iterations. This criterion is used to check the convergence of the algorithm. If you do not specify this option, then PROC SEVSELECT uses a default value of 1.0E-8.

MAXITER=number

specifies the maximum number of iterations to attempt to find the empirical estimates. If you do not specify this option, then PROC SEVSELECT uses a default value of 500.

ZEROPROB=number

specifies the threshold below which an empirical estimate of the probability is considered zero. This option is used to decide if the final estimate is a maximum likelihood estimate. This option does not have an effect if you do not specify the ENSUREMLE option. If you specify the ENSUREMLE option, but do not specify this option, then PROC SEVSELECT uses a default value of 1.0E-8.

For more information about each of the methods, see the section “[Empirical Distribution Function Estimation Methods](#)” on page 1799.

INITSAMPLE (initsample-option)**INITSAMPLE (initsample-option ... initsample-option)**

specifies that a sample of the input data be used for initializing the distribution parameters. If you specify more than one *initsample-option*, then separate them with spaces.

When you do not specify initial values for the distribution parameters, PROC SEVSELECT needs to compute the empirical distribution function (EDF) estimates as part of the default method for parameter

initialization. The EDF estimation process can be expensive, especially when you specify censoring or truncation effects for the loss variable. Furthermore, it is not amenable to parallelism due to the sequential nature of the algorithm for truncation effects. You can use the INITSAMPLE option to specify that only a fraction of the input data be used in order to reduce the time taken to compute the EDF estimates. PROC SEVSELECT uses the uniform random sampling method to select the sample, the size and randomness of which are controlled by the following *initsample-options*:

FRACTION=number

specifies the fraction, between 0 and 1, of the input data to be used for sampling.

SEED=number

specifies the seed to be used for the uniform random number generator. This option enables you to select the same sample from the same input data across different runs of PROC SEVSELECT, which can be useful for replicating the results across different runs. If you do not specify the seed value, PROC SEVSELECT generates a seed that is based on the system clock.

SIZE=number

specifies the size of the sample. If the data are distributed across different nodes, then this size applies to the sample that is prepared at each node. For example, let the input data table of size 100,000 observations be distributed across 10 nodes such that each node has 10,000 observations. If you specify SIZE=1000, then each node computes a local EDF estimate by using a sample of size 1,000 selected randomly from its 10,000 observations.

If you specify both the SIZE= and FRACTION= options, then the value that you specify in the SIZE= option is used and the FRACTION= option is ignored.

If you do not specify the INITSAMPLE option, then a uniform random sample of at most 10,000 observations is used for EDF estimation on each node that has observations.

NOBALANCETHREADS

NOBALTHR

specifies that the observations do not need to be balanced among threads of computation.

Starting with SAS Econometrics 8.5, the parameter estimation phase balances the observations among all threads of computation by default; this helps achieve significantly faster estimation times. However, this balanced processing can cause small numerical differences compared to the prior releases that did not balance observations among threads of computation. You should specify this option only if you want to restore the numerical behavior of releases prior to 8.5. However, use of this option can lead to a significantly slower estimation phase in most cases, and therefore it is strongly discouraged.

NOCONSTFITSTATS

NOCONSTSOF

excludes the constant distribution parameters, if any are specified, from the calculations of likelihood-based fit statistics (AIC, AICC, and SBC) that depend on the number of model parameters.

By default, constant distribution parameters are assumed to be estimable (even if PROC SEVSELECT does not estimate them) and are included in the calculations of the likelihood-based fit statistics.

OBJECTIVE=*symbol-name*

names the symbol that represents the objective function in the SAS programming statements that you specify. For each model to be estimated, PROC SEVSELECT executes the programming statements to compute the value of this symbol for each observation. The values are added across all observations to obtain the value of the objective function. The optimization algorithm estimates the model parameters such that the objective function value is *minimized*. A separate optimization problem is solved for each candidate distribution. If you specify a BY statement, then a separate optimization problem is solved for each candidate distribution within each BY group.

For more information about writing SAS programming statements to define your own objective function, see the section “[Custom Objective Functions](#)” on page 1836.

SELECTNLOTECH=CONGRA | DBLDOG | NEWRAP | NMSIMP | NRRIDG | QUANEW | TRUREG

specifies the nonlinear optimization technique to use for the intermediate steps of the regression effect selection process. The can specify one of the following techniques:

CONGRA	performs a conjugate-gradient optimization.
DBLDOG	performs a version of double-dogleg optimization.
NEWRAP	performs a Newton-Raphson optimization that combines a line-search algorithm with ridging.
NMSIMP	performs a Nelder-Mead simplex optimization.
NRRIDG	performs a Newton-Raphson optimization with ridging.
QUANEW	performs a dual quasi-Newton optimization.
TRUREG	performs a trust region optimization.

This option has no effect if you do not specify the SELECTION statement.

If you omit this option, then the default optimization technique for the intermediate steps of the selection process is the same technique that PROC SEVSELECT uses to estimate the parameters of the final selected model. You can control that technique by specifying the [TECHNIQUE=](#) option in the [NLOPTIONS](#) statement.

BY Statement

BY *variable-list* ;

A BY statement can be used in the SEVSELECT procedure to process the input data table in groups of observations defined by the BY variables.

If you specify the BY statement, PROC SEVSELECT does not need the input data table to be sorted in the order of the BY variables. As a consequence, the NOTSORTED and DESCENDING options have no effect and PROC SEVSELECT ignores them.

CLASS Statement

CLASS *variable* <(*options*)> . . . <*variable* <(*options*)> > </ *global-options* > ;

The CLASS statement names the classification variables to be used as explanatory variables in the analysis. You can list the response variable for binary models in the CLASS statement, but this is not required. Table 26.2 summarizes the values that you can use for either an *option* or a *global-option*. The options are fully documented in the section “CLASS Statement” on page 56 in Chapter 4, “Shared Concepts.”

Table 26.2 CLASS Statement Options

Option	Description
DESCENDING	Reverses the sort order
MISSING	Treats missing values as valid levels
ORDER=	Specifies the sort order for the levels
PARAM=	Specifies the parameterization of the variable
REF=	Specifies the reference level of the variable
SPLIT	Splits levels of CLASS variables into independent effects

DISPLAY Statement

DISPLAY <*table-list*> </ *options* > ;

The DISPLAY statement enables you to specify a list of display tables to display or exclude. This statement is similar to the ODS SELECT, ODS EXCLUDE, and ODS TRACE statements. However, the DISPLAY statement can improve performance when a large number of tables could be generated (such as in BY-group processing). The procedure processes the DISPLAY statement on a CAS server and thus sends only a subset of ODS tables to the SAS client. Because ODS statements are processed on a SAS client, first all the generated display tables are sent to the client, and then the client creates a subset.

If you use both DISPLAY and ODS statements together, the DISPLAY statement takes precedence over the ODS statements. Note that the ODS EXCLUDE statement processes tables that are sent to the client after they have been filtered by the DISPLAY statement. In some cases, it might appear that the ODS EXCLUDE statement is taking precedence because it can further filter the tables. For more information about ODS, see *SAS Output Delivery System: Procedures Guide*.

You can specify the *table-list* as a list of table names, paths, partial pathnames, and regular expressions.

The table names that you can specify are listed in the section “Displayed Output” on page 1845. A path is a table name that is prefixed with dot-separated grouping information. For example, a SelectionSummary table that a procedure produces during a selection routine might have the path *Bygroup1.Summary.SelectionSummary*. A partial pathname does not include all groups; for example, *Selection-Summary* and *Summary.SelectionSummary* are partial pathnames for *Bygroup1.Summary.SelectionSummary*.

When you specify a table name or partial pathname, all display tables whose paths end in the specified name are selected for display or exclusion. For example, both *SelectionSummary* and *Summary.SelectionSummary* select *Bygroup1.Summary.SelectionSummary*.

A regular expression is enclosed in forward slashes (/). For example, specifying “/tions/” selects all pathnames that contain the substring “tions”; in particular, the *Bygroup1.Summary.SelectionSummary* table is selected. Specifying “!/tions/” selects all pathnames that do not contain the substring “tions”; in particular, the *Bygroup1.Summary.SelectionSummary* table is not selected.

You can specify the following *options* after a slash (/):

CASESENSITIVE

performs a case-sensitive comparison of table names in the *table-list* to display table names when tables are subsetting for display. To preserve case, you must enclose table names in the *table-list* in quotation marks.

EXCLUDE

displays all display tables except those that you specify in the *table-list*.

EXCLUDEALL

suppresses display of all tables. This option takes precedence over the other options.

TRACE

displays the display table names, labels, and paths.

DISPLAYOUT Statement

DISPLAYOUT *table-spec-list* < / *options* > ;

The DISPLAYOUT statement enables you to create output tables from your displayed output. This statement is similar to the ODS OUTPUT statement. For more information about ODS, see [SAS Output Delivery System: Procedures Guide](#).

The *table-spec-list* specifies a list of output tables to create. Each entry in the list has either a *key=value* format or a *key* format:

<i>key=value</i>	specifies <i>key</i> as the ODS table name, path, or partial pathname, and specifies <i>value</i> as the output table name.
<i>key</i>	specifies <i>key</i> as the ODS table name and also as the output table name.

The ODS table names that you can specify are listed in the section “[Displayed Output](#)” on page 1845. You cannot specify the ODS table named OutputCasTables in the *table-spec-list*.

Table names and partial pathnames are discussed under the [DISPLAY](#) statement. The DISPLAYOUT statement does not support regular expressions.

You can specify the following *options* after a slash (/):

INCLUDEALL

creates output tables for all display tables. The name of the created output table is the same as the name of the corresponding display table. If you specify this option, the *table-spec-list* specification is ignored.

NOREPLACE

does not replace any existing output table of the same name.

REPEATED

replicates all output tables on all nodes.

DIST Statement

DIST *distribution-name-or-keyword* < (*distribution-option*) < *distribution-name-or-keyword* < (*distribution-option*) > > ... > < / *options* > ;

The DIST statement specifies candidate distributions to be estimated by the SEVSELECT procedure. You can specify multiple DIST statements, and each statement can contain one or more distribution specifications.

For your convenience, PROC SEVSELECT provides the following 10 different predefined distributions (the name in parentheses is the name to use in the DIST statement): Burr (BURR), exponential (EXP), gamma (GAMMA), generalized Pareto (GPD), inverse Gaussian or Wald (IGAUSS), lognormal (LOGN), Pareto (PARETO), Tweedie (TWEEDIE), scaled Tweedie (STWEEDIE), and Weibull (WEIBULL). These are described in detail in the section “[Predefined Distributions](#)” on page 1779.

You can specify any of the predefined distributions or any distribution that you have defined. If a distribution that you specify is not a predefined distribution, then you must submit the CMPLIB= system option with appropriate libraries before you submit the PROC SEVSELECT step to enable the procedure to find the functions associated with your distribution. The predefined distributions are defined in the Sashelp.Svrtldist library. However, you are not required to specify this library in the CMPLIB= system option. For more information about defining your own distributions, see the section “[Defining a Severity Distribution Model with the FCMP Procedure](#)” on page 1811.

As a convenience, you can also use a shortcut keyword to indicate a list of distributions. You can specify one or more of the following keywords:

ALL

specifies all the predefined distributions and the distributions that you have defined in the libraries that you specify in the CMPLIB= system option. In addition to the eight predefined distributions included by the _PREDEFINED_ keyword, this list also includes the Tweedie and scaled Tweedie distributions that are defined in the Sashelp.Svrtldist library.

PREDEFINED

specifies the list of eight predefined distributions: BURR, EXP, GAMMA, GPD, IGAUSS, LOGN, PARETO, and WEIBULL. Although the TWEEDIE and STWEEDIE distributions are available in the Sashelp.Svrtldist library along with these eight distributions, they are not included by this keyword. If you want to fit the TWEEDIE and STWEEDIE distributions, then you must specify them explicitly or use the _ALL_ keyword.

USER

specifies the list of all the distributions that you have defined in the libraries that you specify in the CMPLIB= system option. This list does not include the distributions defined in the Sashelp.Svrtldist library, even if you specify the Sashelp.Svrtldist library in the CMPLIB= option.

The use of these keywords, especially `_ALL_`, can result in a large list of distributions, which might take a longer time to estimate. A warning is printed to the SAS log if the number of total distribution models to estimate exceeds 10.

The following *distribution-option* values can be used in the DIST statement for a distribution name that is not a shortcut keyword:

INIT=(name=value ... name=value)

specifies the initial values to be used for the distribution parameters to start the parameter estimation process. You must specify the values by parameter names, and the parameter names must match the names used in the model definition. For example, let a model M's definition contain an `M_PDF` function with the following signature:

```
function M_PDF(x, alpha, beta);
```

For this model, the names `alpha` and `beta` must be used for the INIT option. The names are case-insensitive. If you do not specify initial values for some parameters in the INIT statement, then a default value of 0.001 is assumed for those parameters. If you specify an incorrect parameter, PROC SEVSELECT prints a warning to the SAS log and does not fit the model. All specified values must be nonmissing.

If you are modeling regression effects, then the initial value of the first distribution parameter (`alpha` in the preceding example) should be the initial *base* value of the scale parameter or log-transformed scale parameter. For more information, see the section “[Estimating Regression Effects](#)” on page 1794.

The use of INIT= option is one of the three methods available for initializing the parameters. For more information, see the section “[Parameter Initialization](#)” on page 1793. If none of the initialization methods is used, then PROC SEVSELECT initializes all parameters to 0.001.

You can specify the following *options* in the DIST statement:

INFUNCDEF="table-name"

INTAB="table-name"

INFUNCDEF=table-name<(CASLIB="library")>

INTAB=table-name<(CASLIB="library")>

specifies a data table that contains the distribution function definitions. If you use the first form to specify the data table, then PROC SEVSELECT assumes that the table is in the library that is active in the current CAS session. To specify a different library, use the second form.

LISTONLY

prints the list of all candidate distributions to the SAS log without doing any further processing on them. This option is especially useful when you use a shortcut keyword to include a list of distributions. It enables you to find out which distributions are included by the keyword.

OUTFUNCDEF="table-name"<option>

OUTTAB="table-name" <option>

specifies the output data table to write the distribution function definitions to. The table is created in the library that is active for the current CAS session.

This option is useful for creating a data table that you can use to invoke the actions in the **severity** action set from the PROC CAS, Lua, or Python client.

You can specify the following *option*:

GLOBAL

PROMOTED

promotes the data table to make it available globally.

If you do not specify this option, the table is session-local, which means it is accessible only to the current CAS session that is executing the PROC SEVSELECT step. When the current CAS session is terminated, the UTFUNCDEF= table is deleted.

When you specify this option, the table persists in the memory of the CAS server and is available to other CAS sessions that you might start after the CAS session that is executing the current PROC SEVSELECT step is terminated.

If you do not specify the UTFUNCDEF= or INFUNCDEF= option, then PROC SEVSELECT creates a session-local data table named svrtdist in the library that is active for the current CAS session.

VALIDATEONLY

VALIDATEONLY (NOSCALEMODEL)

checks all candidate distributions for validity without doing any further processing on them. The first form checks whether each distribution's first parameter is a scale parameter, which is a requirement for fitting a scale regression model for that distribution. You can disable that check by using the second form, which specifies the NOSCALEMODEL option; this is useful if you do not want to fit a scale regression model for a distribution.

PROC SEVSELECT writes the distribution information to the DistributionInfo ODS table.

This option is especially useful when you specify your own distributions or when you specify the `_USER_` or `_ALL_` keyword in the DIST statement. It enables you to check whether your custom distribution definitions satisfy PROC SEVSELECT's requirements for the specified modeling task. It is recommended that you specify the SCALEMODEL statement if you intend to fit a model with regression effects, because the SCALEMODEL statement instructs PROC SEVSELECT to perform additional checks to validate whether regression effects can be modeled on each candidate distribution.

This option is also useful in conjunction with the `UTFUNCDEF=` option when you define or update a custom distribution and want to write its definition to the CAS table that you can use to invoke the actions in the **severity** action set from the PROC CAS, Lua, or Python client.

EFFECT Statement

EFFECT *name=effect-type* (*variables* < / *options* >) ;

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 94 in Chapter 4, “Shared Concepts.”

You can specify the following *effect-types*:

COLLECTION	specifies a collection effect that defines one or more variables as a single effect that has multiple degrees of freedom. The variables in a collection are considered as a unit for purposes of estimation and inference.
MULTIMEMBER MM	specifies a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.
POLYNOMIAL POLY	specifies a multivariate polynomial effect in the specified numeric variables.
SPLINE	specifies a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables.

Table 26.3 summarizes the *options* available in the EFFECT statement.

Table 26.3 EFFECT Statement Options

Option	Description
Collection Effects Options	
DETAILS	Displays the constituents of the collection effect
Multimember Effects Options	
DETAILS	Displays the levels of the multimember effect
NOEFFECT	Specifies that observations whose levels are all missing for the multimember variables should have 0 values in the corresponding design matrix columns
STDIZE	Standardizes the design matrix entries so that each observation has a sum of 1
WEIGHT=	Specifies the weight variable for the contributions of each classification effect
Polynomial Effects Options	
DEGREE=	Specifies the degree of the polynomial
DETAILS	Displays details of the specified polynomial
MDEGREE=	Specifies the maximum degree of any variable in a term of the polynomial
NOSEPARATE	Treats the polynomial as a single effect with multiple degrees of freedom
STANDARDIZE=	Specifies centering and scaling suboptions for the variables that define the polynomial

Table 26.3 *continued*

Option	Description
Spline Effects Options	
BASIS=	Specifies the type of basis (B-spline basis or truncated power function basis) for the spline effect
DATABOUNDARY	Uses the extremes of the data as boundary knots for a B-spline basis
DEGREE=	Specifies the degree of the spline effect
DETAILS	Displays the knots and locations for each spline basis function
KNOTMAX=	Requests equally spaced right-side boundary knots starting at the variables' maximum and ending at the KNOTMAX= value
KNOTMETHOD=	Specifies how to construct the knots for the spline effect
KNOTMIN=	Requests equally spaced left-side boundary knots starting at the KNOTMIN= value and ending at the variables' minimum value
NATURALCUBIC	Specifies a natural cubic spline basis for the spline effect
SEPARATE	Treats the spline basis for each variable as a separate effect when multiple variables are specified
SPLIT	Treats each design matrix column as a separate effect for selection methods

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “[EFFECT Statement](#)” on page 62 in Chapter 4, “[Shared Concepts](#).” Each *effect-type* has a **DETAILS** option that you can use to print tables that contain the details of the effect. However, these tables are produced only if you also specify **PRINT=ALL** option in the PROC SEVSELECT statement.

LOSS Statement

LOSS < *response-variable-name* > < / *censoring-truncation-options* > ;

The LOSS statement specifies the name of the response or loss variable whose distribution needs to be modeled. You can also specify additional options to indicate any truncation or censoring of the response. The specification of response variable is optional if you specify at least one type of censoring. You must specify a response variable if you do not specify any censoring. If you specify more than one LOSS statement, then the first statement is used.

All the analysis variables that you specify in this statement must be present in the input data table that you specify by using the **DATA=** option in the PROC SEVSELECT statement. The response variable is expected to have nonmissing values. If the variable has a missing value in an observation, then a warning is written to the SAS log and that observation is ignored.

The following *censoring-truncation-options* can be used in the LOSS statement:

LEFTCENSORED | LC=variable-name**LEFTCENSORED | LC=number**

specifies the left-censoring variable or a global left-censoring limit.

You can use the *variable-name* argument to specify a data table variable that contains the left-censoring limit. If the value of this variable is missing, then PROC SEVSELECT assumes that such observations are not left-censored.

Alternatively, you can use the *number* argument to specify a left-censoring limit value that applies to all the observations in the data table. This limit must be a nonzero positive number.

By the definition of left-censoring, an exact value of the response is not known when it is less than or equal to the left-censoring limit. If you specify the response variable and the value of that variable is less than or equal to the value of the left-censoring limit for some observations, then PROC SEVSELECT treats such observations as left-censored and the value of the response variable is ignored. If you specify the response variable and the value of that variable is greater than the value of the left-censoring limit for some observations, then PROC SEVSELECT assumes that such observations are not left-censored and the value of the left-censoring limit is ignored.

If you specify both right-censoring and left-censoring limits, then the left-censoring limit must be greater than or equal to the right-censoring limit. If both limits are identical, then the observation is assumed to be uncensored.

For more information about left-censoring, see the section “[Censoring and Truncation](#)” on page 1789.

LEFTTRUNCATED | LT=variable-name < (left-truncation-option) >**LEFTTRUNCATED | LT=number < (left-truncation-option) >**

specifies the left-truncation variable or a global left-truncation threshold.

You can use the *variable-name* argument to specify a data table variable that contains the left-truncation threshold. If the value of this variable is missing or 0 for some observations, then PROC SEVSELECT assumes that such observations are not left-truncated.

Alternatively, you can use the *number* argument to specify a left-truncation threshold that applies to all the observations in the data table. This threshold must be a nonzero positive number.

It is assumed that the response variable contains the observed values. By the definition of left-truncation, you can observe only a value that is greater than the left-truncation threshold. If a response variable value is less than or equal to the left-truncation threshold, a warning is printed to the SAS log, and the observation is ignored. For more information about left-truncation, see the section “[Censoring and Truncation](#)” on page 1789.

You can specify the following *left-truncation-option* for an alternative interpretation of the left-truncation threshold:

PROBOBSERVED | POBS=number

specifies the probability of observability, which is defined as the probability that the underlying severity event is observed (and recorded) for the specified left-threshold value.

The specified *number* must lie in the (0.0, 1.0] interval. A value of 1.0 is equivalent to specifying that there is no left-truncation, because it means that no severity events can occur with a value less than or equal to the threshold. If you specify value of 1.0, PROC SEVSELECT prints a warning to the SAS log and proceeds by assuming that LEFTTRUNCATED= option is not specified.

For more information, see the section “[Probability of Observability](#)” on page 1790.

RIGHTCENSORED | **RC=***variable-name*

RIGHTCENSORED | **RC=***number*

specifies the right-censoring variable or a global right-censoring limit.

You can use the *variable-name* argument to specify a data table variable that contains the right-censoring limit. If the value of this variable is missing, then PROC SEVSELECT assumes that such observations are not right-censored.

Alternatively, you can use the *number* argument to specify a right-censoring limit value that applies to all the observations in the data table. This limit must be a nonzero positive number.

By the definition of right-censoring, an exact value of the response is not known when it is greater than or equal to the right-censoring limit. If you specify the response variable and the value of that variable is greater than or equal to the value of the right-censoring limit for some observations, then PROC SEVSELECT treats such observations as right-censored and the value of the response variable is ignored. If you specify the response variable and the value of that variable is less than the value of the right-censoring limit for some observations, then PROC SEVSELECT assumes that such observations are not right-censored and the value of the right-censoring limit is ignored.

If you specify both right-censoring and left-censoring limits, then the left-censoring limit must be greater than or equal to the right-censoring limit. If both limits are identical, then the observation is assumed to be uncensored.

For more information about right-censoring, see the section “[Censoring and Truncation](#)” on page 1789.

RIGHTTRUNCATED | **RT=***variable-name*

RIGHTTRUNCATED | **RT=***number*

specifies the right-truncation variable or a global right-truncation threshold.

You can use the *variable-name* argument to specify a data table variable that contains the right-truncation threshold. If the value of this variable is missing for some observations, then PROC SEVSELECT assumes that such observations are not right-truncated.

Alternatively, you can use the *number* argument to specify a right-truncation threshold that applies to all the observations in the data table. This threshold must be a nonzero positive number.

It is assumed that the response variable contains the observed values. By the definition of right-truncation, you can observe only a value that is less than or equal to the right-truncation threshold. If a response variable value is greater than the right-truncation threshold, a warning is printed to the SAS log, and the observation is ignored. For more information about right-truncation, see the section “[Censoring and Truncation](#)” on page 1789.

NLOPTIONS Statement

NLOPTIONS *options* ;

The SEVSELECT procedure uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization of the likelihood function to obtain the estimates of distribution and regression parameters. You can use the NLOPTIONS statement to control different aspects of this optimization process. If you specify more than one NLOPTIONS statement, then the first statement is used.

For most problems, the default settings of the optimization process are adequate. However, in some cases it might be useful to change the optimization technique or to change the maximum number of iterations. The following statement uses the MAXITER= option to set the maximum number of iterations to 200 and uses the TECH= option to change the optimization technique to the double-dogleg optimization (DBLDOG) rather than the default technique, the trust region optimization (TRUREG), used in the SEVSELECT procedure:

```
nloptions tech=dbldog maxiter=200;
```

For more information about the options you can specify in the NLOPTIONS statement, see the section “[Optimization Options](#)” on page 84. For more information about the optimization methods, see the section “[Choosing an Optimization Algorithm](#)” on page 108.

OUTPUT Statement

OUTPUT < **OUT**=*libref.data-table* > *output-options* ;

The OUTPUT statement creates the output data table that contains the estimates of scoring functions and quantiles.

You must specify the following option:

OUT=*libref.data-table*

names the output data table for PROC SEVSELECT to use. You must specify this option before any other options. *libref.data-table* is a two-level name, where

<i>libref</i>	refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to where the data table is to be stored, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about <i>libref</i> , see the section “ Using CAS Sessions and CAS Engine Librefs ” on page 1724.
---------------	---

<i>data-table</i>	specifies the name of the output data table.
-------------------	--

The *libref* must be identical to the *libref* that you specify in the **DATA**= option.

To control the contents of the OUT= data table, specify the following *output-options*:

COPYVARS=*variable-list*

specifies the names of the variables that you want to copy from the input DATA= data table to the OUT= data table. If you want to specify more than one name, then separate them by spaces.

If you specify the BY statement, then the BY variables are not automatically copied to the OUT= data table, so you must specify the BY variables in the COPYVARS= option.

FUNCTIONS=(*function*<(arg)><=*variable*> <*function*<(arg)><=*variable*>> ...)

specifies the scoring functions that you want to estimate. For each scoring function that you want to estimate, specify the suffix of the scoring function as the *function*. For each *function* that you specify in this option and for each distribution *D* that you specify in the DIST statement, the FCMP function *D_function* must be available in the search path that you specify by using the CMPLIB= system option. The signature of *D_function* must be identical to the signature of the required distribution function such as *D_CDF* or *D_LOGCDF*. For example, for the function 'FOO_BAR' to be a scoring function, you must specify the distribution 'FOO' in the DIST statement, and you must define 'FOO_BAR' in the following manner if the distribution 'FOO' has parameters named 'P1' and 'P2':

```
function FOO_BAR(y, P1, P2);
  /* Code to compute BAR by using y, P1, and P2 */
  R = <computed BAR>;
  return (R);
endsub;
```

You can then specify BAR as the *function* in the FUNCTIONS= option. For more information about the signature that defines a distribution function, see the description of the [D_CDF](#) function in the section “[Defining a Severity Distribution Model with the FCMP Procedure](#)” on page 1811.

If you want to evaluate the scoring function at a specific value of the response variable, then specify a number *arg*, which is enclosed in parentheses immediately after the *function*. If you do not specify *arg* or if you specify a missing value as *arg*, then for each observation in the DATA= data table, PROC SEVSELECT computes the value *v* by using the following table and evaluates the scoring function at *v*, where *y*, *r*, and *l* denote the values of the response variable, right-censoring limit, and left-censoring limit, respectively:

Right-Censored	Left-Censored	<i>v</i>
No	No	<i>y</i>
No	Yes	<i>l</i>
Yes	No	<i>r</i>
Yes	Yes	$(l + r)/2$

You can specify the suffix of the variable that contains the estimate of the scoring function by specifying a valid SAS name as a *variable*. If you do not specify a *variable*, then PROC SEVSELECT uses *function* as the suffix of the variable name.

To illustrate the FUNCTIONS= option with an example, assume that you specify the following DIST and OUTPUT statements:

```
dist exp logn;
output out=mylib.score functions=(cdf pdf(1000)=f1000 mean);
```

Let both exponential (EXP) and lognormal (LOGN) distributions converge. If $\hat{\theta}$ is the final estimate of the scale parameter of the exponential distribution, then PROC SEVSELECT creates the following three scoring function variables for the exponential (EXP) distribution in the mylib.Score data table:

EXP_CDF	contains the CDF estimate $F_{\text{exp}}(v, \hat{\theta})$, where F_{exp} denotes the CDF of the exponential distribution and v is the value that is determined by the preceding table.
EXP_F1000	contains the PDF estimate $f_{\text{exp}}(1000, \hat{\theta})$, where f_{exp} denotes the PDF of the exponential distribution.
EXP_MEAN	contains the mean of the exponential distribution for the scale parameter $\hat{\theta}$.

Similarly, if $\hat{\mu}$ and $\hat{\sigma}$ are the final estimates of the log-scale and shape parameters of the lognormal distribution, respectively, then PROC SEVSELECT creates the following three scoring function variables for the lognormal (LOGN) distribution in the mylib.Score data table:

LOGN_CDF	contains the CDF estimate $F_{\text{logn}}(v, \hat{\mu}, \hat{\sigma})$, where F_{logn} denotes the CDF of the lognormal distribution and v is the value that is determined by the preceding table.
LOGN_F1000	contains the probability density function (PDF) estimate $f_{\text{logn}}(1000, \hat{\mu}, \hat{\sigma})$, where f_{logn} denotes the PDF of the lognormal distribution.
LOGN_MEAN	contains the mean of the lognormal distribution for the parameters $\hat{\mu}$ and $\hat{\sigma}$.

If you specify the SCALEMODEL statement, then the value of the scale parameter of a distribution depends on the values of the regression parameters. So it might be different for different observations. In this example, the values of $\hat{\theta}$ and $\hat{\mu}$ might vary by observation, which might cause the values of the EXP_F1000, EXP_MEAN, LOGN_F1000, and LOGN_MEAN variables to vary by observation. The values of the EXP_CDF and LOGN_CDF variables might vary not only because of the varying values of v but also because of the varying values of $\hat{\theta}$ and $\hat{\mu}$.

If you do not specify the SCALEMODEL statement, then the values of scoring functions for which you specify a nonmissing argument *arg* and scoring functions that do not depend on the response variable value do not vary by observation. In this example, the values of the EXP_F1000, EXP_MEAN, LOGN_F1000, and LOGN_MEAN variables do not vary by observation.

If a distribution does not converge, then the scoring function variables for that distribution contain missing values in all observations.

QUANTILES=*quantile-options*

specifies the quantiles that you want to estimate. To use this option, for each distribution that you specify in the DIST statement, the FCMP function *D_QUANTILE* must be defined in the search path that you specify by using the CMPLIB= system option.

You can specify the following *quantile-options*:

CDF=*CDF-values*

POINTS=*CDF-values*

specifies the CDF values at which you want to estimate the quantiles. *CDF-values* can be one or more numbers, separated by spaces. Each number must be in the interval (0,1).

NAMES=(*variable-names*)

specifies the suffixes of the names of the variables for each of the quantile estimates. If you specify n ($n \geq 0$) names in the *variable-names* option and k values in the CDF= option, and if $n < k$, then PROC SEVSELECT uses the n names to name the variables that correspond to the first n CDF values. For each of the remaining $k - n$ CDF values, p_i ($n < i \leq k$), PROC SEVSELECT creates a variable name P_t , where t is the text representation of $100p_i$ that is formed by retaining at most NDECIMAL= digits after the decimal point and replacing the decimal point with an underscore ('_').

NDECIMAL=*number*

specifies the number of digits to keep after the decimal point when PROC SEVSELECT creates the name of the quantile estimate variable. If you do not specify this option, then the default value is 3.

For example, assume that you specify the following DIST and OUTPUT statements:

```
dist burr;
output out=score quantiles=(cdf=0.9 0.975 0.995 names=(ninety var));
```

PROC SEVSELECT creates three quantile estimate variables, BURR_NINETY, BURR_VAR, and BURR_P99_5, in the mylib.Score data table for the Burr distribution. These variables contain the estimates of $Q_{\text{Burr}}(p, \hat{\theta}, \hat{\alpha}, \hat{\gamma})$, for $p = 0.9, 0.975$, and 0.995 , respectively, where Q_{Burr} denotes the quantile function and $\hat{\theta}$, $\hat{\alpha}$, and $\hat{\gamma}$ denote the parameter estimates of the Burr distribution.

If you specify the SCALEMODEL statement, then the quantile estimate might vary by observation, because the scale parameter of a distribution depends on the values of the regression parameters.

If you do not specify the SCALEMODEL statement, then the quantile estimates do not vary by observation, and if you do not specify any scoring functions in the FUNCTIONS= option whose estimates vary by observation, then the OUT= data table contains only one observation per BY group.

If a distribution does not converge, then the quantile estimate variables for that distribution contain missing values for all observations.

For more information about the variables and observations in the OUT= data table, see the section “[OUT= Data Table](#)” on page 1840.

OUTSCORELIB Statement

OUTSCORELIB <**OUTLIB=**> *fcmp-library-name* options ;

The OUTSCORELIB statement specifies the library to write scoring functions to. Scoring functions enable you to easily compute a distribution function on the fitted parameters of the distribution without going through a potentially complex process of extracting the fitted parameter estimates from other output, such as the OUTEST= data table that PROC SEVSELECT creates.

If you specify the SCALEMODEL statement and specify interaction or classification effects, then PROC SEVSELECT ignores the OUTSCORELIB statement and does not generate scoring functions. In other words, if you specify the SCALEMODEL statement, then PROC SEVSELECT generates scoring functions if you specify only singleton continuous effects in the SCALEMODEL statement.

You must specify the following option as the first option in the statement:

OUTLIB=*fcmp-library-name*

names the FCMP library to contain the scoring functions. PROC SEVSELECT writes the scoring functions to the FCMP library named *fcmp-library-name*. If a library or data set named *fcmp-library-name* already exists, PROC SEVSELECT deletes it before proceeding.

This option is similar to the OUTLIB= option that you would specify in a PROC FCMP statement, except that *fcmp-library-name* must be a two-level name, whereas the OUTLIB= option in the PROC FCMP statement requires a three-level name. The third level of a three-level name specifies the package to which the functions belong. You do not need to specify the package name in the *fcmp-library-name*, because PROC SEVSELECT automatically creates the package for you. By default, it creates a separate package for each distribution that has not failed to converge. Each package is named for a distribution. For example, if you define and fit a distribution named *mydist*, and if *mydist* does not fail to converge, then PROC SEVSELECT creates a package named *mydist* in the OUTLIB= library that you specify. Further, suppose that the definition of the *mydist* distribution contains three distribution functions, *mydist_PDF*(*x*,*Parm1*,*Parm2*), *mydist_LOGCDF*(*x*,*Parm1*,*Parm2*), and *mydist_XYZ*(*x*,*Parm1*,*Parm2*). If you specify the OUTSCORELIB statement

```
outscorelib outlib=sasuser.scorefunc;
```

then the library Sasuser.Scorefunc contains the following three functions in a package named *mydist*: *SEV_PDF*(*x*), *SEV_LOGCDF*(*x*), and *SEV_XYZ*(*x*).

The key feature of scoring functions is that they do not require the parameter arguments (*Parm1* and *Parm2* in this example). The fitted parameter estimates are encoded inside the scoring function so that you can compute or score the value of each function for a given value of the loss variable without having to know or extract the parameter estimates through some other means.

For convenience, you can omit the OUTLIB= portion of the specification and specify only the name, as in the following example:

```
outscorelib sasuser.scorefunc;
```

When the SEVSELECT procedure runs successfully, the *fcmp-library-name* is appended to the CMPLIB system option, so you can immediately start using the scoring functions in a DATA step or PROC FCMP step. Note that the generated scoring FCMP functions can be used only in a DATA step that runs on the client machine; you cannot use them in a DATA step that runs on the CAS server.

You can specify the following *options* in the OUTSCORELIB statement:

COMMONPACKAGE

ONEPACKAGE

creates one common package to contain all the scoring functions.

If you specify this option, then all the scoring functions are created in a package called *sevfit*. For each distribution function that has the name *distribution_suffix*, the name of the corresponding scoring function is formed as *SEV_suffix_distribution*. For example, the scoring function of the distribution function 'MYDIST_BAR' is named 'SEV_BAR_MYDIST'.

If you do not specify this option, then all scoring functions for a distribution are created in a package that has the same name as the distribution, and for each distribution function that has the name *distribution_suffix*, the name of the corresponding scoring function is formed as *SEV_suffix*. For example, the scoring function of the distribution function 'MYDIST_BAR' is named 'SEV_BAR'.

OUTBYID=*libref.data-table*

names the output data table to contain the unique identifier for each BY group. This unique identifier is used as part of the name of the package or scoring function for each distribution. This is a required option when you specify a BY statement in PROC SEVSELECT.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1724. The *libref* must be identical to the *libref* that you specify in the DATA= option.

The OUTBYID= data table contains one observation per BY group and a variable named *_ID_* in addition to the BY variables that you specify in the BY statement. The *_ID_* variable contains the unique identifier for each BY group. The identifier of the BY group is the decimal representation of the sequence number of the BY group. The first BY group has an identifier of 1, the second BY group has an identifier of 2, the tenth BY group has an identifier of 10, and so on.

If you do not specify the COMMONPACKAGE option in the OUTSCORELIB statement, then for each distribution, PROC SEVSELECT creates as many packages as the number of BY groups. The unique BY-group identifier is used as a suffix for the package name. For example, if your DATA= data table has three BY groups and you specify the OUTSCORELIB statement

```
outscorelib outlib=sasuser.byscorefunc outbyid=sasuser.byid;
```

then for the distribution 'MYDIST', the library Sasuser.Byscorefunc contains the three packages 'MYDIST1', 'MYDIST2', and 'MYDIST3', and each package contains one scoring function named 'SEV_BAR' for each distribution function named 'MYDIST_BAR'.

If you specify the COMMONPACKAGE option in the OUTSCORELIB statement, PROC SEVSELECT creates as many versions of the distribution function as the number of BY groups. The unique BY-group identifier is used as a suffix for the function name. Extending the previous example, if you specify the OUTSCORELIB statement with the COMMONPACKAGE option,

```
outscorelib outlib=sasuser.byscorefunc outbyid=sasuser.byid commonpackage;
```

then for the distribution function ‘MYDIST_BAR’ of the distribution ‘MYDIST’, the Sasuser.Byscorefunc library contains the following three scoring functions: ‘SEV_BAR_MYDIST1’, ‘SEV_BAR_MYDIST2’, and ‘SEV_BAR_MYDIST3’. All the scoring functions are created in one common package named *sevfit*.

For both the preceding examples, the data table Sasuser.Byid contains three observations, one for each BY group. The value of the *_ID_* variable is 1 for the first BY group, 2 for the second BY group, and 3 for the third BY group.

For more information about scoring functions, see the section “[Scoring Functions](#)” on page 1829.

RESTRICT Statement

```
RESTRICT restriction1 [, restriction2 ...] ;
```

The RESTRICT statement imposes linear restrictions on the regression effect parameter estimates of the scale model that is specified in the [SCALEMODEL](#) statement. The restrictions are applied to all distributions that are specified in the DIST statement, including user-supplied distributions. The RESTRICT statement allows you to restrict only the parameters that are associated with the regression effects in the SCALEMODEL statement. If you want to restrict the distribution parameters, then you can define your own distribution function in the FCMP procedure and specify the desired restrictions. For more information about defining your own distributions, see the section “[Defining a Severity Distribution Model with the FCMP Procedure](#)” on page 1811.

You can specify any number of RESTRICT statements. Each *restriction* is written either as a single linear equation or as a comma-separated list of two or more linear equations. A restriction equation consists of an *expression*, followed by an equality *operator* (=) or an inequality *operator* (<, >, <=, >=), followed by a second *expression*:

expression operator expression

The *operator* can be =, <, >, <=, or >=.

RESTRICT Statement Expressions

A restriction expression in a RESTRICT statement is composed of parameter names, constants, and the operators times (*), plus (+), and minus (–). Each restriction expression must be a linear function of the parameters in the model. In addition, no grouping symbols (such as parentheses) are allowed, and the constant factor in any product can appear only on the left-hand side of the times (*) operator.

In the following example, the assumption is that you have a data table in which *y* is the loss variable and *x1*–*x3* are continuous variables. The PROC SEVSELECT program uses a RESTRICT statement to impose a restriction on the estimate for the parameter that is associated with the variable *x2*. Thus, in any solution that the optimizer finds, the solution must satisfy the condition that the parameter that is associated with the variable *x2* is equal to 1.5:

```
proc sevselect data=mylib.exrestrict;
  loss y;
  scalemodel x1-x3;
  dist stweedie;
  restrict x2=1.5;
run;
```

It is important to keep in mind that the parameters that are associated with the variables, not the variables themselves, are restricted. Thus, in the preceding RESTRICT statement, the variable name “x2” refers to the parameter that is associated with the variable x2, not to the variable itself.

Parameter names are shown in the Parameter column of the “Parameter Estimates” table. If a parameter name contains a blank or some other special character (such as “*”, “-”, “(”, or “)”), then you must use the internal name of the parameter in order to refer to that parameter in the RESTRICT statement. You can specify the [PRINTINTERNALNAMES](#) option in the [PROC SEVSELECT](#) statement if you want to see the internal names of the parameters. When you specify the [PRINTINTERNALNAMES](#) option, an extra column is added to the “Parameter Estimates” table to show the internal name of each parameter.

Restrictions should be consistent and not redundant. All restriction equations in all RESTRICT statements are applied jointly.

RESTRICT Statement Examples

Examples of valid RESTRICT statements include the following:

```
restrict x1=0.1;
restrict a+b=1;
restrict a-b=0, b+c=1.5;
restrict 2*f=g+h, f+g=0;
```

Examples of invalid RESTRICT statements include the following:

```
restrict x1^2=4;
restrict x1*x3=4;
restrict x1/x3=2;
restrict sin(a)=0;
restrict a*0.5=1;
restrict 2*(f+h)=1;
```

In the first four examples of invalid RESTRICT statements, the equation is nonlinear. The fifth example is invalid because the constant factor (0.5) cannot appear on the right-hand side of the times (*) operator. The last example is invalid because grouping symbols are not allowed.

The set of restrictions must be consistent. For example, you cannot specify the following statement because the three restrictions are not consistent:

```
restrict f-g=0,
       f-h=0,
       g-h=1;
```

Lagrange multipliers are reported in the “Parameter Estimates” table for all the active linear constraints along with a test of the null hypothesis that the restriction is satisfied. They are identified by the names Restrict1, Restrict2, and so on. The test statistic is the estimate divided by its standard error, and it is asymptotically

normally distributed. This distribution is used to compute the p -value for the test. Nonactive (nonbinding) restrictions have no effect on the estimation results and are not included in the output.

SCALEMODEL Statement

SCALEMODEL *regression-effect-list* < / *scalemodel-options* > ;

The SCALEMODEL statement specifies regression effects. A regression effect is formed from one or more regressor variables according to effect construction rules. Each regression effect forms one element of $\mathbf{X}$ in the linear model structure $\mathbf{X}\boldsymbol{\beta}$ that affects the scale parameter of the distribution. The SCALEMODEL statement in conjunction with the CLASS statement supports a rich set of effects. Effects are specified by a special notation that uses regressor variable names and operators. There are two types of regressor variables: classification (or CLASS) variables and continuous variables. Classification variables can be either numeric or character and are specified in a CLASS statement. To include CLASS variables in regression effects, you must specify the CLASS statement so that it appears before the SCALEMODEL statement. A regressor variable that is not declared in the CLASS statement is assumed to be continuous. For information about effect construction rules, see the section “[Specification and Parameterization of Model Effects](#)” on page 91 in Chapter 4, “[Shared Concepts](#).”

All the regressor variables must be present in the input data table that you specify by using the DATA= option in the PROC SEVSELECT statement. The scale parameter of each candidate distribution is linked to the linear predictor $\mathbf{X}\boldsymbol{\beta}$ that includes an intercept. If a distribution does not have a scale parameter, then a model based on that distribution is not estimated. If you specify more than one SCALEMODEL statement, then the first statement is used.

The regressor variables are expected to have nonmissing values. If any of the variables has a missing value in an observation, then a warning is written to the SAS log and that observation is ignored.

For more information about modeling regression effects, see the section “[Estimating Regression Effects](#)” on page 1794.

You can specify the following *scalemodel-options* in the SCALEMODEL statement:

DFMIXTURE=*method-name* < (*method-options*) >

specifies the method for computing representative estimates of the cumulative distribution function (CDF) and the probability density function (PDF).

When you specify regression effects, the scale of the distribution depends on the values of the regressors. For a particular distribution family, each observation in the input data table implies a different scaled version of the distribution. To compute estimates of CDF and PDF that are comparable across different distribution families, PROC SEVSELECT needs to construct a single representative distribution from all such distributions. You can specify one of the following *method-name* values to specify the method that is used to construct the representative distribution. For more information about each of the methods, see the section “[CDF and PDF Estimates with Regression Effects](#)” on page 1797.

FULL

specifies that the representative distribution be the mixture of N distributions such that each distribution has a scale value that is implied by each of the N observations that are used for estimation. This method is the slowest.

MEAN

specifies that the representative distribution be the one-point mixture of the distribution whose scale value is computed by using the mean of the N values of the linear predictor that are implied by the N observations that are used for estimation. If you do not specify the `DFMIXTURE=` option, then this method is used by default. This is also the fastest method.

QUANTILE <(K=q)>

specifies that the representative distribution be the mixture of a fixed number of distributions whose scale values are computed by using the quantiles from the sample of N values of the linear predictor that are implied by the N observations that are used for estimation.

You can use the `K=` option to specify the number of distributions in the mixture. If you specify `K=q`, then the mixture contains $(q - 1)$ distributions such that each distribution has as its scale one of the $(q - 1)$ -quantiles.

If you do not specify the `K=` option, then PROC SEVSELECT uses the default of 2, which implies the use of a one-point mixture with a distribution whose scale value is the median of all scale values.

RANDOM <(random-method-options)>

specifies that the representative distribution be the mixture of a fixed number of distributions whose scale values are computed by using the values of the linear predictor that are implied by a randomly chosen subset of the set of all observations that are used for estimation. The same subset of observations is used for each distribution family.

You can specify the following *random-method-options* to specify how the subset is chosen:

K=r

specifies the number of distributions to include in the mixture. If you do not specify this option, then PROC SEVSELECT uses the default of 15.

SEED=number

specifies the seed that is used to generate the uniform random sample of observation indices. If you do not specify this option, then PROC SEVSELECT generates a seed internally that is based on the current value of the system clock.

INCLUDE=n**INCLUDE=single-effect****INCLUDE=(effects)**

forces effects to be included in all models. If you specify `INCLUDE=n`, then the first n effects that are listed in the `SCALEMODEL` statement are included in all models. If you specify `INCLUDE=single-effect` or `INCLUDE=(single-effect)`, then the specified effects are forced into all models. The `INCLUDE=` option has no effect if you do not specify the `SELECTION` statement.

INFORMATIVE

models missing values by using extra model effects. These effects consist of dummy variables that take the value 1 when the value of a continuous model variable involved in the effect is missing, and take the value 0 otherwise. The missing value in the original model effect is replaced by the average value of the effect for the nonmissing values. For continuous-by-class effects, such as $A*x$, where A is a classification variable and x is a continuous variable, informative missingness creates multiple dummy columns and substitutes the effect mean of x that corresponds to the respective level of A . Missing

values for classification variables are treated as valid levels. For more information about informative missingness, see the section “[Informative Missingness](#)” on page 106 in Chapter 4, “[Shared Concepts](#).”

OFFSET=*offset-variable-name*

specifies the name of the offset variable in the scale regression model. An offset variable is a regressor variable whose regression coefficient is known to be 1. For more information, see the section “[Offset Variable](#)” on page 1795.

START=*n*

START=*single-effect*

START=(*effects*)

specifies how to begin the selection process in the FORWARD, FORWARDSWAP, and STEPWISE selection methods from the initial model that you designate. If you specify **START=***n*, then the starting model consists of the first *n* effects that are listed in the [SCALEMODEL](#) statement. If you specify **START=***single-effect* or **START=**(*single-effect*), then the starting model consists of these specified effects.

The **START=** option has no effect if you do not specify the [SELECTION](#) statement. This option is not supported when you specify **METHOD=BACKWARD** in the [SELECTION](#) statement.

SELECTION Statement

SELECTION < **METHOD=***method* < (*method-options*) > > < *options* > ;

The **SELECTION** statement performs model selection by examining whether effects should be added to or removed from the model according to rules that are defined by the selection methods. The statement is fully documented in the section “[SELECTION Statement](#)” on page 78 in Chapter 4, “[Shared Concepts](#).” The SEVSELECT procedure supports only a subset of the *method* values and *method-options* that are listed in that section.

NOTE: In the context of the **SELECTION** statement, the term *model* refers to the set of regression effects in the scale regression model. The final severity model consists of the set of distribution parameters and the set of selected regression effects.

You can use the following option to specify the selection method:

METHOD=BACKWARD | FORWARD | FORWARDSWAP | STEPWISE

specifies the selection method to use. You can specify one of the following methods:

BACKWARD	specifies the backward elimination method.
FORWARD	specifies the forward selection method.
FORWARDSWAP	specifies forward-swap selection, which is an extension of the forward selection method.
STEPWISE	specifies the stepwise regression method.

By default, **METHOD=STEPWISE**. For more information about each of the selection methods, see the section “[Model Selection Methods](#)” on page 102

The SEVSELECT procedure supports a specific set of values for the following *method-options*:

CHOOSE=criterion

chooses from the list of models (at each step of the selection process) the model that yields the best value of the specified criterion. The SEVSELECT procedure supports only the following values for *criterion*:

- AIC** specifies Akaike's information criterion.
- AICC** specifies the corrected Akaike's information criterion.
- SBC** specifies the Schwarz Bayesian information criterion.

By default, the CHOOSE= criterion is the same as the SELECT= criterion. For more information, see the detailed description of the [CHOOSE=](#) option.

SELECT=criterion

specifies the criterion that the procedure uses to determine the order in which effects enter or leave at each step of the selection method. The SEVSELECT procedure supports the following values for *criterion*:

- AIC** specifies Akaike's information criterion.
- AICC** specifies the corrected Akaike's information criterion.
- SBC** specifies the Schwarz Bayesian information criterion.

By default, SELECT=SBC. For more information, see the detailed description of the [SELECT=](#) option.

STOP=criterion

specifies a criterion that is used to stop the selection process. The SEVSELECT procedure supports only the following values for *criterion*:

- AIC** specifies Akaike's information criterion.
- AICC** specifies the corrected Akaike's information criterion.
- SBC** specifies the Schwarz Bayesian information criterion.

By default, the STOP= criterion is the same as the SELECT= criterion. For more information, see the detailed description of the [STOP=](#) option.

The SEVSELECT procedure supports the following *method-options* as they are described in the section “[SELECTION Statement](#)” on page 78 in Chapter 4, “[Shared Concepts](#)”:

- [COMPETITIVE](#)
- [MAXEFFECTS=](#)
- [MAXSTEPS=](#)
- [MINEFFECTS=](#)

The SEVSELECT procedure supports the following statement *options* as they are described in the section “[SELECTION Statement](#)” on page 78 in Chapter 4, “[Shared Concepts](#)”:

- DETAILS=
- HIERARCHY=
- ORDERSELECT
- STOPHORIZON=

WEIGHT Statement

WEIGHT *variable-name* ;

The WEIGHT statement specifies the name of a variable whose values represent the weight of each observation. PROC SEVSELECT associates a weight of w to each observation, where w is the value of the WEIGHT variable for the observation. If the weight value is missing or less than or equal to 0, then the observation is ignored and a warning is written to the SAS log. When you do not specify the WEIGHT statement, each observation is assigned a weight of 1. If you specify more than one WEIGHT statement, then the last statement is used.

The weights are normalized so that they add up to the actual sample size. In particular, the weight of each observation is multiplied by $\frac{N}{\sum_{i=1}^N w_i}$, where N is the sample size. All computations, including the computations of the EDF-based statistics of fit, use normalized weights.

Programming Statements

You can use a series of programming statements that use variables in the input data table that you specify in the DATA= option in the PROC SEVSELECT statement to assign a value to an objective function symbol. You must specify the objective function symbol by using the **OBJECTIVE=** option in the PROC SEVSELECT statement. If you do not specify the **OBJECTIVE=** option in the PROC SEVSELECT statement, then the programming statements are ignored and models are estimated using the maximum likelihood method.

You can use most DATA step statements and functions in your program. Any additional functions, restrictions, and differences are listed in the section “[Custom Objective Functions](#)” on page 1836.

Details: SEVSELECT Procedure

Predefined Distributions

For the response variable Y , PROC SEVSELECT assumes the model

$$Y \sim \mathcal{F}(\Theta)$$

where $\mathcal{F}$ is a continuous probability distribution with parameters Θ . The model hypothesizes that the observed response is generated from a stochastic process that is governed by the distribution $\mathcal{F}$. This model is usually referred to as the error model. Given a representative input sample of response variable values, PROC SEVSELECT estimates the model parameters for any distribution $\mathcal{F}$ and computes the statistics of fit for each model. This enables you to find the distribution that is most likely to generate the observed sample.

A set of predefined distributions is provided with the SEVSELECT procedure. A summary of the distributions is provided in [Table 26.4](#). For each distribution, the table lists the name of the distribution that should be used in the DIST statement, the parameters of the distribution along with their bounds, and the mathematical expressions for the probability density function (PDF) and cumulative distribution function (CDF) of the distribution.

All the predefined distributions, except LOGN and TWEEDIE, are parameterized such that their first parameter is the scale parameter. For LOGN, the first parameter μ is a log-transformed scale parameter. TWEEDIE does not have a scale parameter. The presence of scale parameter or a log-transformed scale parameter enables you to use all of the predefined distributions, except TWEEDIE, as a candidate for estimating regression effects.

A distribution model is associated with each predefined distribution. You can also define your own distribution model, which is a set of functions and subroutines that you define by using the FCMP procedure. For more information, see the section “[Defining a Severity Distribution Model with the FCMP Procedure](#)” on page 1811.

Table 26.4 Predefined PROC SEVSELECT Distributions

Name	Distribution	Parameters	PDF (f) and CDF (F)
BURR	Burr	$\theta > 0, \alpha > 0,$ $\gamma > 0$	$f(x) = \frac{\alpha \gamma z^\gamma}{x(1+z^\gamma)^{(\alpha+1)}}$ $F(x) = 1 - \left(\frac{1}{1+z^\gamma}\right)^\alpha$
EXP	Exponential	$\theta > 0$	$f(x) = \frac{1}{\theta} e^{-z}$ $F(x) = 1 - e^{-z}$
GAMMA	Gamma	$\theta > 0, \alpha > 0$	$f(x) = \frac{z^\alpha e^{-z}}{x \Gamma(\alpha)}$ $F(x) = \frac{\gamma(\alpha, z)}{\Gamma(\alpha)}$
GPD	Generalized Pareto	$\theta > 0, \xi > 0$	$f(x) = \frac{1}{\theta} (1 + \xi z)^{-1-1/\xi}$ $F(x) = 1 - (1 + \xi z)^{-1/\xi}$
IGAUSS	Inverse Gaussian (Wald)	$\theta > 0, \alpha > 0$	$f(x) = \frac{1}{\theta} \sqrt{\frac{\alpha}{2\pi z^3}} e^{\frac{-\alpha(z-1)^2}{2z}}$ $F(x) = \Phi\left((z-1)\sqrt{\frac{\alpha}{z}}\right) + \Phi\left(-(z+1)\sqrt{\frac{\alpha}{z}}\right) e^{2\alpha}$
LOGN	Lognormal	μ (no bounds), $\sigma > 0$	$f(x) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\log(x)-\mu}{\sigma}\right)^2}$ $F(x) = \Phi\left(\frac{\log(x)-\mu}{\sigma}\right)$
PARETO	Pareto	$\theta > 0, \alpha > 0$	$f(x) = \frac{\alpha \theta^\alpha}{(x+\theta)^{\alpha+1}}$ $F(x) = 1 - \left(\frac{\theta}{x+\theta}\right)^\alpha$
TWEEDIE	Tweedie**	$p > 1, \mu > 0,$ $\phi > 0$	$f(x) = a(x, \phi) \exp\left[\frac{1}{\phi} \left(\frac{x\mu^{1-p}}{1-p} - \kappa(\mu, p)\right)\right]$ $F(x) = \int_0^x f(t) dt$
STWEEDIE	Scaled Tweedie**	$\theta > 0, \lambda > 0,$ $1 < p < 2$	$f(x) = a(x, \theta, \lambda, p) \exp\left(-\frac{x}{\theta} - \lambda\right)$ $F(x) = \int_0^x f(t) dt$
WEIBULL	Weibull	$\theta > 0, \tau > 0$	$f(x) = \frac{\tau}{\theta} z^{\tau-1} e^{-z^\tau}$ $F(x) = 1 - e^{-z^\tau}$

**For more information, see the section “[Tweedie Distributions](#)” on page 1781.

Notes:

1. $z = x/\theta$, wherever z is used.
2. θ denotes the scale parameter for all the distributions. For LOGN, $\log(\theta) = \mu$.
3. Parameters are listed in the order in which they are defined in the distribution model.
4. $\gamma(a, b) = \int_0^b t^{a-1} e^{-t} dt$ is the lower incomplete gamma function.
5. $\Phi(y) = \frac{1}{2} \left(1 + \operatorname{erf}\left(\frac{y}{\sqrt{2}}\right)\right)$ is the standard normal CDF.

Tweedie Distributions

Tweedie distributions are a special case of the exponential dispersion family (Jørgensen 1987) with a property that the variance of the distribution is equal to $\phi\mu^p$, where μ is the mean of the distribution, ϕ is a dispersion parameter, and p is an index parameter as discovered by Tweedie (1984). The distribution is defined for all values of p except for values of p in the open interval $(0, 1)$. Many important known distributions are a special case of Tweedie distributions including normal ($p=0$), Poisson ($p=1$), gamma ($p=2$), and the inverse Gaussian ($p=3$). Apart from these special cases, the probability density function (PDF) of the Tweedie distribution does not have an analytic expression. For $p > 1$, it has the form (Dunn and Smyth 2005),

$$f(x; \mu, \phi, p) = a(x, \phi) \exp \left[\frac{1}{\phi} \left(\frac{x\mu^{1-p}}{1-p} - \kappa(\mu, p) \right) \right]$$

where $\kappa(\mu, p) = \mu^{2-p}/(2-p)$ for $p \neq 2$ and $\kappa(\mu, p) = \log(\mu)$ for $p = 2$. The function $a(x, \phi)$ does not have an analytical expression. It is typically evaluated using series expansion methods described in Dunn and Smyth (2005).

For $1 < p < 2$, the Tweedie distribution is a compound Poisson-gamma mixture distribution, which is the distribution of S defined as

$$S = \sum_{i=1}^N X_i$$

where $N \sim \text{Poisson}(\lambda)$ and $X_i \sim \text{gamma}(\alpha, \theta)$ are independent and identically distributed gamma random variables with shape parameter α and scale parameter θ . At $X = 0$, the density is a probability mass that is governed by the Poisson distribution, and for values of $X > 0$, it is a mixture of gamma variates with Poisson mixing probability. The parameters λ , α , and θ are related to the natural parameters μ , ϕ , and p of the Tweedie distribution as

$$\begin{aligned}\lambda &= \frac{\mu^{2-p}}{\phi(2-p)} \\ \alpha &= \frac{2-p}{p-1} \\ \theta &= \phi(p-1)\mu^{p-1}\end{aligned}$$

The mean of a Tweedie distribution is positive for $p > 1$.

Two predefined versions of the Tweedie distribution are provided with the SEVSELECT procedure. The first version, named TWEEDIE and defined for $p > 1$, has the natural parameterization with parameters μ , ϕ , and p . The second version, named STWEEDIE and defined for $1 < p < 2$, is the version with a scale parameter. It corresponds to the compound Poisson-gamma distribution with gamma scale parameter θ , Poisson mean parameter λ , and the index parameter p . The index parameter decides the shape parameter α of the gamma distribution as

$$\alpha = \frac{2-p}{p-1}$$

The parameters θ and λ of the STWEEDIE distribution are related to the parameters μ and ϕ of the TWEEDIE distribution as

$$\begin{aligned}\mu &= \lambda\theta\alpha \\ \phi &= \frac{(\lambda\theta\alpha)^{2-p}}{\lambda(2-p)} = \frac{\theta}{(p-1)(\lambda\theta\alpha)^{p-1}}\end{aligned}$$

You can fit either version when there are no regression variables. Each version has its own merits. If you fit the TWEEDIE version, you have the direct estimate of the overall mean of the distribution. If you are interested in the most practical range of the index parameter $1 < p < 2$, then you can fit the STWEEDIE version, which provides you direct estimates of the Poisson and gamma components that comprise the distribution (an estimate of the gamma shape parameter α is easily obtained from the estimate of p).

If you want to estimate the effect of exogenous (regression) variables on the distribution, then you must use the STWEEDIE version, because PROC SEVSELECT requires a distribution to have a scale parameter in order to estimate regression effects. For more information, see the section “[Estimating Regression Effects](#)” on page 1794. The gamma scale parameter θ is the scale parameter of the STWEEDIE distribution. If you are interested in determining the effect of regression variables on the mean of the distribution, you can do so by first fitting the STWEEDIE distribution to determine the effect of the regression variables on the scale parameter θ . Then, you can easily estimate how the mean of the distribution μ is affected by the regression variables using the relationship $\mu = c\theta$, where $c = \lambda\alpha = \lambda(2 - p)/(p - 1)$. The estimates of the regression parameters remain the same, whereas the estimate of the intercept parameter is adjusted by the estimates of the λ and p parameters.

Parameter Initialization for Predefined Distributions

The parameters are initialized by using the method of moments for all the distributions, except for the gamma and the Weibull distributions. For the gamma distribution, approximate maximum likelihood estimates are used. For the Weibull distribution, the method of percentile matching is used.

Given n observations of the severity value y_i ($1 \leq i \leq n$), the estimate of k th raw moment is denoted by m_k and computed as

$$m_k = \frac{1}{n} \sum_{i=1}^n y_i^k$$

The 100 p th percentile is denoted by π_p ($0 \leq p \leq 1$). By definition, π_p satisfies

$$F(\pi_p-) \leq p \leq F(\pi_p)$$

where $F(\pi_p-) = \lim_{h \downarrow 0} F(\pi_p - h)$. PROC SEVSELECT uses the following practical method of computing π_p . Let $\hat{F}_n(y)$ denote the empirical distribution function (EDF) estimate at a severity value y . Let y_p^- and y_p^+ denote two consecutive values in the ascending sequence of y values such that $\hat{F}_n(y_p^-) < p$ and $\hat{F}_n(y_p^+) \geq p$. Then, the estimate $\hat{\pi}_p$ is computed as

$$\hat{\pi}_p = y_p^- + \frac{p - \hat{F}_n(y_p^-)}{\hat{F}_n(y_p^+) - \hat{F}_n(y_p^-)}(y_p^+ - y_p^-)$$

Let ϵ denote the smallest double-precision floating-point number such that $1 + \epsilon > 1$. This machine precision constant can be obtained by using the CONSTANT function in Base SAS software.

The details of how parameters are initialized for each predefined distribution are as follows:

BURR Burr proposed 12 types of families of continuous distributions (Burr 1942; Rodriguez and Balan 2006). The predefined BURR distribution in PROC SEVSELECT implements Burr's

type XII distribution. The parameters are initialized by using the method of moments. The k th raw moment of the Burr distribution of type XII is

$$E[X^k] = \frac{\theta^k \Gamma(1 + k/\gamma) \Gamma(\alpha - k/\gamma)}{\Gamma(\alpha)}, \quad -\gamma < k < \alpha\gamma$$

Three moment equations $E[X^k] = m_k$ ($k = 1, 2, 3$) need to be solved for initializing the three parameters of the distribution. In order to get an approximate closed form solution, the second shape parameter $\hat{\gamma}$ is initialized to a value of 2. If $2m_3 - 3m_1m_2 > 0$, then simplifying and solving the moment equations yields the following feasible set of initial values:

$$\hat{\theta} = \sqrt{\frac{m_2m_3}{2m_3 - 3m_1m_2}}, \quad \hat{\alpha} = 1 + \frac{m_3}{2m_3 - 3m_1m_2}, \quad \hat{\gamma} = 2$$

If $2m_3 - 3m_1m_2 < \epsilon$, then the parameters are initialized as follows:

$$\hat{\theta} = \sqrt{m_2}, \quad \hat{\alpha} = 2, \quad \hat{\gamma} = 2$$

EXP The parameters are initialized by using the method of moments. The k th raw moment of the exponential distribution is

$$E[X^k] = \theta^k \Gamma(k + 1), \quad k > -1$$

Solving $E[X] = m_1$ yields the initial value of $\hat{\theta} = m_1$.

GAMMA The parameter α is initialized by using its *approximate* maximum likelihood (ML) estimate. For a set of n independent and identically distributed observations y_i ($1 \leq i \leq n$) drawn from a gamma distribution, the log likelihood l is defined as follows:

$$\begin{aligned} l &= \sum_{i=1}^n \log \left(y_i^{\alpha-1} \frac{e^{-y_i/\theta}}{\theta^\alpha \Gamma(\alpha)} \right) \\ &= (\alpha - 1) \sum_{i=1}^n \log(y_i) - \frac{1}{\theta} \sum_{i=1}^n y_i - n\alpha \log(\theta) - n \log(\Gamma(\alpha)) \end{aligned}$$

Using a shorter notation of $\sum$ to denote $\sum_{i=1}^n$ and solving the equation $\partial l / \partial \theta = 0$ yields the following ML estimate of θ :

$$\hat{\theta} = \frac{\sum y_i}{n\alpha} = \frac{m_1}{\alpha}$$

Substituting this estimate in the expression of l and simplifying gives

$$l = (\alpha - 1) \sum \log(y_i) - n\alpha - n\alpha \log(m_1) + n\alpha \log(\alpha) - n \log(\Gamma(\alpha))$$

Let d be defined as follows:

$$d = \log(m_1) - \frac{1}{n} \sum \log(y_i)$$

Solving the equation $\partial l / \partial \alpha = 0$ yields the following expression in terms of the digamma function, $\psi(\alpha)$:

$$\log(\alpha) - \psi(\alpha) = d$$

The digamma function can be approximated as follows:

$$\hat{\psi}(\alpha) \approx \log(\alpha) - \frac{1}{\alpha} \left(0.5 + \frac{1}{12\alpha + 2} \right)$$

This approximation is within 1.4% of the true value for all the values of $\alpha > 0$ except when α is arbitrarily close to the positive root of the digamma function (which is approximately 1.461632). Even for the values of α that are close to the positive root, the absolute error between true and approximate values is still acceptable ($|\hat{\psi}(\alpha) - \psi(\alpha)| < 0.005$ for $\alpha > 1.07$). Solving the equation that arises from this approximation yields the following estimate of α :

$$\hat{\alpha} = \frac{3 - d + \sqrt{(d - 3)^2 + 24d}}{12d}$$

If this approximate ML estimate is infeasible, then the method of moments is used. The k th raw moment of the gamma distribution is

$$E[X^k] = \theta^k \frac{\Gamma(\alpha + k)}{\Gamma(\alpha)}, \quad k > -\alpha$$

Solving $E[X] = m_1$ and $E[X^2] = m_2$ yields the following initial value for α :

$$\hat{\alpha} = \frac{m_1^2}{m_2 - m_1^2}$$

If $m_2 - m_1^2 < \epsilon$ (almost zero sample variance), then α is initialized as follows:

$$\hat{\alpha} = 1$$

After computing the estimate of α , the estimate of θ is computed as follows:

$$\hat{\theta} = \frac{m_1}{\hat{\alpha}}$$

Both the maximum likelihood method and the method of moments arrive at the same relationship between $\hat{\alpha}$ and $\hat{\theta}$.

GPD

The parameters are initialized by using the method of moments. Notice that for $\xi > 0$, the CDF of the generalized Pareto distribution (GPD) is:

$$\begin{aligned} F(x) &= 1 - \left(1 + \frac{\xi x}{\theta} \right)^{-1/\xi} \\ &= 1 - \left(\frac{\theta/\xi}{x + \theta/\xi} \right)^{1/\xi} \end{aligned}$$

This is equivalent to a Pareto distribution with scale parameter $\theta_1 = \theta/\xi$ and shape parameter $\alpha = 1/\xi$. Using this relationship, the parameter initialization method used for the PARETO distribution is used to get the following initial values for the parameters of the GPD distribution:

$$\hat{\theta} = \frac{m_1 m_2}{2(m_2 - m_1^2)}, \quad \hat{\xi} = \frac{m_2 - 2m_1^2}{2(m_2 - m_1^2)}$$

If $m_2 - m_1^2 < \epsilon$ (almost zero sample variance) or $m_2 - 2m_1^2 < \epsilon$, then the parameters are initialized as follows:

$$\hat{\theta} = \frac{m_1}{2}, \quad \hat{\xi} = \frac{1}{2}$$

IGAUSS

The parameters are initialized by using the method of moments. The standard parameterization of the inverse Gaussian distribution (also known as the Wald distribution), in terms of the location parameter μ and shape parameter λ , is as follows (Klugman, Panjer, and Willmot 1998, p. 583):

$$f(x) = \sqrt{\frac{\lambda}{2\pi x^3}} \exp\left(\frac{-\lambda(x - \mu)^2}{2\mu^2 x}\right)$$

$$F(x) = \Phi\left(\left(\frac{x}{\mu} - 1\right) \sqrt{\frac{\lambda}{x}}\right) + \Phi\left(-\left(\frac{x}{\mu} + 1\right) \sqrt{\frac{\lambda}{x}}\right) \exp\left(\frac{2\lambda}{\mu}\right)$$

For this parameterization, it is known that the mean is $E[X] = \mu$ and the variance is $\text{Var}[X] = \mu^3/\lambda$, which yields the second raw moment as $E[X^2] = \mu^2(1 + \mu/\lambda)$ (computed by using $E[X^2] = \text{Var}[X] + (E[X])^2$).

The predefined IGAUSS distribution in PROC SEVSELECT uses the following alternate parameterization to allow the distribution to have a scale parameter, θ :

$$f(x) = \sqrt{\frac{\alpha\theta}{2\pi x^3}} \exp\left(\frac{-\alpha(x - \theta)^2}{2x\theta}\right)$$

$$F(x) = \Phi\left(\left(\frac{x}{\theta} - 1\right) \sqrt{\frac{\alpha\theta}{x}}\right) + \Phi\left(-\left(\frac{x}{\theta} + 1\right) \sqrt{\frac{\alpha\theta}{x}}\right) \exp(2\alpha)$$

The parameters θ (scale) and α (shape) of this alternate form are related to the parameters μ and λ of the preceding form such that $\theta = \mu$ and $\alpha = \lambda/\mu$. Using this relationship, the first and second raw moments of the IGAUSS distribution are

$$E[X] = \theta$$

$$E[X^2] = \theta^2 \left(1 + \frac{1}{\alpha}\right)$$

Solving $E[X] = m_1$ and $E[X^2] = m_2$ yields the following initial values:

$$\hat{\theta} = m_1, \quad \hat{\alpha} = \frac{m_1^2}{m_2 - m_1^2}$$

If $m_2 - m_1^2 < \epsilon$ (almost zero sample variance), then the parameters are initialized as follows:

$$\hat{\theta} = m_1, \quad \hat{\alpha} = 1$$

LOGN

The parameters are initialized by using the method of moments. The k th raw moment of the lognormal distribution is

$$E[X^k] = \exp\left(k\mu + \frac{k^2\sigma^2}{2}\right)$$

Solving $E[X] = m_1$ and $E[X^2] = m_2$ yields the following initial values:

$$\hat{\mu} = 2 \log(m_1) - \frac{\log(m_2)}{2}, \quad \hat{\sigma} = \sqrt{\log(m_2) - 2 \log(m_1)}$$

PARETO The parameters are initialized by using the method of moments. The k th raw moment of the Pareto distribution is

$$E[X^k] = \frac{\theta^k \Gamma(k+1) \Gamma(\alpha-k)}{\Gamma(\alpha)}, -1 < k < \alpha$$

Solving $E[X] = m_1$ and $E[X^2] = m_2$ yields the following initial values:

$$\hat{\theta} = \frac{m_1 m_2}{m_2 - 2m_1^2}, \quad \hat{\alpha} = \frac{2(m_2 - m_1^2)}{m_2 - 2m_1^2}$$

If $m_2 - m_1^2 < \epsilon$ (almost zero sample variance) or $m_2 - 2m_1^2 < \epsilon$, then the parameters are initialized as follows:

$$\hat{\theta} = m_1, \quad \hat{\alpha} = 2$$

TWEEDIE The parameter p is initialized by assuming that the sample is generated from a gamma distribution with shape parameter α and by computing $\hat{p} = \frac{\hat{\alpha}+2}{\hat{\alpha}+1}$. The initial value $\hat{\alpha}$ is obtained from using the method previously described for the GAMMA distribution. The parameter μ is the mean of the distribution. Hence, it is initialized to the sample mean as

$$\hat{\mu} = m_1$$

Variance of a Tweedie distribution is equal to $\phi \mu^p$. Thus, the sample variance is used to initialize the value of ϕ as

$$\hat{\phi} = \frac{m_2 - m_1^2}{\hat{\mu}^{\hat{p}}}$$

STWEEDIE STWEEDIE is a compound Poisson-gamma mixture distribution with mean $\mu = \lambda \theta \alpha$, where α is the shape parameter of the gamma random variables in the mixture and the parameter p is determined solely by α . First, the parameter p is initialized by assuming that the sample is generated from a gamma distribution with shape parameter α and by computing $\hat{p} = \frac{\hat{\alpha}+2}{\hat{\alpha}+1}$. The initial value $\hat{\alpha}$ is obtained from using the method previously described for the GAMMA distribution. As done for initializing the parameters of the TWEEDIE distribution, the sample mean and variance are used to compute the values $\hat{\mu}$ and $\hat{\phi}$ as

$$\hat{\mu} = m_1$$

$$\hat{\phi} = \frac{m_2 - m_1^2}{\hat{\mu}^{\hat{p}}}$$

Based on the relationship between the parameters of TWEEDIE and STWEEDIE distributions described in the section “[Tweedie Distributions](#)” on page 1781, values of θ and λ are initialized as

$$\hat{\theta} = \hat{\phi}(\hat{p} - 1)\hat{\mu}^{p-1}$$

$$\hat{\lambda} = \frac{\hat{\mu}}{\hat{\theta}\hat{\alpha}}$$

WEIBULL The parameters are initialized by using the percentile matching method. Let $q1$ and $q3$ denote the estimates of the 25th and 75th percentiles, respectively. Using the formula for the CDF of Weibull distribution, they can be written as

$$1 - \exp(-(q1/\theta)^\tau) = 0.25$$

$$1 - \exp(-(q3/\theta)^\tau) = 0.75$$

Simplifying and solving these two equations yields the following initial values,

$$\hat{\theta} = \exp\left(\frac{r \log(q1) - \log(q3)}{r - 1}\right), \quad \hat{\tau} = \frac{\log(\log(4))}{\log(q3) - \log(\hat{\theta})}$$

where $r = \log(\log(4)) / \log(\log(4/3))$. These initial values agree with those suggested in Klugman, Panjer, and Willmot (1998).

A summary of the initial values of all the parameters for all the predefined distributions is given in [Table 26.5](#). The table also provides the names of the parameters to use in the **INIT=** option in the DIST statement if you want to provide a different initial value.

Table 26.5 Parameter Initialization for Predefined Distributions

Distribution	Parameter	Name for INIT Option	Default Initial Value
BURR	θ	theta	$\sqrt{\frac{m_2 m_3}{2m_3 - 3m_1 m_2}}$
	α	alpha	$1 + \frac{m_3}{2m_3 - 3m_1 m_2}$
	γ	gamma	2
EXP	θ	theta	m_1
GAMMA	θ	theta	m_1/α
	α	alpha	$\frac{3-d+\sqrt{(d-3)^2+24d}}{12d}$
GPD	θ	theta	$m_1 m_2 / (2(m_2 - m_1^2))$
	ξ	xi	$(m_2 - 2m_1^2) / (2(m_2 - m_1^2))$
IGAUSS	θ	theta	m_1
	α	alpha	$m_1^2 / (m_2 - m_1^2)$
LOGN	μ	mu	$2 \log(m_1) - \log(m_2)/2$
	σ	sigma	$\sqrt{\log(m_2) - 2 \log(m_1)}$
PARETO	θ	theta	$m_1 m_2 / (m_2 - 2m_1^2)$
	α	alpha	$2(m_2 - m_1^2) / (m_2 - 2m_1^2)$
TWEEDIE	μ	mu	m_1
	ϕ	phi	$(m_2 - m_1^2) / m_1^p$
	p	p	$(\alpha + 2) / (\alpha + 1)$
			where $\alpha = \frac{3-d+\sqrt{(d-3)^2+24d}}{12d}$
STWEEDIE	θ	theta	$(m_2 - m_1^2)(p - 1) / m_1$
	λ	lambda	$m_1^2 / (\alpha(m_2 - m_1^2)(p - 1))$
	p	p	$(\alpha + 2) / (\alpha + 1)$
			where $\alpha = \frac{3-d+\sqrt{(d-3)^2+24d}}{12d}$
WEIBULL	θ	theta	$\exp\left(\frac{r \log(q1) - \log(q3)}{r-1}\right)$
	τ	tau	$\log(\log(4)) / (\log(q3) - \log(\hat{\theta}))$

Notes:

1. m_k denotes the k th raw moment.
2. $d = \log(m_1) - (\sum \log(y_i))/n$
3. $q1$ and $q3$ denote the 25th and 75th percentiles, respectively.
4. $r = \log(\log(4)) / \log(\log(4/3))$

Censoring and Truncation

One of the key features of PROC SEVSELECT is that it enables you to specify whether the severity event's magnitude is observable and if it is observable, then whether the exact value of the magnitude is known. If an event is unobservable when the magnitude is in certain intervals, then it is referred to as a truncation effect. If the exact magnitude of the event is not known, but it is known to have a value in a certain interval, then it is referred to as a censoring effect.

PROC SEVSELECT allows a severity event to be subject to any combination of the following four censoring and truncation effects:

- **Left-truncation:** An event is said to be left-truncated if it is observed only when $Y > T^l$, where Y denotes the random variable for the magnitude and T^l denotes a random variable for the truncation threshold. You can specify left-truncation using the `LEFTTRUNCATED=` option in the LOSS statement.
- **Right-truncation:** An event is said to be right-truncated if it is observed only when $Y \leq T^r$, where Y denotes the random variable for the magnitude and T^r denotes a random variable for the truncation threshold. You can specify right-truncation using the `RIGHTTRUNCATED=` option in the LOSS statement.
- **Left-censoring:** An event is said to be left-censored if it is known that the magnitude is $Y \leq C^l$, but the exact value of Y is not known. C^l is a random variable for the censoring limit. You can specify left-censoring using the `LEFTCENSORED=` option in the LOSS statement.
- **Right-censoring:** An event is said to be right-censored if it is known that the magnitude is $Y > C^r$, but the exact value of Y is not known. C^r is a random variable for the censoring limit. You can specify right-censoring using the `RIGHTCENSORED=` option in the LOSS statement.

For each effect, you can specify a different threshold or limit for each observation or specify a single threshold or limit that applies to all the observations.

If all four types of effects are present on an event, then the following relationship holds: $T^l < C^r \leq C^l \leq T^r$. PROC SEVSELECT checks these relationships and writes a warning to the SAS log if any relationship is violated.

If you specify the response variable in the LOSS statement, then PROC SEVSELECT also checks whether each observation satisfies the definitions of the specified censoring and truncation effects. If you specify left-truncation, then PROC SEVSELECT ignores observations where $Y \leq T^l$, because such observations are not observable by definition. Similarly, if you specify right-truncation, then PROC SEVSELECT ignores observations where $Y > T^r$. If you specify left-censoring, then PROC SEVSELECT treats an observation with $Y > C^l$ as uncensored and ignores the value of C^l . The observations with $Y \leq C^l$ are considered as left-censored, and the value of Y is ignored. If you specify right-censoring, then PROC SEVSELECT treats an observation with $Y \leq C^r$ as uncensored and ignores the value of C^r . The observations with $Y > C^r$ are considered as right-censored, and the value of Y is ignored. If you specify both left-censoring and right-censoring, it is referred to as interval-censoring. If $C^r < C^l$ is satisfied for an observation, then it is considered as interval-censored and the value of the response variable is ignored. If $C^r = C^l$ for an observation, then PROC SEVSELECT assumes that observation to be uncensored. If all the observations in a data table are censored in some form, then the specification of the response variable in the LOSS statement is

optional, because the actual value of the response variable is not required for the purposes of estimating a model.

Specification of censoring and truncation affects the likelihood of the data (see the section “[Likelihood Function](#)” on page 1791) and how the empirical distribution function (EDF) is estimated (see the section “[Empirical Distribution Function Estimation Methods](#)” on page 1799).

Probability of Observability

For left-truncated data, PROC SEVSELECT also enables you to provide additional information in the form of *probability of observability* by using the `PROBOBSERVED=` option. It is defined as the probability that the underlying severity event gets observed (and recorded) for the specified left-truncation threshold value. For example, if you specify a value of 0.75, then for every 75 observations recorded above a specified threshold, 25 more events have happened with a severity value less than or equal to the specified threshold. Although the exact severity value of those 25 events is not known, PROC SEVSELECT can use the information about the number of those events.

In particular, for each left-truncated observation, PROC SEVSELECT assumes a presence of $(1 - p)/p$ additional observations with $y_i = t_i$. These additional observations are then used for computing the likelihood (see the section “[Probability of Observability and Likelihood](#)” on page 1792) and an unconditional estimate of the empirical distribution function (see the section “[EDF Estimates and Truncation](#)” on page 1804).

Truncation and Conditional CDF Estimates

If you specify left-truncation without the probability of observability or if you specify right-truncation, then the EDF estimates that are computed by all methods except the STANDARD method are conditional on the truncation information. For more information, see the section “[EDF Estimates and Truncation](#)” on page 1804. In such cases, PROC SEVSELECT uses conditional estimates of the CDF for computational or visual comparison to the EDF estimates.

Let $t_{\min}^l = \min_i \{t_i^l\}$ be the smallest value of the left-truncation threshold (t_i^l is the left-truncation threshold for observation i) and $t_{\max}^r = \max_i \{t_i^r\}$ be the largest value of the right-truncation threshold (t_i^r is the right-truncation threshold for observation i). If $\hat{F}(y)$ denotes the unconditional estimate of the CDF at y , then the conditional estimate $\hat{F}^c(y)$ is computed as follows:

- If you do not specify the probability of observability, then the EDF estimates are conditional on the left-truncation information. If an observation is both left-truncated and right-truncated, then

$$\hat{F}^c(y) = \frac{\hat{F}(y) - \hat{F}(t_{\min}^l)}{\hat{F}(t_{\max}^r) - \hat{F}(t_{\min}^l)}$$

If an observation is left-truncated but not right-truncated, then

$$\hat{F}^c(y) = \frac{\hat{F}(y) - \hat{F}(t_{\min}^l)}{1 - \hat{F}(t_{\min}^l)}$$

If an observation is right-truncated but not left-truncated, then

$$\hat{F}^c(y) = \frac{\hat{F}(y)}{\hat{F}(t_{\max}^r)}$$

- If you specify the probability of observability, then EDF estimates are not conditional on the left-truncation information. If an observation is not right-truncated, then the conditional estimate is the same as the unconditional estimate. If an observation is right-truncated, then the conditional estimate is computed as

$$\hat{F}^c(y) = \frac{\hat{F}(y)}{\hat{F}(t_{\max}^r)}$$

If you specify regression effects, then $\hat{F}(y)$, $\hat{F}(t_{\min}^l)$, and $\hat{F}(t_{\max}^r)$ are all computed from a mixture distribution, as described in the section “CDF and PDF Estimates with Regression Effects” on page 1797.

Parameter Estimation Method

PROC SEVSELECT uses the maximum likelihood (ML) method to estimate the parameters of each model. A nonlinear optimization process is used to maximize the log of the likelihood function.

Likelihood Function

Let $f_{\Theta}(x)$ and $F_{\Theta}(x)$ denote the PDF and CDF, respectively, evaluated at x for a set of parameter values Θ . Let Y denote the random response variable, and let y denote its value recorded in an observation in the input data table. Let T^l and T^r denote the random variables for the left-truncation and right-truncation threshold, respectively, and let t^l and t^r denote their values for an observation, respectively. If there is no left-truncation, then $t^l = \tau^l$, where τ^l is the smallest value in the support of the distribution; so $F(t^l) = 0$. If there is no right-truncation, then $t^r = \tau_h$, where τ_h is the largest value in the support of the distribution; so $F(t^r) = 1$. Let C^l and C^r denote the random variables for the left-censoring and right-censoring limit, respectively, and let c^l and c^r denote their values for an observation, respectively. If there is no left-censoring, then $c^l = \tau_h$; so $F(c^l) = 1$. If there is no right-censoring, then $c^r = \tau^l$; so $F(c^r) = 0$.

The set of input observations can be categorized into the following four subsets within each BY group:

- E is the set of uncensored and untruncated observations. The likelihood of an observation in E is

$$l_E = \Pr(Y = y) = f_{\Theta}(y)$$

- E_t is the set of uncensored observations that are truncated. The likelihood of an observation in E_t is

$$l_{E_t} = \Pr(Y = y | t^l < Y \leq t^r) = \frac{f_{\Theta}(y)}{F_{\Theta}(t^r) - F_{\Theta}(t^l)}$$

- C is the set of censored observations that are not truncated. The likelihood of an observation C is

$$l_C = \Pr(c^r < Y \leq c^l) = F_{\Theta}(c^l) - F_{\Theta}(c^r)$$

- C_t is the set of censored observations that are truncated. The likelihood of an observation C_t is

$$l_{C_t} = \Pr(c^r < Y \leq c^l | t^l < Y \leq t^r) = \frac{F_{\Theta}(c^l) - F_{\Theta}(c^r)}{F_{\Theta}(t^r) - F_{\Theta}(t^l)}$$

Note that $(E \cup E_t) \cap (C \cup C_t) = \emptyset$. Also, the sets E_t and C_t are empty when you do not specify truncation, and the sets C and C_t are empty when you do not specify censoring.

Given this, the likelihood of the data L is as follows:

$$L = \prod_E f_{\Theta}(y) \prod_{E_t} \frac{f_{\Theta}(y)}{F_{\Theta}(t^r) - F_{\Theta}(t^l)} \prod_C F_{\Theta}(c^l) - F_{\Theta}(c^r) \prod_{C_t} \frac{F_{\Theta}(c^l) - F_{\Theta}(c^r)}{F_{\Theta}(t^r) - F_{\Theta}(t^l)}$$

The maximum likelihood procedure used by PROC SEVSELECT finds an optimal set of parameter values $\hat{\Theta}$ that maximizes $\log(L)$ subject to the boundary constraints on parameter values. For a distribution *dist*, you can specify such boundary constraints by using the *dist_LOWERBOUNDS* and *dist_UPPERBOUNDS* subroutines. For more information, see the section “[Defining a Severity Distribution Model with the FCMP Procedure](#)” on page 1811. Some aspects of the optimization process can be controlled by using the *NLOPTIONS* statement.

Probability of Observability and Likelihood

If you specify the probability of observability for the left-truncation, then PROC SEVSELECT uses a modified likelihood function for each truncated observation. If the probability of observability is $p \in (0.0, 1.0]$, then for each left-truncated observation with truncation threshold t^l , there exist $(1-p)/p$ observations with a response variable value less than or equal to t^l . Each such observation has a probability of $\Pr(Y \leq t^l) = F_{\Theta}(t^l)$. The right-truncation and censoring information does not apply to these added observations. Thus, following the notation of the section “[Likelihood Function](#)” on page 1791, the likelihood of the data is as follows:

$$L = \prod_E f_{\Theta}(y) \prod_{E_t, t^l = \tau^l} \frac{f_{\Theta}(y)}{F_{\Theta}(t^r)} \prod_{E_t, t^l > \tau^l} \frac{f_{\Theta}(y)}{F_{\Theta}(t^r)} F_{\Theta}(t^l)^{\frac{1-p}{p}} \\ \prod_C F_{\Theta}(c^l) - F_{\Theta}(c^r) \prod_{C_t, t^l = \tau^l} \frac{F_{\Theta}(c^l) - F_{\Theta}(c^r)}{F_{\Theta}(t^r)} \prod_{C_t, t^l > \tau^l} \frac{F_{\Theta}(c^l) - F_{\Theta}(c^r)}{F_{\Theta}(t^r)} F_{\Theta}(t^l)^{\frac{1-p}{p}}$$

Note that the likelihood of the observations that are not left-truncated (observations in sets E and C , and observations in sets E_t and C_t for which $t^l = \tau^l$) is not affected.

If you specify a custom objective function, then PROC SEVSELECT accounts for the probability of observability only while computing the empirical distribution function estimate. The parameter estimates are affected only by your custom objective function.

Estimating Covariance and Standard Errors

PROC SEVSELECT computes an estimate of the covariance matrix of the parameters by using the asymptotic theory of the maximum likelihood estimators (MLE). If N denotes the number of observations used for estimating a parameter vector θ , then the theory states that as $N \rightarrow \infty$, the distribution of $\hat{\theta}$, the estimate of θ , converges to a normal distribution with mean θ and covariance $\hat{C}$ such that $\mathbf{I}(\theta) \cdot \hat{C} \rightarrow 1$, where $\mathbf{I}(\theta) = -E[\nabla^2 \log(L(\theta))]$ is the information matrix for the likelihood of the data, $L(\theta)$. The covariance estimate is obtained by using the inverse of the information matrix.

In particular, if $\mathbf{G} = \nabla^2(-\log(L(\boldsymbol{\theta})))$ denotes the Hessian matrix of the negative of log likelihood, then the covariance estimate is computed as

$$\hat{\mathbf{C}} = \frac{N}{d} \mathbf{G}^{-1}$$

where d is a denominator that is determined by the **VARDEF=** option. If **VARDEF=N**, then $d = N$, which yields the asymptotic covariance estimate. If **VARDEF=DF**, then $d = N - k$, where k is number of parameters (the model's degrees of freedom). The **VARDEF=DF** option is the default, because it attempts to correct the potential bias introduced by the finite sample.

The standard error s_i of the parameter θ_i is computed as the square root of the i th diagonal element of the estimated covariance matrix; that is, $s_i = \sqrt{\hat{C}_{ii}}$.

If you specify a custom objective function, then the covariance matrix of the parameters is still computed by inverting the information matrix, except that the Hessian matrix $\mathbf{G}$ is computed as $\mathbf{G} = \nabla^2 \log(U(\boldsymbol{\theta}))$, where U denotes your custom objective function that is minimized by the optimizer.

Covariance and standard error estimates might not be available if the Hessian matrix is found to be singular at the end of the optimization process. This can especially happen if the optimization process stops without converging.

Parameter Initialization

PROC SEVSELECT enables you to initialize parameters of a model in different ways. A model can have two kinds of parameters: distribution parameters and regression parameters.

The distribution parameters can be initialized by using one of the following three methods:

INIT= option	You can use the INIT= option in the DIST statement.
INEST= option	You can use the INEST= data table in the PROC SEVSELECT statement.
PARMINIT subroutine	You can define a <i>dist_PARMINIT</i> subroutine in the distribution model. For more information, see the section “ Defining a Severity Distribution Model with the FCMP Procedure ” on page 1811.

Note that only one of the initialization methods is used. You cannot combine them. They are used in the following order:

- The method that uses the **INIT=** option takes the highest precedence. If you use the **INIT=** option to provide an initial value for at least one parameter, then other initialization methods (**INEST=** or **PARMINIT**) are not used. If you specify initial values for some but not all the parameters by using the **INIT=** option, then the uninitialized parameters are initialized to the default value of 0.001.

If you use this option and if you specify the regression effects, then the value of the first distribution parameter must be related to the initial value for the *base* value of the scale or log-transformed scale parameter. For more information, see the section “[Estimating Regression Effects](#)” on page 1794.

- The method that uses the **INEST=** data table takes second precedence. If the **INEST=** data table contains a nonmissing value for even one distribution parameter, then the **PARMINIT** method is not used and any uninitialized parameters are initialized to the default value of 0.001.

- If none of the distribution parameters are initialized by using the INIT= option or the INEST= data table, but the distribution model defines a PARMINIT subroutine, then PROC SEVSELECT invokes that subroutine with appropriate inputs to initialize the parameters. If the PARMINIT subroutine returns missing values for some parameters, then those parameters are initialized to the default value of 0.001.
- If none of the initialization methods are used, each distribution parameter is initialized to the default value of 0.001.

For more information about regression models and initialization of regression parameters, see the section “[Estimating Regression Effects](#)” on page 1794.

PARMINIT-Based Parameter Initialization Method and Distributed Data

If the input data are distributed across the computational nodes and if you use the PARMINIT subroutine to initialize the distribution parameters, then PROC SEVSELECT invokes that subroutine on each computational node with the data that are local to that node. The EDF estimates that are supplied to the PARMINIT subroutine are also computed using the local data. The initial values of the parameters that are supplied to the optimizer are the average of the local estimates that are computed on each node. This approach works well if the data are distributed randomly across nodes.

Estimating Regression Effects

The SEVSELECT procedure enables you to estimate the influence of regression (exogenous) effects while fitting a distribution if the distribution has a scale parameter or a log-transformed scale parameter.

Let x_j , $j = 1, \dots, k$, denote the k regression effects. Let β_j denote the regression parameter that corresponds to the effect x_j . If you do not specify regression effects, then the model for the response variable Y is of the form

$$Y \sim \mathcal{F}(\Theta)$$

where $\mathcal{F}$ is the distribution of Y with parameters Θ . This model is usually referred to as the error model. The regression effects are modeled by extending the error model to the following form:

$$Y \sim \exp\left(\sum_{j=1}^k \beta_j x_j\right) \cdot \mathcal{F}(\Theta)$$

Under this model, the distribution of Y is valid and belongs to the same parametric family as $\mathcal{F}$ if and only if $\mathcal{F}$ has a scale parameter. Let θ denote the scale parameter and Ω denote the set of nonscale distribution parameters of $\mathcal{F}$. Then the model can be rewritten as

$$Y \sim \mathcal{F}(\theta, \Omega)$$

such that θ is modeled by the regression effects as

$$\theta = \theta_0 \cdot \exp\left(\sum_{j=1}^k \beta_j x_j\right)$$

where θ_0 is the *base* value of the scale parameter. Thus, the scale regression model consists of the following parameters: θ_0 , Ω , and β_j ($j = 1, \dots, k$).

Given this form of the model, distributions without a scale parameter cannot be considered when regression effects are to be modeled. If a distribution does not have a direct scale parameter, then PROC SEVSELECT accepts it only if it has a log-transformed scale parameter—that is, if it has a parameter $p = \log(\theta)$.

Offset Variable

You can specify that an offset variable be included in the scale regression model by specifying it in the **OFFSET=** option of the SCALEMODEL statement. The offset variable is a regressor whose regression coefficient is known to be 1. If x_o denotes the offset variable, then the scale regression model becomes

$$\theta = \theta_0 \cdot \exp(x_o + \sum_{j=1}^k \beta_j x_j)$$

The regression coefficient of the offset variable is fixed at 1 and not estimated, so it is not reported in the ParameterEstimates ODS table. However, if you specify the OUTEST= data table, then the regression coefficient is added as a variable to that data table. The value of the offset variable in OUTEST= data table is equal to 1 for the estimates row (_TYPE_='EST') and is equal to the special missing value .F for the standard error (_TYPE_='STDERR') and covariance (_TYPE_='COV') rows.

An offset variable is useful to model the scale parameter per unit of some measure of exposure. For example, in the automobile insurance context, measure of exposure can be the number of car-years insured or the total number of miles driven by a fleet of cars at a rental car company. For worker's compensation insurance, if you want to model the expected loss per enterprise, then you can use the number of employees or total employee salary as the measure of exposure. For epidemiological data, measure of exposure can be the number of people who are exposed to a certain pathogen when you are modeling the loss associated with an epidemic. In general, if e denotes the value of the exposure measure and if you specify $x_o = \log(e)$ as the offset variable, then you are modeling the influence of other regression effects (x_j) on the size of the scale of the distribution *per unit of exposure*.

Another use for an offset variable is when you have a priori knowledge of the influence of some exogenous variables that cannot be included in the SCALEMODEL statement. You can model the combined influence of such variables as an offset variable in order to correct for the omitted variable bias.

Parameter Initialization for Regression Models

The regression parameters are initialized either by using the values that you specify or by the default method.

- If you provide initial values for the regression parameters, then you must provide valid, nonmissing initial values for θ_0 and β_j parameters for all j .

You can specify the initial value for θ_0 by using either the INEST= data table or the INIT= option in the DIST statement. If the distribution has a direct scale parameter (no transformation), then the initial value for the first parameter of the distribution is used as an initial value for θ_0 . If the distribution has a log-transformed scale parameter, then the initial value for the first parameter of the distribution is used as an initial value for $\log(\theta_0)$.

If you use the INEST= data table to specify the initial values for β_j , then the INEST= data table must be an unmodified version of a OUTEST= data table that you have created in a previous PROC SEVSELECT step with the same set of regression effects.

- If you do not specify valid initial values for θ_0 or β_j parameters for all j , then PROC SEVSELECT initializes those parameters by using the following method:

Let a random variable Y be distributed as $\mathcal{F}(\theta, \Omega)$, where θ is the scale parameter. By the definition of the scale parameter, a random variable $W = Y/\theta$ is distributed as $\mathcal{G}(\Omega)$ such that $\mathcal{G}(\Omega) = \mathcal{F}(1, \Omega)$. Given a random error term e that is generated from a distribution $\mathcal{G}(\Omega)$, a value y from the distribution of Y can be generated as

$$y = \theta \cdot e$$

Taking the logarithm of both sides and using the relationship of θ with the regression effects yields

$$\log(y) = \log(\theta_0) + \sum_{j=1}^k \beta_j x_j + \log(e)$$

PROC SEVSELECT makes use of the preceding relationship to initialize parameters of a regression model with distribution *dist* as follows:

1. The following linear regression problem is solved to obtain initial estimates of β_0 and β_j :

$$\log(y) = \beta_0 + \sum_{j=1}^k \beta_j x_j$$

The estimates of $\beta_j (j = 1, \dots, k)$ in the solution of this regression problem are used to initialize the respective regression parameters of the model. The estimate of β_0 is later used to initialize the value of θ_0 .

The results of this regression are also used to detect whether any regression parameters are linearly dependent on the other regression parameters. If any such parameters are found, then a warning is written to the SAS log and the corresponding parameter is eliminated from further analysis. The estimates for linearly dependent regression parameters are denoted by the special missing value .R in the OUTEST= data table and in any displayed output.

2. Let s_0 denote the initial value of the scale parameter.

If the distribution model of *dist* does not contain the *dist_PARMINIT* subroutine, then s_0 and all the nonscale distribution parameters are initialized to the default value of 0.001.

However, it is strongly recommended that each distribution's model contain the *dist_PARMINIT* subroutine. For more information, see the section “[Defining a Severity Distribution Model with the FCMP Procedure](#)” on page 1811. If that subroutine is defined, then s_0 is initialized as follows: Each input value y_i of the response variable is transformed to its scale-normalized version w_i as

$$w_i = \frac{y_i}{\exp(\beta_0 + \sum_{j=1}^k \beta_j x_{ij})}$$

where x_{ij} denotes the value of j th regression effect in the i th input observation. These w_i values are used to compute the input arguments for the *dist_PARMINIT* subroutine. The values that are computed by the subroutine for nonscale parameters are used as their respective initial values. If the distribution has an untransformed scale parameter, then s_0 is set to the value of the scale parameter that is computed by the subroutine. If the distribution has a log-transformed scale parameter P , then s_0 is computed as $s_0 = \exp(l_0)$, where l_0 is the value of P computed by the subroutine.

3. The value of θ_0 is initialized as

$$\theta_0 = s_0 \cdot \exp(\beta_0)$$

Reporting Estimates of Regression Parameters

When you request estimates to be written to the output (either ODS displayed output or in the OUTEST= data table), the estimate of the base value of the first distribution parameter is reported. If the first parameter is the log-transformed scale parameter, then the estimate of $\log(\theta_0)$ is reported; otherwise, the estimate of θ_0 is reported. The transform of the first parameter of a distribution *dist* is controlled by the *dist_SCALETRANSFORM* function that is defined for it.

CDF and PDF Estimates with Regression Effects

When regression effects are estimated, the estimate of the scale parameter depends on the values of the regressors and the estimates of the regression parameters. This dependency results in a potentially different distribution for each observation. To make estimates of the cumulative distribution function (CDF) and probability density function (PDF) comparable across distributions and comparable to the empirical distribution function (EDF), PROC SEVSELECT computes and reports the CDF and PDF estimates from a representative distribution. The *representative distribution* is a mixture of a certain number of distributions, where each distribution differs only in the value of the scale parameter. You can specify the number of distributions in the mixture and how their scale values are chosen by using the *DFMIXTURE*= option in the SCALEMODEL statement.

Let N denote the number of observations that are used for estimation, K denote the number of components in the mixture distribution, s_k denote the scale parameter of the k th mixture component, and d_k denote the weight associated with k th mixture component.

Let $f(y; s_k, \hat{\Omega})$ and $F(y; s_k, \hat{\Omega})$ denote the PDF and CDF, respectively, of the k th component distribution, where $\hat{\Omega}$ denotes the set of estimates of all parameters of the distribution other than the scale parameter. Then, the PDF and CDF estimates, $f^*(y)$ and $F^*(y)$, respectively, of the mixture distribution at y are computed as

$$f^*(y) = \frac{1}{D} \sum_{k=1}^K d_k f(y; s_k, \hat{\Omega})$$

$$F^*(y) = \frac{1}{D} \sum_{k=1}^K d_k F(y; s_k, \hat{\Omega})$$

where D is the normalization factor ($D = \sum_{k=1}^K d_k$).

PROC SEVSELECT uses the $F^*(y)$ values to compute the EDF-based statistics of fit.

The scale values s_k for the K mixture components are derived from the set $\{\hat{\lambda}_i\}$ ($i = 1, \dots, N$) of N linear predictor values, where $\hat{\lambda}_i$ denotes the estimate of the linear predictor due to observation i . It is computed as

$$\hat{\lambda}_i = \log(\hat{\theta}_0) + \sum_{j=1}^k \hat{\beta}_j x_{ij}$$

where $\hat{\theta}_0$ is an estimate of the base value of the scale parameter, $\hat{\beta}_j$ are the estimates of regression coefficients, and x_{ij} is the value of j th regression effect in observation i .

Let w_i denote the weight of observation i . If you specify the WEIGHT statement, then the weight is equal to the value of the specified weight variable for the corresponding observation in the DATA= data table; otherwise, the weight is set to 1.

You can specify one of the following *method-names* in the DFMIXTURE= option in the SCALEMODEL statement to specify the method of choosing K and the corresponding s_k and d_k values:

FULL In this method, there are as many mixture components as the number of observations that are used for estimation. In other words, $K = N$, $s_k = \hat{\theta}_k$, and $d_k = w_k$ ($k = 1, \dots, N$). This is the slowest method, because it requires $O(N)$ computations to compute the mixture CDF $F^*(y_i)$ or the mixture PDF $f^*(y_i)$ of one observation. For N observations, the computational complexity in terms of number of CDF or PDF evaluations is $O(N^2)$. Even for moderately large values of N , the time that is taken to compute the mixture CDF and PDF can significantly exceed the time that is taken to estimate the model parameters. So it is recommended that you use the FULL method only for small data tables.

MEAN In this method, the mixture contains only one distribution, whose scale value is determined by the mean of the linear predictor values that are implied by all the observations. In other words, s_1 is computed as

$$s_1 = \exp \left(\frac{1}{N} \sum_{i=1}^N \hat{\lambda}_i \right)$$

The component's weight d_1 is set to 1.

This method is the fastest because it requires only one CDF or PDF evaluation per observation. The computational complexity is $O(N)$ for N observations.

If you do not specify the DFMIXTURE= option in the SCALEMODEL statement, then this is the default method.

QUANTILE In this method, a certain number of quantiles are chosen from the set of all linear predictor values. If you specify a value of q for the K= option when specifying this method, then $K = q - 1$ and s_k ($k = 1, \dots, K$) is computed as $s_k = \exp(\hat{\lambda}_k)$, where $\hat{\lambda}_k$ is the k th q -quantile from the set $\{\hat{\lambda}_i\}$ ($i = 1, \dots, N$). The weight of each of the components (d_k) is assumed to be 1 for this method.

The default value of q is 2, which implies a one-point mixture that has a distribution whose scale value is equal to the median scale value.

For this method, PROC SEVSELECT needs to sort the N linear predictor values in the set $\{\hat{\lambda}_i\}$; the sorting requires $O(N \log(N))$ computations. Then, computing the mixture estimate of one observation requires $(q - 1)$ CDF or PDF evaluations. Hence, the computational complexity of this method is $O(qN) + O(N \log(N))$ for computing a mixture CDF or PDF of N observations. For $q \ll N$, the QUANTILE method is significantly faster than the FULL method.

RANDOM In this method, a uniform random sample of observations is chosen, and the mixture contains the distributions that are implied by those observations. If you specify a value of r for the K= option when specifying this method, then the size of the sample is r . Hence, $K = r$. If l_j denotes the index of j th observation in the sample ($j = 1, \dots, r$), such that $1 \leq l_j \leq N$, then the scale of k th component distribution in the mixture is $s_k = \exp(\hat{\lambda}_{l_k})$. The weight of each of the components (d_k) is assumed to be 1 for this method.

You can also specify the seed to be used for generating the random sample by using the SEED= option for this method. The same sample of observations is used for all models.

Computing a mixture estimate of one observation requires r CDF or PDF evaluations. Hence, the computational complexity of this method is $O(rN)$ for computing a mixture CDF or PDF of N observations. For $r \ll N$, the RANDOM method is significantly faster than the FULL method.

Empirical Distribution Function Estimation Methods

The empirical distribution function (EDF) is a nonparametric estimate of the cumulative distribution function (CDF) of the distribution. PROC SEVSELECT computes EDF estimates for two purposes: to send the estimates to a distribution's [PARMINIT](#) subroutine in order to initialize the distribution parameters, and to compute the EDF-based statistics of fit.

To reduce the time that it takes to compute the EDF estimates, you can use the [INITSAMPLE](#) option to specify that only a fraction of the input data be used. If you do not specify the INITSAMPLE option and the data table has more than 10,000 valid observations, then a uniform random sample of at most 10,000 observations is used for EDF estimation.

In the distributed mode of execution, in which data are distributed across the grid nodes, the EDF estimates are computed on each node by using the portion of the input data that is located on that node. These local EDF estimates are an approximation of the global EDF estimates, which would have been computed by using the entire input data table. PROC SEVSELECT does not compute global EDF estimates. Let X denote a quantity that depends on the EDF estimates. X can be either an EDF-based initial value of a distribution parameter or an EDF-based statistic of fit. PROC SEVSELECT estimates X as follows: First, each grid node k computes an estimate X_k by using the local EDF estimates that are computed on that node. Then, the estimate $\hat{X}$ of X is computed as an average of all the X_k values; that is, $\hat{X} = \sum_{i=1}^K X_k$, where K denotes the total number of nodes where the data reside.

This section describes the methods that are used for computing EDF estimates.

Notation

Let there be a set of N observations, each containing a quintuplet of values $(y_i, t_i^l, t_i^r, c_i^r, c_i^l)$, $i = 1, \dots, N$, where y_i is the value of the response variable, t_i^l is the value of the left-truncation threshold, t_i^r is the value of the right-truncation threshold, c_i^r is the value of the right-censoring limit, and c_i^l is the value of the left-censoring limit.

If an observation is not left-truncated, then $t_i^l = \tau^l$, where τ^l is the smallest value in the support of the distribution; so $F(t_i^l) = 0$. If an observation is not right-truncated, then $t_i^r = \tau_h$, where τ_h is the largest value in the support of the distribution; so $F(t_i^r) = 1$. If an observation is not right-censored, then $c_i^r = \tau^l$; so $F(c_i^r) = 0$. If an observation is not left-censored, then $c_i^l = \tau_h$; so $F(c_i^l) = 1$.

Let w_i denote the weight associated with i th observation. If you specify the [WEIGHT](#) statement, then w_i is the normalized value of the weight variable; otherwise, it is set to 1. The weights are normalized such that they sum up to N .

An indicator function $I[e]$ takes a value of 1 or 0 if the expression e is true or false, respectively.

Estimation Methods

If the response variable is subject to both left-censoring and right-censoring effects and if you explicitly specify the `EMPIRICALCDF=TURNBULL` option, then PROC SEVSELECT uses the Turnbull's method. This section describes methods other than Turnbull's method. For Turnbull's method, see the next section "Turnbull's EDF Estimation Method" on page 1802.

The method descriptions assume that all observations are either uncensored or right-censored; that is, each observation is of the form $(y_i, t_i^l, t_i^r, \tau^l, \tau_h)$ or $(y_i, t_i^l, t_i^r, c_i^r, \tau_h)$.

If all observations are either uncensored or left-censored, then each observation is of the form $(y_i, t_i^l, t_i^r, \tau_l, c_i^l)$. It is converted to an observation $(-y_i, -t_i^r, -t_i^l, -c_i^l, \tau_h)$; that is, the signs of all the response variable values are reversed, the new left-truncation threshold is equal to the negative of the original right-truncation threshold, the new right-truncation threshold is equal to the negative of the original left-truncation threshold, and the negative of the original left-censoring limit becomes the new right-censoring limit. With this transformation, each observation is either uncensored or right-censored. The methods described for handling uncensored or right-censored data are now applicable. After the EDF estimates are computed, the observations are transformed back to the original form and EDF estimates are adjusted such $F_n(y_i) = 1 - F_n(-y_i-)$, where $F_n(-y_i-)$ denotes the EDF estimate of the value slightly less than the transformed value $-y_i$.

Further, a set of uncensored or right-censored observations can be converted to a set of observations of the form $(y_i, t_i^l, t_i^r, \delta_i)$, where δ_i is the indicator of right-censoring. $\delta_i = 0$ indicates a right-censored observation, in which case y_i is assumed to record the right-censoring limit c_i^r . $\delta_i = 1$ indicates an uncensored observation, and y_i records the exact observed value. In other words, $\delta_i = I[Y \leq C^r]$ and $y_i = \min(y_i, c_i^r)$.

Given this notation, the EDF is estimated as

$$F_n(y) = \begin{cases} 0 & \text{if } y < y^{(1)} \\ \hat{F}_n(y^{(k)}) & \text{if } y^{(k)} \leq y < y^{(k+1)}, k = 1, \dots, N-1 \\ \hat{F}_n(y^{(N)}) & \text{if } y^{(N)} \leq y \end{cases}$$

where $y^{(k)}$ denotes the k th-order statistic of the set $\{y_i\}$ and $\hat{F}_n(y^{(k)})$ is the estimate computed at that value. The definition of $\hat{F}_n$ depends on the estimation method. You can specify a particular method or let PROC SEVSELECT choose an appropriate method by using the `EMPIRICALCDF=` option in the PROC SEVSELECT statement. Each method computes $\hat{F}_n$ as follows:

NOTURNBULL This is the default method. First, censored observations, if any, are processed as follows:

- An observation that is left-censored but not right-censored is converted to an uncensored observation $(y_i^u, t_i^l, t_i^r, \tau^l, \tau_h)$, where $y_i^u = c_i^l/2$.
- An observation that is both left-censored and right-censored is converted to an uncensored observation $(y_i^u, t_i^l, t_i^r, \tau^l, \tau_h)$, where $y_i^u = (c_i^r + c_i^l)/2$.
- An observation that is right-censored but not left-censored is left unchanged.

If the processed set of observations contains any truncated or right-censored observations, the KAPLANMEIER method is used. Otherwise, the STANDARD method is used.

The observations are modified only for the purpose of computing the EDF estimates. The original censoring information is used by the parameter estimation process.

STANDARD

This method is the standard way of computing EDF. The EDF estimate at observation i is computed as follows:

$$\hat{F}_n(y_i) = \frac{1}{N} \sum_{j=1}^N w_j \cdot I[y_j \leq y_i]$$

If you do not specify any censoring or truncation information, then this method is chosen. If you explicitly specify this method, then PROC SEVSELECT ignores any censoring and truncation information that you specify in the LOSS statement.

The standard error of $\hat{F}_n(y_i)$ is computed by using the normal approximation method:

$$\hat{\sigma}_n(y_i) = \sqrt{\hat{F}_n(y_i)(1 - \hat{F}_n(y_i))/N}$$

KAPLANMEIER

The Kaplan-Meier (KM) estimator, also known as the product-limit estimator, was first introduced by Kaplan and Meier (1958) for censored data. Lynden-Bell (1971) derived a similar estimator for left-truncated data. PROC SEVSELECT uses the definition that combines both censoring and truncation information (Klein and Moeschberger 1997; Lai and Ying 1991).

The EDF estimate at observation i is computed as

$$\hat{F}_n(y_i) = 1 - \prod_{\tau \leq y_i} \left(1 - \frac{n(\tau)}{R_n(\tau)}\right)$$

where $n(\tau)$ and $R_n(\tau)$ are defined as follows:

- $n(\tau) = \sum_{k=1}^N w_k \cdot I[y_k = \tau \text{ and } \tau \leq t_k^r \text{ and } \delta_k = 1]$, which is the number of uncensored observations ($\delta_k = 1$) for which the response variable value is equal to τ and τ is observable according to the right-truncation threshold of that observation ($\tau \leq t_k^r$).
- $R_n(\tau) = \sum_{k=1}^N w_k \cdot I[y_k \geq \tau > t_k^l]$, which is the size (cardinality) of the risk set at τ . The term *risk set* has its origins in survival analysis; it contains the events that are at risk of failure at a particular time, τ . In other words, it contains the events that have survived up to time τ and might fail at or after τ . For PROC SEVSELECT, *time* is equivalent to the magnitude of the event and *failure* is equivalent to an uncensored and observable event, where observable means it satisfies the truncation thresholds.

This method is chosen when you specify at least one form of censoring or truncation.

The standard error of $\hat{F}_n(y_i)$ is computed by using Greenwood's formula (Greenwood 1926):

$$\hat{\sigma}_n(y_i) = \sqrt{(1 - \hat{F}_n(y_i))^2 \cdot \sum_{\tau \leq y_i} \left(\frac{n(\tau)}{R_n(\tau)(R_n(\tau) - n(\tau))} \right)}$$

MODIFIEDKM

The product-limit estimator used by the KAPLANMEIER method does not work well if the risk set size becomes very small. For right-censored data, the size can become

small towards the right tail. For left-truncated data, the size can become small at the left tail and can remain so for the entire range of data. This was demonstrated by Lai and Ying (1991). They proposed a modification to the estimator that ignores the effects due to small risk set sizes.

The EDF estimate at observation i is computed as

$$\hat{F}_n(y_i) = 1 - \prod_{\tau \leq y_i} \left(1 - \frac{n(\tau)}{R_n(\tau)} \cdot I[R_n(\tau) \geq cN^\alpha] \right)$$

where the definitions of $n(\tau)$ and $R_n(\tau)$ are identical to those used for the KAPLAN-MEIER method described previously.

You can specify the values of c and α by using the **C=** and **ALPHA=** options. If you do not specify a value for c , the default value used is $c = 1$. If you do not specify a value for α , the default value used is $\alpha = 0.5$.

As an alternative, you can also specify an absolute lower bound, say L , on the risk set size by using the **RSLB=** option, in which case $I[R_n(\tau) \geq cN^\alpha]$ is replaced by $I[R_n(\tau) \geq L]$ in the definition.

The standard error of $\hat{F}_n(y_i)$ is computed by using Greenwood's formula (Greenwood 1926):

$$\hat{\sigma}_n(y_i) = \sqrt{(1 - \hat{F}_n(y_i))^2 \cdot \sum_{\tau \leq y_i} \left(\frac{n(\tau)}{R_n(\tau)(R_n(\tau) - n(\tau))} \cdot I[R_n(\tau) \geq cN^\alpha] \right)}$$

Turnbull's EDF Estimation Method

If the response variable is subject to both left-censoring and right-censoring effects and if you explicitly specify the **EMPIRICALCDF=TURNBULL** option, then the SEVSELECT procedure uses a method proposed by Turnbull (1976) to compute the nonparametric estimates of the cumulative distribution function. The original Turnbull's method is modified using the suggestions made by Frydman (1994) when truncation effects are present.

Let the input data consist of N observations in the form of quintuplets of values $(y_i, t_i^l, t_i^r, c_i^r, c_i^l)$, $i = 1, \dots, N$ with notation described in the section “**Notation**” on page 1799. For each observation, let $A_i = (c_i^r, c_i^l]$ be the censoring interval; that is, the response variable value is known to lie in the interval A_i , but the exact value is not known. If an observation is uncensored, then $A_i = (y_i - \epsilon, y_i]$ for any arbitrarily small value of $\epsilon > 0$. If an observation is censored, then the value y_i is ignored. Similarly, for each observation, let $B_i = (t_i^l, t_i^r]$ be the truncation interval; that is, the observation is drawn from a truncated (conditional) distribution $F(y, B_i) = P(Y \leq y | Y \in B_i)$.

Two sets, L and R , are formed using A_i and B_i as follows:

$$L = \{c_i^r, 1 \leq i \leq N\} \cup \{t_i^r, 1 \leq i \leq N\}$$

$$R = \{c_i^l, 1 \leq i \leq N\} \cup \{t_i^l, 1 \leq i \leq N\}$$

The sets L and R represent the left endpoints and right endpoints, respectively. A set of disjoint intervals $C_j = [q_j, p_j]$, $1 \leq j \leq M$ is formed such that $q_j \in L$ and $p_j \in R$ and $q_j \leq p_j$ and $p_j < q_{j+1}$. The value of M is dependent on the nature of censoring and truncation intervals in the input data. Turnbull (1976)

showed that the maximum likelihood estimate (MLE) of the EDF can increase only inside intervals C_j . In other words, the MLE estimate is constant in the interval (p_j, q_{j+1}) . The likelihood is independent of the behavior of F_n inside any of the intervals C_j . Let s_j denote the increase in F_n inside an interval C_j . Then, the EDF estimate is as follows:

$$F_n(y) = \begin{cases} 0 & \text{if } y < q_1 \\ \sum_{k=1}^j s_k & \text{if } p_j < y < q_{j+1}, 1 \leq j \leq M-1 \\ 1 & \text{if } y > p_M \end{cases}$$

PROC SEVSELECT computes the estimates $F_n(p_j+) = F_n(q_{j+1}-) = \sum_{k=1}^j s_k$ at points p_j and q_{j+1} and computes $F_n(q_1-) = 0$ at point q_1 , where $F_n(x+)$ denotes the limiting estimate at a point that is infinitesimally larger than x when approaching x from values larger than x and where $F_n(x-)$ denotes the limiting estimate at a point that is infinitesimally smaller than x when approaching x from values smaller than x .

PROC SEVSELECT uses the expectation-maximization (EM) algorithm proposed by Turnbull (1976), who referred to the algorithm as the self-consistency algorithm. By default, the algorithm runs until one of the following criteria is met:

- Relative-error criterion: The maximum relative error between the two consecutive estimates of s_j falls below a threshold ϵ . If l indicates an index of the current iteration, then this can be formally stated as

$$\arg \max_{1 \leq j \leq M} \left\{ \frac{|s_j^l - s_j^{l-1}|}{s_j^{l-1}} \right\} \leq \epsilon$$

You can control the value of ϵ by specifying the **EPS=** suboption of the EDF=TURNBULL option in the PROC SEVSELECT statement. The default value is 1.0E-8.

- Maximum-iteration criterion: The number of iterations exceeds an upper limit that you specify for the **MAXITER=** suboption of the EDF=TURNBULL option in the PROC SEVSELECT statement. The default number of maximum iterations is 500.

The self-consistent estimates obtained in this manner might not be maximum likelihood estimates. Gentleman and Geyer (1994) suggested the use of the Kuhn-Tucker conditions for the maximum likelihood problem to ensure that the estimates are MLE. If you specify the **ENSUREMLE** suboption of the EDF=TURNBULL option in the PROC SEVSELECT statement, then PROC SEVSELECT computes the Kuhn-Tucker conditions at the end of each iteration to determine whether the estimates $\{s_j\}$ are MLE. If you do not specify any truncation effects, then the Kuhn-Tucker conditions derived by Gentleman and Geyer (1994) are used. If you specify any truncation effects, then PROC SEVSELECT uses modified Kuhn-Tucker conditions that account for the truncation effects. An integral part of checking the conditions is to determine whether an estimate s_j is zero or whether an estimate of the Lagrange multiplier or the reduced gradient associated with the estimate s_j is zero. PROC SEVSELECT declares these values to be zero if they are less than or equal to a threshold δ . You can control the value of δ by specifying the **ZEROPROB=** suboption of the EDF=TURNBULL option in the PROC SEVSELECT statement. The default value is 1.0E-8. The algorithm continues until the Kuhn-Tucker conditions are satisfied or the number of iterations exceeds the upper limit. The relative-error criterion stated previously is not used when you specify the ENSUREMLE option.

The standard errors for Turnbull's EDF estimates are computed by using the asymptotic theory of the maximum likelihood estimators (MLE), even though the final estimates might not be MLE. Turnbull's

estimator essentially attempts to maximize the likelihood L , which depends on the parameters s_j ($j = 1, \dots, M$). Let $\mathbf{s} = \{s_j\}$ denote the set of these parameters. If $\mathbf{G}(\mathbf{s}) = \nabla^2(-\log(L(\mathbf{s})))$ denotes the Hessian matrix of the negative of log likelihood, then the variance-covariance matrix of $\mathbf{s}$ is estimated as $\hat{\mathbf{C}}(\mathbf{s}) = \mathbf{G}^{-1}(\mathbf{s})$. Given this matrix, the standard error of $F_n(y)$ is computed as

$$\sigma_n(y) = \sqrt{\sum_{k=1}^j \left(\hat{C}_{kk} + 2 \cdot \sum_{l=1}^{k-1} \hat{C}_{kl} \right)}, \text{ if } p_j < y < q_{j+1}, 1 \leq j \leq M-1$$

The standard error is undefined outside of these intervals.

EDF Estimates and Truncation

If you specify truncation, then the estimate $\hat{F}_n(y)$ that is computed by any method other than the STANDARD method is a *conditional* estimate. In other words, $\hat{F}_n(y) = \Pr(Y \leq y | \tau_G < Y \leq \tau_H)$, where G and H denote the (unknown) distribution functions of the left-truncation threshold variable T^l and the right-truncation threshold variable T^r , respectively, τ_G denotes the smallest left-truncation threshold with a nonzero cumulative probability, and τ_H denotes the largest right-truncation threshold with a nonzero cumulative probability. Formally, $\tau_G = \inf\{s : G(s) > 0\}$ and $\tau_H = \sup\{s : H(s) > 0\}$. For computational purposes, PROC SEVSELECT estimates τ_G and τ_H by $t_{\min}^l$ and $t_{\max}^r$, respectively, defined as

$$t_{\min}^l = \min\{t_k^l : 1 \leq k \leq N\}$$

$$t_{\max}^r = \max\{t_k^r : 1 \leq k \leq N\}$$

These estimates of $t_{\min}^l$ and $t_{\max}^r$ are used to compute the conditional estimates of the CDF as described in the section “[Truncation and Conditional CDF Estimates](#)” on page 1790.

If you specify left-truncation *with* the probability of observability p , then PROC SEVSELECT uses the additional information provided by p to compute an estimate of the EDF that is not conditional on the left-truncation information. In particular, for each left-truncated observation i with response variable value y_i and truncation threshold t_i^l , an observation j is added with *weight* $w_j = (1 - p)/p$ and $y_j = t_j^l$. Each added observation is assumed to be uncensored and untruncated. Then, your specified EDF method is used by assuming no left-truncation. The EDF estimate that is obtained using this method is not conditional on the left-truncation information. For the KAPLANMEIER and MODIFIEDKM methods with uncensored or right-censored data, definitions of $n(\tau)$ and $R_n(\tau)$ are modified to account for the added observations. If N^a denotes the total number of observations including the added observations, then $n(\tau)$ is defined as $n(\tau) = \sum_{k=1}^{N^a} w_k I[y_k = \tau \text{ and } \tau \leq t_k^r \text{ and } \delta_k = 1]$, and $R_n(\tau)$ is defined as $R_n(\tau) = \sum_{k=1}^{N^a} w_k I[y_k \geq \tau]$. In the definition of $R_n(\tau)$, the left-truncation information is not used, because it was used along with p to add the observations.

If the original data are a combination of left- and right-censored data and if you specify the EMPIRICALCDF=TURNBULL option, then Turnbull’s method is applied to the appended set that contains no left-truncated observations.

Supplying EDF Estimates to Functions and Subroutines

The parameter initialization subroutines in distribution models and some predefined utility functions require EDF estimates. For more information, see the sections “[Defining a Severity Distribution Model with the FCMP Procedure](#)” on page 1811 and “[Predefined Utility Functions](#)” on page 1824.

PROC SEVSELECT supplies the EDF estimates to these subroutines and functions by using two arrays, x and F , the dimension of each array, and a type of the EDF estimates. The type identifies how the EDF estimates are computed and stored. They are as follows:

- Type 1 specifies that EDF estimates are computed using the STANDARD method; that is, the data that are used for estimation are neither censored nor truncated.
- Type 2 specifies that EDF estimates are computed using either the KAPLANMEIER or the MODIFIEDKM method; that is, the data that are used for estimation are subject to truncation and one type of censoring (left or right, but not both).
- Type 3 specifies that EDF estimates are computed using the TURNBULL method; that is, the data that are used for estimation are subject to both left- and right-censoring. The data might or might not be truncated.

For Types 1 and 2, the EDF estimates are stored in arrays x and F of dimension N such that the following holds,

$$F_n(y) = \begin{cases} 0 & \text{if } y < x[1] \\ F[k] & \text{if } x[k] \leq y < x[k+1], k = 1, \dots, N-1 \\ F[N] & \text{if } x[N] \leq y \end{cases}$$

where $[k]$ denotes k th element of the array ($[1]$ denotes the first element of the array).

For Type 3, the EDF estimates are stored in arrays x and F of dimension N such that the following holds:

$$F_n(y) = \begin{cases} 0 & \text{if } y < x[1] \\ \text{undefined} & \text{if } x[2k-1] \leq y < x[2k], k = 1, \dots, (N-1)/2 \\ F[2k] = F[2k+1] & \text{if } x[2k] \leq y < x[2k+1], k = 1, \dots, (N-1)/2 \\ F[N] & \text{if } x[N] \leq y \end{cases}$$

Although the behavior of EDF is theoretically undefined for the interval $[x[2k-1], x[2k])$, for computational purposes, all predefined functions and subroutines assume that the EDF increases linearly from $F[2k-1]$ to $F[2k]$ in that interval if $x[2k-1] < x[2k]$. If $x[2k-1] = x[2k]$, which can happen when the EDF is estimated from a combination of uncensored and interval-censored data, the predefined functions and subroutines assume that $F_n(x[2k-1]) = F_n(x[2k]) = F[2k]$.

Statistics of Fit

PROC SEVSELECT computes and reports various statistics of fit to indicate how well the estimated model fits the data. The statistics belong to two categories: likelihood-based statistics and EDF-based statistics. Neg2LogLike, AIC, AICC, and SBC are likelihood-based statistics, and KS, AD, and CvM are EDF-based statistics.

In the distributed mode of execution, in which data are distributed across the grid nodes, the EDF estimates are computed by using the local data. The EDF-based statistics are computed by using these local EDF estimates. The reported value of each EDF-based statistic is an average of the values of the statistic that are computed by all the grid nodes where the data reside.

Also, for large data tables, in both single-machine and distributed modes of execution, the EDF estimates are computed by using a fraction of the input data that is governed by either the [INITSAMPLE](#) option or the default sample size.

Because of this nature of computing the EDF estimates, the EDF-based statistics of fit are an approximation of the values that would have been computed if the entire input data table were used for computing the EDF estimates. So the values that are reported for EDF-based statistics should be used only for comparing different models. The reported values should not be interpreted as true estimates of the corresponding statistics.

The likelihood-based statistics are reported for the entire input data table in both single-machine and distributed modes of execution.

The following subsections provide definitions of each category of statistics.

Likelihood-Based Statistics of Fit

Let $y_i, i = 1, \dots, N$, denote the response variable values. Let L be the likelihood as defined in the section “[Likelihood Function](#)” on page 1791. Let p denote the number of model parameters that are estimated. Note that $p = p_d + (k - k_r)$, where p_d is the number of distribution parameters, k is the number of all regression parameters, and k_r is the number of regression parameters that are found to be linearly dependent (redundant) on other regression parameters. By default, the value of p_d includes the distribution parameters that you have defined as constant by using the [dist_CONSTANTPARM](#) subroutine. You can exclude them by specifying the [NOCONSTFITSTATS](#) option in the PROC SEVSELECT statement. Given this notation, the likelihood-based statistics are defined as follows:

Neg2LogLike The log likelihood is reported as

$$\text{Neg2LogLike} = -2 \log(L)$$

The multiplying factor -2 makes it easy to compare it to the other likelihood-based statistics. A model that has a smaller value of Neg2LogLike is deemed better.

AIC Akaike’s information criterion (AIC) is defined as

$$\text{AIC} = -2 \log(L) + 2p$$

A model that has a smaller AIC value is deemed better.

AICC The corrected Akaike’s information criterion (AICC) is defined as

$$\text{AICC} = -2 \log(L) + \frac{2Np}{N - p - 1}$$

A model that has a smaller AICC value is deemed better. It corrects the finite-sample bias that AIC has when N is small compared to p . AICC is related to AIC as

$$\text{AICC} = \text{AIC} + \frac{2p(p+1)}{N-p-1}$$

As N becomes large compared to p , AICC converges to AIC. AICC is usually recommended over AIC as a model selection criterion.

SBC

The Schwarz Bayesian information criterion (SBC) is defined as

$$\text{SBC} = -2 \log(L) + p \log(N)$$

A model that has a smaller SBC value is deemed better.

EDF-Based Statistics

This class of statistics is based on the difference between the estimate of the cumulative distribution function (CDF) and the estimate of the empirical distribution function (EDF). A model that has a smaller value of the chosen EDF-based statistic is deemed better.

Let $y_i, i = 1, \dots, N$, denote the sample of N values of the response variable. Let w_i denote the normalized weight of the i th observation. If w_i^o denotes the original, unnormalized weight of the i th observation, then $w_i = N w_i^o / (\sum_{i=1}^N w_i^o)$. Let N_u denote the number of observations with unique (nonduplicate) values of the response variable. Let $W_i = \sum_{j=1}^N w_j I[y_j = y_i]$ denote the total weight of observations with a value y_i , where I is an indicator function. Let $r_i = \sum_{j=1}^N w_j I[y_j \leq y_i]$ denote the total weight of observations with a value less than or equal to y_i . Let $W = \sum_{i=1}^{N_u} W_i$ denote the total weight of all observations. Use of normalized weights implies that $W = N$.

Let $F_n(y_i)$ denote the EDF estimate that is computed by using the method that you specify in the **EMPIRICALCDF=** option. Let $Z_i = \hat{F}(y_i)$ denote the estimate of the CDF. Let $F_n(Z_i)$ denote the EDF estimate of Z_i values that are computed using the same method that is used to compute the EDF of y_i values. Using the probability integral transformation, if $F(y)$ is the true distribution of the random variable Y , then the random variable $Z = F(y)$ is uniformly distributed between 0 and 1 (D'Agostino and Stephens 1986, Ch. 4). Thus, comparing $F_n(y_i)$ with $\hat{F}(y_i)$ is equivalent to comparing $F_n(Z_i)$ with $\hat{F}(Z_i) = Z_i$ (uniform distribution).

Note the following two points regarding which CDF estimates are used for computing the test statistics:

- If you specify regression effects, then the CDF estimates Z_i that are used for computing the EDF test statistics are from a mixture distribution. For more information, see the section “[CDF and PDF Estimates with Regression Effects](#)” on page 1797.
- If the EDF estimates are conditional because of the truncation information, then each unconditional estimate Z_i is converted to a conditional estimate using the method described in the section “[Truncation and Conditional CDF Estimates](#)” on page 1790.

In the following, it is assumed that Z_i denotes an appropriate estimate of the CDF if you specify any truncation or regression effects. Given this, the EDF-based statistics of fit are defined as follows:

KS The Kolmogorov-Smirnov (KS) statistic computes the largest vertical distance between the CDF and the EDF. It is formally defined as follows:

$$KS = \sup_y |F_n(y) - F(y)|$$

If the STANDARD method is used to compute the EDF, then the following formula is used:

$$\begin{aligned} D^+ &= \max_i \left(\frac{r_i}{W} - Z_i \right) \\ D^- &= \max_i \left(Z_i - \frac{r_{i-1}}{W} \right) \\ KS &= \sqrt{W} \max(D^+, D^-) + \frac{0.19}{\sqrt{W}} \end{aligned}$$

Note that r_0 is assumed to be 0.

If the method used to compute the EDF is any method other than the STANDARD method, then the following formula is used:

$$\begin{aligned} D^+ &= \max_i (F_n(Z_i) - Z_i), \text{ if } F_n(Z_i) \geq Z_i \\ D^- &= \max_i (Z_i - F_n(Z_i)), \text{ if } F_n(Z_i) < Z_i \\ KS &= \sqrt{W} \max(D^+, D^-) + \frac{0.19}{\sqrt{W}} \end{aligned}$$

AD The Anderson-Darling (AD) statistic is a quadratic EDF statistic that is proportional to the expected value of the weighted squared difference between the EDF and CDF. It is formally defined as follows:

$$AD = N \int_{-\infty}^{\infty} \frac{(F_n(y) - F(y))^2}{F(y)(1 - F(y))} dF(y)$$

If the STANDARD method is used to compute the EDF, then the following formula is used:

$$AD = -W - \frac{1}{W} \sum_{i=1}^{N_u} W_i [(2r_i - 1) \log(Z_i) + (2W + 1 - 2r_i) \log(1 - Z_i)]$$

If the method used to compute the EDF is any method other than the STANDARD method, then the statistic can be computed by using the following two pieces of information:

- If the EDF estimates are computed using the KAPLANMEIER or MODIFIEDKM methods, then EDF is a step function such that the estimate $F_n(z)$ is a constant equal to $F_n(Z_{i-1})$ in interval $[Z_{i-1}, Z_i]$. If the EDF estimates are computed using the TURNBULL method, then there are two types of intervals: one in which the EDF curve is constant and the other in which the EDF curve is theoretically undefined. For computational purposes, it is assumed that the EDF curve is linear for the latter type of the interval. For each method, the EDF estimate $F_n(y)$ at y can be written as

$$F_n(z) = F_n(Z_{i-1}) + S_i(z - Z_{i-1}), \text{ for } z \in [Z_{i-1}, Z_i]$$

where S_i is the slope of the line defined as

$$S_i = \frac{F_n(Z_i) - F_n(Z_{i-1})}{Z_i - Z_{i-1}}$$

For the KAPLANMEIER or MODIFIEDKM method, $S_i = 0$ in each interval.

- Using the probability integral transform $z = F(y)$, the formula simplifies to

$$AD = N \int_{-\infty}^{\infty} \frac{(F_n(z) - z)^2}{z(1-z)} dz$$

The computation formula can then be derived from the approximation,

$$\begin{aligned} AD &= N \sum_{i=1}^{K+1} \int_{Z_{i-1}}^{Z_i} \frac{(F_n(z) - z)^2}{z(1-z)} dz \\ &= N \sum_{i=1}^{K+1} \int_{Z_{i-1}}^{Z_i} \frac{(F_n(Z_{i-1}) + S_i(z - Z_{i-1}) - z)^2}{z(1-z)} dz \\ &= N \sum_{i=1}^{K+1} \int_{Z_{i-1}}^{Z_i} \frac{(P_i - Q_i z)^2}{z(1-z)} dz \end{aligned}$$

where $P_i = F_n(Z_{i-1}) - S_i Z_{i-1}$, $Q_i = 1 - S_i$, and K is the number of points at which the EDF estimate are computed. For the TURNBULL method, $K = 2k$ for some k .

Assuming $Z_0 = 0$, $Z_{K+1} = 1$, $F_n(0) = 0$, and $F_n(Z_K) = 1$ yields the computation formula,

$$\begin{aligned} AD &= -N(Z_1 + \log(1 - Z_1) + \log(Z_K) + (1 - Z_K)) \\ &\quad + N \sum_{i=2}^K [P_i^2 A_i - (Q_i - P_i)^2 B_i - Q_i^2 C_i] \end{aligned}$$

where $A_i = \log(Z_i) - \log(Z_{i-1})$, $B_i = \log(1 - Z_i) - \log(1 - Z_{i-1})$, and $C_i = Z_i - Z_{i-1}$.

If EDF estimates are computed using the KAPLANMEIER or MODIFIEDKM method, then $P_i = F_n(Z_{i-1})$ and $Q_i = 1$, which simplifies the formula as

$$\begin{aligned} AD &= -N(1 + \log(1 - Z_1) + \log(Z_K)) \\ &\quad + N \sum_{i=2}^K [F_n(Z_{i-1})^2 A_i - (1 - F_n(Z_{i-1}))^2 B_i] \end{aligned}$$

CvM The Cramér–von Mises (CvM) statistic is a quadratic EDF statistic that is proportional to the expected value of the squared difference between the EDF and CDF. It is formally defined as follows:

$$CvM = N \int_{-\infty}^{\infty} (F_n(y) - F(y))^2 dF(y)$$

If the STANDARD method is used to compute the EDF, then the following formula is used:

$$CvM = \frac{1}{12W} + \sum_{i=1}^{N_u} W_i \left(Z_i - \frac{(2r_i - 1)}{2W} \right)^2$$

If the method used to compute the EDF is any method other than the STANDARD method, then the statistic can be computed by using the following two pieces of information:

- As described previously for the AD statistic, the EDF estimates are assumed to be piecewise linear such that the estimate $F_n(y)$ at y is

$$F_n(z) = F_n(Z_{i-1}) + S_i(z - Z_{i-1}), \text{ for } z \in [Z_{i-1}, Z_i]$$

where S_i is the slope of the line defined as

$$S_i = \frac{F_n(Z_i) - F_n(Z_{i-1})}{Z_i - Z_{i-1}}$$

For the KAPLANMEIER or MODIFIEDKM method, $S_i = 0$ in each interval.

- Using the probability integral transform $z = F(y)$, the formula simplifies to

$$\text{CvM} = N \int_{-\infty}^{\infty} (F_n(z) - z)^2 dz$$

The computation formula can then be derived from the following approximation,

$$\begin{aligned} \text{CvM} &= N \sum_{i=1}^{K+1} \int_{Z_{i-1}}^{Z_i} (F_n(z) - z)^2 dz \\ &= N \sum_{i=1}^{K+1} \int_{Z_{i-1}}^{Z_i} (F_n(Z_{i-1}) + S_i(z - Z_{i-1}) - z)^2 dz \\ &= N \sum_{i=1}^{K+1} \int_{Z_{i-1}}^{Z_i} (P_i - Q_i z)^2 dz \end{aligned}$$

where $P_i = F_n(Z_{i-1}) - S_i Z_{i-1}$, $Q_i = 1 - S_i$, and K is the number of points at which the EDF estimate are computed. For the TURNBULL method, $K = 2k$ for some k .

Assuming $Z_0 = 0$, $Z_{K+1} = 1$, and $F_n(0) = 0$ yields the following computation formula,

$$\text{CvM} = N \frac{Z_1^3}{3} + N \sum_{i=2}^{K+1} \left[P_i^2 A_i - P_i Q_i B_i - \frac{Q_i^2}{3} C_i \right]$$

where $A_i = Z_i - Z_{i-1}$, $B_i = Z_i^2 - Z_{i-1}^2$, and $C_i = Z_i^3 - Z_{i-1}^3$.

If EDF estimates are computed using the KAPLANMEIER or MODIFIEDKM method, then $P_i = F_n(Z_{i-1})$ and $Q_i = 1$, which simplifies the formula as

$$\text{CvM} = \frac{N}{3} + N \sum_{i=2}^{K+1} [F_n(Z_{i-1})^2(Z_i - Z_{i-1}) - F_n(Z_{i-1})(Z_i^2 - Z_{i-1}^2)]$$

which is similar to the formula proposed by Koziol and Green (1976).

Defining a Severity Distribution Model with the FCMP Procedure

A *severity distribution model* consists of a set of functions and subroutines that are defined using the FCMP procedure. The FCMP procedure is part of Base SAS software. Each function or subroutine must be named as `<distribution-name>_<keyword>`, where *distribution-name* is the identifying short name of the distribution and *keyword* identifies one of the functions or subroutines. The total length of the name should not exceed 32. Each function or subroutine must have a specific signature, which consists of the number of arguments, sequence and types of arguments, and return value type. The summary of all the recognized function and subroutine names and their expected behavior is given in [Table 26.6](#).

Consider the following points when you define a distribution model:

- When you define a function or subroutine requiring parameter arguments, the names and order of those arguments must be the same. Arguments other than the parameter arguments can have any name, but they must satisfy the requirements on their type and order.
- When the SEVSELECT procedure invokes any function or subroutine, it provides the necessary input values according to the specified signature, and expects the function or subroutine to prepare the output and return it according to the specification of the return values in the signature.
- You can use most of the SAS programming statements and SAS functions that you can use in a DATA step for defining the FCMP functions and subroutines. However, there are a few differences in the capabilities of the DATA step and the FCMP procedure. To learn more, see the documentation of the FCMP procedure in the [Base SAS Procedures Guide](#).
- You must specify either the PDF or the LOGPDF function. Similarly, you must specify either the CDF or the LOGCDF function. All other functions are optional, except when necessary for correct definition of the distribution. It is strongly recommended that you define the PARMINIT subroutine to provide a good set of initial values for the parameters. The information that PROC SEVSELECT provides to the PARMINIT subroutine enables you to use popular initialization approaches based on the method of moments and the method of percentile matching, but you can implement any algorithm to initialize the parameters by using the values of the response variable and the estimate of its empirical distribution function.
- The LOWERBOUNDS subroutines should be defined if the lower bound on at least one distribution parameter is different from the default lower bound of 0. If you define a LOWERBOUNDS subroutine but do not set a lower bound for some parameter inside the subroutine, then that parameter is assumed to have no lower bound (or a lower bound of $-\infty$). Hence, it is recommended that you explicitly return the lower bound for each parameter when you define the LOWERBOUNDS subroutine.
- The UPPERBOUNDS subroutines should be defined if the upper bound on at least one distribution parameter is different from the default upper bound of ∞ . If you define an UPPERBOUNDS subroutine but do not set an upper bound for some parameter inside the subroutine, then that parameter is assumed to have no upper bound (or a upper bound of ∞). Hence, it is recommended that you explicitly return the upper bound for each parameter when you define the UPPERBOUNDS subroutine.
- If you want to use the distribution in a model with regression effects, then make sure that the first parameter of the distribution is the scale parameter itself or a log-transformed scale parameter. If the first parameter is a log-transformed scale parameter, then you must define the SCALETRANSFORM function.

- In general, it is not necessary to define the gradient and Hessian functions, because the SEVSELECT procedure uses an internal system to evaluate the required derivatives. The internal system typically computes the derivatives analytically. But it might not be able to do so if your function definitions use other functions that it cannot differentiate analytically. In such cases, derivatives are approximated using a finite difference method and a note is written to the SAS log to indicate the components that are differentiated using such approximations. PROC SEVSELECT does reasonably well with these finite difference approximations. But, if you know of a way to compute the derivatives of such components analytically, then you should define the gradient and Hessian functions.

In order to use your distribution with PROC SEVSELECT, you need to record the FCMP library that contains the functions and subroutines for your distribution and other FCMP libraries that contain FCMP functions or subroutines used within your distribution's functions and subroutines. Specify all those libraries in the CMPLIB= system option by using the OPTIONS global statement. For more information about the OPTIONS statement, see *SAS Global Statements: Reference*. For more information about the CMPLIB= system option, see *SAS System Options: Reference*.

Each predefined distribution mentioned in the section “[Predefined Distributions](#)” on page 1779 has a distribution model associated with it. The functions and subroutines of all those models are available in the Sashelp.Svrtldist library. The order of the parameters in the signatures of the functions and subroutines is the same as listed in [Table 26.4](#). You do not need to use the CMPLIB= option in order to use the predefined distributions with PROC SEVSELECT. However, if you need to use the functions or subroutines of the predefined distributions in SAS statements other than the PROC SEVSELECT step (such as in a DATA step), then specify the Sashelp.Svrtldist library in the CMPLIB= system option by using the OPTIONS global statement prior to using them.

[Table 26.6](#) shows functions and subroutines that define a distribution model, and subsections after the table provide more detail. The functions are listed in alphabetical order of the keyword suffix.

Table 26.6 List of Functions and Subroutines That Define a Distribution Model

Name	Type	Required	Expected to Return
<i>dist_CDF</i>	Function	YES ¹	Cumulative distribution function value
<i>dist_CDFGRADIENT</i>	Subroutine	NO	Gradient of the CDF
<i>dist_CDFHESSIAN</i>	Subroutine	NO	Hessian of the CDF
<i>dist_CONSTANTPARM</i>	Subroutine	NO	Constant parameters
<i>dist_DESCRIPTION</i>	Function	NO	Description of the distribution
<i>dist_LOGCDF</i>	Function	YES ¹	Log of cumulative distribution function value
<i>dist_LOGCDFGRADIENT</i>	Subroutine	NO	Gradient of the LOGCDF
<i>dist_LOGCDFHESSIAN</i>	Subroutine	NO	Hessian of the LOGCDF
<i>dist_LOGPDF</i>	Function	YES ²	Log of probability density function value
<i>dist_LOGPDFGRADIENT</i>	Subroutine	NO	Gradient of the LOGPDF
<i>dist_LOGPDFHESSIAN</i>	Subroutine	NO	Hessian of the LOGPDF
<i>dist_LOGSDF</i>	Function	NO	Log of survival function value
<i>dist_LOGSDFGRADIENT</i>	Subroutine	NO	Gradient of the LOGSDF
<i>dist_LOGSDFHESSIAN</i>	Subroutine	NO	Hessian of the LOGSDF
<i>dist_LOWERBOUNDS</i>	Subroutine	NO	Lower bounds on parameters
<i>dist_PARMINIT</i>	Subroutine	NO	Initial values for parameters
<i>dist_PDF</i>	Function	YES ²	Probability density function value
<i>dist_PDFGRADIENT</i>	Subroutine	NO	Gradient of the PDF
<i>dist_PDFHESSIAN</i>	Subroutine	NO	Hessian of the PDF
<i>dist_QUANTILE</i>	Function	NO	Quantile for a particular CDF value
<i>dist_SCALETRANSFORM</i>	Function	NO	Type of relationship between the first distribution parameter and the scale parameter
<i>dist_SDF</i>	Function	NO	Survival function value
<i>dist_SDFGRADIENT</i>	Subroutine	NO	Gradient of the SDF
<i>dist_SDFHESSIAN</i>	Subroutine	NO	Hessian of the SDF
<i>dist_UPPERBOUNDS</i>	Subroutine	NO	Upper bounds on parameters

Notes:

1. Either the *dist_CDF* or the *dist_LOGCDF* function must be defined.
2. Either the *dist_PDF* or the *dist_LOGPDF* function must be defined.

The signature syntax and semantics of each function or subroutine are as follows:

dist_CDF

defines a function that returns the value of the cumulative distribution function (CDF) of the distribution at the specified values of the random variable and distribution parameters.

- *Type:* Function
- *Required:* YES
- *Number of arguments:* $m + 1$, where m is the number of distribution parameters
- *Sequence and type of arguments:*
 - x Numeric value of the random variable at which the CDF value should be evaluated
 - $p1$ Numeric value of the first parameter
 - $p2$ Numeric value of the second parameter
 - $\vdots$
 - pm Numeric value of the m th parameter
- *Return value:* Numeric value that contains the CDF value $F(x; p_1, p_2, \dots, p_m)$

If you want to consider this distribution as a candidate distribution when you estimate a response variable model with regression effects, then the first parameter of this distribution must be a scale parameter or log-transformed scale parameter. In other words, if the distribution has a scale parameter, then the following equation must be satisfied:

$$F(x; p_1, p_2, \dots, p_m) = F\left(\frac{x}{p_1}; 1, p_2, \dots, p_m\right)$$

If the distribution has a log-transformed scale parameter, then the following equation must be satisfied:

$$F(x; p_1, p_2, \dots, p_m) = F\left(\frac{x}{\exp(p_1)}; 0, p_2, \dots, p_m\right)$$

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_CDF(x, P1, P2);
  /* Code to compute CDF by using x, P1, and P2 */

  F = <computed CDF>;
  return (F);
endsub;
```

dist_CONSTANTPARM

defines a subroutine that specifies constant parameters. A parameter is *constant* if it is required for defining a distribution but is not subject to optimization in PROC SEVSELECT. Constant parameters are required to be part of the model in order to compute the PDF or the CDF of the distribution. Typically, values of these parameters are known a priori or estimated using some means other than the maximum likelihood method used by PROC SEVSELECT. You can estimate them inside the *dist_PARMINIT* subroutine. Once initialized, the parameters remain constant in the context of PROC SEVSELECT; that is, they retain their initial value. PROC SEVSELECT estimates only the nonconstant parameters.

- *Type*: Subroutine
- *Required*: NO
- *Number of arguments*: k , where k is the number of constant parameters
- *Sequence and type of arguments*:

```
constant parameter 1  Name of the first constant parameter
                    ⋮
constant parameter  $k$   Name of the  $k$ th constant parameter
```

- *Return value*: None

Here is a sample structure of the subroutine for a distribution named ‘FOO’ that has P3 and P5 as its constant parameters, assuming that distribution has at least three parameters:

```
subroutine FOO_CONSTANTPARM(p5, p3);
endsub;
```

Note the following points when you specify the constant parameters:

- At least one distribution parameter must be free to be optimized; that is, if a distribution has total m parameters, then k must be strictly less than m .
- If you want to use this distribution for modeling regression effects, then the first parameter must not be a constant parameter.
- The order of arguments in the signature of this subroutine does not matter as long as each argument’s name matches the name of one of the parameters that are defined in the signature of the *dist_PDF* function.
- The constant parameters must be specified in signatures of all the functions and subroutines that accept distribution parameters as their arguments.
- You must provide a nonmissing initial value for each constant parameter by using one of the supported parameter initialization methods.

*dist_***DESCRIPTION**

defines a function that returns a description of the distribution.

- *Type*: Function
- *Required*: NO
- *Number of arguments*: None
- *Sequence and type of arguments*: Not applicable
- *Return value*: Character value containing a description of the distribution

Here is a sample structure of the function for a distribution named ‘FOO’:

```

function FOO_DESCRIPTION() $48;
  length desc $48;
  desc = "A model for a continuous distribution named foo";
  return (desc);
endsub;

```

dist_LOGcore

defines a function that returns the natural logarithm of the specified *core* function of the distribution at the specified values of the random variable and distribution parameters. The *core* keyword can be PDF, CDF, or SDF.

- *Type*: Function
- *Required*: YES only if *core* is PDF or CDF and you have not defined that *core* function; otherwise, NO
- *Number of arguments*: $m + 1$, where m is the number of distribution parameters
- *Sequence and type of arguments*:
 - x Numeric value of the random variable at which the natural logarithm of the *core* function should be evaluated
 - p1 Numeric value of the first parameter
 - p2 Numeric value of the second parameter
 - ⋮
 - pm Numeric value of the m th parameter
- *Return value*: Numeric value that contains the natural logarithm of the *core* function

Here is a sample structure of the function for the core function PDF of a distribution named 'FOO':

```

function FOO_LOGPDF(x, P1, P2);
  /* Code to compute LOGPDF by using x, P1, and P2 */

  l = <computed LOGPDF>;
  return (l);
endsub;

```

dist_LOWERBOUNDS

defines a subroutine that returns lower bounds for the parameters of the distribution. If this subroutine is not defined for a particular distribution, then the SEVSELECT procedure assumes a lower bound of 0 for each parameter. If a lower bound of l_i is returned for a parameter p_i , then the SEVSELECT procedure assumes that $l_i < p_i$ (strict inequality). If a missing value is returned for some parameter, then the SEVSELECT procedure assumes that there is no lower bound for that parameter (equivalent to a lower bound of $-\infty$).

- *Type*: Subroutine
- *Required*: NO
- *Number of arguments*: m , where m is the number of distribution parameters
- *Sequence and type of arguments*:

- | | |
|----|---|
| p1 | Output argument that returns the lower bound on the first parameter. You must specify this in the OUTARGS statement inside the subroutine's definition. |
| p2 | Output argument that returns the lower bound on the second parameter. You must specify this in the OUTARGS statement inside the subroutine's definition. |
| ⋮ | |
| pm | Output argument that returns the lower bound on the <i>m</i> th parameter. You must specify this in the OUTARGS statement inside the subroutine's definition. |
- *Return value:* The results, lower bounds on parameter values, should be returned in the parameter arguments of the subroutine.

Here is a sample structure of the subroutine for a distribution named 'FOO':

```
subroutine FOO_LOWERBOUNDS(p1, p2);
    outargs p1, p2;

    p1 = <lower bound for P1>;
    p2 = <lower bound for P2>;
endsub;
```

*dist_***PARMINIT**

defines a subroutine that returns the initial values for the distribution's parameters given an empirical distribution function (EDF) estimate.

- *Type:* Subroutine
- *Required:* NO
- *Number of arguments:* $m + 4$, where m is the number of distribution parameters
- *Sequence and type of arguments:*

- | | |
|-------|---|
| dim | Input numeric value that contains the dimension of the x, nx, and F array arguments. |
| x{*} | Input numeric array of dimension <i>dim</i> that contains values of the random variables at which the EDF estimate is available. It can be assumed that x contains values in an increasing order. In other words, if $i < j$, then $x[i] < x[j]$. |
| nx{*} | Input numeric array of dimension <i>dim</i> . Each $nx[i]$ contains the number of observations in the original data that have the value $x[i]$. |
| F{*} | Input numeric array of dimension <i>dim</i> . Each $F[i]$ contains the EDF estimate for $x[i]$. This estimate is computed by the SEVSELECT procedure based on the options that you specify in the LOSS statement and the EMPIRICALCDF= option. |
| Ftype | Input numeric value that contains the type of the EDF estimate that is stored in x and F. For definitions of types, see the section " Supplying EDF Estimates to Functions and Subroutines " on page 1805. |
| p1 | Output argument that returns the initial value of the first parameter. You must specify this in the OUTARGS statement inside the subroutine's definition. |

p2 Output argument that returns the initial value of the second parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.
 ⋮

pm Output argument that returns the initial value of the m th parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.

- *Return value:* The results, initial values of the parameters, should be returned in the parameter arguments of the subroutine.

Here is a sample structure of the subroutine for a distribution named 'FOO':

```
subroutine FOO_PARMINIT(dim, x{*}, nx{*}, F{*}, Ftype, p1, p2);
  outargs p1, p2;

  /* Code to initialize values of P1 and P2 by using
    dim, x, nx, and F */

  p1 = <initial value for p1>;
  p2 = <initial value for p2>;
endsub;
```

dist_PDF

defines a function that returns the value of the probability density function (PDF) of the distribution at the specified values of the random variable and distribution parameters.

- *Type:* Function
- *Required:* YES
- *Number of arguments:* $m + 1$, where m is the number of distribution parameters
- *Sequence and type of arguments:*

x Numeric value of the random variable at which the PDF value should be evaluated

p1 Numeric value of the first parameter

p2 Numeric value of the second parameter

⋮

pm Numeric value of the m th parameter

- *Return value:* Numeric value that contains the PDF value $f(x; p_1, p_2, \dots, p_m)$

If you want to consider this distribution as a candidate distribution when you estimate a response variable model with regression effects, then the first parameter of this distribution must be a scale parameter or log-transformed scale parameter. In other words, if the distribution has a scale parameter, then the following equation must be satisfied:

$$f(x; p_1, p_2, \dots, p_m) = \frac{1}{p_1} f\left(\frac{x}{p_1}; 1, p_2, \dots, p_m\right)$$

If the distribution has a log-transformed scale parameter, then the following equation must be satisfied:

$$f(x; p_1, p_2, \dots, p_m) = \frac{1}{\exp(p_1)} f\left(\frac{x}{\exp(p_1)}; 0, p_2, \dots, p_m\right)$$

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_PDF(x, P1, P2);
    /* Code to compute PDF by using x, P1, and P2 */

    f = <computed PDF>;
    return (f);
endsub;
```

*dist_***QUANTILE**

defines a function that returns the quantile of the distribution at the specified value of the CDF for the specified values of distribution parameters.

- *Type:* Function
- *Required:* NO
- *Number of arguments:* $m + 1$, where m is the number of distribution parameters
- *Sequence and type of arguments:*
 - cdf Numeric value of the cumulative distribution function (CDF) for which the quantile should be evaluated
 - p1 Numeric value of the first parameter
 - p2 Numeric value of the second parameter
 - ⋮
 - pm Numeric value of the m th parameter
- *Return value:* Numeric value that contains the quantile $F^{-1}(\text{cdf}; p_1, p_2, \dots, p_m)$

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_QUANTILE(c, P1, P2);
    /* Code to compute quantile by using c, P1, and P2 */

    Q = <computed quantile>;
    return (Q);
endsub;
```

*dist_***SCALETRANSFORM**

defines a function that returns a keyword to identify the transform that needs to be applied to the scale parameter to convert it to the first parameter of the distribution.

If you want to use this distribution for modeling regression effects, then the first parameter of this distribution must be a scale parameter. However, for some distributions, a typical or convenient parameterization might not have a scale parameter, but one of the parameters can be a simple transform of the scale parameter. As an example, consider a typical parameterization of the lognormal distribution with two parameters, location μ and shape σ , for which the PDF is defined as follows:

$$f(x; \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{\log(x)-\mu}{\sigma}\right)^2}$$

You can reparameterize this distribution to contain a parameter θ instead of the parameter μ such that $\mu = \log(\theta)$. The parameter θ would then be a scale parameter. However, if you want to specify the distribution in terms of μ and σ (which is a more recognized form of the lognormal distribution) and still allow it as a candidate distribution for estimating regression effects, then instead of writing another distribution with parameters θ and σ , you can simply define the distribution with μ as the first parameter and specify that it is the logarithm of the scale parameter.

- *Type:* Function
- *Required:* NO
- *Number of arguments:* None
- *Sequence and type of arguments:* Not applicable
- *Return value:* Character value that contains one of the following keywords:

LOG	specifies that the first parameter is the logarithm of the scale parameter.
IDENTITY	specifies that the first parameter is a scale parameter without any transformation.

If you do not specify this function, then the IDENTITY transform is assumed.

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_SCALETRANSFORM() $8;
  length xform $8;
  xform = "IDENTITY";
  return (xform);
endsub;
```

dist_SDF

defines a function that returns the value of the survival distribution function (SDF) of the distribution at the specified values of the random variable and distribution parameters.

- *Type:* Function
- *Required:* NO
- *Number of arguments:* $m + 1$, where m is the number of distribution parameters
- *Sequence and type of arguments:*

x	Numeric value of the random variable at which the SDF value should be evaluated
p1	Numeric value of the first parameter
p2	Numeric value of the second parameter
⋮	
pm	Numeric value of the m th parameter

- *Return value:* Numeric value that contains the SDF value $S(x; p_1, p_2, \dots, p_m)$

If you want to consider this distribution as a candidate distribution when estimating a response variable model with regression effects, then the first parameter of this distribution must be a scale parameter or log-transformed scale parameter. In other words, if the distribution has a scale parameter, then the following equation must be satisfied:

$$S(x; p_1, p_2, \dots, p_m) = S\left(\frac{x}{p_1}; 1, p_2, \dots, p_m\right)$$

If the distribution has a log-transformed scale parameter, then the following equation must be satisfied:

$$S(x; p_1, p_2, \dots, p_m) = S\left(\frac{x}{\exp(p_1)}; 0, p_2, \dots, p_m\right)$$

Here is a sample structure of the function for a distribution named 'FOO':

```
function FOO_SDF(x, P1, P2);
  /* Code to compute SDF by using x, P1, and P2 */

  S = <computed SDF>;
  return (S);
endsub;
```

dist_UPPERBOUNDS

defines a subroutine that returns upper bounds for the parameters of the distribution. If this subroutine is not defined for a particular distribution, then the SEVSELECT procedure assumes that there is no upper bound for any of the parameters. If an upper bound of u_i is returned for a parameter p_i , then the SEVSELECT procedure assumes that $p_i < u_i$ (strict inequality). If a missing value is returned for some parameter, then the SEVSELECT procedure assumes that there is no upper bound for that parameter (equivalent to an upper bound of ∞).

- *Type:* Subroutine
- *Required:* NO
- *Number of arguments:* m , where m is the number of distribution parameters
- *Sequence and type of arguments:*

p_1	Output argument that returns the upper bound on the first parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.
p_2	Output argument that returns the upper bound on the second parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.
$\vdots$	
p_m	Output argument that returns the upper bound on the m th parameter. You must specify this in the OUTARGS statement inside the subroutine's definition.
- *Return value:* The results, upper bounds on parameter values, should be returned in the parameter arguments of the subroutine.

Here is a sample structure of the subroutine for a distribution named 'FOO':

```

subroutine FOO_UPPERBOUNDS(p1, p2);
    outargs p1, p2;

    p1 = <upper bound for P1>;
    p2 = <upper bound for P2>;
endsub;

```

*dist_core*GRADIENT

defines a subroutine that returns the gradient vector of the specified *core* function of the distribution at the specified values of the random variable and distribution parameters. The *core* keyword can be PDF, CDF, SDF, LOGPDF, LOGCDF, or LOGSDF.

- *Type*: Subroutine
- *Required*: NO
- *Number of arguments*: $m + 2$, where m is the number of distribution parameters
- *Sequence and type of arguments*:

x	Numeric value of the random variable at which the gradient should be evaluated
p_1	Numeric value of the first parameter
p_2	Numeric value of the second parameter
$\vdots$	
p_m	Numeric value of the m th parameter
$\text{grad}\{*\}$	Output numeric array of size m that contains the gradient vector evaluated at the specified values. If h denotes the value of the <i>core</i> function, then the expected order of the values in the array is as follows: $\frac{\partial h}{\partial p_1} \frac{\partial h}{\partial p_2} \dots \frac{\partial h}{\partial p_m}$

- *Return value*: Numeric array that contains the gradient evaluated at x for the parameter values $(p_1, p_2, \dots, p_m)$

Here is a sample structure of the function for the core function CDF of a distribution named 'FOO':

```

subroutine FOO_CDFGRADIENT(x, P1, P2, grad{*});
    outargs grad;

    /* Code to compute gradient by using x, P1, and P2 */
    grad[1] = <partial derivative of CDF w.r.t. P1
              evaluated at x, P1, P2>;
    grad[2] = <partial derivative of CDF w.r.t. P2
              evaluated at x, P1, P2>;
endsub;

```

dist_coreHESSIAN

defines a subroutine that returns the Hessian matrix of the specified *core* function of the distribution at the specified values of the random variable and distribution parameters. The *core* keyword can be PDF, CDF, SDF, LOGPDF, LOGCDF, or LOGSDF.

- *Type*: Subroutine
- *Required*: NO
- *Number of arguments*: $m + 2$, where m is the number of distribution parameters
- *Sequence and type of arguments*:

x	Numeric value of the random variable at which the Hessian matrix should be evaluated
p1	Numeric value of the first parameter
p2	Numeric value of the second parameter
⋮	
pm	Numeric value of the m th parameter
hess{*}	Output numeric array of size $m(m + 1)/2$ that contains the lower triangular portion of the Hessian matrix in a packed vector form, evaluated at the specified values. If h denotes the value of the <i>core</i> function, then the expected order of the values in the array is as follows: $\frac{\partial^2 h}{\partial p_1^2} \mid \frac{\partial^2 h}{\partial p_1 \partial p_2} \frac{\partial^2 h}{\partial p_2^2} \mid \dots \mid \frac{\partial^2 h}{\partial p_1 \partial p_m} \frac{\partial^2 h}{\partial p_2 \partial p_m} \dots \frac{\partial^2 h}{\partial p_m^2}$

- *Return value*: Numeric array that contains the lower triangular portion of the Hessian matrix evaluated at x for the parameter values $(p_1, p_2, \dots, p_m)$

Here is a sample structure of the subroutine for the core function LOGSDF of a distribution named 'FOO':

```
subroutine FOO_LOGSDFHESSIAN(x, P1, P2, hess{*});
    outargs hess;

    /* Code to compute Hessian by using x, P1, and P2 */
    hess[1] = <second order partial derivative of LOGSDF
              w.r.t. P1 evaluated at x, P1, P2>;
    hess[2] = <second order partial derivative of LOGSDF
              w.r.t. P1 and P2 evaluated at x, P1, P2>;
    hess[3] = <second order partial derivative of LOGSDF
              w.r.t. P2 evaluated at x, P1, P2>;
endsub;
```

Predefined Utility Functions

The following predefined utility functions are provided with the SEVSELECT procedure and are available in the Sashelp.SvrtDIST library:

SVRTUTIL_EDF

This function computes the empirical distribution function (EDF) estimate at the specified value of the random variable given the EDF estimate for a sample.

- *Type:* Function
- *Signature:* SVRTUTIL_EDF(y, n, x{*}, F{*}, Ftype)
- *Argument description:*

y	Value of the random variable at which the EDF estimate is desired
n	Dimension of the x and F input arrays
x{*}	Input numeric array of dimension n that contains values of the random variable observed in the sample. These values are sorted in nondecreasing order.
F{*}	Input numeric array of dimension n in which each $F[i]$ contains the EDF estimate for $x[i]$. These values must be sorted in nondecreasing order.
Ftype	Type of the empirical estimate that is stored in the x and F arrays. For definitions of types, see the section “ Supplying EDF Estimates to Functions and Subroutines ” on page 1805.
- *Return value:* The EDF estimate at y

The type of the sample EDF estimate determines how the EDF estimate at y is computed. For more information, see the section “[Supplying EDF Estimates to Functions and Subroutines](#)” on page 1805.

SVRTUTIL_EMPLIMMOMENT

This function computes the empirical estimate of the limited moment of specified order for the specified upper limit, given the EDF estimate for a sample.

- *Type:* Function
- *Signature:* SVRTUTIL_EMPLIMMOMENT(k, u, n, x{*}, F{*}, Ftype)
- *Argument description:*

k	Order of the desired empirical limited moment
u	Upper limit on the value of the random variable to be used in the computation of the desired empirical limited moment
n	Dimension of the x and F input arrays
x{*}	Input numeric array of dimension n that contains values of the random variable observed in the sample. These values are sorted in nondecreasing order.
F{*}	Input numeric array of dimension n in which each $F[i]$ contains the EDF estimate for $x[i]$. These values must be sorted in nondecreasing order.

Ftype Type of the empirical estimate that is stored in the x and F arrays. For definitions of types, see the section “[Supplying EDF Estimates to Functions and Subroutines](#)” on page 1805.

- *Return value:* The desired empirical limited moment

The empirical limited moment is computed by using the empirical estimate of the CDF. If $F_n(x)$ denotes the EDF at x , then the empirical limited moment of order k with upper limit u is defined as

$$E_n[(X \wedge u)^k] = k \int_0^u (1 - F_n(x))x^{k-1} dx$$

The SVRTUTIL_EMPLIMMOMENT function uses the piecewise linear nature of $F_n(x)$ as described in the section “[Supplying EDF Estimates to Functions and Subroutines](#)” on page 1805 to compute the integration.

SVRTUTIL_HILLCUTOFF

This function computes an estimate of the value where the right tail of a distribution is expected to begin. The function implements the algorithm described in Danielsson et al. 2001. The description of the algorithm uses the following notation:

n	Number of observations in the original sample
B	Number of bootstrap samples to draw
m_1	Size of the bootstrap sample in the first step of the algorithm ($m_1 < n$)
$x_{(i)}^{j,m}$	i th-order statistic of j th bootstrap sample of size m ($1 \leq i \leq m, 1 \leq j \leq B$)
$x_{(i)}$	i th-order statistic of the original sample ($1 \leq i \leq n$)

Given the input sample x and values of B and m_1 , the steps of the algorithm are as follows:

1. Take B bootstrap samples of size m_1 from the original sample.
2. Find the integer k_1 that minimizes the bootstrap estimate of the mean squared error:

$$k_1 = \arg \min_{1 \leq k < m_1} Q(m_1, k)$$

3. Take B bootstrap samples of size $m_2 = m_1^2/n$ from the original sample.
4. Find the integer k_2 that minimizes the bootstrap estimate of the mean squared error:

$$k_2 = \arg \min_{1 \leq k < m_2} Q(m_2, k)$$

5. Compute the integer k_{opt} , which is used for computing the cutoff point:

$$k_{\text{opt}} = \frac{k_1^2}{k_2} \left(\frac{\log(k_1)}{2 \log(m_1) - \log(k_1)} \right)^{2 - 2 \log(k_1) / \log(m_1)}$$

6. Set the cutoff point equal to $x_{(k_{\text{opt}}+1)}$.

The bootstrap estimate of the mean squared error is computed as

$$Q(m, k) = \frac{1}{B} \sum_{j=1}^B \text{MSE}_j(m, k)$$

The mean squared error of j th bootstrap sample is computed as

$$\text{MSE}_j(m, k) = (M_j(m, k) - 2(\gamma_j(m, k))^2)^2$$

where $M_j(m, k)$ is a control variate proposed by Danielsson et al. 2001,

$$M_j(m, k) = \frac{1}{k} \sum_{i=1}^k \left(\log(x_{(m-i+1)}^{j,m}) - \log(x_{(m-k)}^{j,m}) \right)^2$$

and $\gamma_j(m, k)$ is the Hill's estimator of the tail index (Hill 1975),

$$\gamma_j(m, k) = \frac{1}{k} \sum_{i=1}^k \log(x_{(m-i+1)}^{j,m}) - \log(x_{(m-k)}^{j,m})$$

This algorithm has two tuning parameters, B and m_1 . The number of bootstrap samples B is chosen based on the availability of computational resources. The optimal value of m_1 is chosen such that the following ratio, $R(m_1)$, is minimized:

$$R(m_1) = \frac{(Q(m_1, k_1))^2}{Q(m_2, k_2)}$$

The SVRTUTIL_HILLCUTOFF utility function implements the preceding algorithm. It uses the grid search method to compute the optimal value of m_1 .

- *Type:* Function
- *Signature:* SVRTUTIL_HILLCUTOFF(n , $x\{*\}$, b , s , $status$)
- *Argument description:*

n	Dimension of the array x
$x\{*\}$	Input numeric array of dimension n that contains the sample
b	Number of bootstrap samples used to estimate the mean squared error. If b is less than 10, then a default value of 50 is used.
s	Approximate number of steps used to search the optimal value of m_1 in the range $[n^{0.75}, n - 1]$. If s is less than or equal to 1, then a default value of 10 is used.
$status$	Output argument that contains the status of the algorithm. If the algorithm succeeds in computing a valid cutoff point, then <i>status</i> is set to 0. If the algorithm fails, then <i>status</i> is set to 1.
- *Return value:* The cutoff value where the right tail is estimated to start. If the size of the input sample is inadequate ($n \leq 5$), then a missing value is returned and *status* is set to a missing value. If the algorithm fails to estimate a valid cutoff value (*status* = 1), then the fifth-largest value in the input sample is returned.

SVRTUTIL_PERCENTILE

This function computes the specified empirical percentile given the EDF estimates.

- *Type:* Function
- *Signature:* SVRTUTIL_PERCENTILE(p, n, x{*}, F{*}, Ftype)
- *Argument description:*

p	Desired percentile. The value must be in the interval (0,1). The function returns the 100 p th percentile.
n	Dimension of the x and F input arrays
x{*}	Input numeric array of dimension n that contains values of the random variable observed in the sample. These values are sorted in nondecreasing order.
F{*}	Input numeric array of dimension n in which each $F[i]$ contains the EDF estimate for $x[i]$. These values must be sorted in nondecreasing order.
Ftype	Type of the empirical estimate that is stored in the x and F arrays. For definitions of types, see the section “ Supplying EDF Estimates to Functions and Subroutines ” on page 1805.
- *Return value:* The 100 p th percentile of the input sample

The method used to compute the percentile depends on the type of the EDF estimate (Ftype argument).

Ftype = 1 Smoothed empirical estimates are computed using the method described in Klugman, Panjer, and Willmot (1998). Let $\lfloor x \rfloor$ denote the greatest integer less than or equal to x . Define $g = \lfloor p(n+1) \rfloor$ and $h = p(n+1) - g$. Then the empirical percentile $\hat{\pi}_p$ is defined as

$$\hat{\pi}_p = (1-h)x[g] + hx[g+1]$$

This method does not work if $p < 1/(n+1)$ or $p > n/(n+1)$. If $p < 1/(n+1)$, then the function returns $\hat{\pi}_p = x[1]/2$, which assumes that the EDF is 0 in the interval $[0, x[1])$. If $p > n/(n+1)$, then $\hat{\pi}_p = x[n]$.

Ftype = 2 If $p < F[1]$, then $\hat{\pi}_p = x[1]/2$, which assumes that the EDF is 0 in the interval $[0, x[1])$. If $|p - F[i]| < \epsilon$ for some value of i and $i < n$, then $\hat{\pi}_p$ is computed as

$$\hat{\pi}_p = \frac{x[i] + x[i+1]}{2}$$

where ϵ is a machine-precision constant as returned by the SAS function CONSTANT(‘MACEPS’). If $F[i-1] < p < F[i]$, then $\hat{\pi}_p$ is computed as

$$\hat{\pi}_p = x[i]$$

If $p \geq F[n]$, then $\hat{\pi}_p = x[n]$.

Ftype = 3 If $p < F[1]$, then $\hat{\pi}_p = x[1]/2$, which assumes that the EDF is 0 in the interval $[0, x[1])$. If $|p - F[i]| < \epsilon$ for some value of i and $i < n$, then $\hat{\pi}_p$ is computed as

$$\hat{\pi}_p = \frac{x[i] + x[i+1]}{2}$$

where ϵ is a machine-precision constant as returned by the SAS function `CONSTANT('MACEPS')`. If $F[i - 1] < p < F[i]$, then $\hat{\pi}_p$ is computed as

$$\hat{\pi}_p = x[i - 1] + (p - F[i - 1]) \frac{x[i] - x[i - 1]}{F[i] - F[i - 1]}$$

If $p \geq F[n]$, then $\hat{\pi}_p = x[n]$.

SVRTUTIL_RAWMOMENTS

This subroutine computes the raw moments of a sample.

- *Type:* Subroutine
- *Signature:* `SVRTUTIL_RAWMOMENTS(n, x{*}, nx{*}, nRaw, raw{*})`
- *Argument description:*

<code>n</code>	Dimension of the <code>x</code> and <code>nx</code> input arrays
<code>x{*}</code>	Input numeric array of dimension <code>n</code> that contains distinct values of the random variable that are observed in the sample
<code>nx{*}</code>	Input numeric array of dimension <code>n</code> in which each <code>nx[i]</code> contains the number of observations in the sample that have the value <code>x[i]</code>
<code>nRaw</code>	Desired number of raw moments. The output array <code>raw</code> contains the first <code>nRaw</code> raw moments.
<code>raw{*}</code>	Output array of raw moments. The k th element in the array (<code>raw{k}</code>) contains the k th raw moment, where $1 \leq k \leq nRaw$.
- *Return value:* Numeric array `raw` that contains the first `nRaw` raw moments. The array contains missing values if the sample has no observations (that is, if all the values in the `nx` array add up to zero).

SVRTUTIL_SORT

This function sorts an array of numeric values in an ascending or descending order.

- *Type:* Subroutine
- *Signature:* `SVRTUTIL_SORT(n, x{*}, flag)`
- *Argument description:*

<code>n</code>	Dimension of the input array <code>x</code>
<code>x{*}</code>	Numeric array that contains the values to be sorted at input. The subroutine uses the same array to return the sorted values.
<code>flag</code>	A numeric value that controls the sort order. If <code>flag</code> is 0, then the values are sorted in an ascending order. If <code>flag</code> has any value other than 0, then the values are sorted in descending order.
- *Return value:* Numeric array `x`, which is sorted in place (that is, the sorted array is stored in the same storage area occupied by the input array `x`)

You can use the following predefined functions when you use the FCMP procedure to define functions and subroutines. They are summarized here for your information. For more information, see the FCMP procedure documentation in *Base SAS Procedures Guide*.

INVCDF

This function computes the quantile from any continuous probability distribution by numerically inverting the CDF of that distribution. You need to specify the CDF function of the distribution, the values of its parameters, and the cumulative probability to compute the quantile.

LIMMOMENT

This function computes the limited moment of order k with upper limit u for any continuous probability distribution. The limited moment is defined as

$$\begin{aligned} E[(X \wedge u)^k] &= \int_0^u x^k f(x) dx + \int_u^\infty u^k f(x) dx \\ &= \int_0^u x^k f(x) dx + u^k (1 - F(u)) \end{aligned}$$

where $f(x)$ and $F(x)$ denote the PDF and the CDF of the distribution, respectively. The LIMMOMENT function uses the following alternate definition, which can be derived using integration-by-parts:

$$E[(X \wedge u)^k] = k \int_0^u (1 - F(x)) x^{k-1} dx$$

You need to specify the CDF function of the distribution, the values of its parameters, and the values of k and u to compute the limited moment.

Scoring Functions

Scoring refers to the act of evaluating a distribution function, such as LOGPDF, SDF, or QUANTILE, on an observation by using the fitted parameter estimates of that distribution. You can do scoring in a DATA step by using the `OUTEST=` data table that you create using PROC SEVSELECT. However, that approach requires some cumbersome programming. To simplify the scoring process, you can use PROC SEVSELECT to create scoring functions for each fitted distribution.

As an example, assume that you fit the Pareto distribution by using PROC SEVSELECT and that it converges. Further assume that you want to use the fitted distribution to evaluate the probability of observing a loss value greater than some set of regulatory limits $\{L\}$ that are encoded in a data table. You can simplify this scoring process as follows. First, in the PROC SEVSELECT step that fits your distributions, you create the scoring functions library by specifying the `OUTSCORELIB` statement as illustrated in the following steps:

```
proc sevselect data=mylib.input;
  loss lossclaim;
  dist pareto;
  outscorelib outlib=sasuser.fitdist;
run;
```

Upon successful completion, if the Pareto distribution model has converged, then the library Sasuser.Fitdist contains the `SEV_SDF` scoring function in addition to other scoring functions, such as `SEV_PDF`, `SEV_LOGPDF`, and so on. Further, PROC SEVSELECT also sets the CMPLIB system option to include the Sasuser.Fitdist library. If the set of limits $\{L\}$ is recorded in the variable Limit in the scoring data set Work.Limits, then you can submit the following DATA step to compute the probability of seeing a loss greater than each limit:

```

data prob;
  set work.limits;
  exceedance_probability = sev_sdf(limit);
run;

```

Without using scoring functions, you can still perform this scoring task, but the DATA step that you need to accomplish it becomes more complicated and less flexible. For example, you would need to read the parameter estimates from some output created by PROC SEVSELECT. To do that, you would need to know the parameter names, which are different for different distributions; this in turn would require you to write a specific DATA step for each distribution or to write a SAS macro. Scoring functions enable you to accomplish that task much more easily.

If you fit multiple distributions, then you can specify the COMMONPACKAGE option in the OUTSCORELIB statement as follows:

```

proc sevselect data=mylib.input;
  loss lossclaim;
  dist exp pareto weibull;
  outscorelib outlib=sasuser.fitdist commonpackage;
run;

```

The preceding step creates scoring functions such as *SEV_SDF_Exp*, *SEV_SDF_Pareto*, and *SEV_SDF_Weibull*. You can use them to compare the probabilities of exceeding the limit for different distributions by using the following DATA step:

```

data prob;
  set work.limits;
  exceedance_exp = sev_sdf_exp(limit);
  exceedance_pareto = sev_sdf_pareto(limit);
  exceedance_weibull = sev_sdf_weibull(limit);
run;

```

Formal Description

PROC SEVSELECT creates a scoring function for each distribution function. A distribution function is defined as any function named *dist_suffix*, where *dist* is the name of a distribution that you specify in the DIST statement and the function's signature is identical to the signature of the required distribution function, such as *dist_CDF* or *dist_LOGCDF*. For example, for the function 'FOO_BAR' to be a distribution function, you must specify the distribution 'FOO' in the DIST statement, and you must define 'FOO_BAR' in the following manner if the distribution 'FOO' has parameters named 'P1' and 'P2':

```

function FOO_BAR(y, P1, P2);
  /* Code to compute BAR by using y, P1, and P2 */
  R = <computed BAR>;
  return (R);
endsub;

```

For more information about the signature that defines a distribution function, see the description of the *dist_CDF* function in the section “[Defining a Severity Distribution Model with the FCMP Procedure](#)” on page 1811.

The name and package of the scoring function of a distribution function depend on whether you specify the COMMONPACKAGE option in the OUTSCORELIB statement.

When you do not specify the `COMMONPACKAGE` option, the scoring function that corresponds to the distribution function *dist_suffix* is named *SEV_suffix*, where *SEV_* is the standard prefix of all scoring functions. The scoring function is created in a package named *dist*. Each scoring function accepts only one argument, the value of the loss variable, and returns the same value as the value that is returned by the corresponding distribution function for the final estimates of the distribution's parameters. For example, for the preceding 'FOO_BAR' distribution function, the scoring function named 'SEV_BAR' is created in the package named 'FOO' and 'SEV_BAR' has the following signature:

```
function SEV_BAR(y);
  /* returns value of FOO_BAR for the supplied value
    of y and fitted values of P1, P2 */
endsub;
```

If you specify the `COMMONPACKAGE` option in the `OUTSCORELIB` statement, then the scoring function that corresponds to the distribution function *dist_suffix* is named *SEV_suffix_dist*, where *SEV_* is the standard prefix of all scoring functions. The scoring function is created in a package named *sevfit*. For example, for the preceding 'FOO_BAR' distribution function, if you specify the `COMMONPACKAGE` option, the scoring function named 'SEV_BAR_FOO' is created in the *sevfit* package and 'SEV_BAR_FOO' has the following signature:

```
function SEV_BAR_FOO(y);
  /* returns value of FOO_BAR for the supplied value
    of y and fitted values of P1, P2 */
endsub;
```

Scoring Functions for the Scale Regression Model

If you use the `SCALEMODEL` statement to specify a scale regression model, then `PROC SEVSELECT` generates the scoring functions when you specify only singleton continuous effects. If you specify interaction or classification effects, then scoring functions are not generated.

For a scale regression model, the estimate of the scale parameter or the log-transformed scale parameter of the distribution depends on the values of the regressors. So `PROC SEVSELECT` creates a scoring function that has the following signature, where *x{*}* represents the array of regressors:

```
function SEV_BAR(y, x{*});
  /* returns value of FOO_BAR for the supplied value of x and fitted values of P1, P2 */
endsub;
```

As an illustration of using this form, assume that you submit the following `PROC SEVSELECT` step to create the scoring library `Sasuser.Scalescore`:

```
proc sevselect data=mylib.input;
  loss lossclaim;
  scalemodel x1-x3;
  dist pareto;
  outscorelib outlib=sasuser.scalescore;
run;
```

Your scoring data set must contain all the regressors that you specify in the `SCALEMODEL` statement. You can submit the following `DATA` step to score observations by using the scale regression model:

```

data prob;
  array regvals{*} x1-x3;
  set work.limits;
  exceedance_probability = sev_sdf(limit, regvals);
run;

```

PROC SEVSELECT creates two utility functions—SEV_NUMREG and SEV_REGNAME—in the OUTLIB= library, which return the number of regressors and name of a given regressor, respectively. They are described in detail in the next section. These utility functions are useful when you do not have easy access to the regressor names in the SCALEMODEL statement. You can use the utility functions as follows:

```

data prob;
  array regvals{10} _temporary_;
  set work.limits;
  do i = 1 to sev_numreg();
    regvals(i) = input(vvaluex(sev_regname(i)), best12.);
  end;
  exceedance_probability = sev_sdf(limit, regvals);
run;

```

The dimension of the regressor values array that you supply to the scoring function must be equal to $K + L$, where K is the number of regressors that you specify in the SCALEMODEL statement irrespective of whether PROC SEVSELECT deems any of those regressors to be redundant. L is 1 if you specify an OFFSET= variable in the SCALEMODEL statement, and 0 otherwise.

Utility Functions and Subroutines in the OUTLIB= Library

In addition to creating the scoring functions for all distribution functions, PROC SEVSELECT creates the following utility functions and subroutines in the OUTLIB= library.

SEV_NUMPARM | SEV_NUMPARM_dist

is a function that returns the number of distribution parameters and has the following signature:

- *Type:* Function
- *Number of arguments:* 0
- *Sequence and type of arguments:* Not applicable
- *Return value:* Numeric value that contains the number of distribution parameters

If you do not specify the COMMONPACKAGE option in the OUTSCORELIB statement, then a function named SEV_NUMPARM is created in the package of each distribution. Here is a sample structure of the code that PROC SEVSELECT uses to define the function:

```

function SEV_NUMPARM();
  n = <number of distribution parameters>;
  return (n);
endsub;

```

If you specify the COMMONPACKAGE option in the OUTSCORELIB statement, then for each distribution *dist*, the function named SEV_NUMPARM_dist is created in the *sevfit* package. SEV_NUMPARM_dist has the same structure as the SEV_NUMPARM function that is described previously.

SEV_PARMEST | SEV_PARMEST_dist

is a subroutine that returns the estimate and standard error of a specified distribution parameter and has the following signature:

- *Type:* Subroutine
- *Number of arguments:* 3
- *Sequence and type of arguments:*
 - index* specifies the numeric value of the index of the distribution parameter for which you want the information. The value of *index* must be in the interval $[1, m]$, where m is the number of parameters in the distribution to which this subroutine belongs.
 - est* specifies the output argument that returns the estimate of the requested parameter.
 - stderr* specifies the output argument that returns the standard error of the requested parameter.
- *Return value:* Estimate and standard error of the requested distribution parameter that are returned in the output arguments *est* and *stderr*, respectively

If you do not specify the COMMONPACKAGE option in the OUTSCORELIB statement, then a subroutine named SEV_PARMEST is created in the package of each distribution. Here is a sample structure of the code that PROC SEVSELECT uses to define the subroutine:

```
subroutine SEV_PARMEST(index, est, stderr);
  outargs est, stderr;
  est = <value of the estimate for the distribution parameter
        at position 'index'>;
  stderr = <value of the standard error for distribution parameter
           at position 'index'>;
endsub;
```

If you specify the COMMONPACKAGE option in the OUTSCORELIB statement, then for each distribution *dist*, the subroutine named SEV_PARMEST_dist is created in the *sevfit* package. SEV_PARMEST_dist has the same structure as the SEV_PARMEST subroutine that is described previously.

If you use the SCALEMODEL statement to specify a scale regression model, and if you specify only singleton continuous effects, then for *index*=1, the returned estimates are of θ_0 (the base value of the scale parameter) or $\log(\theta_0)$ if the distribution has a log-scale parameter. For more information about θ_0 , see the section “[Estimating Regression Effects](#)” on page 1794.

SEV_PARMNAME | SEV_PARMNAME_dist

is a function that returns the name of a specified distribution parameter and has the following signature:

- *Type:* Function
- *Number of arguments:* 1
- *Sequence and type of arguments:*
 - index* specifies the numeric value of the index of the distribution parameter for which you want the information. The value of *index* must be in the interval $[1, m]$, where m is the number of parameters in the distribution to which this function belongs.

- *Return value:* Character value that contains the name of the distribution parameter that appears at the position *index* in the distribution's definition

If you do not specify the COMMONPACKAGE option in the OUTSCORELIB statement, then a function named SEV_PARMNAME is created in the package of each distribution.

Here is a sample structure of the code that PROC SEVSELECT uses to define the function:

```
function SEV_PARMNAME(index) $32;
    name = <name of the distribution parameter at position 'index'>;
    return (name);
endsub;
```

If you specify the COMMONPACKAGE option in the OUTSCORELIB statement, then for each distribution *dist*, a function named SEV_PARMNAME_*dist* is created in the *sevfit* package. SEV_PARMNAME_*dist* has the same structure as the SEV_PARMNAME function that is described previously.

If you use the SCALEMODEL statement to specify a scale regression model, and if you specify only singleton continuous effects, then the following helper functions and subroutines are also created in the OUTLIB= library.

SEV_NUMREG

is a function that returns the number of regressors and has the following signature:

- *Type:* Function
- *Number of arguments:* 0
- *Sequence and type of arguments:* Not applicable
- *Return value:* Numeric value that contains the number of regressors that you specify in the SCALEMODEL statement. If you specify an OFFSET= option variable in the SCALEMODEL statement, then the returned value is equal to 1 plus the number of regressors that you specify in the SCALEMODEL statement.

Here is a sample structure of the code that PROC SEVSELECT uses to define the function:

```
function SEV_NUMREG();
    m = <number of regressors>;
    if (<offset variable is specified>) then m = m + 1;
    return (m);
endsub;
```

This function does not depend on any distribution, so it is always created in the *sevfit* package.

SEV_REGEST | SEV_REGEST_*dist*

is a subroutine that returns the estimate and standard error of a specified regression parameter and has the following signature:

- *Type:* Subroutine
- *Number of arguments:* 3
- *Sequence and type of arguments:*

index specifies the numeric value of the index of the regression parameter for which you want the information. The value of *index* must be in the interval $[1, K]$, where K is the number of regressors that is returned by the SEV_NUMREG function. If you specify an OFFSET= option variable in the SCALEMODEL statement, then an *index* value of K corresponds to the offset variable.

est specifies the output argument that returns the estimate of the requested regression parameter.

stderr specifies the output argument that returns the standard error of the requested regression parameter.

- *Return value:* Estimate and standard error of the requested regression parameter that are returned in the output arguments *est* and *stderr*, respectively

If you do not specify the COMMONPACKAGE option in the OUTSCORELIB statement, then a subroutine named SEV_REGEST is created in the package of each distribution. Here is a sample structure of the code that PROC SEVSELECT uses to define the subroutine:

```
subroutine SEV_REGEST(index, est, stderr);
  outargs est, stderr;
  est = <value of the estimate for the regression parameter
        at position 'index'>;
  stderr = <value of the standard error for regression parameter
           at position 'index'>;
endsub;
```

If you specify the COMMONPACKAGE option in the OUTSCORELIB statement, then for each distribution *dist*, the subroutine named SEV_REGEST_*dist* is created in the *sevfit* package. SEV_REGEST_*dist* has the same structure as the SEV_REGEST subroutine that is described previously.

If the regressor that corresponds to the specified *index* value is a redundant regressor, the returned values of both *est* and *stderr* are equal to the special missing value of .R. If you specify an OFFSET= option variable in the SCALEMODEL statement and if the *index* value corresponds to the offset variable—that is, it is equal to the value that the SEV_NUMREG function returns—then the returned value of *est* is equal to 1 and the returned value of *stderr* is equal to the special missing value of .F.

SEV_REGNAME

is a function that returns the name of a specified regressor and has the following signature:

- *Type:* Function
- *Number of arguments:* 1
- *Sequence and type of arguments:*

index specifies the numeric value of the index of the regressor for which you want the name. The value of *index* must be in the interval $[1, K]$, where K is the number of regressors that is returned by the SEV_NUMREG function. If you specify an OFFSET= option variable in the SCALEMODEL statement, then an *index* value of K corresponds to the offset variable.

- *Return value:* Character value that contains the name of the regressor that appears at the position *index* in the SCALEMODEL statement. If you specify an OFFSET= option variable in the SCALEMODEL statement, then for an *index* value of *K*, the returned value contains the name of the offset variable.

Here is a sample structure of the code that PROC SEVSELECT uses to define the function:

```
function SEV_REGNAME(index) $32;
    name = <name of regressor at position 'index'>;
    return (name);
endsub;
```

This function does not depend on any distribution, so it is always created in the *sevfit* package.

Custom Objective Functions

You can use a series of programming statements that use variables in the DATA= data table to assign a value to an objective function symbol. You must specify the objective function symbol by using the **OBJECTIVE=** option in the PROC SEVSELECT statement.

The objective function can be programmed such that it applies to any distribution that is used in the model. For that purpose, PROC SEVSELECT recognizes the following *keyword* functions in the programming statements:

<code>_PDF_(x)</code>	evaluates the probability density function (PDF) of a distribution at the current value of a data table variable <i>x</i> .
<code>_CDF_(x)</code>	evaluates the cumulative distribution function (CDF) of a distribution at the current value of a data table variable <i>x</i> .
<code>_SDF_(x)</code>	evaluates the survival distribution function (SDF) of a distribution at the current value of a data table variable <i>x</i> .
<code>_LOGPDF_(x)</code>	evaluates the natural logarithm of the PDF of a distribution at the current value of a data table variable <i>x</i> .
<code>_LOGCDF_(x)</code>	evaluates the natural logarithm of the CDF of a distribution at the current value of a data table variable <i>x</i> .
<code>_LOGSDF_(x)</code>	evaluates the natural logarithm of the SDF of a distribution at the current value of a data table variable <i>x</i> .
<code>_EDF_(x)</code>	evaluates the empirical distribution function (EDF) estimate at the current value of a data table variable <i>x</i> . Internally, PROC SEVSELECT computes the estimate by using the SVRTUTIL_EDF function as described in the section “ Predefined Utility Functions ” on page 1824. The EDF estimate that the SVRTUTIL_EDF function requires is computed by using a subset of observations in the current BY group or a subset of the input data table if you do not specify the BY statement. The subset of observations is randomly chosen on each worker node by using the values that you specify in the INITSAMPLE option.

EMPLIMMOMENT(k, u)

evaluates the empirical limited moment of order k at the current value of a data table variable u that represents the upper limit of the limited moment. The order k can also be a data table variable. Internally, PROC SEVSELECT computes the moment by using the SVRTUTIL_EMPLIMMOMENT function as described in the section “[Predefined Utility Functions](#)” on page 1824. The EDF estimate that the SVRTUTIL_EMPLIMMOMENT function requires is computed by using a subset of observations in the current BY group or a subset of the input data table if you do not specify the BY statement. The subset of observations is randomly chosen on each worker node by using the values that you specify in the [INITSAMPLE](#) option.

LIMMOMENT(k, u)

evaluates the limited moment of order k at the current value of a data table variable u that represents the upper limit of the limited moment. The order k can be a data table variable or a constant. Internally, for each candidate distribution, PROC SEVSELECT computes the moment by using the LIMMOMENT function as described in the section “[Predefined Utility Functions](#)” on page 1824.

All the preceding functions are right-hand-side functions. They act as placeholders for distribution-specific functions, with the exception of `_EDF_` and `_EMPLIMMOMENT_` functions.

As an example, suppose that the data table `mylib.Test` contains a response variable Y and a left-truncation threshold variable T . The following statements use the values in this data table to fit a model with distribution D such that the parameters of the model minimize the value of the objective function symbol `MYOBJ`:

```
options cmplib=(work.mydist);
proc sevselect data=mylib.test objective=myobj;
  loss y / lt=t;

  myobj = -_LOGPDF_(y);
  if (not(missing(t))) then
    myobj = myobj + log(1-_CDF_(t));

  dist d;
run;
```

You designate the symbol `MYOBJ` as an objective function symbol by using the [OBJECTIVE=](#) option in the PROC SEVSELECT statement. The response variable Y and left-truncation variable T are specified in the LOSS statement. The distribution D is specified in the DIST statement. The remaining statements constitute a program that computes the value of the `MYOBJ` symbol.

Let the distribution D have the parameters $P1$ and $P2$. To estimate the model for this distribution, PROC SEVSELECT internally converts the generic program to the following program specific to distribution D :

```
myobj = -D_LOGPDF(y, p1, p2);
if (not(missing(t))) then
  myobj = myobj + log(1-D_CDF(t, p1, p2));
```

Note that the generic keyword functions `_LOGPDF_` and `_CDF_` have been replaced by the distribution-specific functions `D_LOGPDF` and `D_CDF`, respectively, and the argument list of each is expanded to include the distribution parameters. You must have defined the `D_LOGPDF` and `D_CDF` functions previously; they are assumed to be available in the library `Work.Mydist` that you specify in the `CMPLIB=` option.

The program is executed for each observation in the data table `mylib.Test` to compute the value of `MYOBJ` by using the values of variables `Y` and `T` in that observation and internally computed values of the model parameters `P1` and `P2`. The values of `MYOBJ` are then added over all the observations of the data table or over all the observations of the current `BY` group if you specify the `BY` statement. The resulting aggregate value is the value of the objective function, and it is supplied to the optimizer. If the optimizer requires derivatives of the objective function, then `PROC SEVSELECT` automatically differentiates `MYOBJ` with respect to the parameters `P1` and `P2`. The optimizer iterates through various combinations of the values of `P1` and `P2`; in each iteration, it computes a new value of the objective function and the needed derivatives of it, until it finds a combination that minimizes the objective function.

Note the following points when you define your own program to compute the custom objective function:

- The value of the objective function is always minimized by `PROC SEVSELECT`. If you want to maximize the value of a certain objective, then add a statement that assigns the negated value of the maximization objective to the objective function symbol that you specify in the `OBJECTIVE=` option. Minimization of the negated objective is equivalent to maximization of the original objective.
- The contributions of individual observations are always added together to compute the overall objective function in a given iteration of the optimizer. If you specify the `WEIGHT` statement, then the contribution of each observation is weighted by multiplying it by the normalized value of the weight variable for that observation.
- If you are fitting multiple distributions in one `PROC SEVSELECT` step and you use any of the keyword functions in your program, then it is recommended that you not explicitly use the parameters of any of the specified distributions in your programming statements.
- If you use a specific keyword function in your programming statements, then the corresponding distribution functions must be defined in a library that you specify in the `CMPLIB=` system option or in `Sashelp.Svrtlist`, the predefined functions library. In the preceding example, it is assumed that the functions `D_LOGPDF` and `D_CDF` are defined in the library `Work.Mydist`, which you specify in the `CMPLIB=` option.
- You can use most `DATA` step statements and functions in your program. The `DATA` step file and the data set I/O statements (for example, `INPUT`, `FILE`, `SET`, and `MERGE`) are not available. However, some `PUT` statement functionality is supported. For more information, see the section “`PROC FCMP` and `DATA` Step Differences” in *Base SAS Procedures Guide*. In addition to the differences that are listed in that section, the following differences exist:
 - You can use only numeric-valued variables in `PROC SEVSELECT` programming statements. This restriction also implies that you cannot use SAS functions or call routines that require character-valued arguments, unless you pass those arguments as constant (literal) strings or characters.
 - You cannot use functions that create lagged versions of a variable in `PROC SEVSELECT` programming statements. If you need lagged versions, then you can use a `DATA` step before the `PROC SEVSELECT` step to add those versions to the input data table.
- When you are writing your programming statements, avoid defining variables that begin with an underscore (`_`), because they might conflict with internal variables that `PROC SEVSELECT` creates.

Custom Objective Functions and Regression Effects

If you specify regression effects by using the SCALEMODEL statement, then PROC SEVSELECT automatically adds a statement before your programming statements to compute the value of the scale parameter or the log-transformed scale parameter of the distribution by using the values of the regression variables and internally created regression parameters. For example, if your specification of the SCALEMODEL statement results in three regression effects, x_1 , x_2 , and x_3 , then for a model that contains the distribution D with scale parameter S, PROC SEVSELECT adds to the beginning of your program a statement that is equivalent to the following statement:

$$S = _SEVTHETA0 * \exp(_SEVBETA1 * x_1 + _SEVBETA2 * x_2 + _SEVBETA3 * x_3);$$

If a model contains a distribution D1 with a log-transformed scale parameter M, PROC SEVSELECT adds to the beginning of your program a statement that is equivalent to the following statement:

$$M = _SEVTHETA0 + _SEVBETA1 * x_1 + _SEVBETA2 * x_2 + _SEVBETA3 * x_3;$$

The internal symbols $_SEVTHETA0$, $_SEVBETA1$, $_SEVBETA2$, and $_SEVBETA3$ represent the regression parameters that are associated with the intercept and the regression effects x_1 , x_2 , and x_3 , respectively.

Because the names of the internal regression parameter symbols start with the prefix $_SEV$, if you use a variable in your program whose name begins with $_SEV$, then PROC SEVSELECT writes an error message to the SAS log and stops processing.

Input Data Tables

PROC SEVSELECT accepts DATA= and INEST= data tables as input data tables. This section details the information that they are expected to contain.

DATA= Data Table

The DATA= data table is expected to contain the values of the analysis variables that you specify in the CLASS, EFFECT, LOSS, and SCALEMODEL statements.

If you specify the BY statement, then the DATA= data table must contain all the BY variables that you specify in the BY statement. However, it is not required to be sorted by the BY variables.

INEST= Data Table

The INEST= data table is expected to contain the initial values of the parameters for the parameter estimation process.

If you specify the BY statement, then the INEST= data table must contain all the BY variables that you specify in the BY statement. The data table is not required to be sorted by BY variables, and it is not required to contain all the BY groups present in the DATA= data table. For the BY groups that are not present in the INEST= data table, the default parameter initialization method is used.

The INEST= data table must be created by using the OUTEST= option in a PROC SEVSELECT step that uses the same BY and SCALEMODEL statements as the PROC SEVSELECT step where you specify the INEST= option.

Output Data Tables

PROC SEVSELECT produces the OUTEST=, OUTMODELINFO=, and OUTSTAT= data tables when requested by their respective options in the PROC SEVSELECT statement. It also produces the OUT= data table when you specify the OUTPUT statement. The data tables and their contents are described in the following sections.

OUT= Data Table

The OUT= data table that you specify in the OUTPUT statement records the estimates of the scoring functions and quantiles that you specify in the OUTPUT statement.

For each distribution that you specify in the DIST statement, the OUT= data table contains one variable for each scoring function that you specify in the FUNCTIONS= option and one variable for each quantile that you specify in the QUANTILES= option. The prefix of the variable's name is <distribution-name>_, whereas the suffix of the variable's name is determined by the information that you specify in the respective option or by the default method that PROC SEVSELECT uses. For more information about variable names, see the description of the OUTPUT statement.

The OUT= data table also contains the variables that you specify in the COPYVARS= option. If you specify the BY statement and if you want PROC SEVSELECT to copy the BY variables from the DATA= data table to the OUT= data table, then you must specify them in the COPYVARS= option.

The number of observations in the OUT= data table depends on the options that you specify in the OUTPUT statement and whether or not you specify the SCALEMODEL statement.

If either of the following conditions is met, then the number of observations in the OUT= data table is equal to the number of observations in the DATA= data table:

- You specify the SCALEMODEL statement.
- You specify the FUNCTIONS= option in the OUTPUT statement such that at least one scoring function does not have a constant, nonmissing argument.

If neither of the preceding conditions is met, then the number of observations in the OUT= data table is equal to the number of BY groups, which is equal to 1 if you do not specify the BY statement.

OUTEST= Data Table

The OUTEST= data table records the estimates of the model parameters. It also contains estimates of their standard errors and optionally their covariance structure. If you specify BY variables, then the data are organized in BY groups and the data table contains variables that you specify in the BY statement.

If you do not specify the COVOUT option, then the data table contains the following variables:

<code>_MODEL_</code>	identifying name of the distribution model. The observation contains information about this distribution.
<code>_TYPE_</code>	type of the estimates reported in this observation. It can take one of the following two values:

EST point estimates of model parameters
 STDERR standard error estimates of model parameters

`_STATUS_` status of the reported estimates. The possible values are listed in the section “[_STATUS_ Variable Values](#)” on page 1844.

`<Parameter 1> ... <Parameter M>`

M variables, named after the parameters of all candidate distributions, that contain estimates of the respective parameters. M is the cardinality of the union of parameter name sets from all candidate distributions. In an observation, estimates are populated only for parameters that correspond to the distribution that is indicated by the `_MODEL_` variable. If `_TYPE_` is EST, then the estimates are missing if the model does not converge. If `_TYPE_` is STDERR, then the estimates are missing if covariance estimates cannot be obtained.

If you specify regression effects, then the estimate that is reported for the first parameter of each distribution is the estimate of the base value of the scale or log-transformed scale parameter. For more information, see the section “[Estimating Regression Effects](#)” on page 1794.

`<Regression Parameter 1> ... <Regression Parameter K>`

If your effect specification in the [SCALEMODEL](#) statement results in K regression parameters and if you do not specify the [SELECTOUT](#) option, then the OUTEST= data table contains K regression parameter variables.

The name of each variable is formed by using the name of the effect and the levels of the CLASS variables that the effect might contain. If the effect name or level names are too long, then the variable name is constructed by using a part of the effect name and parts of the levels of the CLASS variables. The label of the variable is more descriptive than the name of the variable. The variables contain different types of estimates for their respective regression parameters.

If `_TYPE_` is EST, then a variable contains the estimate of the regression coefficient (β_j) of the respective regression parameter, unless one of the following conditions applies:

- If the model does not converge, then it contains an ordinary missing value.
- If the regression parameter is linearly dependent on other regression parameters for a particular BY group and
 - if you specify the [ZEROEST](#) option, then it contains a value of 0.
 - if you do not specify the [ZEROEST](#) option, then it contains the special missing value .R.
- If you specify the SELECTION statement and if the regression parameter is not part of the selected model for a particular BY group, then
 - if you specify the [ZEROEST](#) option, then it contains a value of 0.
 - if you do not specify the [ZEROEST](#) option, then it contains the special missing value .N.

If `_TYPE_` is STDERR, then a variable contains the estimate of the standard error of the respective regression parameter, unless one of the following conditions applies:

- If covariance estimates cannot be obtained, then it contains an ordinary missing value.
- If the regression parameter is linearly dependent on other regression parameters for a particular BY group, then it contains the special missing value .R.
- If you specify the SELECTION statement and if the regression parameter is not part of the selected model for a particular BY group, then it contains the special missing value .N.

<Offset Variable>

If you specify an OFFSET= variable in the SCALEMODEL statement, then the OUTEST= data table contains a variable that is named after the offset variable. If _TYPE_ is EST, then the value of this variable is 1. If _TYPE_ is STDERR, then the value of this variable is the special missing value .F.

If you specify the COVOUT option in the PROC SEVSELECT statement, then the OUTEST= data table contains additional observations that contain the estimates of the covariance structure. In addition to the variables listed and described previously, the data table contains the following variables that are either new or have a modified description:

<u>_TYPE_</u>	type of the estimates reported in this observation. For observations that contain rows of the covariance structure, the value is COV.
<u>_STATUS_</u>	status of the reported estimates. For observations that contain rows of the covariance structure, the status is 0 if covariance estimation was successful. If estimation fails, the status is 1 and a single observation is reported with _TYPE_=COV and missing values for all the parameter variables.
<u>_NAME_</u>	name of the parameter for the row of covariance matrix that is reported in the current observation.

If _TYPE_ is COV, then a variable contains the estimate of the covariance between the respective parameter and the parameter that is named in the _NAME_ variable, unless one of the following conditions applies:

- If covariance estimates cannot be obtained, then it contains an ordinary missing value.
- If the variable corresponds to a regression parameter and
 - if the regression parameter is linearly dependent on other regression parameters for a particular BY group, then it contains the special missing value .R.
 - if you specify the SELECTION statement and if the regression parameter is not in the selected model for a particular BY group, then it contains the special missing value .N.

If you specify the SELECTION statement and the SELECTOUT option, then the OUTEST= data table contains only the regression parameters that correspond to the final selected effects. For the selected parameters, the values are written according to the rules stated previously for _TYPE_ values of EST, STDERR, and COV.

If you specify the BY and CLASS statements and if the names and values of some CLASS variables are long, then it is possible for a regression parameter with the same name to have different labels in different BY groups. In such cases, the OUTEST= data table contains rows with _TYPE_='COV' and an additional

variable called `_LABEL_`. You can use the values of `_NAME_` and `_LABEL_` variables in such rows to obtain the label for multilabel regression parameters in each BY group. When the `OUTEST=` data table does not contain the `_LABEL_` variable, then the label of a regression parameter is the label of the variable that contains the estimate of that regression parameter.

OUTMODELINFO= Data Table

The `OUTMODELINFO=` data table records the information about each candidate distribution that you specify in the `DIST` statement. It contains the following variables:

<code>_MODEL_</code>	identifying name of the distribution model. The observation contains information about this distribution.
<code>_DEPVAR_</code>	name of the loss variable.
<code>_DESCRIPTION_</code>	descriptive name of the model. This has a nonmissing value only if the <code>DESCRIPTION</code> function has been defined for this model.
<code>_VALID_</code>	validity of the distribution definition. This has a value of 1 for valid definitions and a value of 0 for invalid definitions. If the definition is invalid, then <code>PROC SEVSELECT</code> writes the reason for invalidity to the SAS log.
<code>_PARAMNAME1 ... _PARAMNAMEM</code>	M variables that contain names of parameters of the distribution model, where M is the maximum number of parameters across all the specified distribution models. For a given distribution with m parameters, values of the variables <code>_PARAMNAMEj</code> ($j > m$) are missing.

OUTSTAT= Data Table

The `OUTSTAT=` data table records statistics of fit and model selection information. If you specify BY variables, then the data are organized in BY groups and the data table contains variables that you specify in the BY statement. The data table contains the following variables:

<code>_MODEL_</code>	identifying name of the distribution model. The observation contains information about this distribution.
<code>_NMODELPARAM_</code>	number of parameters in the distribution.
<code>_NESTPARAM_</code>	number of estimated parameters. This includes the regression parameters, if you specify any regression effects.
<code>_NOBS_</code>	number of nonmissing observations that are used for parameter estimation.
<code>_STATUS_</code>	status of the parameter estimation process for this model. The possible values are listed in the section “ _STATUS_ Variable Values ” on page 1844.
<code>_SELECTED_</code>	indicator of the best distribution model. If the value is 1, then this model is the best model for the current BY group according to the specified model selection criterion.
<Custom Objective>	value of the custom objective function that is obtained at the end of the parameter estimation process. <code>PROC SEVSELECT</code> creates this variable only if you specify the <code>OBJECTIVE=</code> option.

Neg2LogLike	value of the log likelihood, multiplied by -2 , that is obtained at the end of the parameter estimation process.
AIC	value of Akaike's information criterion (AIC) that is obtained at the end of the parameter estimation process.
AICC	value of the corrected Akaike's information criterion (AICC) that is obtained at the end of the parameter estimation process.
BIC	value of the Schwarz Bayesian information criterion (SBC) that is obtained at the end of the parameter estimation process.
KS	value of the Kolmogorov-Smirnov (KS) statistic that is obtained at the end of the parameter estimation process.
AD	value of the Anderson-Darling (AD) statistic that is obtained at the end of the parameter estimation process.
CVM	value of the Cramér-von Mises (CvM) statistic that is obtained at the end of the parameter estimation process.

The values of the variables that correspond to the fit statistics and the `_SELECTED_` variable are missing if the parameter estimation process does not converge for the model in the `_MODEL_` variable.

`_STATUS_` Variable Values

The `_STATUS_` variable in the `OUTEST=` and `OUTSTAT=` data tables contains a value that indicates the status of the parameter estimation process for the respective distribution model. The variable can take the following values in the `OUTEST=` data table for `_TYPE_=EST` observations and in the `OUTSTAT=` data table:

- 0 The parameter estimation process converged for this model.
- 301 The parameter estimation process might not have converged for this model because there is no improvement in the objective function value. This might indicate that the initial values of the parameters are optimal, or you can try different convergence criteria in the `NLOPTIONS` statement.
- 302 The parameter estimation process might not have converged for this model because the number of iterations exceeded the maximum allowed value. You can try setting a larger value for the `MAXITER=` options in the `NLOPTIONS` statement.
- 303 The parameter estimation process might not have converged for this model because the number of objective function evaluations exceeded the maximum allowed value. You can try setting a larger value for the `MAXFUNC=` options in the `NLOPTIONS` statement.
- 304 The parameter estimation process might not have converged for this model because the time taken by the process exceeded the maximum allowed value. You can try setting a larger value for the `MAXTIME=` option in the `NLOPTIONS` statement.
- 400 The parameter estimation process did not converge for this model.

The `_STATUS_` variable can take the following values in the `OUTEST=` data table for `_TYPE_=STDERR` and `_TYPE_=COV` observations:

- 0 The covariance and standard error estimates are available and valid.
- 1 The covariance and standard error estimates are not available, because the process of computing covariance estimates failed.

Displayed Output

The SEVSELECT procedure optionally produces displayed output by using the Output Delivery System (ODS). All output is controlled by the PRINT= option in the PROC SEVSELECT statement. [Table 26.7](#) relates the ODS tables to PRINT= options.

Table 26.7 ODS Tables Produced in PROC SEVSELECT

ODS Table Name	Description	Option
AllFitStatistics	Statistics of fit for all the distribution models	PRINT=ALLFITSTATS
BSplineDetails	Basis details for B-spline effects	PRINT=ALL and EFFECT SPLINE statement
ClassLevels	Level information for classification variables	Default for CLASS statement
CollectionLevelInfo	Level details for collection effects	PRINT=ALL and EFFECT COLLECTION statement
ConvergenceStatus	Convergence status of parameter estimation process	PRINT=CONVSTATUS
CorrB	Correlations of parameter estimates	PRINT=CORRB
CovB	Covariances of parameter estimates	PRINT=COVB
DescStats	Descriptive statistics for the response variable	PRINT=DESCSTATS
Distribution	Information about number of parameters in a distribution's model	Default
DistributionInfo	Detailed information about all distributions	PRINT=DISTINFO
EntryCandidates	Details about candidates for entry into the model	PRINT=ALL and SELECTION statement
EstimationDetails	Details of the estimation process for all the distribution models	PRINT=ESTIMATIONDETAILS
FitStatistics	Statistics of fit	PRINT=STATISTICS
InitialValues	Initial parameter values and bounds	PRINT=INITIALVALUES
IterationHistory	Optimization iteration history	PRINT=NLOHISTORY
MMLevelInfo	Level information for multimember effects	PRINT=ALL and EFFECT MULTIMEMBER statement
ModelSelection	Model selection summary	PRINT=SELECTION

Table 26.7 *continued*

ODS Table Name	Description	Option
OptimizationSummary	Optimization summary	PRINT=NLOSUMMARY
ParameterEstimates	Final parameter estimates	PRINT=ESTIMATES
PolyDetails	Number of variables and columns, polynomial degree, and standardization method	PRINT=ALL and EFFECT POLY statement
PolyScaling	Centering and scaling details	PRINT=ALL and EFFECT POLY statement
RegDescStats	Descriptive statistics for the regression effects that do not contain a CLASS variable	PRINT=DESCSTATS
RemovalCandidates	Details about candidates for removal from the model	PRINT=ALL and SELECTION statement
SelectedEffects	List of effects selected for the model	Default for SELECTION statement
SelectionEstimationDetails	Details of the estimation process for all selection steps of a distribution's model	PRINT=ESTIMATIONDETAILS and SELECTION statement
SelectionInfo	Information about the settings for model selection	Default for SELECTION statement
SelectionReason	Reason why the particular model was selected	Default for SELECTION statement
SelectionSummary	Summary information about model selection steps	Default for SELECTION statement
SplineKnots	Knot and boundary knot values	PRINT=ALL and EFFECT SPLINE statement
StopReason	Reason for termination of model selection	Default for SELECTION statement
TPFSplineDetails	Truncated power function (TPF) spline basis details	PRINT=ALL and EFFECT SPLINE statement
Timing	Timing information for various computational stages of the procedure	PRINT=ALL

If you do not specify the PRINT= option, then by default PROC SEVSELECT produces the ModelSelection, ConvergenceStatus, OptimizationSummary, FitStatistics, and ParameterEstimates ODS tables.

If you specify the CLASS statement and if you do not specify the **NOCLPRINT** option, then by default PROC SEVSELECT produces the ClassLevels table.

If you specify the SELECTION statement, then by default PROC SEVSELECT produces the SelectedEffects, SelectionInfo, SelectionReason, SelectionSummary, and StopReason ODS tables.

The following list presents further details of the contents of some of the tables:

AllFitStatistics (PRINT=ALLFITSTATS)

displays the comparison of all the statistics of fit for all the models in one table. The table does not include the models whose parameter estimation process does not converge. If no models converge, then this table is not produced. If the table contains more than one model, then the best model according to each statistic is indicated by an asterisk (*) in that statistic's column.

CorrB (PRINT=CORRB)

displays the estimated correlation matrix of parameters of the fitted model. You can control the display of this matrix by specifying the SHAPE= and NOUNITDIAG suboptions of the PRINT([SYMMETRIC=](#)) option. The estimates are not displayed for models whose parameter estimation process does not converge.

CovB (PRINT=COVB)

displays the estimated variance-covariance matrix of parameters of the fitted model. You can control the display of this matrix by specifying the SHAPE= suboption of the PRINT([SYMMETRIC=](#)) option. The estimates are not displayed for models whose parameter estimation process does not converge.

DistributionInfo (PRINT=DISTINFO)

displays the information about all the candidate distribution. It includes the name, the description, the number of distribution parameters, and whether the distribution is valid for the specified modeling task.

FitStatistics (PRINT=STATISTICS)

displays the statistics of fit for each model. The statistics of fit are not displayed for models whose parameter estimation process does not converge.

ModelSelection (PRINT=SELECTION)

displays the model selection table. The table shows the convergence status of each candidate model and the value of the selection criterion along with an indication of the selected model.

ParameterEstimates (PRINT=ESTIMATES)

displays the estimates of parameters of the fitted model. The estimates are not displayed for models whose parameter estimation process does not converge.

ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in the “Statistical Graphics Using ODS” chapter in *SAS/STAT User's Guide*.

Before you create graphs, ODS Graphics must be enabled (for example, by using the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” in that chapter.

This section describes how the SEVSELECT procedure uses ODS to create graphics.

ODS Graph Names

PROC SEVSELECT assigns a name to each graph that it creates by using ODS. You can use these names to selectively reference the graphs. The names are listed in [Table 26.8](#).

Table 26.8 ODS Graphics Produced by PROC SEVSELECT

ODS Graph Name	Plot Description	PLOTS= Option
Comparative Plots		
CDFPlot	Comparative CDF plot	CDF

Comparative CDF Plot

The comparative CDF plot helps you visually compare the cumulative distribution function (CDF) estimates of all the candidate distribution models to the empirical distribution function (EDF) estimate. The plot does not contain CDF estimates for models whose parameter estimation process does not converge. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the CDF or EDF estimates.

If you specify truncation, then conditional CDF estimates are plotted. Otherwise, unconditional CDF estimates are plotted. The conditional estimates are computed by using the method that is described in the section “[Truncation and Conditional CDF Estimates](#)” on page 1790.

If you specify regression effects, then the plotted CDF estimates are those of a mixture distribution. For more information, see the section “[CDF and PDF Estimates with Regression Effects](#)” on page 1797.

Comparative PDF Plot

The comparative PDF plot helps you visually compare the probability density function (PDF) estimates of all the candidate distribution models. The plot does not contain PDF estimates for models whose parameter estimation process does not converge. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the PDF estimates.

If you specify the HISTOGRAM option, then the plot also contains the histogram of response variable values. If you specify the KERNEL option, then the plot also contains the kernel density estimate of the response variable values.

If you specify regression effects, then the plotted PDF estimates are those of a mixture distribution. For more information, see the section “[CDF and PDF Estimates with Regression Effects](#)” on page 1797.

Comparative Conditional PDF Plot

The comparative conditional PDF plot helps you visually compare the conditional probability density function (PDF) estimates of all the candidate distribution models in up to three ranges of values of the response variable. The plot does not contain conditional PDF estimates for models whose parameter estimation process does not converge. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the conditional PDF estimates.

For a region that has values in the interval $(L, R]$, PROC SEVSELECT computes the conditional PDF estimate, $\hat{f}^c$, for a distribution as $\hat{f}^c(y) = \hat{f}(y)/(\hat{F}(R) - \hat{F}(L))$, where $\hat{f}$ and $\hat{F}$ denote the estimated unconditional PDF and CDF, respectively, of the distribution. You can control the regions and the values of L and R for each region by specifying the **LEFTQ=**, **RIGHTQ=**, and **SHOWREGION=** suboptions of the **PLOT=CONDITIONALPDF** option.

If you specify the **HISTOGRAM** option, then the plot also contains the histogram of response variable values in each region.

If you specify regression effects, then the plotted conditional PDF estimates are those of a mixture distribution. For more information, see the section “[CDF and PDF Estimates with Regression Effects](#)” on page 1797.

CDF Plot per Distribution

The CDF plot per distribution shows the CDF estimates of each candidate distribution model unless that model's parameter estimation process does not converge. The plot also contains estimates of the EDF. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the CDF or EDF estimates.

This plot shows the lower and upper pointwise confidence limits for the EDF estimates. For an EDF estimate F_n with standard error σ_n , they are computed as $\max(0, F_n - z_{(1-\alpha/2)}\sigma_n)$ and $\min(1, F_n + z_{(1-\alpha/2)}\sigma_n)$, respectively, where z_p is the p th quantile from the standard normal distribution and α denotes the confidence level that you specify in the **EDFALPHA=** option (the default is $\alpha = 0.05$).

If you specify truncation, then conditional CDF estimates are plotted. Otherwise, unconditional CDF estimates are plotted. The conditional estimates are computed by using the method that is described in the section “[Truncation and Conditional CDF Estimates](#)” on page 1790.

If you specify regression effects, then the plotted CDF estimates are those of a mixture distribution. For more information, see the section “[CDF and PDF Estimates with Regression Effects](#)” on page 1797.

PDF Plot per Distribution

The PDF plot per distribution shows the PDF estimates of each candidate distribution model unless that model's parameter estimation process does not converge. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the PDF estimates.

If you specify the **HISTOGRAM** option, then the plot also contains the histogram of response variable values. If you specify the **KERNEL** option, then the plot also contains the kernel density estimate of the response variable values.

If you specify regression effects, then the plotted PDF estimates are those of a mixture distribution. For more information, see the section “[CDF and PDF Estimates with Regression Effects](#)” on page 1797.

Conditional PDF Plot per Distribution

The conditional PDF plot per distribution shows the conditional PDF estimates of each candidate distribution model unless that model's parameter estimation process does not converge. The horizontal axis represents the values of the response variable. The vertical axis represents the values of the conditional PDF estimates.

For a region that has values in the interval $(L, R]$, PROC SEVSELECT computes the conditional PDF estimate, $\hat{f}^c$, for a distribution as $\hat{f}^c(y) = \hat{f}(y)/(\hat{F}(R) - \hat{F}(L))$, where $\hat{f}$ and $\hat{F}$ denote the estimated unconditional PDF and CDF, respectively, of the distribution. You can control the regions and the values of L and R for each region by specifying the **LEFTQ=**, **RIGHTQ=**, and **SHOWREGION=** suboptions of the **PLOT=CONDITIONALPDFPERDIST** option.

If you specify the **HISTOGRAM** option, then the plot also contains the histogram of response variable values in each region.

If you specify regression effects, then the plotted PDF estimates are those of a mixture distribution. For more information, see the section “[CDF and PDF Estimates with Regression Effects](#)” on page 1797.

P-P Plot of CDF and EDF

The P-P plot of CDF and EDF is the probability-probability plot that compares the CDF estimates of a distribution to the EDF estimates. A plot is not prepared for models whose parameter estimation process does not converge. The horizontal axis represents the CDF estimates of a candidate distribution, and the vertical axis represents the EDF estimates.

This plot can be interpreted as displaying the data that are used for computing the EDF-based statistics of fit for the given candidate distribution. As described in the section “[EDF-Based Statistics](#)” on page 1807, these statistics are computed by comparing the EDF, denoted by $F_n(y)$, to the CDF, denoted by $F(y)$, at each of the response variable values y . Using the probability inverse transform $z = F(y)$, this is equivalent to comparing the EDF of z , denoted by $F_n(z)$, to the CDF of z , denoted by $F(z)$ (D’Agostino and Stephens 1986, Ch. 4). Because the CDF of z is a uniform distribution ($F(z) = z$), the EDF-based statistics can be computed by comparing the estimate of the EDF of z to the estimate of z itself, which is the estimate of the CDF. The horizontal axis of the plot represents $\hat{z} = \hat{F}(y)$. The vertical axis represents the estimated EDF of z , $\hat{F}_n(z)$. The plot contains a scatter plot of $(\hat{z}, \hat{F}_n(z))$ points and a reference line, $F_n(z) = z$, that represents the expected uniform distribution of z . Points that are scattered closer to the reference line indicate a better fit than points that are scattered farther away from the reference line.

If you specify truncation, then the EDF estimates are conditional, as described in the section “[EDF Estimates and Truncation](#)” on page 1804. So conditional estimates of CDF are displayed; these estimates are computed by using the method that is described in the section “[Truncation and Conditional CDF Estimates](#)” on page 1790.

If you specify regression effects, then the displayed CDF estimates, both unconditional and conditional, are those of a mixture distribution. For more information, see the section “[CDF and PDF Estimates with Regression Effects](#)” on page 1797.

Q-Q Plot

The Q-Q plot is a quantile-quantile scatter plot that compares the empirical quantiles to the quantiles from a candidate distribution. A plot is not prepared for models whose parameter estimation process does not converge. The horizontal axis represents the quantiles from a candidate distribution, and the vertical axis represents the empirical quantiles.

Each point in the plot corresponds to a specific value of the EDF estimate, F_n . The Y coordinate is the value of the response variable for which F_n is computed. The X coordinate is computed by using one of the two following methods for a candidate distribution named *dist*:

- If you have defined the *dist_QUANTILE* function that satisfies the requirements listed in the section “[dist_QUANTILE](#)” on page 1819, then that function is invoked by using F_n and estimated distribution parameters as arguments. The QUANTILE function is defined in the Sashelp.Svrtldist library for all the predefined distributions.
- If the *dist_QUANTILE* function is not defined, then PROC SEVSELECT numerically inverts the *dist_CDF* function at the CDF value of F_n for the estimated distribution parameters. If the *dist_CDF* function is not defined, then the *exp(dist_LOGCDF)* function is inverted. If the inversion fails, the corresponding point is not plotted in the Q-Q plot.

If you specify truncation, then the EDF estimates are conditional, as described in the section “[EDF Estimates and Truncation](#)” on page 1804. The CDF inversion process, whether done numerically or by evaluating the *dist_QUANTILE* function, needs to accept an unconditional CDF value. So the F_n value is first transformed to an unconditional estimate F_n^u as

$$F_n^u = F_n \cdot (\hat{F}(t_{\max}^r) - \hat{F}(t_{\min}^l)) + \hat{F}(t_{\min}^l)$$

where $\hat{F}(t_{\max}^r)$ and $\hat{F}(t_{\min}^l)$ are as defined in the section “[Truncation and Conditional CDF Estimates](#)” on page 1790.

If you specify regression effects, then the value of the first distribution parameter is determined by using the method that is equivalent to specifying the DFMIXTURE=MEAN option in the SCALEMODEL statement. This is described in the section “[CDF and PDF Estimates with Regression Effects](#)” on page 1797.

Examples: SEVSELECT Procedure

Example 26.1: Defining a Model for the Gaussian Distribution with a Scale Parameter

If you want to estimate the influence of regression effects, then the model needs to be parameterized to have a scale parameter. Although this might not be always possible, it is possible for certain distributions. This example illustrates it for the Gaussian distribution. To obtain a parameterization with scale parameter, you replace the location parameter μ with another parameter, $\alpha = \mu/\sigma$, and define the PDF (f) and the CDF (F) as follows:

$$f(x; \sigma, \alpha) = \frac{1}{\sigma \sqrt{2\pi}} \exp\left(-\frac{1}{2} \left(\frac{x}{\sigma} - \alpha\right)^2\right)$$

$$F(x; \sigma, \alpha) = \frac{1}{2} \left(1 + \operatorname{erf}\left(\frac{1}{\sqrt{2}} \left(\frac{x}{\sigma} - \alpha\right)\right)\right)$$

Then, you can verify that σ is the scale parameter, because both of the following equalities are true:

$$f(x; \sigma, \alpha) = \frac{1}{\sigma} f\left(\frac{x}{\sigma}; 1, \alpha\right)$$

$$F(x; \sigma, \alpha) = F\left(\frac{x}{\sigma}; 1, \alpha\right)$$

NOTE: The Gaussian distribution is not a commonly used severity distribution. It is used in this example primarily to illustrate the concept of parameterizing a distribution such that it has a scale parameter. Although the distribution has a support over the entire real line, you can fit the distribution with PROC SEVSELECT only if the input sample contains nonnegative values.

The following statements use the alternate parameterization to define a new model named NORMAL_S. The definition is stored in the library Work.Sevexmpl.

```
/*----- Define normal distribution with scale parameter -----*/
proc fcmp library=sashelp.svrtldist outlib=work.sevexmpl.models;
  function normal_s_pdf(x, Sigma, Alpha);
    /* Sigma : Scale & Standard Deviation */
    /* Alpha : Scaled mean */
    return ( exp(-(x/Sigma - Alpha)**2/2) /
              (Sigma * sqrt(2*constant('PI')))) );
  endsub;

  function normal_s_cdf(x, Sigma, Alpha);
    /* Sigma : Scale & Standard Deviation */
    /* Alpha : Scaled mean */
    z = x/Sigma - Alpha;
    return (0.5 + 0.5*erf(z/sqrt(2)));
  endsub;

  subroutine normal_s_parinit(dim, x[*], nx[*], F[*], Ftype, Sigma, Alpha);
```

```

    outargs Sigma, Alpha;
    array m[2] / nosymbols;
    /* Compute estimates by using method of moments */
    call svrtutil_rawmoments(dim, x, nx, 2, m);
    Sigma = sqrt(m[2] - m[1]**2);
    Alpha = m[1]/Sigma;
endsub;

subroutine normal_s_lowerbounds(Sigma, Alpha);
    outargs Sigma, Alpha;
    Alpha = .; /* Alpha has no lower bound */
    Sigma = 0; /* Sigma > 0 */
endsub;
quit;

```

An important point to note is that the scale parameter *Sigma* is the first distribution parameter (after the 'x' argument) listed in the signatures of NORMAL_S_PDF and NORMAL_S_CDF functions. *Sigma* is also the first distribution parameter listed in the signatures of other subroutines. This is required by PROC SEVSELECT, so that it can identify which is the scale parameter. When you specify regression effects, PROC SEVSELECT checks whether the first parameter of each candidate distribution is a scale parameter (or a log-transformed scale parameter if [dist_SCALETRANSFORM](#) subroutine is defined for the distribution with LOG as the transform). If it is not, then an appropriate message is written the SAS log and that distribution is not fitted.

Let the following DATA step statements simulate a sample from the normal distribution where the parameter σ is affected by the regressors as follows:

$$\sigma = \exp(1 + 0.5 X_1 + 0.75 X_3 - 2 X_4 + X_5)$$

The sample is simulated such that the regressor X_2 is linearly dependent on regressors X_1 and X_3 .

```

/*--- Simulate a normal distribution's sample affected by regressors ---*/
data testnorm_reg(keep=y x1-x5 Sigma);
    array x{*} x1-x5;
    array b{6} _TEMPORARY_ (1 0.5 . 0.75 -2 1);
    call streaminit(34567);
    label y='Normal Response Influenced by Regressors';

    do n = 1 to 100;
        /* simulate regressors */
        do i = 1 to dim(x);
            x(i) = rand('UNIFORM');
        end;
        /* make x2 linearly dependent on x1 */
        x(2) = 5 * x(1);

        /* compute log of the scale parameter */
        logSigma = b(1);
        do i = 1 to dim(x);
            if (i ne 2) then
                logSigma = logSigma + b(i+1) * x(i);
        end;

        Sigma = exp(logSigma);
    end;

```

```

        y = rand('NORMAL', 25, Sigma);
        output;
    end;
run;

```

You can use a DATA step as follows to load the data set `Work.Test_reg` into a data table in your session that is associated with the `mylib` libref. The DATA step assumes that your libref is named `mylib`, but you can substitute any appropriately defined libref.

```

data mylib.testnorm_reg;
    set testnorm_reg;
run;

```

The following statements use PROC SEVSELECT to fit the NORMAL_S distribution model along with some of the predefined distributions to the simulated sample:

```

/*--- Set the search path for functions defined with PROC FCMP ---*/
options cmplib=(work.sevexmpl);

/*----- Fit models with PROC SEVSELECT -----*/
proc sevselect data=mylib.testnorm_reg print=all;
    loss y;
    scalemodel x1-x5;
    dist Normal_s burr logn pareto weibull;
run;

```

The “Model Selection” table in [Output 26.1.1](#) indicates that all the models, except the Burr distribution model, have converged. Also, only three models, Normal_s, Burr, and Weibull, seem to have a good fit for the data. The table that compares all the fit statistics indicates that Normal_s model is the best according to the likelihood-based statistics; however, the Burr model is the best according to the EDF-based statistics.

Output 26.1.1 Summary of Results for Fitting the Normal Distribution with Regressors

The SEVSELECT Procedure

Model Selection

Asterisk (*) denotes the best model in the column.

This prompts you to further evaluate why the model with Burr distribution has not converged. The initial values, convergence status, and the optimization summary for the Burr distribution are shown in [Output 26.1.2](#). The initial values table indicates that the regressor X2 is redundant, which is expected. More importantly, the convergence status indicates that it requires more than 50 iterations. PROC SEVSELECT enables you to change several settings of the optimizer by using the [NLOPTIONS](#) statement. In this case, you can increase the limit of 50 on the iterations, change the convergence criterion, or change the technique to something other than the default trust-region technique.

Output 26.1.2 Details of the Fitted Burr Distribution Model

The SEVSELECT Procedure

Burr Distribution

Model Information	
Distribution	Burr
Description	Burr Distribution (Type XII Family)
Distribution Parameters	3
Regression Parameters	4

Initial Parameter Values and Bounds			
Parameter	Initial Value	Lower Bound	Upper Bound
Theta	25.75198	1.05367E-8	Infy
Alpha	2.00000	1.05367E-8	Infy
Gamma	2.00000	1.05367E-8	Infy
x1	0.07345	-709.78271	709.78271
x2	Redundant	-709.78271	709.78271
x3	-0.14056	-709.78271	709.78271
x4	0.27064	-709.78271	709.78271
x5	-0.23230	-709.78271	709.78271

Convergence Status
Needs more than 50 iterations.

Optimization Summary	
Optimization Technique	Trust Region
Iterations	50
Function Calls	137
Log Likelihood	-306.4084238

The following PROC SEVSELECT step uses the NLOPTIONS statement to change the convergence criterion and the limits on the iterations and function evaluations, exclude the lognormal and Pareto distributions that have been confirmed previously to fit the data poorly, and exclude the redundant regressor X2 from the model:

```
/*--- Refit and compare models with higher limit on iterations ---*/
proc sevselect data=mylib.testnorm_reg print=all;
  loss y;
  scalemodel x1 x3-x5;
  dist Normal_s burr weibull;
  nloptions absfconv=2.0e-5 maxiter=100 maxfunc=500;
run;
```

The results shown in [Output 26.1.3](#) indicate that the Burr distribution has now converged. The NORMAL_S distribution is still the best distribution according to the likelihood-based criteria.

Output 26.1.3 Summary of Results after Changing Maximum Number of Iterations

The SEVSELECT Procedure

Asterisk (*) denotes the best model in the column.

Example 26.2: Defining a Model for Mixed-Tail Distributions

In some applications, a few severity values tend to be extreme as compared to the typical values. The extreme values represent the worst-case scenarios and cannot be discarded as outliers. Instead, their distribution must be modeled to prepare for their occurrences. In such cases, it is often useful to fit one distribution to the non-extreme values and another distribution to the extreme values. The *mixed-tail* distribution mixes two distributions: one for the *body* region, which contains the non-extreme values, and another for the *tail* region, which contains the extreme values. The tail distribution is usually a generalized Pareto distribution (GPD), because it is usually good for modeling the conditional excess severity above a threshold. The body distribution can be any distribution. The following definitions are used in describing a generic formulation of a mixed-tail distribution:

$g(x)$	PDF of the body distribution
$G(x)$	CDF of the body distribution
$h(x)$	PDF of the tail distribution
$H(x)$	CDF of the tail distribution
θ	scale parameter for the body distribution
Ω	set of nonscale parameters for the body distribution
ξ	shape parameter for the GPD tail distribution
x_r	normalized value of the response variable at which the tail starts
p_n	mixing probability

Given these notations, the PDF $f(x)$ and the CDF $F(x)$ of the mixed-tail distribution are defined as

$$f(x) = \begin{cases} \frac{p_n}{G(x_b)} g(x) & \text{if } x \leq x_b \\ (1 - p_n) h(x - x_b) & \text{if } x > x_b \end{cases}$$

$$F(x) = \begin{cases} \frac{p_n}{G(x_b)} G(x) & \text{if } x \leq x_b \\ p_n + (1 - p_n) H(x - x_b) & \text{if } x > x_b \end{cases}$$

where $x_b = \theta x_r$ is the value of the response variable at which the tail starts.

These definitions indicate the following:

- The body distribution is conditional on $X \leq x_b$, where X denotes the random response variable.
- The tail distribution is the generalized Pareto distribution of the $(X - x_b)$ values.
- The probability that a response variable value belongs to the body is p_n . Consequently the probability that the value belongs to the tail is $(1 - p_n)$.

The parameters of this distribution are θ , Ω , ξ , x_r , and p_n . The scale of the GPD tail distribution θ_t is computed as

$$\theta_t = \frac{G(x_b; \theta, \Omega) (1 - p_n)}{g(x_b; \theta, \Omega) p_n} = \theta \frac{G(x_r; \theta = 1, \Omega) (1 - p_n)}{g(x_r; \theta = 1, \Omega) p_n}$$

The parameter x_r is usually initialized using a tail index estimation algorithm. One such algorithm is Hill's algorithm (Danielsson et al. 2001), which is implemented by the predefined utility function SVRTUTIL_HILLCUTOFF available to you in the Sashelp.Svrtldist library. The algorithm and the utility function are described in detail in the section “[Predefined Utility Functions](#)” on page 1824. The function computes an estimate of x_b , which can be used to compute an initial estimate of x_r as $x_r = x_b / \hat{\theta}$, where $\hat{\theta}$ is the estimate of the scale parameter of the body distribution.

The parameter p_n is usually determined by the domain expert based on the fraction of losses that are expected to belong to the tail.

The following SAS statements define the LOGNGPD distribution model for a mixed-tail distribution with the lognormal distribution as the body distribution and GPD as the tail distribution:

```
/*----- Define lognormal Body-GPD tail mixed distribution -----*/
proc fcmp library=sashelp.svrtldist outlib=work.sevexmpl.models;
  function LOGNGPD_DESCRIPTION() $256;
    length desc $256;
    desc1 = "Lognormal Body-GPD Tail Distribution";
    desc2 = " (Mu, Sigma, Xi, and Xr are free parameters;";
    desc3 = " Pn is fixed at 0.8)";
    desc = desc1 || desc2 || desc3;
    return(desc);
  endsub;

  function LOGNGPD_SCALETRANSFORM() $3;
    length xform $3;
    xform = "LOG";
    return (xform);
```

```

endsub;

subroutine LOGNGPD_CONSTANTPARM(Pn);
endsub;

function LOGNGPD_PDF(x, Mu, Sigma, Xi, Xr, Pn);
  cutoff = exp(Mu) * Xr;
  p = CDF('LOGN', cutoff, Mu, Sigma);
  if (x < cutoff + constant('MACEPS')) then do;
    return ((Pn/p)*PDF('LOGN', x, Mu, Sigma));
  end;
  else do;
    gpd_scale = p*((1-Pn)/Pn)/PDF('LOGN', cutoff, Mu, Sigma);
    h = (1+Xi*(x-cutoff)/gpd_scale)**(-1-(1/Xi))/gpd_scale;
    return ((1-Pn)*h);
  end;
endsub;

function LOGNGPD_CDF(x, Mu, Sigma, Xi, Xr, Pn);
  cutoff = exp(Mu) * Xr;
  p = CDF('LOGN', cutoff, Mu, Sigma);
  if (x < cutoff + constant('MACEPS')) then do;
    return ((Pn/p)*CDF('LOGN', x, Mu, Sigma));
  end;
  else do;
    gpd_scale = p*((1-Pn)/Pn)/PDF('LOGN', cutoff, Mu, Sigma);
    H = 1 - (1 + Xi*((x-cutoff)/gpd_scale))**(-1/Xi);
    return (Pn + (1-Pn)*H);
  end;
endsub;

subroutine LOGNGPD_PARMINIT(dim, x[*], nx[*], F[*], Ftype,
                          Mu, Sigma, Xi, Xr, Pn);
  outargs Mu, Sigma, Xi, Xr, Pn;

  array nxe[1] / nosymbols;

  eps = constant('MACEPS');

  Pn = 0.8; /* Set mixing probability */
  _status_ = .;
  call streaminit(56789);
  Xb = svrtutil_hillcutoff(dim, x, 100, 25, _status_);
  if (missing(_status_) or _status_ = 1) then
    Xb = svrtutil_percentile(Pn, dim, x, F, Ftype);

  /* Initialize lognormal parameters */
  call logn_parminit(dim, x, nx, F, Ftype, Mu, Sigma);
  if (not(missing(Mu))) then
    Xr = Xb/exp(Mu);
  else
    Xr = .;

  /* Prepare arrays for excess values */

```

```

i = 1;
do while (i <= dim and x[i] < Xb+eps);
    i = i + 1;
end;
dime = dim-i+1;
if (dime > 0) then do;
    call dynamic_array(xe, dime);
    call dynamic_array(nxe, dime);
    j = 1;
    do while(i <= dim);
        xe[j] = x[i] - Xb;
        nxe[j] = nx[i];
        i = i + 1;
        j = j + 1;
    end;

    /* Initialize GPD's shape parameter using excess values */
    call gpd_parminit(dime, xe, nxe, F, Ftype, theta_gpd, Xi);
end;
else do;
    Xi = .;
end;
endsub;

subroutine LOGNGPD_LOWERBOUNDS (Mu, Sigma, Xi, Xr, Pn);
    outargs Mu, Sigma, Xi, Xr, Pn;

    Mu    = .; /* Mu has no lower bound */
    Sigma = 0; /* Sigma > 0 */
    Xi    = 0; /* Xi > 0 */
    Xr    = 0; /* Xr > 0 */
endsub;
quit;

```

Note the following points about the LOGNGPD definition:

- In this example, the parameter p_n is not estimated with the maximum likelihood method used by PROC SEVSELECT, so you need to specify it as a *constant* parameter by defining the [dist_CONSTANTPARM](#) subroutine. The signature of the LOGNGPD_CONSTANTPARM subroutine lists only the constant parameter P_n .
- The LOGNGPD_PARMINIT subroutine initializes the parameter x_r by first using the SVRTUTIL_HILLCUTOFF utility function to compute an estimate of the cutoff point $\hat{x}_b$ and then computing $x_r = \hat{x}_b / e^{\hat{\mu}}$. If SVRTUTIL_HILLCUTOFF fails to compute a valid estimate, then the SVRTUTIL_PERCENTILE utility function is used to set $\hat{x}_b$ to the p_n th percentile of the data. The parameter p_n is fixed to 0.8.
- The Sashelp.SvrtDIST library is specified with the LIBRARY= option in the PROC FCMP statement to enable the LOGNGPD_PARMINIT subroutine to use the predefined utility functions (SVRTUTIL_HILLCUTOFF and SVRTUTIL_PERCENTILE) and parameter initialization subroutines (LOGN_PARMINIT and GPD_PARMINIT).
- The LOGNGPD_LOWERBOUNDS subroutine defines the lower bounds for all parameters. This subroutine is required because the parameter μ has a non-default lower bound. The bounds for σ

and X_i must be specified. If they are not specified, they are returned as missing values, which PROC SEVSELECT interprets as having no lower bound. You do not need to specify any bounds for the constant parameter P_n , because it is not subject to optimization.

The following DATA step statements simulate a sample from a mixed-tail distribution with a lognormal body and GPD tail. The parameter p_n is fixed to 0.8, the same value used in the LOGNGPD_PARMINIT subroutine defined previously.

```
/*----- Simulate a sample for the mixed-tail distribution -----*/
data testmixdist(keep=y label='Lognormal Body-GPD Tail Sample');
  call streaminit(45678);
  label y='Response Variable';
  N = 1000;
  Mu = 1.5;
  Sigma = 0.25;
  Xi = 0.7;
  Pn = 0.8;

  /* Generate data for the lognormal body */
  Nbody = N*Pn;
  do i=1 to Nbody;
    y = exp(Mu) * rand('LOGNORMAL')**Sigma;
    output;
  end;

  /* Generate data for the GPD tail */
  cutoff = quantile('LOGNORMAL', Pn, Mu, Sigma);
  gpd_scale = (1-Pn) / pdf('LOGNORMAL', cutoff, Mu, Sigma);
  do i=Nbody+1 to N;
    y = cutoff + ((1-rand('UNIFORM'))**(-Xi) - 1)*gpd_scale/Xi;
    output;
  end;
run;
```

You can use a DATA step as follows to load the data set Work.Testmixdist into a data table in your session that is associated with the mylib libref. The DATA step assumes that your libref is named mylib, but you can substitute any appropriately defined libref.

```
data mylib.testmixdist;
  set testmixdist;
run;
```

The following statements use PROC SEVSELECT to fit the LOGNGPD distribution model to the simulated sample. They also fit three other predefined distributions (BURR, LOGN, and GPD). The final parameter estimates are written to the mylib.Parmest data table.

```
/*--- Set the search path for functions defined with PROC FCMP ---*/
options cmplib=(work.sevexmpl);

/*----- Fit LOGNGPD model with PROC SEVSELECT -----*/
proc sevselect data=mylib.testmixdist print=all outest=mylib.parmest;
  loss y;
  dist logngpd burr logn gpd;
run;
```

Some of the results that PROC SEVSELECT produces are shown in [Output 26.2.1](#) and [Output 26.2.2](#). The “Model Selection” table in [Output 26.2.1](#) indicates that all models converged. The “All Fit Statistics” table in [Output 26.2.1](#) shows that the model with LOGNGPD distribution has the best fit according to all the fit statistics. The Burr distribution model is the closest contender to the LOGNGPD model, but the GPD distribution model fits the data very poorly.

Output 26.2.1 Summary of Fitting Mixed-Tail Distribution

The SEVSELECT Procedure

Model Selection							
Distribution	Converged	-2 Log Likelihood		Selected			
Logngpd	Yes	3640	Yes

Burr	3687	3693	3693	3708	1.33323	2.34704	0.39000
Logn	3862	3866	3866	3875	2.20231	7.31780	0.94769
Gpd	5344	5348	5348	5358	12.27970	218.30354	44.54186

Asterisk (*) denotes the best model in the column.

The detailed results for the LOGNGPD distribution are shown in [Output 26.2.2](#). The initial values table shows the fixed value of the P_n parameter that the LOGNGPD_PARMINIT subroutine sets. The table uses the bounds columns to indicate that it is a constant parameter. The last table in the figure shows the final parameter estimates. The estimates of all free parameters are significantly different from 0. As expected, the final estimate of the constant parameter P_n has not changed from its initial value.

Output 26.2.2 Detailed Results for the LOGNGPD Distribution

The SEVSELECT Procedure

Logngpd Distribution

Xr	1	1.19816	0.03925	30.52	<.0001
Pn	1	0.80000	Constant	.	.

The following SAS statements use the parameter estimates to compute the value where the tail region is estimated to start ($x_b = e^{\hat{\mu}} \hat{x}_r$) and the scale of the GPD tail distribution ($\theta_t = \frac{G(x_b)}{g(x_b)} \frac{(1-p_n)}{p_n}$):

```

/*----- Compute tail cutoff and tail distribution's scale -----*/
data xb_thetat(keep=x_b theta_t);
  set mylib.parmest(where=(_MODEL_='Logngpd' and _TYPE_='EST'));
  x_b = exp(Mu) * Xr;
  theta_t = (CDF('LOGN', x_b, Mu, Sigma) / PDF('LOGN', x_b, Mu, Sigma)) *
            ((1-Pn) / Pn);
run;

proc print data=xb_thetat noobs;
run;

```

Output 26.2.3 Start of the Tail and Scale of the GPD Tail Distribution

x_b	theta_t
6.01665	1.00677

The computed values of x_b and θ_t are shown as `x_b` and `theta_t` in [Output 26.2.3](#). Equipped with this additional derived information, you can now interpret the results of fitting the mixed-tail distribution as follows:

- The tail starts at $y \approx 6.02$. Optimizing the scale-normalized relative cutoff (x_r) in addition to optimizing the scale of the body region ($\theta = e^\mu$) gives you more flexibility in optimizing the absolute cutoff (x_b). If X_r is declared as a constant parameter, then x_b is optimized by virtue of optimizing the scale of the body region ($\theta = e^\mu$), and you must rely on Hill's tail index estimator to yield an initial estimate of x_b that is close to an optimal estimate. By keeping X_r as a free parameter, you account for the possibility that Hill's estimator can yield a suboptimal estimate.
- The values $y \leq 6.02$ follow the lognormal distribution with parameters $\mu \approx 1.614$ and $\sigma \approx 0.317$. These parameter estimates are reasonably close to the parameters of the body distribution that is used for simulating the sample.
- If X_t denotes the loss random variable for the tail defined as $X_t = X - x_b$, where X is the original loss variable, then for this example, $\Pr[X_t = X - 6.02 | X_t > 0]$ follows the GPD density function with scale $\theta_t \approx 1.005$ and shape $\xi \approx 0.539$.

Example 26.3: Fitting a Scaled Tweedie Model with Regressors

The Tweedie distribution is often used in the insurance industry to explain the influence of regression effects on the distribution of losses. PROC SEVSELECT provides a predefined scaled Tweedie distribution (STWEEDIE) that enables you to model the influence of regression effects on the scale parameter. The scale regression model has its own advantages such as the ability to easily account for inflation effects. This example illustrates how that model can be used to evaluate the influence of regression effects on the *mean* of the Tweedie distribution, which is useful in problems such rate-making and pure premium modeling.

Assume a Tweedie process, whose mean μ is affected by k regression effects x_j , $j = 1, \dots, k$, as follows,

$$\mu = \mu_0 \exp \left(\sum_{j=1}^k \beta_j x_j \right)$$

where μ_0 represents the base value of the mean (you can think of μ_0 as $\exp(\beta_0)$, where β_0 is the intercept). This model for the mean is identical to the popular generalized linear model for the mean with a logarithmic link function.

More interestingly, it parallels the model used by PROC SEVSELECT for the scale parameter θ ,

$$\theta = \theta_0 \exp \left(\sum_{j=1}^k \beta_j x_j \right)$$

where θ_0 represents the base value of the scale parameter. As described in the section “[Tweedie Distributions](#)” on page 1781, for the parameter range $p \in (1, 2)$, the mean of the Tweedie distribution is given by

$$\mu = \theta \lambda \frac{2-p}{p-1}$$

where λ is the Poisson mean parameter of the scaled Tweedie distribution. This relationship enables you to use the scale regression model to infer the influence of regression effects on the mean of the distribution.

Let the data set `Work.Test_Sevtw` contain a sample generated from a Tweedie distribution with dispersion parameter $\phi = 0.5$, index parameter $p = 1.75$, and the mean parameter that is affected by three regression variables x_1 , x_2 , and x_3 as follows:

$$\mu = 5 \exp(0.25 x_1 - x_2 + 3 x_3)$$

Thus, the population values of regression parameters are $\mu_0 = 5$, $\beta_1 = 0.25$, $\beta_2 = -1$, and $\beta_3 = 3$.

The following DATA step generates a sample of the Tweedie distribution:

```
/*--- Simulate a Tweedie sample that is affected by regressors ---*/
%let samplesize=300;
data test_sevtw(keep=y x1-x3
                 label='A Tweedie Sample Affected by Regressors');
  array x{*} x1-x3;
  array b{4} _TEMPORARY_ (5 0.25 -1 3);
  call streaminit(45678);
  label y='Response Influenced by Regressors';

  Phi = 0.5;
  P = 1.75;
  do n = 1 to &samplesize;
    Mu = 0;
    do i = 1 to dim(x);
      x(i) = rand('UNIFORM');
      Mu = Mu + b(i+1) * x(i);
    end;
    Mu = b(1) * exp(Mu); /* b(1) is base value of mean */

    cdf = rand('UNIFORM');
    y = quantile('TWEEDIE', cdf, P, Mu, Phi);
    output;
  end;
run;
```

You can use a DATA step as follows to load the data set `Work.Test_sevtw` into a data table in your session that is associated with the `mylib` libref. The DATA step assumes that your libref is named `mylib`, but you can substitute any appropriately defined libref.

```
data mylib.test_sevtw;
  set test_sevtw;
run;
```

The following PROC SEVSELECT step uses the sample in `mylib.Test_Sevtw` data table to estimate the parameters of the scale regression model for the predefined scaled Tweedie distribution (STWEEDIE) with the dual quasi-Newton (QUANEW) optimization technique:

```
/*--- Fit the scale parameter version of the Tweedie distribution ---*/
proc sevselect data=mylib.test_sevtw outest=mylib.estw covout print=all;
  loss y;
  scalemodel x1-x3;

  dist stweedie;
  nloptions tech=quanew;
run;
```

The dual quasi-Newton technique is used because it requires only the first-order derivatives of the objective function, and it is harder to compute reasonably accurate estimates of the second-order derivatives of Tweedie distribution's PDF with respect to the parameters.

Some of the key results that PROC SEVSELECT prepares are shown in [Output 26.3.1](#) and [Output 26.3.2](#). The model information and the convergence results are shown in [Output 26.3.1](#).

Output 26.3.1 Convergence Results for the STWEEDIE Model with Regressors

The SEVSELECT Procedure

Stweedie Distribution

Model Information	
Distribution	Stweedie
Description	Tweedie Distribution with Scale Parameter
Distribution Parameters	3
Regression Parameters	3

Convergence Status	
Convergence criterion (FCONV=2.220446E-16) satisfied.	

Optimization Summary	
Optimization Technique	Dual Quasi-Newton
Iterations	42
Function Calls	137
Log Likelihood	-1044.321485

The final parameter estimates of the STWEEDIE regression model are shown in [Output 26.3.2](#). The estimate that is reported for the parameter Theta is the estimate of the base value θ_0 . The estimates of regression coefficients β_1 , β_2 , and β_3 are indicated by the rows of x1, x2, and x3, respectively.

Output 26.3.2 Parameter Estimates for the STWEEDIE Model with Regressors

Parameter Estimates					
Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Theta	1	0.82442	0.28548	2.89	0.0042
Lambda	1	16.31209	13.75533	1.19	0.2366
P	1	1.75037	0.21870	8.00	<.0001
x1	1	0.27941	0.09877	2.83	0.0050
x2	1	-0.76724	0.10315	-7.44	<.0001
x3	1	3.03195	0.10142	29.89	<.0001

If your goal is to explain the influence of regression effects on the scale parameter, then the output displayed in [Output 26.3.2](#) is sufficient. But, if you want to compute the influence of regression effects on the mean of the distribution, then you need to do some postprocessing. Using the relationship between μ and θ , μ can be

written in terms of the parameters of the STWEEDIE model as

$$\mu = \theta_0 \exp \left(\sum_{j=1}^k \beta_j x_j \right) \lambda \frac{2-p}{p-1}$$

This shows that the parameters β_j are identical for the mean and the scale model, and the base value μ_0 of the mean model is

$$\mu_0 = \theta_0 \lambda \frac{2-p}{p-1}$$

The estimate of μ_0 and the standard error associated with it can be computed by using the property of the functions of maximum likelihood estimators (MLE). If $g(\Omega)$ represents a totally differentiable function of parameters Ω , then the MLE of g has an asymptotic normal distribution with mean $g(\hat{\Omega})$ and covariance $C = (\partial g)' \Sigma (\partial g)$, where $\hat{\Omega}$ is the MLE of Ω , Σ is the estimate of covariance matrix of Ω , and ∂g is the gradient vector of g with respect to Ω evaluated at $\hat{\Omega}$. For μ_0 , the function is $g(\Omega) = \theta_0 \lambda (2-p)/(p-1)$. The gradient vector is

$$\begin{aligned} \partial g &= \left(\frac{\partial g}{\partial \theta_0} \quad \frac{\partial g}{\partial \lambda} \quad \frac{\partial g}{\partial p} \quad \frac{\partial g}{\partial \beta_1} \cdots \frac{\partial g}{\partial \beta_k} \right) \\ &= \left(\frac{\mu_0}{\theta_0} \quad \frac{\mu_0}{\lambda} \quad \frac{-\mu_0}{(p-1)(2-p)} \quad 0 \dots 0 \right) \end{aligned}$$

You can write a DATA step that implements these computations by using the parameter and covariance estimates that the PROC SEVSELECT step prepares. The following statements show one such implementation:

```
/*--- Compute the estimate, standard error, and p-value of the mean ---*/
data Mu0(keep=Parameter Estimate Stderr T probT);
  Parameter='Mu0';
  label Estimate='Estimate' Stderr='Standard;Error'
        T='t Value' probT='Approx;Pr > |t|';

  array cov{3,3} _temporary_;
  array parms{3} _temporary_;
  array parmrow{3} theta lambda p;
  set mylib.estw(where=( _MODEL_='Stweedie' and
                        (_type_='COV' or _type_='EST'))) end=eof;

  n = _n_-1;
  if (n = 0) then do;
    do i=1 to 3;
      parms[i] = parmrow[i];
    end;
  end;
  else do;
    do i=1 to n;
      cov[n,i] = parmrow[i];
    end;
  end;
  if (eof or n = 3) then do;
```

```

mu0 = parms[1]*parms[2]*(2-parms[3])/(parms[3]-1);
Estimate = mu0;

a = mu0/parms[1]; /* dMu0_T0 */
b = mu0/parms[2]; /* dMu0_L */
c = -mu0/((parms[3]-1)*(2-parms[3])); /* dMu0_P */

varMu0 = a * (a*cov[1,1]+b*cov[2,1]+c*cov[3,1]) +
          b * (a*cov[2,1]+b*cov[2,2]+c*cov[3,2]) +
          c * (a*cov[3,1]+b*cov[3,2]+c*cov[3,3]);

Stderr = sqrt(varMu0);

df = &samplesize-6;
T = mu0/Stderr;
probtT = (1-probt(T, df))*2;
output;
stop;
end;
run;

proc print data=Mu0 noobs s='';
run;

```

The estimates of μ_0 that the preceding DATA step prepares are shown in [Output 26.3.3](#). These estimates and the estimates of β_j as shown in [Output 26.3.2](#) are reasonably close (that is, within one or two standard errors) to the parameters of the population from which the sample in mylib.Test_Sevtw data table was drawn.

Output 26.3.3 Estimate of the Base Value Mu0 of the Mean Parameter

Parameter	Estimate	Standard Error	t Value	Approx Pr > t
Mu0	4.47382	0.42251	10.5886	0

Another outcome of using the scaled Tweedie distribution to model the influence of regression effects is that the regression effects also influence the variance V of the Tweedie distribution. The variance is related to the mean as $V = \phi\mu^p$, where ϕ is the dispersion parameter. Using the relationship between the parameters TWEEDIE and STWEEDIE distributions as described in the section “[Tweedie Distributions](#)” on page 1781, the regression model for the dispersion parameter is

$$\begin{aligned}
 \log(\phi) &= (2 - p) \log(\mu) - \log(\lambda(2 - p)) \\
 &= ((2 - p) \log(\mu_0) - \log(\lambda(2 - p))) + (2 - p) \sum_{j=1}^k \beta_j x_j
 \end{aligned}$$

Subsequently, the regression model for the variance is

$$\begin{aligned}
 \log(V) &= 2 \log(\mu) - \log(\lambda(2 - p)) \\
 &= (2 \log(\mu_0) - \log(\lambda(2 - p))) + 2 \sum_{j=1}^k \beta_j x_j
 \end{aligned}$$

In summary, PROC SEVSELECT enables you to estimate regression effects on various parameters and statistics of the Tweedie model.

Example 26.4: Fitting Distributions to Interval-Censored Data

In some applications, the data available for modeling might not be exact. A commonly encountered scenario is the use of grouped data from an external agency, which for several reasons, including privacy, does not provide information about individual loss events. The losses are grouped into disjoint bins, and you know only the range and number of values in each bin. Each group is essentially interval-censored, because you know that a loss magnitude is in certain interval, but you do not know the exact magnitude. This example illustrates how you can use PROC SEVSELECT to model such data.

The following DATA step generates sample grouped data for dental insurance claims, which is taken from Klugman, Panjer, and Willmot (1998):

```
/* Grouped dental insurance claims data (Klugman, Panjer, and Willmot 1998) */
data gdental;
  input lowerbd upperbd count @@;
  datalines;
0 25 30 25 50 31 50 100 57 100 150 42 150 250 65 250 500 84
500 1000 45 1000 1500 10 1500 2500 11 2500 4000 3
;
run;
```

To analyze small data sets such as this, you might want to restrict the number of workers that are used by PROC SEVSELECT by submitting the following statements:

```
cas mysess terminate;
cas mysess sessopts=(nworkers=1);
libname mylib cas sessref=mysess;
```

The first CAS statement terminates the current CAS session named mysess. It also clears the mylib libref that was associated with the session. The second CAS statement creates another session that uses only one worker of the server. The LIBNAME statement associates the mylib libref with the new session. For more information about the CAS statement and the CAS LIBNAME engine, see [SAS Cloud Analytic Services: User's Guide](#).

If you want to load a SAS data set into a data table on the CAS server, then it is recommended that you restrict the number of workers before you load the data set. If you restrict the number of workers after you load the data, then PROC SEVSELECT needs to redistribute the data table so that it resides on the restricted number of workers; this can cause unnecessary deterioration of performance.

You can use a DATA step as follows to load the data set Work.Gdental into a data table in your session that is associated with the mylib libref. The DATA step assumes that your libref is named mylib, but you can substitute any appropriately defined libref.

```
data mylib.gdental;
  set gdental;
run;
```

The following PROC SEVSELECT step fits all the predefined distributions to the data in the mylib.Gdental data table:

```

/* Fit all predefined distributions */
proc sevselect data=mylib.gdental edf=turnbull print=all criterion=aicc;
  loss / rc=lowerbd lc=upperbd;
  weight count;
  dist _predef_;
run;

```

The EDF= option in the PROC SEVSELECT statement specifies that the Turnbull's method be used for EDF estimation. The LOSS statement specifies the left and right boundaries of each group as the right-censoring and left-censoring limits, respectively. The variable count records the number of losses in each group and is specified in the WEIGHT statement. Note that no response variable is specified in the LOSS statement, which is allowed as long as each observation in the input data table is censored.

Some of the key results that PROC SEVSELECT produces are shown in [Output 26.4.1](#). According to the “Model Selection” table in [Output 26.4.1](#), all distribution models have converged. The “All Fit Statistics” table in [Output 26.4.1](#) indicates that the exponential distribution (EXP) has the best fit for data according to a majority of the likelihood-based statistics and that the Burr distribution (BURR) has the best fit according to all the EDF-based statistics.

Output 26.4.1 Statistics of Fit for Interval-Censored Data

Asterisk (*) denotes the best model in the column.

When the best distributions that are chosen by the likelihood-based and EDF-based statistics are different, you need to decide which fit statistic best represents your objective. In this example, if your objective is to minimize the distance between EDF and CDF values, then you should choose the Burr distribution. On the other hand, if your objective is to maximize the likelihood of the observed data while minimizing the

model complexity, then you should choose the exponential distribution. Note that the exponential distribution has worse (lower) raw likelihood than the Burr distribution, but it has better AIC, AICC, and SBC statistics than the Burr distribution because the exponential distribution has only one parameter compared to the three parameters of the Burr distribution. Further, the small sample size of 10 helps accentuate the role of model complexity in the AIC, AICC, and SBC statistics. If the sample size would have been larger, the exponential distribution might not have won according to the likelihood-based statistics.

Example 26.5: Defining a Finite Mixture Model That Has a Scale Parameter

A finite mixture model is a stochastic model that postulates that the probability distribution of the data generation process is a mixture of a finite number of probability distributions. For example, when an insurance company analyzes loss data from multiple policies that are underwritten in different geographic regions, some regions might behave similarly, but the distribution that governs some regions might be different from the distribution that governs other regions. Further, it might not be known which regions behave similarly. Also, the larger amounts of losses might follow a different stochastic process from the stochastic process that governs the smaller amounts of losses. It helps to model all policies together in order to pool the data together and exploit any commonalities among the regions, and the use of a finite mixture model can help capture the differences in distributions across regions and ranges of loss amounts.

Formally, if f_i and F_i denote the PDF and CDF, respectively, of component distribution i and p_i represents the mixing probability that is associated with component i , then the PDF and CDF of the finite mixture of K distribution components are

$$f(x; \Theta, \mathbf{p}) = \sum_{i=1}^K p_i f_i(x; \Theta_i)$$

$$F(x; \Theta, \mathbf{p}) = \sum_{i=1}^K p_i F_i(x; \Theta_i)$$

where Θ_i denotes the parameters of component distribution i and Θ denotes the parameters of the mixture distribution, which is a union of all the Θ_i parameters. $\mathbf{p}$ denotes the set of mixing probabilities. All mixing probabilities must add up to 1 ($\sum_{i=1}^K p_i = 1$).

You can define the finite mixture of a specific number of components and specific distributions for each of the components by defining the FCMP functions for the PDF and CDF. However, in general, it is not possible to fit a scale regression model by using any finite mixture distribution unless you take special care to ensure that the mixture distribution has a scale parameter. This example provides a formulation of a two-component finite mixture model that has a scale parameter.

To start with, each component distribution must have either a scale parameter or a log-transformed scale parameter. Let θ_1 and θ_2 denote the scale parameters of the first and second components, respectively. Let $p_1 = p$ be the mixing probability, which makes $p_2 = 1 - p$ by using the constraint on $\mathbf{p}$. The PDF of the mixture of these two distributions can be written as

$$f(x; \theta_1, \theta_2, \Phi, p) = \frac{p}{\theta_1} f_1\left(\frac{x}{\theta_1}; \Phi_1\right) + \frac{1-p}{\theta_2} f_2\left(\frac{x}{\theta_2}; \Phi_2\right)$$

where Φ_1 and Φ_2 denote the sets of nonscale parameters of the first and second components, respectively, and Φ denotes a union of Φ_1 and Φ_2 . For the mixture to have the scale parameter θ , the PDF must be of the

form

$$f(x; \theta, \Phi', p) = \frac{1}{\theta} \left(p f_1\left(\frac{x}{\theta}; \Phi'_1\right) + (1 - p) f_2\left(\frac{x}{\theta}; \Phi'_2\right) \right)$$

where Φ' , Φ'_1 , and Φ'_2 denote the modified sets of nonscale parameters. One simple way to achieve this is to make $\theta_1 = \theta_2 = \theta$ and $\Phi' = \Phi$; that is, you simply equate the scale parameters of both components and keep the set of nonscale parameters unchanged. However, forcing the scale parameters to be equal in both components is restrictive, because the mixture cannot model potential differences in the scales of the two components. A better approach is to tie the scale parameters of the two components by a ratio such that $\theta_1 = \theta$ and $\theta_2 = \rho\theta$. If the ratio parameter ρ is estimated along with the other parameters, then the mixture distribution becomes flexible enough to model the variations across the scale parameters of individual components.

To summarize, the PDF and CDF are of the following form for the two-component mixture that has a scale parameter:

$$f(x; \theta, \rho, \Phi, p) = \frac{1}{\theta} \left(p f_1\left(\frac{x}{\theta}; \Phi_1\right) + (1 - p) f_2\left(\frac{x}{\theta}; \rho, \Phi_2\right) \right)$$

$$F(x; \theta, \rho, \Phi, p) = p F_1\left(\frac{x}{\theta}; \Phi_1\right) + (1 - p) F_2\left(\frac{x}{\theta}; \rho, \Phi_2\right)$$

This can be generalized to a mixture of K components by introducing the $K - 1$ ratio parameters ρ_i that relate the scale parameters of each of the K components to the scale parameter θ of the mixture distribution as follows:

$$\theta_1 = \theta$$

$$\theta_i = \rho_i \theta; i \in [2, K]$$

In order to illustrate this approach, define a mixture of two lognormal distributions by using the following PDF function:

$$f(x; \mu, \sigma_1, p_2, \rho_2, \sigma_2) = \frac{(1 - p_2)}{\sigma_1 x \sqrt{2\pi}} \exp\left(\frac{-(\log(x) - \mu)^2}{2\sigma_1^2}\right) +$$

$$\frac{p_2}{\sigma_2 x \sqrt{2\pi}} \exp\left(\frac{-(\log(x) - \mu - \log(\rho_2))^2}{2\sigma_2^2}\right)$$

You can verify that μ serves as the log of the scale parameter θ ($\mu = \log(\theta)$).

The following PROC FCMP steps encode this formulation in a distribution named SLOGNMIX2 for use with PROC SEVSELECT:

```
/*- Define mixture of 2 lognormal distributions with a log-scale parameter -*/
proc fcmp library=sashelp.svrtldist outlib=work.sevexmpl.models;
    function slognmix2_description() $128;
        return ("Mixture of two lognormals with a log-scale parameter Mu");
    endsub;

    function slognmix2_scaletransform() $8;
        return ("LOG");
    endsub;
```

```

function slognmix2_pdf(x, Mu, Sigma1, p2, Rho2, Sigma2);
    Mu1 = Mu;
    Mu2 = Mu + log(Rho2);
    pdf1 = logn_pdf(x, Mu1, Sigma1);
    pdf2 = logn_pdf(x, Mu2, Sigma2);
    return ((1-p2)*pdf1 + p2*pdf2);
endsub;

function slognmix2_cdf(x, Mu, Sigma1, p2, Rho2, Sigma2);
    Mu1 = Mu;
    Mu2 = Mu + log(Rho2);
    cdf1 = logn_cdf(x, Mu1, Sigma1);
    cdf2 = logn_cdf(x, Mu2, Sigma2);
    return ((1-p2)*cdf1 + p2*cdf2);
endsub;

subroutine slognmix2_parinit(dim, x[*], nx[*], F[*], Ftype,
                           Mu, Sigma1, p2, Rho2, Sigma2);
    outargs Mu, Sigma1, p2, Rho2, Sigma2;
    array m[1] / nosymbols;
    p2 = 0.5;
    Rho2 = 0.5;
    median = svrtutil_percentile(0.5, dim, x, F, Ftype);
    Mu = log(2*median/1.5);
    call svrtutil_rawmoments(dim, x, nx, 1, m);
    lm1 = log(m[1]);

    /* Search Rho2 that makes log(sample mean) > Mu */
    do while (lm1 <= Mu and Rho2 < 1);
        Rho2 = Rho2 + 0.01;
        Mu = log(2*median/(1+Rho2));
    end;
    if (Rho2 >= 1) then
        /* If Mu cannot be decreased enough to make it less
           than log(sample mean), then revert to Rho2=0.5.
           That will set Sigma1 and possibly Sigma2 to missing.
           PROC SEVSELECT replaces missing initial values with 0.001. */
        Mu = log(2*median/1.5);

        Sigma1 = sqrt(2.0*(log(m[1])-Mu));
        Sigma2 = sqrt(2.0*(log(m[1])-Mu-log(Rho2)));
    endsub;

subroutine slognmix2_lowerbounds(Mu, Sigma1, p2, Rho2, Sigma2);
    outargs Mu, Sigma1, p2, Rho2, Sigma2;
    Mu = .; /* Mu has no lower bound */
    Sigma1 = 0; /* Sigma1 > 0 */
    p2 = 0; /* p2 > 0 */
    Rho2 = 0; /* Rho2 > 0 */
    Sigma2 = 0; /* Sigma2 > 0 */
endsub;

subroutine slognmix2_upperbounds(Mu, Sigma1, p2, Rho2, Sigma2);

```

```

outargs Mu, Sigma1, p2, Rho2, Sigma2;
Mu = .; /* Mu has no upper bound */
Sigma1 = .; /* Sigma1 has no upper bound */
p2 = 1; /* p2 < 1 */
Rho2 = 1; /* Rho2 < 1 */
Sigma2 = .; /* Sigma2 has no upper bound */
endsub;
quit;

```

As shown in previous examples, an important aspect of defining a distribution for use with PROC SEVSELECT is the definition of the PARMINIT subroutine that initializes the parameters. For mixture distributions, in general, the parameter initialization is a nontrivial task. For a two-component mixture, some simplifying assumptions make the problem easier to handle. For the initialization of SLOGNMIX2, the initial values of p_2 and ρ_2 are fixed at 0.5, and the following two simplifying assumptions are made:

- The median of the mixture is the average of the medians of the two components:

$$F^{-1}(0.5) = (\exp(\mu_1) + \exp(\mu_2))/2 = \exp(\mu)(1 + \rho_2)/2$$

Solution of this equation yields the value of μ in terms of ρ_2 and the sample median.

- Each component has the same mean, which implies the following:

$$\exp(\mu + \sigma_1^2/2) = \exp(\mu + \log(\rho_2) + \sigma_2^2/2)$$

If X_i represents the random variable of component distribution i and X represents the random variable of the mixture distribution, then the following equation holds for the raw moment of any order k :

$$E[X^k] = \sum_{i=1}^K p_i E[X_i^k]$$

This, in conjunction with the assumption on component means, leads to the equations

$$\log(m_1) = \mu + \frac{\sigma_1^2}{2}$$

$$\log(m_1) = \mu + \log(\rho_2) + \frac{\sigma_2^2}{2}$$

where m_1 denotes the first raw moment of the sample. Solving these equations leads to the following values of σ_1 and σ_2 :

$$\sigma_1^2 = 2(\log(m_1) - \mu)$$

$$\sigma_2^2 = 2(\log(m_1) - \mu - \log(\rho_2))$$

Note that σ_1 has a valid value only if $\log(m_1) > \mu$. Among the many possible methods of ensuring this condition, the SLOGNMIX2_PARMINIT subroutine uses the method of doing a linear search over ρ_2 .

Even when the preceding assumptions are not true for a particular problem, they produce reasonable initial values to help guide the nonlinear optimizer to an acceptable optimum if the mixture of two lognormal distributions is indeed a good fit for your input data. This is illustrated by the results of the following steps that fit the SLOGNMIX2 distribution to simulated data, which have different means for the two components (12.18 and 22.76, respectively), and the median of the sample (15.95) is not equal to the average of the medians of the two components (7.39 and 20.09, respectively):

```

/*----- Simulate a lognormal mixture sample -----*/
data testlognmix(keep=y);
  call streaminit(12345);
  Mu1 = 2;
  Sigma1 = 1;
  i = 0;
  do j=1 to 2000;
    y = exp(Mu1) * rand('LOGNORMAL')**Sigma1;
    output;
  end;
  Mu2 = 3;
  Sigma2 = 0.5;
  do j=1 to 3000;
    y = exp(Mu2) * rand('LOGNORMAL')**Sigma2;
    output;
  end;
run;

/*----- Load data into the session -----*/
data mylib.testlognmix;
  set testlognmix;
run;

/*-- Fit and compare scale regression models with 2-component --*/
/*-- lognormal mixture and the standard lognormal distribution --*/
options cmplib=(work.sevexmpl);

proc sevselect data=mylib.testlognmix print=all;
  loss y;
  dist slognmix2 logn;
run;

```

The comparison of the fit statistics of SLOGNMIX2 and LOGN, as shown in [Output 26.5.1](#), confirms that the two-component mixture is certainly a better fit to these data than the single lognormal distribution.

Optimization Summary

Optimization Technique	Trust Region
Iterations	7
Function Calls	18
Log Likelihood	-19171.54807

Parameter Estimates

Parameter	DF	Estimate	Standard Error	t Value	Approx Pr > t
Mu	1	3.00922	0.01554	193.68	<.0001
Sigma1	1	0.49516	0.01451	34.13	<.0001
P2	1	0.40619	0.02600	15.62	<.0001
Rho2	1	0.37212	0.02038	18.26	<.0001
Sigma2	1	1.00019	0.02124	47.09	<.0001

By using the relationship that $\mu_2 = \mu + \log(\rho_2)$, you can see that the final parameter estimates are reasonably close to the true parameter values that were used to simulate the input sample.

Example 26.6: Scale Regression with Rich Regression Effects

This example illustrates the use of regression effects that include CLASS variables and interaction effects.

Consider that you, as an actuary at an automobile insurance company, want to evaluate the effect of certain external factors on the distribution of the severity of the losses that your policyholders incur. Such analysis can help you determine the relative differences in premiums that you should charge to policyholders who have different characteristics. Assume that when you collect and record the information about each claim, you also collect and record some key characteristics of the policyholder and the vehicle that is involved in the claim. This example focuses on the following five factors: type of car, safety rating of the car, gender of the policyholder, education level of the policyholder, and annual household income of the policyholder (which can be thought of as a proxy for the luxury level of the car). Let these regressors be recorded in the variables CarType (1: sedan, 2: sport utility vehicle), CarSafety (scaled to be between 0 and 1, the safest being 1), Gender (1: female, 2: male), Education (1: high school graduate, 2: college graduate, 3: advanced degree holder), and Income (scaled by a factor of 1/100,000), respectively. Let the historical data about the severity of each loss be recorded in the LossAmount variable of the mylib.Losses data table. Let the data table also contain two additional variables, Deductible and Limit, that record the deductible and ground-up loss limit provisions, respectively, of the insurance policy that the policyholder has. The limit on ground-up loss is usually derived from the payment limit that a typical insurance policy states. Deductible serves as the left-truncation variable, and Limit serves as the right-censoring variable.

The following SAS statements simulate an example of the mylib.Losses data table:

```
proc format casfmtlib='myfmtlib';
    value genderFmt 1='Female'
                  2='Male';
run;

data losses(keep=gender carType education carSafety income
               lossAmount deductible limit);
    call streaminit(12345);
    array sx{8} _temporary_;
    array sbeta{9} _TEMPORARY_ (5 0.6 0.4 -0.75 -0.3 0.4 0.7 -0.5 -0.3);

    length carType $8 education $16;
    format gender genderFmt.;

    sigma = 0.5;
    do lossEventId=1 to 6000;
        /* Simulate policyholder and vehicle attributes */
        do i=1 to dim(sx);
            sx(i) = 0;
        end;

        if (rand('UNIFORM') < 0.5) then do;
            gender = 1; * female;
            sx(2) = 1;
        end;
        else do;
            gender = 2; * male;
        end;
    end;
```

```

if (rand('UNIFORM') < 0.7) then do;
    carInt = 1;
    carType = 'Sedan';
end;
else do;
    carInt = 2;
    carType = 'SUV';
    sx(1) = 1;
end;

educationLevel = rand('UNIFORM');
if (educationLevel < 0.5) then do;
    eduInt = 1;
    education = 'High School';
end;
else if (educationLevel < 0.85) then do;
    eduInt = 2;
    education = 'College';
    if (carInt=1) then
        sx(8) = 1;
    else
        sx(6) = 1;
end;
else do;
    eduInt = 3;
    education = 'AdvancedDegree';
    if (carInt=1) then
        sx(7) = 1;
    else
        sx(5) = 1;
end;

carSafety = rand('UNIFORM'); /* scaled to be between 0 & 1 */
sx(3) = carSafety;

income = MAX(15000,int(rand('NORMAL', eduInt*30000, 50000)))/100000;
sx(4) = income;

/* Simulate lognormal severity */
Mu = sbeta(1);
do i=1 to dim(sx);
    Mu = Mu + sx(i) * sbeta(i+1);
end;
lossAmount = exp(Mu) * rand('LOGNORMAL')**Sigma;
loglossAmount = log(lossAmount);

deductible = lossAmount * rand('UNIFORM');
if (rand('UNIFORM') < 0.25) then
    limit = lossAmount;

output;
end;
run;

```

```
data mylib.losses;
  set losses;
run;
```

The variables CarType, Education, and Gender each contain a known, finite set of discrete values. By specifying such variables as classification variables, you can separately identify the effect of each level of the variable on the severity distribution. For example, you might be interested in finding out how the magnitude of loss for a sport utility vehicle (SUV) differs from that for a sedan. This is an example of a main effect. You might also want to evaluate how the distribution of losses that are incurred by a policyholder with a college degree who drives a SUV differs from that of a policyholder with an advanced degree who drives a sedan. This is an example of an interaction effect. You can include various such types of effects in the scale regression model. For more information about the effect types, see the section “[Specification and Parameterization of Model Effects](#)” on page 91 in Chapter 4, “[Shared Concepts](#).”

Analyzing such a rich set of regression effects can help you make more accurate predictions about the losses that a new applicant with certain characteristics might incur when he or she requests insurance for a specific vehicle, which can further help you with ratemaking decisions.

The following PROC SEVSELECT step fits the scale regression model with a lognormal distribution to data in the mylib.Losses data table, and stores the model and parameter estimate information in the mylib.Est data table on the CAS server:

```
/* Fit scale regression model with different types of regression effects */
proc sevselect data=mylib.losses outest=mylib.est print=all;
  loss lossAmount / lt=deductible rc=limit;
  class carType gender education;
  scalemodel carType gender carSafety income education*carType
             income*gender carSafety*income;
  dist logn;
run;
```

The SCALEMODEL statement in the preceding PROC SEVSELECT step includes two main effects (carType and gender), two singleton continuous effects (carSafety and income), one interaction effect (education*carType), one continuous-by-class effect (income*gender), and one polynomial continuous effect (carSafety*income).

When you specify a CLASS statement, it is recommended that you observe the “Class Level Information” table. For this example, the table is shown in [Output 26.6.1](#). Note that if you specify BY-group processing, then the class level information might change from one BY group to the next, potentially resulting in a different parameterization for each BY group.

Output 26.6.1 Class Level Information Table
The SEVSELECT Procedure

Class Level Information		
Class	Levels	Values
carType	2	SUV Sedan
gender	2	Female Male
education	3	AdvancedDegree College High School

The regression modeling results for the lognormal distribution are shown in [Output 26.6.2](#). The “Initial Parameter Values and Bounds” table is important especially because the preceding PROC SEVSELECT

step uses the default GLM parameterization, which is a singular parameterization—that is, it results in some redundant parameters. As shown in the table, the redundant parameters correspond to the last level of each classification variable; this correspondence is a defining characteristic of a GLM parameterization. An alternative would be to use the reference parameterization by specifying the `PARAM=REFERENCE` option in the `CLASS` statement, which does not generate redundant parameters for effects that contain `CLASS` variables and enables you to specify a reference level for each `CLASS` variable.

Output 26.6.2 Initial Values for the Scale Regression Model with Class and Interaction Effects

Iterations	5
Function Calls	14
Log Likelihood	-19716.25785

The “Parameter Estimates” table in [Output 26.6.4](#) shows the distribution parameter estimates and estimates for various regression effects. You can use the estimates for effects that contain `CLASS` variables to infer the relative influence of various `CLASS` variable levels. For example, on average, the magnitude of losses that are incurred by the female drivers is $\exp(0.41714) \approx 1.52$ times greater than that of male drivers, and an SUV driver with an advanced degree incurs a loss that is on average $\exp(0.42454) / \exp(-0.35208) \approx 2.174$

times greater than the loss that a college-educated sedan driver incurs. Neither the continuous-by-class effect `income*gender` nor the polynomial continuous effect `carSafety*income` is significant in this example.

Output 26.6.4 Parameter Estimates for the Scale Regression with Class and Interaction Effects

If you want to update the model when new claims data arrive, then you can potentially speed up the estimation process by specifying the `OUTEST=` data table that is created by the preceding PROC SEVSELECT step as an `INEST=` data table in a new PROC SEVSELECT step. To illustrate, the following PROC SEVSELECT step refits the model on the same input data as the preceding PROC SEVSELECT, but it uses the `mylib.Est` data table that is created by that step as an `INEST=` data table:

```
/* Refit scale regression model on new data */
proc sevselect data=mylib.losses inest=mylib.est print=all;
  loss lossAmount / lt=deductible rc=limit;
  class carType gender education;
  scalemodel carType gender carSafety income education*carType
             income*gender carSafety*income;
  dist logn;
run;
```

Because the `INEST=` data table is used to initialize the distribution and regression parameters, the optimization occurs in very few iterations, as shown in [Output 26.6.5](#).

Output 26.6.5 Optimization Summary for Refitting the Scale Regression Model with the `INEST=` Option

The SEVSELECT Procedure

Logn Distribution

Convergence Status
Convergence criterion (ABSGCONV=0.00001) satisfied.

Output 26.6.5 *continued*

Example 26.7: Scale Regression Model Selection

This example extends “[Example 26.6: Scale Regression with Rich Regression Effects](#)” to illustrate the model selection features of the SEVSELECT procedure. There are two phases of model selection when you fit a scale regression model. First, you want to select an optimal set of regression effects for each distribution’s scale regression model. The SELECTION statement provides several methods to do that. Second, you want to identify the best severity distribution by comparing the final selected scale regression models for each distribution. PROC SEVSELECT displays tables to help you do that.

The following SEVSELECT step uses the same data table as in [Example 26.6](#) to find the best set of scale regression effects for three severity distributions—lognormal (Logn), Burr, and Weibull:

```
proc sevselect data=mylib.losses outest=mylib.est print=all;
  loss lossAmount / lt=deductible rc=limit;
  class carType gender education;
  scalemodel carType gender carSafety income education*carType
             income*gender carSafety*income;
  selection;
  dist logn burr weibull;
  output out=mylib.score copyvars=(carType gender education carSafety income)
         functions=(mean) quantiles=(points=0.5 0.975 names=(median var));
run;
```

The SELECTION statement without any options uses the stepwise selection method by default. PROC SEVSELECT reports the settings of the selection process in the “Selection Information” table, as shown in [Output 26.7.1](#).

Output 26.7.1 Selection Method Settings**The SEVSELECT Procedure****Logn Distribution**

Selection Information	
Selection Method	Stepwise
Select Criterion	SBC
Stop Criterion	SBC
Effect Hierarchy Enforced	None
Stop Horizon	3

For each severity distribution, PROC SEVSELECT reports the summary of the selection process, as shown in [Output 26.7.2](#) for the lognormal distribution. The “Selection Summary” table shows the order in which

regression effects enter or leave the model. In this case, no effect leaves the model after entering the model. In the first step, PROC SEVSELECT fits seven models, each with an intercept and one of the seven eligible effects in the SCALEMODEL statement. The model that contains the intercept and carType*education effect has the lowest value of the Schwarz Bayesian criterion (SBC) statistic in the first step, and hence it enters the model. In the second step, PROC SEVSELECT compares the model that does not contain the existing effect, carType*education, with models that contain that effect and one of the remaining six effects. The model that contains the intercept, carType*education, and carSafety effects is the best in the second step according to the SBC statistic. The process of removing an effect from the model or adding an effect that is not in the model continues until the stop criterion does not improve or the stop horizon condition is met. As the results in [Output 26.7.2](#) show, the optimal value of the SBC criterion is achieved in the fourth step. The final scale regression model for the lognormal distribution contains the following effects: intercept, gender, carSafety, carType*education, and income*gender.

Output 26.7.2 Stepwise Selection Summary for the Lognormal Distribution

The SEVSELECT Procedure

Logn Distribution Selection Details

Selection Summary			
Step	Effect Entered	Number Effects In	SBC
0	Intercept	1	35975.2456
1	carType*education	2	34121.0008
2	carSafety	3	33709.8419
3	income*gender	4	33298.5871
4	gender	5	33159.7903*
* Optimal Value Of Criterion			

Stepwise selection stopped because adding or removing an effect does not improve the SBC criterion.

The model at step 4 is selected.

Selected Effects: Intercept gender carSafety carType*education income*gender

The selection summary information for the Weibull distribution is shown in [Output 26.7.3](#). It shows that the best model in the sixth step is obtained by removing the carSafety*income effect, which was added in the second step. The model in the sixth step also has the lowest value of the SBC criterion; hence, it is the best model and contains the following effects: intercept, gender, carSafety, income, and carType*education.

Output 26.7.3 Stepwise Selection Summary for the Weibull Distribution**The SEVSELECT Procedure****Weibull Distribution
Selection Details**

Selection Summary			
Step	Effect Entered	Effect Removed	Number Effects In SBC
0	Intercept		1 36381.5042
1	carType*education		2 34477.5474
2	carSafety*income		3 34092.5186
3	gender		4 33684.7598
4	carSafety		5 33573.1854
5	income		6 33517.6460
6		carSafety*income	5 33509.5021*
* Optimal Value Of Criterion			

Stepwise selection stopped because adding or removing an effect does not improve the SBC criterion.

The model at step 6 is selected.

Selected Effects: Intercept gender carSafety income carType*education

PROC SEVSELECT reports the optimization summary, fit statistics, and parameter estimates for the final selected model of each severity distribution. The results for the lognormal distribution are shown in [Output 26.7.4](#). The “Parameter Estimates” table shows that all regression parameters in the final model are statistically significant. Comparison of these parameter estimates with those in [Output 26.6.4](#), which were obtained without using the SELECTION statement, shows that the statistically insignificant effect, carSafety*income, is not present in the final selected model. The comparison also shows that the stepwise selection process prefers income*gender effect over the income effect and, because of the exclusion of the income effect, the income*gender effect has become statistically significant.

Output 26.7.4 Selected Scale Regression Model for the Lognormal Distribution

After the effect selection process chooses the best scale regression model for each severity distribution, the next phase of model selection is to compare the final models across all severity distributions and identify the best severity distribution. You can do that by using the “All Fit Statistics” table, which helps you compare the final selected models according to all the fit statistics. For this example, [Output 26.7.5](#) compares the final models of the three severity distributions—lognormal, Burr, and Weibull.

Output 26.7.5 Comparison of the Selected Scale Regression Models for Different Severity Distributions

All Fit Statistics							
Distribution	-2 Log Likelihood	AIC	AICC	SBC	KS	AD	CvM
Logn	33066*	33088*	33088*	33160*	11.00535	649.55145	54.77368
Burr	33100	33124	33125	33203	11.28423	519.64162*	55.03613
Weibull	33424	33444	33444	33510	10.39183*	756.77108	36.41622*

Asterisk (*) denotes the best model in the column.

The lognormal distribution's final selected model is the best according to all the likelihood-based statistics, the Burr distribution's final selected model is the best according to the Anderson-Darling (AD) statistic, and the Weibull distribution's final selected model is the best according to the Kolmogorov-Smirnov (KS) and Cramér-von Mises (CvM) statistics. You can choose the fit statistic that is most suitable for your application and use it to identify the best severity distribution. Alternatively, if your goal is to estimate some loss distribution statistic, such as the value-at-risk (VaR), for a particular scenario, then instead of choosing

one severity distribution, you might want to compute and compare the desired statistic for the final scale regression model of each severity distribution that wins according to at least one fit statistic. The **OUTPUT** statement is useful for such evaluation, because it helps you *score* each observation of the input data table that you specify in the **DATA=** option. In the context of PROC SEVSELECT, scoring an observation is equivalent to computing particular statistics for the severity distribution of the losses. The previous PROC SEVSELECT step specifies the following OUTPUT statement to write the scores for each observation to the mylib.Score output table:

```
output out=mylib.score copyvars=(carType gender education carSafety income)
      functions=(mean) quantiles=(cdf=0.5 0.975 names=(median var));
```

When you specify the scale regression model, the scale parameter of each severity distribution depends on the values of the regression effects in the final selected model of that distribution. For each observation in the input table, PROC SEVSELECT computes the estimate of the scale parameter and uses it to evaluate the scoring and quantile functions that you specify in the **FUNCTIONS=** and **QUANTILES=** options, respectively. The OUTPUT statement of this example specifies that three statistics be computed for the final model of each severity distribution: the *mean* scoring function and two quantile functions, $Q_{\text{dist}}(0.5, \hat{\Theta})$ and $Q_{\text{dist}}(0.975, \hat{\Theta})$, where $Q_{\text{dist}}(p, \Theta)$ denotes the value of the quantile function for a distribution *dist* that is evaluated at the CDF value of p for the estimated distribution parameters $\hat{\Theta}$. The variable that contains the estimate of the mean function is named *mean*. The variables that contain the quantile function estimate for $p=0.5$ and $p=0.975$ are named *median* and *var*, respectively; *var* denotes the value-at-risk (VaR). In order to compute a function F in the **FUNCTIONS=** option, for each severity distribution *dist*, the *dist_F* function must be available in the function library search path that you specify in the **CMPLIB=** system option. Also, in order to compute the quantile functions faster, it is recommended that the *dist_QUANTILE* function be available in the **CMPLIB=** search path. If PROC SEVSELECT does not find a quantile function's definition, it computes the quantile function by numerically inverting the cumulative distribution function (CDF). For each predefined distribution, such as the lognormal, Burr, and Weibull distributions of this example, the *dist_MEAN* and *dist_QUANTILE* functions are already defined and available to you in the function library, SasHELP.SvrtDist, that PROC SEVSELECT includes by default.

[Output 26.7.6](#), [Output 26.7.7](#), and [Output 26.7.8](#) compare the estimates of the mean, median, and value-at-risk (*var*), respectively, of the three severity distributions for the first 10 observations that are fetched from the mylib.Score table. **NOTE:** The estimates are all available in the same table but are shown here separately for better comparison among different severity distributions. These results illustrate the following:

- The **OUT=** data table contains the variables that you specify in the **COPYVARS=** option. This helps you associate the scoring statistics with the values of the regression effects that decide the severity distribution's scale parameter.
- The estimates of a particular statistic vary by observation, because the scale parameter value depends on the values of the regression effects. You can interpret the estimate of the mean as the average loss that a particular policyholder will incur if he or she has the characteristics that are quantified in the values of the regression effects. For example, the fifth observation in [Output 26.7.6](#) shows that a male policyholder with a college degree who earns 0.70732 on a normalized scale and drives a sport utility vehicle (SUV) that has a normalized car safety rating of 0.8446 is expected to incur an average loss of 298 units if you use the lognormal distribution's selected scale regression model for estimation, or an average loss of 283 units if you use the Weibull distribution's selected scale regression model for estimation.

Output 26.7.6 Estimates of the Mean for Final Models of All Severity Distributions

Obs	gender	education	income	carType	carSafety	Logn_MEAN	Burr_MEAN	Weibull_MEAN
1	Male	College	1.00896	SUV	0.85747	264.595	279.531	249.048
2	Female	College	0.52584	SUV	0.84267	495.276	514.365	481.811
3	Female	High School	0.15000	SUV	0.84062	264.218	270.823	268.200
4	Male	AdvancedDegree	0.51942	Sedan	0.01410	90.959	93.358	88.674
5	Female	AdvancedDegree	1.27245	SUV	0.84238	262.683	272.801	241.754
6	Female	College	1.12252	Sedan	0.81153	72.069	74.220	69.784
7	Female	College	0.38431	Sedan	0.36374	135.151	137.595	133.730
8	Female	High School	0.49503	SUV	0.69762	264.384	272.216	263.578
9	Female	College	0.98769	SUV	0.06408	809.817	844.885	758.977
10	Male	College	0.67508	Sedan	0.14417	94.361	97.079	90.119

- The estimates of the median, which is a robust estimate of the central tendency, vary less across different severity distributions. So you might want to use the median loss to predict the average loss that a policyholder will incur.

Output 26.7.7 Estimates of the Median for Final Models of All Severity Distributions

Obs	gender	education	income	carType	carSafety	Logn_MEDIAN	Burr_MEDIAN	Weibull_MEDIAN
1	Male	College	1.00896	SUV	0.85747	225.018	228.080	227.398
2	Female	College	0.52584	SUV	0.84267	421.196	419.690	439.925
3	Female	High School	0.15000	SUV	0.84062	224.698	220.975	244.884
4	Male	AdvancedDegree	0.51942	Sedan	0.01410	77.354	76.174	80.966
5	Female	AdvancedDegree	1.27245	SUV	0.84238	223.392	222.589	220.737
6	Female	College	1.12252	Sedan	0.81153	61.289	60.559	63.718
7	Female	College	0.38431	Sedan	0.36374	114.936	112.269	122.104
8	Female	High School	0.49503	SUV	0.69762	224.839	222.112	240.665
9	Female	College	0.98769	SUV	0.06408	688.689	689.375	692.997
10	Male	College	0.67508	Sedan	0.14417	80.247	79.211	82.285

- The estimates of the value-at-risk (var), which depend on the heaviness of the tail of the distribution, vary significantly across severity distributions. For this example, the fitted Burr and Weibull distributions have the heaviest and lightest tails, respectively, among the three severity distributions. The VaR statistic is typically used to assess the worst-case loss that a policyholder might incur. You can interpret it as follows for the ninth observation in [Output 26.7.8](#): for a female policyholder with an advanced degree who earns 0.60157 and drives a sedan with a car safety rating of 0.69361, the probability that she will incur a loss greater than 228 units is 2.5% if you use the Burr distribution's scale regression model for estimation. You can add a CDF value of 0.995 to the CDF= suboption of the QUANTILES= option to get another value-at-risk estimate, which estimates a more extreme loss that a policyholder might incur with a probability of only 0.5%, but you might need to be prepared to cover that loss depending on the policy provisions.

Output 26.7.8 Estimates of the Value-at-Risk (VaR) for Final Models of All Severity Distributions

Obs	gender	education	income	carType	carSafety	Logn_VAR	Burr_VAR	Weibull_VAR
1	Male	College	1.00896	SUV	0.85747	686.68	801.10	585.53
2	Female	College	0.52584	SUV	0.84267	1285.35	1474.10	1132.77
3	Female	High School	0.15000	SUV	0.84062	685.71	776.14	630.55
4	Male	AdvancedDegree	0.51942	Sedan	0.01410	236.06	267.55	208.48
5	Female	AdvancedDegree	1.27245	SUV	0.84238	681.72	781.81	568.38
6	Female	College	1.12252	Sedan	0.81153	187.03	212.71	164.07
7	Female	College	0.38431	Sedan	0.36374	350.75	394.33	314.41
8	Female	High School	0.49503	SUV	0.69762	686.14	780.14	619.69

10	Male	College	0.67508	Sedan	0.14417	244.89	278.22	211.88

PROC SEVSELECT always includes the intercept in all scale regression models, so the selection process never attempts to fit a model without an intercept. In addition to the intercept, you can force other regression effects to be included in each selected model by specifying the **INCLUDE=** option in the **SCALEMODEL** statement. The following SEVSELECT step illustrates this by forcing the carSafety effect into every selected model:

```
proc sevselect data=mylib.losses outest=mylib.est print=all;
  loss lossAmount / lt=deductible rc=limit;
  class carType gender education;
  scalemodel carType gender carType*gender carSafety income education
             income*gender carSafety*income / include=(carSafety);
  selection method=forward(stop=aicc) hierarchy=single stophorizon=2 details=all;
  dist logn weibull;
run;
```

The various options in the SELECTION statement do the following:

- The **METHOD=FORWARD** option specifies that the forward elimination method of selection be used.
- The **HIERARCHY=SINGLE** option instructs PROC SEVSELECT not to add an interaction effect to the model until all the main effects in the interaction are already in the model.
- The **STOPHORIZON=2** option specifies that the **STOP=** criterion, which is the corrected Akaike's information criterion (AICC), must worsen for two steps in order for a local extremum to be detected.
- The **DETAILS=ALL** option displays details of all the steps of the selection process.

The "Selection Information" table in [Output 26.7.9](#) summarizes the selection settings.

Output 26.7.9 Selection Method Settings for Forward Selection**The SEVSELECT Procedure****Logn Distribution**

Selection Information	
Selection Method	Forward
Select Criterion	SBC
Stop Criterion	AICC
Effect Hierarchy Enforced	Single
Stop Horizon	2

The selection summary for the lognormal distribution, shown in [Output 26.7.10](#), illustrates the following:

- The model at step 0 includes both the intercept and carSafety effects. The carSafety effect always stays in the model.
- Because of the HIERARCHY=SINGLE option, the carType*gender interaction effect does not enter the model until the model contains both main effects (carType and gender) that constitute it. Similarly, the carSafety*income interaction effect between two continuous effects also does not enter the model before both carSafety and income are in the model.
- The stop criterion keeps improving for several steps, so even the smaller stop horizon of 2 does not affect the selection process for the lognormal distribution. The selection stops when all effects are in the model.
- The final model is chosen by the optimal value of the STOP= criterion, because the CHOOSE= option is not specified. For the lognormal distribution, it is the model at step 6, which contains all regression effects except the income*gender effect. If you had specified the CHOOSE=SBC option, then the final model would be the model in step 4 that excludes carType*gender, carSafety*income, and income*gender effects, because it has the smallest value for the SBC criterion.

Output 26.7.10 Forward Selection Summary for the Lognormal Distribution**The SEVSELECT Procedure****Logn Distribution
Selection Details**

Selection Summary				
Step	Effect Entered	Number Effects In	AICC	SBC
0	Intercept	1		
	carSafety	2	35766.6044	35786.1512

5	carType*gender	7	33856.5340*	33915.1526
6	carSafety*income	8	33857.1143	33922.2421
* Optimal Value Of Criterion				

Selection stopped at a local minimum of the AICC criterion.

Output 26.7.11 *continued*

The model at step 5 is selected.

Selected Effects: Intercept carType gender carType*gender carSafety income education

As the results in [Output 26.7.10](#) and [Output 26.7.11](#) show, although the SELECT= criterion is reported in the “Selection Summary” table, it does not decide the final selected model. Instead, the SELECT= criterion is used to choose the best effect to add or remove in each step. To illustrate that, [Output 26.7.12](#) shows the details of step 1 for the Weibull distribution. PROC SEVSELECT produces the step details because of the DETAILS=ALL option in the SELECTION statement. Step 1 is the step after the initial step (step 0), which fits the model with the intercept and carSafety effect that the INCLUDE= option forces in. The “Entry Candidates” table of step 1 shows the candidates that PROC SEVSELECT evaluates for entering the model. For each candidate, it shows the value of the SELECT= criterion, which is the SBC statistic, of the model that includes that candidate. The interaction effects carType*gender and carSafety*income are not present in this list of candidates, because of the constraint that the HIERARCHY=SINGLE option imposes. The model that includes the carType effect has the smallest SBC statistic, so PROC SEVSELECT selects it in step 1. The “Optimization Summary” table shows that PROC SEVSELECT uses the trust region optimization method, which is the default optimization method for fitting a model in each step. You can use the [SELECTNLOTECH=](#) option in the PROC SEVSELECT statement to specify a different optimization method to use during each step of the selection. The “Parameter Estimates” table shows that step 1’s model includes the best entry candidate, carType, and the carSafety effect, which entered the model in step 0. The estimate of the intercept effect is reflected in the estimate of the scale parameter Theta, as described in the section “[Reporting Estimates of Regression Parameters](#)” on page 1797.

The fit summary of the final model for the Weibull distribution is shown in [Output 26.7.13](#). It shows that PROC SEVSELECT uses the trust region optimization method to estimate the parameters of the final model. The “Parameter Estimates” table shows that some regression parameters are not significant at the usual 95% confidence level. None of the selection criteria that PROC SEVSELECT supports depend directly on the p -values of regression effects. So a statistically insignificant effect might be included in the final model, as this example illustrates. If you do not want such effects in the final model, you can modify the selection method settings to search for a different model that contains all statistically significant effects. Alternatively, you can use your domain knowledge to decide which effects you want to retain from the selected model and then refit the model by appropriately modifying the SCALEMODEL statement.

Example 26.8: Estimating Parameters Using the Cramér–von Mises Estimator

The SEVSELECT procedure enables you to estimate model parameters by minimizing your own objective function. This example illustrates how you can use PROC SEVSELECT to implement the Cramér–von Mises estimator. Let $F(y_i; \Theta)$ denote the estimate of CDF at y_i for a distribution with parameters Θ , and let $F_n(y_i)$ denote the empirical estimate of CDF (EDF) at y_i that is computed from a sample y_i , $1 \leq i \leq N$. Then, the Cramér–von Mises estimator of the parameters is defined as

$$\hat{\Theta} = \arg \min_{\Theta} \sum_{i=1}^N (F(y_i; \Theta) - F_n(y_i))^2$$

This estimator belongs to the class of minimum distance estimators. It attempts to estimate the parameters such that the squared distance between the CDF and EDF estimates is minimized.

The following PROC SEVSELECT step uses the Cramér–von Mises estimator to fit four candidate distribution models, including the LOGNGPD mixed-tail distribution model that is defined in “[Example 26.2: Defining a Model for Mixed-Tail Distributions](#)” on page 1856. The input sample is the same one that is used in that example.

```
/*--- Set the search path for functions defined with PROC FCMP ---*/
options cmplib=(work.sevexmpl);

/*----- Fit LOGNGPD model with PROC SEVSELECT by using -----
----- the Cramer-von Mises minimum distance estimator -----*/
proc sevselect data=mylib.testmixdist objective=cvmobj print=all;
  loss y;
  dist logngpd burr logn gpd;

  * Cramer-von Mises estimator (minimizes the distance *
  * between parametric and nonparametric estimates)   *;
  cvmobj = (_cdf_(y) - _edf_(y))**2;
run;
```

The OBJECTIVE= option in the PROC SEVSELECT statement specifies that the objective function cvmobj should be minimized. The programming statements compute the contribution of each observation in the input data table to the objective function cvmobj. The use of the keyword functions _CDF_ and _EDF_ makes the program applicable to all the distributions. When PROC SEVSELECT runs on a CAS server that has more than one worker node, each worker node evaluates the _EDF_ function by using a local sample of the input data.

Some of the key results that PROC SEVSELECT produces are shown in [Output 26.8.1](#). The “Model Selection” table indicates that all models converged. When you specify a custom objective function, the default selection criterion is the value of the custom objective function. The “All Fit Statistics” table indicates that LOGNGPD is the best distribution according to all the statistics of fit. Comparing the fit statistics of [Output 26.8.1](#) with those of [Output 26.2.1](#) indicates that the use of the Cramér–von Mises estimator has resulted in smaller values for all the EDF-based statistics of fit for all the models, which is expected from a minimum distance estimator.

Output 26.8.1 Summary of Cramér–von Mises Estimation**The SEVSELECT Procedure**

Asterisk (*) denotes the best model in the column.

Example 26.9: Predicting Mean and Value-at-Risk by Using Scoring Functions

If you work in the risk management department of an insurance company or a bank, then one of your primary applications of severity loss distribution models is to predict the value-at-risk (VaR) so that there is a very low probability of experiencing a loss value greater than the VaR. The probability level at which VaR is measured is prescribed by industry regulations such as Basel III and Solvency II. The VaR level is usually specified in terms of $(1 - \alpha)$, where $\alpha \in (0, 1)$ is the probability that a loss value exceeds the VaR. Typical VaR levels are 0.95, 0.975, and 0.995.

In addition to predicting the VaR, which is regarded as an estimate of the worst-case loss, businesses are often interested in predicting the average loss by estimating either the mean or median of the distribution.

The estimation of the mean and VaR combined with the scale regression model is a very potent tool for analyzing worst-case and average losses for various scenarios. For example, if the regressors that are used in a scale regression model represent some key macroeconomic and operational indicators, which are widely referred to as key risk indicators (KRIs), then you can analyze the VaR and mean loss estimates over various values for the KRIs to get a more comprehensive picture of the risk profile of your organization across various market and internal conditions.

This example illustrates the use of scoring functions to simplify the process of predicting the mean and VaR of scale regression models.

To compute the mean, you need to ensure that the function to compute the mean of a distribution is available in the function library. If you define and fit your own distribution and you want to compute its mean, then you need to use the FCMP procedure to define that function, and you need to use the CMPLIB= system option to specify the location of that function. For your convenience, the *dist_MEAN* function (which computes the mean of the *dist* distribution) is already defined in the library Sashelp.Svrtldist for each of the 10 predefined distributions. The following statements display the definitions of MEAN functions of all distributions. Note that the MEAN functions of the Burr, Pareto, and generalized Pareto distributions check the existence of the first moment for specified parameter values.

```

/*----- Definitions distribution functions that compute the mean -----*/
proc fcmp library=sashelp.svrtldist outlib=work.means.scalemod;
  function BURR_MEAN(x, Theta, Alpha, Gamma);
    if not(Alpha * Gamma > 1) then
      return (.); /* first moment does not exist */
    return (Theta*gamma(1 + 1/Gamma)*gamma(Alpha - 1/Gamma)/gamma(Alpha));
  endsub;
  function EXP_MEAN(x, Theta);
    return (Theta);
  endsub;
  function GAMMA_MEAN(x, Theta, Alpha);
    return (Theta*Alpha);
  endsub;
  function GPD_MEAN(x, Theta, Xi);
    if not(Xi < 1) then
      return (.); /* first moment does not exist */
    return (Theta/(1 - Xi));
  endsub;
  function IGAUSS_MEAN(x, Theta, Alpha);
    return (Theta);
  endsub;
  function LOGN_MEAN(x, Mu, Sigma);
    return (exp(Mu + Sigma*Sigma/2.0));
  endsub;
  function PARETO_MEAN(x, Theta, Alpha);
    if not(Alpha > 1) then
      return (.); /* first moment does not exist */
    return (Theta/(Alpha - 1));
  endsub;
  function STWEEDIE_MEAN(x, Theta, Lambda, P);
    return (Theta* Lambda * (2 - P) / (P - 1));
  endsub;
  function TWEEDIE_MEAN(x, P, Mu, Phi);
    return (Mu);
  endsub;
  function WEIBULL_MEAN(x, Theta, Tau);
    return (Theta*gamma(1 + 1/Tau));
  endsub;
quit;

```

For your further convenience, the *dist*_QUANTILE function (which computes the quantile of the *dist* distribution) is also defined in the Sashelp.Svrtldist library for each of the 10 predefined distributions. Because the MEAN and QUANTILE functions satisfy the definition of a distribution function as described in the section “[Formal Description](#)” on page 1830, PROC SEVSELECT can create scoring functions for them.

To illustrate the creation of scoring functions, let the following SAS statements simulate the input data set Work.Test_sev9 and load it into your session that is associated with the mylib libref. The DATA step assumes that your libref is named mylib, but you can substitute any appropriately defined libref.

```

/*----- Simulate a lognormal sample -----*/
data testSevscore(keep=y x1-x5
  label='A Lognormal Sample Affected by Regressors');
  array x{*} x1-x5;

```

```

array b{6} _TEMPORARY_ (1 0.75 3 -1 0.25 5);
call streaminit(45678);
label y='Response Influenced by Regressors';
Sigma = 0.25;
do n = 1 to 500;
    Mu = b(1); /* log of base value of scale */
    do i = 1 to dim(x);
        x(i) = rand('NORMAL');
        Mu = Mu + b(i+1) * x(i);
    end;
    y = exp(Mu) * rand('LOGNORMAL')**Sigma;
    output;
end;
run;

/*----- Load data into your session -----*/
data mylib.testSevscore;
    set testSevscore;
run;

```

The following PROC SEVSELECT step fits all regression-friendly predefined distributions to the data in the data table mylib.TestSevscore and generates the scoring functions for the MEAN, QUANTILE, and other distribution functions:

```

/*----- Fit all distributions and generate scoring functions -----*/
proc sevselect data=mylib.testSevscore outest=mylib.est print=all;
    loss y;
    scalemodel x1-x5;
    dist _predefined_ stweedie;
    nloptions tech=quanew;
    outscorelib outlib=scorefuncs commonpackage;
run;

```

The OUTLIB= option in the OUTSCORELIB statement requests that the scoring functions be written to the library Work.Scorefuncs, and the COMMONPACKAGE option in the OUTSCORELIB statement requests that all the functions be written to the same package. Upon completion, PROC SEVSELECT sets the CMPLIB= system option to the following value:

```
(sashelp.svrtldist work.scorefuncs)
```

PROC SEVSELECT detects all the distribution functions that are available in the current CMPLIB= search path (which always includes the Sashelp.Svrtldist library) for the distributions that you specify in the DIST statement, and it creates the corresponding scoring functions. You can define any distribution function that has the desired signature to compute an estimate of your choice, include its library in the CMPLIB= system option, and then specify the OUTSCORELIB statement to generate the corresponding scoring functions. Specifying the COMMONPACKAGE option in the OUTSCORELIB statement causes the name of the scoring function to take the form SEV_*function-suffix*_dist. If you do not specify the COMMONPACKAGE option, PROC SEVSELECT creates a scoring function named SEV_*function-suffix* in a package named *dist*. You can invoke functions from a specific package only inside the FCMP procedure. If you want to invoke the scoring functions from a DATA step, then it is recommended that you specify the COMMONPACKAGE option when you specify multiple distributions in the DIST statement.

You can get an idea of the structure of the scoring functions that PROC SEVSELECT defines on your behalf by examining the following PROC FCMP code that the preceding PROC SEVSELECT step creates and

submits to define the scoring functions SEV_MEAN_LOGN and SEV_QUANTILE_IGAUSS:

```
proc fcmp library=(sashelp.svrtdist) outlib=work.scorefuncs.sevfit;
  function SEV_MEAN_LOGN(y, x{*});
    _logscale_=0;
    _logscale_ = _logscale_ + ( 7.64722238665070E-01 * x{1});
    _logscale_ = _logscale_ + ( 2.99209532114045E+00 * x{2});
    _logscale_ = _logscale_ + (-1.00788910539257E+00 * x{3});
    _logscale_ = _logscale_ + ( 2.58883411376730E-01 * x{4});
    _logscale_ = _logscale_ + ( 5.00927459151049E+00 * x{5});
    _logscale_ = _logscale_ + ( 9.95078801087240E-01);
    return (LOGN_MEAN(y, _logscale_, 2.31592996273020E-01));
  endsub;

  function SEV_QUANTILE_IGAUSS(y, x{*});
    _logscale_=0;
    _logscale_ = _logscale_ + ( 7.64581739155730E-01 * x{1});
    _logscale_ = _logscale_ + ( 2.99159055149487E+00 * x{2});
    _logscale_ = _logscale_ + (-1.00793496650702E+00 * x{3});
    _logscale_ = _logscale_ + ( 2.58870461417330E-01 * x{4});
    _logscale_ = _logscale_ + ( 5.00996884583256E+00 * x{5});
    _scale_ = 2.77854870199624E+00 * exp(_logscale_);
    return (IGAUSS_QUANTILE(y, _scale_, 1.815112308761660E+01));
  endsub;
quit;
```

PROC SEVSELECT creates and submits similar code to define several other scoring functions, such as SEV_PDF_dist and SEV_SDF_dist, for each distribution *dist* that you specify in the DIST statement.

To illustrate the use of scoring functions, let the following DATA step simulate the scoring data set Work.RegInput, where the values of regressors in each observation define one scenario:

```
/*--- Simulate scoring data ---*/
data reginput(keep=x1-x5);
  array x{*} x1-x5;
  call streaminit(9041);
  do n=1 to 10;
    do i = 1 to dim(x);
      x(i) = rand('NORMAL');
    end;
    output;
  end;
run;
```

The “All Fit Statistics” table in [Output 26.9.1](#) shows that the lognormal distribution’s scale model is the best and the inverse Gaussian’s scale model is a close second according to the likelihood-based statistics. So the following DATA step uses the scoring functions to compute the mean and VaR (at the 97.5% level) of the scale models of lognormal and inverse Gaussian distributions for each of the scenarios in the Work.RegInput data set:

```
/*--- Set VaR level ---*/
%let varLevel=0.975;

/*--- Compute scores (mean and var) for the ---
```

```

--- scoring data by using the scoring functions ---*/
data scores;
  array x{*} x1-x5;
  set reginput;

  igauss_mean = sev_mean_igauss(., x);
  igauss_var  = sev_quantile_igauss(&varLevel, x);
  logn_mean   = sev_mean_logn(., x);
  logn_var    = sev_quantile_logn(&varLevel, x);
run;

```

Output 26.9.1 Comparison of Fitted Scale Models for Mean and VaR Illustration**The SEVSELECT Procedure**

Asterisk (*) denotes the best model in the column.

The following DATA step accomplishes the same task by reading the parameter estimates in the OUTEST= data table that is created by the same PROC SEVSELECT step that created the scoring functions:

```

/*--- Compute scores (mean and var) for the ---
--- scoring data by using the OUTEST= data set ---*/
data scoresWithoutest(keep=x1-x5 igauss_mean igauss_var logn_mean logn_var);
  array _x{*} x1-x5;
  array _xparmIgauss_{5} _temporary_;
  array _xparmLogn_{5} _temporary_;

  retain _Theta0_ Alpha0;
  retain _Mu0_ Sigma0;
  *--- read parameter estimates for igauss and logn models ---*;
  if (_n_ = 1) then do;
    set mylib.est(where=(upcase(_MODEL_)='IGAUSS' and _TYPE_='EST'));
    _Theta0_ = Theta; Alpha0 = Alpha;
    do _i_=1 to dim(_x_);
      if (_x_(_i_) = .R) then _xparmIgauss_(_i_) = 0;
      else _xparmIgauss_(_i_) = _x_(_i_);
    end;

    set mylib.est(where=(upcase(_MODEL_)='LOGN' and _TYPE_='EST'));
    _Mu0_ = Mu; Sigma0 = Sigma;
    do _i_=1 to dim(_x_);

```

```

        if (_x(_i_) = .R) then _xparmLogn(_i_) = 0;
        else _xparmLogn(_i_) = _x(_i_);
    end;
end;

set reginput;

*--- predict mean and VaR for inverse Gaussian ---*;
* first compute X'*beta for inverse Gaussian *;
_xbeta_ = 0.0;
do _i_ = 1 to dim(_x_);
    _xbeta_ = _xbeta_ + _xparmIgauss(_i_) * _x(_i_);
end;
* now compute scale for inverse Gaussian *;
_SCALE_ = _Theta0_ * exp(_xbeta_);
igauss_mean = igauss_mean(., _SCALE_, Alpha0);
igauss_var = igauss_quantile(&varLevel, _SCALE_, Alpha0);

*--- predict mean and VaR for lognormal ---*;
* first compute X'*beta for lognormal*;
_xbeta_ = 0.0;
do _i_ = 1 to dim(_x_);
    _xbeta_ = _xbeta_ + _xparmLogn(_i_) * _x(_i_);
end;
* now compute Mu=log(scale) for lognormal *;
_MU_ = _Mu0_ + _xbeta_;
logn_mean = logn_mean(., _MU_, Sigma0);
logn_var = logn_quantile(&varLevel, _MU_, Sigma0);
run;

```

The “Values Comparison Summary” table in [Output 26.9.2](#) shows that the difference between the estimates that are produced by both methods is within the acceptable machine precision. However, if you compare the DATA step complexity of the methods, you clearly see that the method that uses the scoring functions is much easier because it saves a lot of programming effort. Further, new distribution functions are automatically discovered and converted to scoring functions by PROC SEVSELECT. That enables you to focus your efforts on writing the distribution function that computes your desired score, which needs to be done only once. Then, you can create and use the corresponding scoring functions multiple times with much less effort.

Output 26.9.2 Comparison of Mean and VaR Estimates of Two Scoring Methods

The COMPARE Procedure
 Comparison of WORK.SCORESWITHOUTEST with WORK.SCORES
 (Method=RELATIVE(0.0222), Criterion=1.0E-12)

NOTE: All values compared are within the equality criterion used. However, 40 of the values compared are not exactly equal.

Overview: SMC Procedure

The sequential Monte Carlo (SMC) method has been widely applied in economics, finance, science, and engineering. It provides solutions to the inference and parameter estimation problems of the nonlinear/non-Gaussian state space models. For more information about the SMC method, see Doucet and Johansen (2011); Doucet, Godsill, and Andrieu (2000); Cappé, Godsill, and Moulines (2007). Here are a few examples in different fields:

- In risk management, asset pricing, and portfolio optimization, volatility forecasting is critical. The stochastic volatility model, as a special case of nonlinear non-Gaussian state space models, is one of the most popular tools for volatility forecasting. However, there was no closed-form solution for such a sophisticated model until the simulation-based solution, especially the SMC method, became available.
- In epidemiology, the SMC method can be used to estimate the stochastic susceptible-infected-recovered (SSIR) model, one of the most popular and accurate models used in epidemiology modeling.
- In engineering, the SMC method has been applied in navigation and object tracking.
- In Internet of Things (IoT), the SMC method can be used to estimate the states of the machines based on the observable information.
- In bioinformatics, the SMC method is used for haplotype inference.
- In marketing, the SMC method is used to model the effect of advertising on demand.

The SMC procedure supports the following:

- three types of SMC filtering algorithms: the sequential importance resampling algorithm, the bootstrap filter algorithm, and the auxiliary particle filter algorithm
- two types of SMC smoothing algorithms: the fixed-lag smoothing algorithm and the fixed-interval smoothing algorithm

- particle Markov chain Monte Carlo parameter estimation method
- proposal distribution for the initial state and transition distributions
- simulation and summary estimates of output of the filtering, smoothing, evaluating, and forecasting estimates
- output of the log likelihood up to any observation
- saving the model information and using it later to score other new data

PROC SMC requires SAS Cloud Analytic Services (CAS) in order to run, and it does the following:

- enables you to run on a cluster of machines that distribute the data and the computations
- exploits all the available cores and concurrent threads

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the `mylib` CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “[Introduction to Shared Concepts](#)” on page 54 in Chapter 4, “[Shared Concepts](#).”

Getting Started: SMC Procedure

This section provides an example that the SMC procedure supports.

Autoregressive Stochastic Volatility Model

This example illustrates how to define an autoregressive stochastic volatility model in the SMC procedure and then estimate the parameters by using the particle Markov chain Monte Carlo (PMCMC) method.

The stochastic volatility model assumes that the volatility is a latent variable with unexpected innovation terms (Shephard 2005). The discrete-time autoregressive stochastic volatility (ARSV) model proposed by Taylor (1982) is one of the simplest stochastic volatility models. The ARSV model, in which the log variance follows a linear Gaussian process, is given as

$$y_t = \beta \exp\left(\frac{x_t}{2}\right) \xi_t, \quad \xi_t \stackrel{\text{iid}}{\sim} N(0, 1)$$

$$x_t = \phi x_{t-1} + \gamma \eta_t, \quad \eta_t \stackrel{\text{iid}}{\sim} N(0, 1), \quad \xi_t \perp \eta_t$$

where $\{y_t\}_{t \geq 1}$ denotes the log daily return series and $\{\beta \exp(\frac{x_t}{2})\}_{t \geq 1}$ denotes the daily volatility series. Suppose that the true parameter values are $\phi = 0.9$, $\gamma = 0.4$, $\beta = 1$, and $x_0 = 0.45$. In order to bring these initial settings in line with the real data, here the $\{y_t\}_{t \geq 1}$ denotes the 100-times-magnified log daily return series; that is, $y_t = 100 \ln \frac{S_t}{S_{t-1}}$, where S_t is the asset price at day t ($t \geq 1$).

The following statements simulate 280 observations by using the given stochastic volatility model:

```
/*--- parameter values ---*/
%let phi = 0.9;
%let gamma = 0.4;
%let beta = 1;

/*--- Simulate a sample for the stochastic volatility model ---*/
data asv_all;
  xlag = 0.45;
  do t = 1 to 280;
    eps = normal(1);
    x = &phi*xlag + &gamma*eps;
    eta = normal(1);
    y = &beta*exp(x/2)*eta;
    output;
    xlag = x;
  end;
run;
```

The following DATA steps load the data set asv_all into a data table in your session that is associated with the mylib libref. The DATA steps assume that your libref is named mylib, but you can substitute any appropriately defined libref. The data set asv_all is split such that the first 275 observations are used as the training set and the last 5 observations are used as the test set.

```

data asv_train;
  set asv_all;
  if (t le 275) then output;
run;

data asv_test;
  set asv_all;
  if (t > 275) then output;
run;

data mylib.asv_train;
  set asv_train;
run;

```

The model specification defines the transition and measurement distributions. For the initialization distribution of the state variable, the normal distribution whose mean is 0 and variance is 4 is used. Moreover, the prior distributions for the parameters are defined as

$$\begin{aligned}\phi &\sim \text{UNIFORM}(0, 1) \\ \gamma^2 &\sim \text{IGAMMA}(0.01, 0.01) \\ \beta^2 &\sim \text{IGAMMA}(0.01, 0.01)\end{aligned}$$

The following statements use PROC SMC to define the preceding ARSV model and then use the PMCMC method to estimate the three parameters for the simulated data set:

```

proc smc data=mylib.asv_train seed=1234;
  id time = t;
  var y;
  statevar x;
  prior phi~uniform(0,1);
  prior gamma_sq beta_sq~igamma(0.01,0.01);
  parm phi=0.6 gamma_sq=0.9 beta_sq=1.5;
  initstate x~normal(0,2);
  state x~normal(x.11*phi, sqrt(gamma_sq));
  model y~normal(0, sqrt(beta_sq)*exp(x/2));
  auxmodel y~normal(0, sqrt(beta_sq)*exp(phi*x.11/2));
  learn nparticle=256 algorithm=apf method=PMCMC(nsample=25000
    nchain=8 nbi=5000 thin=4 seed=1
    outpost=mylib.out samset samsum
    sampler=rwm(ntu=250)
    statistics=all diagnostics=all);
  score outmodel=mylib.asvmodel;
run;

```

For the three parameters, ϕ is represented by phi, γ^2 is represented by gamma_sq, and β^2 is represented by beta_sq. A state variable, x, an a dependent (observation) variable, y, are also specified according to the model specification.

The model information and parameter learning results are stored in the mylib.asvmodel. As for the PMCMC, the likelihood is estimated by the particle filter and the prior density is specified in the PRIOR statement.

The summary tables of the model information are shown in [Figure 27.1](#).

Figure 27.1 Model Information Summary

The SMC Procedure			
State Space Model Information			
Number of Parameters			3
Number of State Variables			1
Number of Dependent Variables			1
Number of Independent Variables			0
Seed Value			1234
Number of Observations			275
Number of Missing Observations			0
Initial Parameters Information			
Parameter	Initial Value	Lower Bound	Upper Bound
phi	0.60000	0	1.00000
gamma_sq	0.90000	0	Infy
beta_sq	1.50000	0	Infy

The summary tables of the posterior samples are shown in [Figure 27.2](#).

Figure 27.2 Posterior Summary

MCMC Sampler Settings	
MCMC Sampling Method	RWM
Random Seed	1
Transformed Sampling	False
Number of Chains	8
Number of Sampling Iterations	25000
Number of Burn-in Iterations	5000
Thinning Interval	4
Number of Tuning Iterations per Tuning Stage	250
Number of Tuning Stages	24
Target Metropolis Acceptance Rate	0.234
Initial RWM Proposal Scale	2.38
Tuning Weight	0.75
Acceptance Tolerance	0.075

The correlation and covariance matrices of the parameter samples that are generated by the PMCMC method are shown in [Figure 27.3](#).

Figure 27.3 Correlation and Covariance Matrices

Posterior Covariance Matrix			
Parameter	phi	gamma_sq	beta_sq
phi	0.006192	-0.00985	0.004117
gamma_sq	-0.00985	0.026624	-0.00822
beta_sq	0.004117	-0.00822	0.074281

The autocorrelation statistics, Heidelberger-Welch diagnostics, effective sample size (ESS) diagnostics, and Monte Carlo Standard Error (MCSE) diagnostics for each parameter are shown in [Figure 27.4](#).

Figure 27.4 Other Bayesian Analysis Tables

The SMC Procedure

MCMC Diagnostic Summaries						
Parameter		MCSE	MCSE/SD	ESS	Autocorrelation	
					Time	ESS/N
phi	*	0.00154	0.0196	2607.9	19.1724	0.0522
gamma_sq	*	0.00517	0.0317	998.0	50.1010	0.0200
beta_sq	*	0.00940	0.0345	841.0	59.4525	0.0168
*Autocorrelation Remains						

Autocorrelation Diagnostics				
Parameter	Lag 1	Lag 5	Lag 10	Lag 50
phi	0.7387	0.3128	0.1604	0.0146
gamma_sq	0.7633	0.4115	0.2826	0.1005
beta_sq	0.7611	0.4061	0.2666	0.1165

Heidelberger-Welch Diagnostics					
Parameter	Stationarity Test			Half-Width Test	
	Largest				
	Chains Tested	Tests Passed	Iterations Discarded	Chains Tested	Tests Passed
phi	8	8	1875	8	8
gamma_sq	8	7	2500	7	7
beta_sq	8	8	1250	8	8

The following statements draw the histogram of the posterior samples of phi, which is shown in [Figure 27.5](#):

```
proc sgplot data=mylib.out;
  histogram phi;
  refline 0.9 /axis=x lineattrs=(thickness=5 color=red) label="True Value";
run;
```

Figure 27.5 Histogram of Posterior Samples of ϕ 

The following statements draw the histogram of the posterior samples of `gamma_sq`, which is shown in Figure 27.6:

```
proc sgplot data=mylib.out;
  histogram gamma_sq;
  refline 0.16 /axis=x lineattrs=(thickness=5 color=red) label="True Value";
run;
```

Figure 27.6 Histogram of Posterior Samples of gamma_sq

The following statements draw the histogram of the posterior samples of beta_sq, which is shown in Figure 27.7:

```
proc sgplot data=mylib.out;
  histogram beta_sq;
  refline 1 /axis=x lineattrs=(thickness=5 color=red) label="True Value";
run;
```

Figure 27.7 Histogram of Posterior Samples of beta_sq

You can apply the model information and parameter estimates from the data table `mylib.asvmodel` to the original data set by specifying the `INMODEL=` option in the `SCORE` statement. The posterior mean acquired by the PMCMC method are used as the parameters in the smoothing and forecasting process. The following statements generate the smoothing and forecasting estimates:

```
proc smc data=mylib.asv_train seed=1 nthreads=32;
  smooth nparticle=10240 parm=median alg=sir method=fixedlag(25)
    out (pct=2.5,97.5)=mylib.asvsm;
  forecast nparticle=10240 parm=median alg=sir lead=5
    out (pct=2.5,97.5)=mylib.asvfc;
  score inmodel=mylib.asvmodel;
run;
```

The following statements sort the summary table of the smoothing estimates of the state variable, `x`, in the session and create a relevant data table, `smoothRes`, in the `Work` library to record the smoothing estimates and actual values:

```

data asvsm; set mylib.asvsm(where=(VariableID=1 and TimeID>=1)); run;
proc sort data=asvsm; by timeId; run;

data smoothRes;
  set asvsm (keep=timeId Q2 P_1 P_2);
  set asv_train (keep=x t);
run;

```

The following statements draw the plot of the smoothing median estimates and the actual values of x . The output is shown in [Figure 27.8](#), where the shadow band indicates the range between the 2.5th and 97.5th percentiles of the smoothing estimates.

```

proc sgplot data=smoothRes;
  band x=TimeID upper=P_2 lower=P_1 / transparency=.3 legendlabel='95% CI';
  series x=TimeId y=Q2 /legendlabel='Smoothing Median'
    markers markerattrs=(color=blue size=5 symbol=triangle)
    lineattrs=(color=blue pattern=solid);
  series x=TimeId y=x /legendlabel='Actual Value'
    markers markerattrs=(color=red size=5 symbol=circlefilled)
    lineattrs=(color=red pattern=shortdash);
  yaxis label='x, Smoothing';
  xaxis label='Time';
run;

```

Figure 27.8 Smoothing Estimates vs. Actual Values, x

The following statements sort the summary table of the forecasting estimates of x in the session and create a relevant data table, `forecastRes_x`, in the Work library to record the forecasting estimates and actual values in the forecasting stage:

```
data asvfc_x; set mylib.asvfc(where=(VariableID=1)); run;
proc sort data=asvfc_x; by _t; run;

data forecastRes_x;
  set asvfc_x (keep=Q2 P_1 P_2 _t);
  set asv_test (keep=x t);
run;
```
