The following statements draw the plot of the forecasting median estimates and the actual values of x . The output is shown in [Figure 27.9](#), where the shadow band indicates the range between the 2.5th and 97.5th percentiles of the forecasting estimates.

```
proc sgplot data=forecastRes_x;
  band x=t upper=P_2 lower=P_1 /transparency=.3 legendlabel='95% CI';
  series x=t y=Q2 /legendlabel='Forecasting Median'
    markers markerattrs=(color=blue size=5 symbol=triangle)
    lineattrs=(color=blue pattern=solid);
```

```

scatter x=t y=x /legendlabel='Actual Value'
      markerattrs=(color=red size=5 symbol=circlefilled);
xaxis integer label='Time';
yaxis label='x, Forecasting';
run;

```

Figure 27.9 Forecasting Estimates vs. Actual Values, x

The following statements sort the summary table of the forecasting estimates of the dependent variable, *y*, in the session and create a relevant data table, *forecastRes_y*, in the Work library to record the forecasting estimates and actual values in the forecasting stage:

```

data asvfc_y; set mylib.asvfc(where=(VariableID=2)); run;
proc sort data=asvfc_y; by _t; run;

data forecastRes_y;
  set asvfc_y (keep=Q2 P_1 P_2 _t);
  set asv_test (keep=y _t);
run;

```

The following statements draw the plot of the forecasting median estimates and the actual values of *y*. The output is shown in [Figure 27.10](#), where the shadow band indicates the range between the 2.5th and 97.5th percentiles of the forecasting estimates.

```

proc sgplot data=forecastRes_y;
  band x=t upper=P_2 lower=P_1 /transparency=.3 legendlabel='95% CI';
  series x=t y=Q2 /legendlabel='Forecasting Median'
    markers markerattrs=(color=blue size=5 symbol=triangle)
    lineattrs=(color=blue pattern=solid);
  scatter x=t y=y /legendlabel='Actual Value'
    markerattrs=(color=red size=5 symbol=circlefilled);
  xaxis integer label='Time';
  yaxis label='y, Forecasting';
run;

```

Figure 27.10 Forecasting Estimates vs. Actual Values, y

Syntax: SMC Procedure

The following statements are available in the SMC procedure. Items within angle brackets (<>) are optional.

```

PROC SMC options ;
    AUXMODEL dependent-variable ~ distribution ;
    ENDSUBMIT ;
    EVALUATE < options > ;
    FILTER < options > ;
    FORECAST < options > ;
    ID < TIME= > variable ;
    INITSTATE state-variable ~ distribution < / option > ;
    LEARN < options > ;
    MODEL dependent-variable ~ distribution ;
    PARAMETERS parameter-specification < ,... , parameter-specification > < / options > ;
    PRIOR parameter-list ~ distribution ;
    SCORE options ;
    SMOOTH < options > ;
    STATE state-variable ~ distribution < / option > ;
    STATEVAR variable-list ;
    SUBMITMODEL dependent-variables < =independent-variables > < / options > ;
    VAR variable-list ;

```

Functional Summary

The statements and options available in the SMC procedure are summarized in [Table 27.1](#). The sections after the table provide a description of each statement in alphabetical order, following the PROC SMC statement.

Table 27.1 Functional Summary

Description	Statement	Option
Input Data Table Options		
Specifies the input data table	PROC SMC	DATA=
Specifies the input data table for model information	SCORE	INMODEL=
Output Data Table Options		
Writes the model information to the specified output data set	SCORE	OUTMODEL=
Writes the evaluation estimates to the specified output data set	EVALUATE	OUT=
Writes the summary of the filtering estimates to the specified output data set	FILTER	OUT=
Writes the filtering estimates to the specified output data set	FILTER	OUTSIM=

Table 27.1 *continued*

Description	Statement	Option
Writes the summary of the forecasting estimates to the specified output data set	FORECAST	OUT=
Writes the forecasting estimates to the specified output data set	FORECAST	OUTSIM=
Writes the summary of the smoothing estimates to the specified output data set	SMOOTH	OUT=
Writes the smoothing estimates to the specified output data set	SMOOTH	OUTSIM=
SMC Common Options		
Specifies the number of particles to use in the SMC algorithms	PROC SMC	NPARTICLE=
Specifies the random seed to use in the SMC algorithms	PROC SMC	SEED=
Variable and Parameter Declaration Options		
Specifies the names and initial values of the model parameters	PARAMETERS	
Specifies the lower bounds of the model parameters	PARAMETERS	LOWER=
Specifies the upper bounds of the model parameters	PARAMETERS	UPPER=
Specifies the names of state variables	STATEVAR	
Specifies the names of dependent and independent (exogenous) variables	VAR	
Model Specification Options		
Specifies the initialization distribution of the state variable	INITSTATE	
Specifies the proposal initialization distribution of the state variable	INITSTATE	PROPOSAL=
Specifies the transition distribution of the state variable	STATE	
Specifies the proposal transition distribution of the state variable	STATE	PROPOSAL=
Specifies the measurement distribution of the dependent variable	MODEL	
Specifies the auxiliary distribution of the dependent variable	AUXMODEL	
Specifies the name of the model of interest	SUBMITMODEL	NAME=
Specifies the number of parameters	SUBMITMODEL	NPARAM=
Specifies the number of state variables	SUBMITMODEL	NSTATE=
Specifies the beginning of program statements	SUBMITMODEL	
Specifies the end of program statements	ENDSUBMIT	

Table 27.1 *continued*

Description	Statement	Option
ID Variables		
Specifies the variable that identifies the time or sequence	ID	TIME=
Parameter Estimation Options		
Specifies the prior distribution and range of the parameters	PRIOR	
Specifies the number of particles to use in the parameter estimation process	LEARN	NPARTICLE=
Specifies the particle filter algorithm to use in the parameter estimation process	LEARN	ALGORITHM=
Specifies the parameter estimation method and options	LEARN	METHOD=PMCMC
Inference Options		
Specifies the particle filter algorithm to use to solve the evaluation problem	EVALUATE	ALGORITHM=
Specifies the number of particles to use in the evaluation process	EVALUATE	NPARTICLE=
Specifies the type of parameter values from the posterior distribution to use in the evaluation process	EVALUATE	PARAM=
Specifies the particle filter algorithm to use to solve the filtering problem	FILTER	ALGORITHM=
Specifies the number of particles to use in the filtering process	FILTER	NPARTICLE=
Specifies the type of parameter values from the posterior distribution to use in the filtering process	FILTER	PARAM=
Specifies the particle filter algorithm to use to get particles before the (multi-step) forecasts	FORECAST	ALGORITHM=
Specifies how many periods to forecast	FORECAST	LEAD=
Specifies the number of particles to use in the forecasting process	FORECAST	NPARTICLE=
Specifies the type of parameter values from the posterior distribution to use in the forecasting process	FORECAST	PARAM=
Specifies that particles are to be resampled before forecasting	FORECAST	RESAMPLE
Specifies the particle filter algorithm to use in the smoothing process	SMOOTH	ALGORITHM=
Specifies the number of particles to use in the smoothing process	SMOOTH	NPARTICLE=

Table 27.1 *continued*

Description	Statement	Option
Specifies the smoothing method	SMOOTH	METHOD=
Specifies the type of parameter values from the posterior distribution to use in the smoothing process	SMOOTH	PARM=

PROC SMC Statement

PROC SMC *options* ;

The PROC SMC statement invokes the SMC procedure. You must specify the following *option*:

DATA=*libref.data-table*

names the input data table for PROC SMC to use. *libref.data-table* is a two-level name, where

libref refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about *libref*, see the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1903.

data-table specifies the name of the input data table.

You can specify the following *options*:

NPARTICLE=*number*

specifies the number of particles to use in the EVALUATE, FILTER, FORECAST, LEARN, and SMOOTH statements if their own corresponding option is not specified. By default, NPARTICLE=1000.

SEED=*number*

specifies a nonnegative integer to use as the seed for generating random number sequences. You can use this option to replicate results from different runs. By default, SEED=1.

AUXMODEL Statement

AUXMODEL *dependent-variable* $\sim$ *distribution* ;

The AUXMODEL statement specifies the auxiliary conditional distribution of the dependent variable given the parameters, the lagged state variables, the lagged dependent variables, and the independent variables; that is, $\hat{p}_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$, $s \geq 0$, $r \geq 1$, $p \geq 1$. For more information about the auxiliary conditional distribution in the state space model, see the section “[Auxiliary Particle Filter](#)” on page 1966.

The AUXMODEL statement is ignored if you specify the SUBMITMODEL statement. The AUXMODEL statement has the following requirements if you omit the SUBMITMODEL statement:

- If you specify the ALGORITHM=APF option in the EVALUATE, FILTER, FORECAST, LEARN, or SMOOTH statement, each dependent variable must have a corresponding AUXMODEL statement.
- Multiple AUXMODEL statements are permitted.

The AUXMODEL statement must have the following components in the order shown:

1. *Dependent variable*: A single dependent variable from the input data table.
2. *Tilde*: A tilde ($\sim$) symbol between the dependent variable and the distribution.
3. *Distribution*: A distribution that is specified in the form *distribution-name*(*distribution-arguments*). The available *distribution-name* and *distribution-arguments* in the AUXMODEL statements are displayed in [Table 27.2](#). For the description of each distribution, see the section “[Standard Distributions](#)” on page 1991.

Table 27.2 Distribution Names and Arguments

Distribution Name	Distribution Arguments	Definitions
BETA	a, b	Beta distribution with arguments shape parameter a and shape parameter b
CAUCHY	l, s	Cauchy distribution with arguments location l and scale s
GAMMA	a, b	Gamma distribution with arguments shape a and scale b
LOGN	m, s	Log-normal distribution with arguments mean m and standard deviation s
NORMAL N	m, s	Normal distribution with arguments mean m and standard deviation s
POISSON	λ	Poisson distribution with argument mean λ
T	m, s, ν	Student's t distribution with arguments mean m , standard deviation s , and degrees of freedom ν
UNIFORM	l, u	Uniform distribution with arguments min l and scale u

The *distribution-arguments* are specified by expressions that are enclosed in parentheses and separated by commas. Such expressions must follow any SAS programming statements. To avoid the possible computation errors, you should make some adjustments to the expressions. For more information about the adjustments, see the section “[Distribution Argument Restriction](#)” on page 1990. The number of expressions is equal to the number of arguments of the given distribution. For the AUXMODEL statement, the variables that can appear in the expressions must be selected from the following list:

- the model parameters
- the lagged state variables
- the lagged dependent variables
- the current and lagged independent variables
- the actual time index, `_time`

For more information about the actual time index, see the section “[Time Index](#)” on page 1995. For more information about the parameters, state variables, and dependent/independent variables, see the sections “[PARAMETERS Statement](#)” on page 1937, “[STATEVAR Statement](#)” on page 1945, and “[VAR Statement](#)” on page 1960, respectively.

Moreover, the following conditions must be satisfied in the AUXMODEL statement:

- The maximum lag order of all the state variables in the *distribution-arguments* of all AUXMODEL statements must be less than or equal to r , where r is defined in the section “[Method 1: Maximum Lag Order of State Variables, \$r\$](#) ” on page 1986.
- The maximum lag order of all the dependent variables in the *distribution-arguments* of all AUXMODEL statements must be less than or equal to p , where p is defined in the section “[Method 1: Maximum Lag Order of Dependent Variables, \$p\$](#) ” on page 1986.
- The maximum lag order of all the independent variables in the *distribution-arguments* of all AUXMODEL statements must be less than or equal to s , where s is defined in the section “[Method 1: Maximum Lag Order of Independent Variables, \$s\$](#) ” on page 1986.
- The dependent variables in all AUXMODEL statements must not have duplicates; that is, each dependent variable should appear only once as the *dependent-variable* in all AUXMODEL statements.

For example, suppose that the auxiliary distributions of the dependent variables y_1 and y_2 are described in the following equations:

$$y_{1,t} = \exp\left(\phi \frac{x_{1,t-1}}{2}\right) \xi_t, \quad \xi_t \stackrel{\text{iid}}{\sim} N(0, 1)$$

$$y_{2,t} = \beta x_{2,t-1} + \gamma \eta_t \quad \eta_t \stackrel{\text{iid}}{\sim} N(0, 1), \quad \xi_t \perp \eta_t$$

Then the following statements define these auxiliary distributions:

```
auxmodel y1 ~ normal(0, exp(phi * x1.l1/2));
auxmodel y2 ~ normal(beta*x2.l1, gamma);
```

where ϕ , β , and γ are model parameters; y_1 and y_2 are current dependent variables; and $x1.l1$ and $x2.l1$ are the first-order lagged state variables, which are constructed by appending the suffix “.11” to the state variables “ $x1$ ” and “ $x2$ ” (see the section “[Method 1: Lagged Variables](#)” on page 1985).

ENDSUBMIT Statement

ENDSUBMIT ;

The ENDSUBMIT statement is required in order to terminate the user-defined program statements in the PROC SMC statement block whenever you specify the SUBMITMODEL statement without the FILE= option. Do not specify the ENDSUBMIT statement if you specify the FILE= option in the SUBMITMODEL statement. If you omit the FILE= option and you do not include an ENDSUBMIT statement to accompany your SUBMITMODEL statement, then the PROC SMC step ends with an error.

EVALUATE Statement

EVALUATE < options > ;

The EVALUATE statement specifies options that are related to the evaluation, which is the log-likelihood calculation (see the section “[SMC Evaluating](#)” on page 1972). If you specify the LEARN statement, the model parameters in the requested evaluation process are set to the posterior mean of the corresponding model parameters; otherwise, the parameters with initial values that you specify in the PARAMETERS statement are used in the evaluation. You can specify the following *options*:

ALGORITHM=*algorithm*

ALG=*algorithm*

specifies the particle filter algorithm to use in the evaluation. You can specify the following *algorithms*:

APF<(ADP)> specifies the auxiliary particle filter (APF) algorithm. The ADP suboption specifies the fully adapted auxiliary particle filter algorithm.

BF specifies the bootstrap filter (BF) algorithm.

SIR<(TH | THRESH | THRESHOLD=*number*)> specifies the sequential importance resampling (SIR) algorithm. The TH= option specifies the threshold (a value between 0 and 1) of the resampling step in the SIR algorithm. The resampling step occurs when the effective sample size is less than the product of the threshold and the number of particles. By default, TH=0.8.

By default, ALGORITHM=SIR.

NPARTICLE=*number*

specifies the number of particles (samples) to use in the evaluation. If you omit this option, the evaluation uses the value of the NPARTICLE= option in the PROC SMC statement.

OUT=*libref.data-table*

writes the evaluation estimates to an output data set. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1903.

PARM=MEAN | MEDIAN

specifies which parameter values from the posterior distribution to use for the evaluation problem when you also specify the LEARN statement. If you omit the LEARN statement, this option is ignored. You can specify one of the following values:

MEAN	solves the evaluation problem by using the estimated posterior means of the parameters.
MEDIAN	solves the evaluation problem by using the estimated posterior medians of the parameters.

By default, PARM=MEAN.

FILTER Statement

FILTER < options > ;

The FILTER statement specifies options that are related to the filtering problem, which is to find the probability distribution of the current state conditional on the observations up to now (see the section “[SMC Filtering](#)” on page 1964). If you specify the LEARN statement, the model parameters in the requested filtering process are set to the posterior mean or median of the corresponding model parameters; otherwise, the parameters whose initial values are specified in the PARAMETERS statement are used in the filtering process. You can specify the following *options*:

ALGORITHM=*algorithm*

ALG=*algorithm*

specifies the particle filter algorithm to use for the filtering problem. You can specify the following *algorithms*:

APF<(ADP)> specifies the auxiliary particle filter (APF) algorithm. The ADP suboption specifies the fully adapted auxiliary particle filter algorithm.

BF specifies the bootstrap filter (BF) algorithm.

SIR<(TH | THRESH | THRESHOLD=*number*)> specifies the sequential importance resampling (SIR) algorithm. The TH= option specifies the threshold (a number between 0 and 1) of the resampling step in the SIR algorithm. The resampling step occurs when the effective sample size is less than the product of the threshold and the number of particles. By default, TH=0.8.

By default, ALGORITHM=SIR.

NPARTICLE=*number*

specifies the number of particles to use for the filtering problem. If you omit this option, the filtering process uses the value of the NPARTICLE= option in the PROC SMC statement.

OUT<(PERCENTILES=*numeric-list*)>=*libref.data-table*

OUT<(PERCENTILE=*numeric-list*)>=*libref.data-table*

OUT<(PERCENT=*numeric-list*)>=*libref.data-table*

OUT<(PERC=*numeric-list*)>=*libref.data-table*

OUT<(PCT=*numeric-list*)>=*libref.data-table*

writes the summary of the filtering estimates to the specified output data table. The weighted average, weighted standard deviation, minimum value, first quantile, second quantile, third quantile, maximum value, and percentile points of each state variable at each time step are displayed. The optional PERCENTILES=*numeric-list* specifies the percentile points in the summary table of the filtering estimates, where each *value* in the *numeric-list* must be between 0 and 100 and values are separated by commas or spaces. By default, PERCENTILES=2.5, 97.5, which yields the 2.5th and 97.5th percentile points, respectively. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1903.

OUTSIM=*libref.data-table*

writes the filtering estimates to the specified output data table. The particle values with the corresponding normalized weights at each time step are displayed. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the DATA= option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1903.

PARM=MEAN | MEDIAN

specifies which parameter values from the posterior distribution to use for the filtering distribution when you also specify the LEARN statement. If you omit the LEARN statement, this option is ignored. You can specify one of the following values:

MEAN	constructs the filtering distribution by using the estimated posterior means of the parameters.
MEDIAN	constructs the filtering distribution by using the estimated posterior medians of the parameters.

By default, PARM=MEAN.

FORECAST Statement

FORECAST < options > ;

The FORECAST statement specifies options that are related to the forecasting problem, which is to find the probability distribution of the state and the dependent variables. If you specify the LEARN statement, the model parameters in the requested forecasting process are set to the posterior mean of the corresponding model parameters; otherwise, the parameters whose initial values are specified in the PARAMETERS statement are used in the forecasting process. You can specify the following *options*:

ALGORITHM=*algorithm*

ALG=*algorithm*

specifies the particle filter algorithm to use for the forecasting problem. You can specify the following *algorithms*:

APF<(ADP)> specifies the auxiliary particle filter (APF) algorithm. The ADP suboption specifies the fully adapted auxiliary particle filter algorithm.

BF specifies the bootstrap filter (BF) algorithm.

SIR<(TH | THRESH | THRESHOLD=*value*)> specifies the sequential importance resampling (SIR) algorithm. The optional TH= option specifies the threshold (a value between 0 and 1) of the resampling step in the SIR algorithm. The resampling step occurs when the effective sample size is less than the product of the threshold and the number of particles. By default, TH=0.8.

By default, ALGORITHM=SIR.

LEAD=*number*

specifies the number of multi-step forecast values to compute, where *number* must be a nonnegative integer. By default, LEAD=1, which means that a one-step-ahead forecast is performed.

NPARTICLE=*number*

specifies the number of particles to use in the forecasting process. If you omit this option, the forecasting process uses the value of the NPARTICLE= option in the PROC SMC statement.

PARM=MEAN | MEDIAN

specifies which parameter values from the posterior distribution to use for the forecasting distribution when you also specify the LEARN statement. If you omit the LEARN statement, this option is ignored. You can specify one of the following values:

MEAN constructs the forecasting distribution by using the estimated posterior means of the parameters.

MEDIAN constructs the forecasting distribution by using the estimated posterior medians of the parameters.

By default, PARM=MEAN.

OUT<(PERCENTILES=*numeric-list*)>=*libref.data-table*

OUT<(PERCENTILE=*numeric-list*)>=*libref.data-table*

OUT<(PERCENT=*numeric-list*)>=*libref.data-table*

OUT<(PERC=*numeric-list*)>=*libref.data-table*

OUT<(PCT=*numeric-list*)>=*libref.data-table*

writes the summary of the forecasting estimates to the specified output data table. The weighted average, weighted standard deviation, minimum value, first quantile, second quantile, third quantile, maximum value, and percentile points of each state variable at each time step are displayed. The optional PERCENTILES=*numeric-list* specifies the percentile points in the summary table of the forecasting estimates, where each *value* in the *numeric-list* must be between 0 and 100 and values are separated by commas or spaces. By default, PERCENTILES=2.5, 97.5, which yields the 2.5th and

97.5th percentile points, respectively. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1903.

OUTSIM=*libref.data-table*

writes the forecasting estimates to the specified output data table. The particle values with the corresponding normalized weights at each time step are displayed. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1903.

RESAMPLE

specifies that particles are to be resampled before the forecasting process.

ID Statement

ID < TIME= *>variable* ;

The ID statement identifies observations in the input data set by specifying a variable for the time series data. The values of the *variable* must not contain duplicated values.

INITSTATE Statement

INITSTATE *state-variable* $\sim$ *distribution* *< / option >* ;

The INITSTATE statement specifies the initialization distribution of the state variable given the parameters; that is, $\mathbf{X}_t \sim \mu_{\theta}(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})$. For more information about the initialization distribution such as the definitions of τ , p , and s , see the section “[Sequential Monte Carlo Methods and State Space Models](#)” on page 1961. The INITSTATE statement is ignored if you specify the SUBMITMODEL statement. The INITSTATE statement has the following requirements if you omit the SUBMITMODEL statement:

- The INITSTATE statement is required. Each state variable must have a corresponding INITSTATE statement.
- Multiple INITSTATE statements are permitted. When you specify multiple INITSTATE statements, be careful about the order if there is any dependency between state variables.

The INITSTATE statement must have the following components in the order shown:

1. *variable-name*: A non-lagged or lagged format of a single state variable that you specify in the [STATEVAR](#) statement.
2. *Tilde*: A tilde ($\sim$) symbol between the state variable and the distribution.
3. *Distribution*: A distribution that is specified in the form *distribution-name(distribution-arguments)*. The available *distribution-name* and *distribution-arguments* in the INITSTATE statements are displayed in [Table 27.3](#). For the description of each distribution, see the section “[Standard Distributions](#)” on page 1991.

Table 27.3 Distribution Names and Arguments

Distribution Name	Distribution Arguments	Definitions
BETA	a, b	Beta distribution with arguments shape parameter a and shape parameter b
CAUCHY	l, s	Cauchy distribution with arguments location l and scale s
DEGENERATE	c	Degenerate distribution with argument c
GAMMA	a, b	Gamma distribution with arguments shape a and scale b
LOGN	m, s	Log-normal distribution with arguments mean m and standard deviation s
NORMAL N	m, s	Normal distribution with arguments mean m and standard deviation s
POISSON	λ	Poisson distribution with argument mean λ
T	m, s, ν	Student's t distribution with arguments mean m , standard deviation s , and degrees of freedom ν
UNIFORM	l, u	Uniform distribution with arguments min l and scale u

The *distribution-arguments* are specified by expressions that are enclosed in parentheses and separated by commas. Such expressions must follow any SAS programming statements. To avoid the possible computation errors, you should make some adjustments to the expressions. For more information about the adjustments, see the section “[Distribution Argument Restriction](#)” on page 1990. The number of expressions is equal to the number of arguments of the given distribution. For the INITSTATE statement, the variables that can appear in the expressions must be selected from the following list:

- the model parameters
- the lagged dependent variables
- the current and lagged independent variables
- the current and lagged state variables that you specify in the preceding INITSTATE statements
- the actual time index, `_time`

For more information about the actual time index, see the section “[Time Index](#)” on page 1995. For more information about the parameters, state variables, and dependent/independent variables, see the sections “[PARAMETERS Statement](#)” on page 1937, “[STATEVAR Statement](#)” on page 1945, and “[VAR Statement](#)” on page 1960, respectively.

You can specify the following *option* after a forward slash (/):

PROPOSAL=*proposal-dist*

IMPORTANCE=*proposal-dist*

specifies the proposal (importance) initialization distribution given the parameters, the dependent and independent variables at the first time step; that is, $\mathbf{X}_1 \sim q_{\theta}^1(\mathbf{X}_1|\mathbf{Y}_1, \mathbf{Z}_1)$. For more information about the proposal initialization equation in the state space model, see the section “[Sequential Monte Carlo Methods and State Space Models](#)” on page 1961. If you omit this *option*, then the corresponding state variable uses the original initialization distribution as its proposal initialization distribution. In the SIR or APF algorithm, each state variable is sampled from its proposal initialization distributions at the first time step. Subsequently, the joint density of both the original and proposal initialization distributions of all the state variables is evaluated within the importance weight calculation. In the BF algorithm, the proposal initialization distribution of each state variable is always same as its original initialization distribution. For more information about the proposal initialization distribution, see the sections “[Sequential Importance Resampling Algorithm](#)” on page 1964 and “[Auxiliary Particle Filter](#)” on page 1966. The format of the *proposal-dist* is *proposal-dist-name(proposal-dist-arguments)*. The available *proposal-dist-name* and *proposal-dist-arguments* in the INITSTATE statements are also displayed in [Table 27.3](#).

The expressions for *proposal-dist-arguments* are enclosed in parentheses and separated by commas. Such expressions must follow any SAS programming statements. To avoid the possible computation errors, you should make some adjustments to the expressions. For more information about the adjustments, see the section “[Distribution Argument Restriction](#)” on page 1990. The number of expressions is equal to the number of arguments of the given distribution type. The variables that are used in the expressions for *proposal-dist-arguments* must be selected from the following list:

- the model parameters
- the current and lagged dependent variables
- the current and lagged independent variables
- the current and lagged state variables that have been specified in the preceding INITSTATE statements
- the actual time index, *_time*

Moreover, the INITSTATE statements must satisfy the following conditions:

- The maximum lag order of all the dependent variables in the *distribution-arguments* and the PROPOSAL= option of all INITSTATE statements must be less than or equal to *p*, where *p* is defined in the section “[Method 1: Maximum Lag Order of Dependent Variables, p](#)” on page 1986.
- The maximum lag order of all the independent variables in the *distribution-arguments* and the PROPOSAL= option of all INITSTATE statements must be less than or equal to *s*, where *s* is defined in the section “[Method 1: Maximum Lag Order of Independent Variables, s](#)” on page 1986.

- The variables that appear as the *variable-name* in all INITSTATE statements must not have duplicates; that is, each state variable or lagged state variable must appear only once as the *variable-name* in all INITSTATE statements.
- Each state variable must appear once as the *variable-name* in one INITSTATE statement.
- The maximum lag order of all the state variables in the *variable-name* of all the INITSTATE statements must be less than or equal to r , where r is defined in the section “[Method 1: Maximum Lag Order of State Variables, \$r\$](#) ” on page 1986
- Suppose there are d_x state variables. For $i = 1, \dots, d_x$, if $\tau_i = \max(r_{1i}, r_{2i} - 1) > 0$, where r_{1i} and r_{2i} are defined in the section “[Method 1: Maximum Lag Order of State Variables, \$r\$](#) ” on page 1986, then *statev.L1*, ..., *statev.L τ_i* must appear once as the *variable-name* in one INITSTATE statement.

For example, suppose the initialization equations are

$$\begin{aligned} x_{1,t} &= \gamma \xi_t, & \xi_t &\stackrel{\text{iid}}{\sim} N(0, 1) \\ x_{2,t} &= \phi x_{1,t} + \eta_t & \eta_t &\stackrel{\text{iid}}{\sim} N(0, 1), \quad \xi_t \perp \eta_t \end{aligned}$$

where $t = 1$. Then the following statements define these initialization equations:

```
initstate x1 ~ normal(0, gamma);
initstate x2 ~ normal(phi*x1, 1);
```

where phi and gamma are parameters and x1 and x2 are current state variables.

If $x_{1,1}$ has the proposal initialization equation

$$x_{1,t} = y_t + \gamma \epsilon_t, \epsilon_t \stackrel{\text{iid}}{\sim} N(0, \gamma), t = 1$$

then the corresponding initialization distributions can be defined by

```
initstate x1 ~ normal(0, gamma) / proposal = normal(y, gamma);
initstate x2 ~ normal(phi*x1, 1);
```

where the state variable x1 has a proposal initialization distribution that incorporates the current dependent variable y, and the state variable x2 uses the original initialization as its proposal initialization distribution.

LEARN Statement

LEARN <options> ;

The LEARN statement estimates the parameters. You can specify the following *options*:

ALGORITHM=*algorithm*

ALG=*algorithm*

specifies the particle filter algorithm. You can specify one of the following *algorithms*:

- APF<(ADP)>** specifies the auxiliary particle filter (APF) algorithm. The ADP suboption specifies the fully adapted auxiliary particle filter algorithm.
- BF** specifies the bootstrap filter (BF) algorithm.
- SIR<(TH | THRESH | THRESHOLD=*number*)>** specifies the sequential importance resampling (SIR) algorithm. The optional TH= option specifies the threshold (a value between 0 and 1) of the resampling step in the SIR algorithm. The resampling step occurs when the effective sample size is less than the product of the threshold and the number of particles. By default, TH=0.8.

By default, ALGORITHM=SIR.

NPARTICLE=*number*

specifies the number of particles to use in the parameter estimation. If you omit this option, the parameter estimation uses the value of the NPARTICLE= option in the PROC SMC statement.

METHOD=PMCMC <(pmcmc-options)>

specifies the particle Markov chain Monte Carlo method and customizes its behavior with the *pmcmc-options*. By default, METHOD=PMCMC.

You can specify the following *pmcmc-options* in parentheses:

DIAGNOSTICS <(diag-options)>=ALL | NONE | keyword-list | (keyword-list)

DIAG <(diag-options)>=ALL | NONE | keyword-list | (keyword-list)

specifies which diagnostics to produce. If the value of the NCHAIN= option is greater than 1, then instead of the diagnostic tables being produced for each Markov chain, by default the results of the diagnostics for all the chains are appropriately combined and summarized. For more information, see the section “[Using Multiple Chains](#)” on page 37 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” You can specify one or both of the following *diag-options*:

BYCHAIN

produces diagnostic tables for each Markov chain. If NCHAIN=1, then the BYCHAIN option does nothing.

SETTINGS

produces a table of all MCMC diagnostic settings.

If you specify both the BYCHAIN and SETTINGS options, separate them by using a space or a comma. To produce all diagnostics, specify DIAGNOSTICS=ALL. To produce no diagnostics, specify DIAGNOSTICS=NONE. To produce some but not all diagnostics, or to change certain settings of these diagnostics, specify one or more of the following keywords. If you specify multiple keywords, separate them by using spaces.

AUTOCORR <(LAGS=*numeric-list*)>

AC <(LAGS=*numeric-list*)>

computes the autocorrelations at lags that you specify in the *numeric-list*. For more information, see the section “[Autocorrelations](#)” on page 34 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” Elements in the *numeric-list* must be positive integers, and values can be separated either by spaces or by commas. Repeated values are removed. If you omit the LAGS= option, autocorrelations of lags 1, 5, 10, and 50 are computed.

GEWEKE <(geweke-options)>

GEW <(geweke-options)>

computes the Geweke spectral density diagnostics. For more information, see the section “[Geweke Diagnostics](#)” on page 28 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” You can specify the following *geweke-options*:

FRAC1=value

F1=value

specifies the fraction f_1 for the first window. By default, FRAC1=0.1.

FRAC2=value

F2=value

specifies the fraction f_2 for the second window. By default, FRAC2=0.5.

HEIDELBERGER <(heidel-options)>

HEIDEL <(heidel-options)>

HB <(heidel-options)>

computes the Heidelberg-Welch diagnostic for each variable. For more information, see the section “[Heidelberg-Welch Diagnostics](#)” on page 30 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” You can specify one or more of the following *heidel-options*:

EPSILON=value

EPS=value

specifies a positive number ϵ such that if the halfwidth is less than ϵ times the sample mean of the retained iterates, the halfwidth test is passed. By default, EPSILON=0.1.

HALFWIDTH_ALPHA=value

HALPHA=value

specifies the α level ($0 < \alpha < 1$) for the halfwidth test. By default, HALFWIDTH_ALPHA=0.05.

STATIONARY_ALPHA=value

SALPHA=value

specifies the α level ($0 < \alpha < 1$) for the stationarity test. By default, STATIONARY_ALPHA=0.05.

RAFTERY <(raftery-options)>

RL <(raftery-options)>

computes the Raftery-Lewis diagnostics. For more information, see the section “[Raftery-Lewis Diagnostics](#)” on page 31 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” You can specify one or more of the following *raftery-options*:

ACCURACY=value

ACC=value

R=value

specifies a small positive number r as the margin of error for measuring the accuracy of estimation of the quantile. By default, ACCURACY=0.005.

EPSILON=*value*

EPS=*value*

specifies the tolerance level (ϵ , a small positive number) for the stationary test. By default, EPSILON=0.001.

PROBABILITY=*value*

PROB=*value*

S=*value*

specifies the probability s of attaining the accuracy of the estimation of the quantile. By default, PROBABILITY=0.95.

QUANTILE=*value*

QUANT=*value*

Q=*value*

specifies the order (q , a value between 0 and 1) of the quantile of interest. By default, QUANTILE=0.025.

SUMMARIES < (**MAXLAG**=*value*) >

SUMMARY < (**MAXLAG**=*value*) >

SUM < (**MAXLAG**=*value*) >

computes a summary of MCMC diagnostics for each parameter in the Markov chain, including effective sample size (ESS), Monte Carlo standard error (MCSE), and related diagnostics. For more information about ESS, see the section “[Effective Sample Size](#)” on page 34 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#)”; for more information about MCSE, see the section “[Standard Error of the Mean Estimate](#)” on page 36 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” MAXLAG=*value* specifies the maximum autocorrelation lag to use for computing ESS, which is used to compute MCSE, where *value* must be a positive integer. By default, MAXLAG=250.

By default, DIAGNOSTICS=SUMMARIES.

NBURNIN=*number*

BURNIN=*number*

NBI=*number*

specifies the number of burn-in iterations to perform in each Markov chain before the chains are saved. For more information, see the section “[Burn-In, Thinning, and Markov Chain Samples](#)” on page 27 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” By default, NBURNIN=0.

NCHAIN=*number*

NCHAINS=*number*

CHAINS=*number*

specifies the number of Markov chains to run. By default, NCHAIN=1.

NSAMPLE=number**NSAM=number****NMC=number**

specifies the number of iterations after tuning and burn-in to save in each Markov chain. For more information, see the section “[Burn-In, Thinning, and Markov Chain Samples](#)” on page 27 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” By default, NSAMPLE=1000.

OUTPOST<(outpost-option)>=libref.data-table

names the SAS data table to contain the posterior sample. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the **DATA=** option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1903. You can specify the following *outpost-option*:

DETAILED

saves any relevant additional variables, such as auxiliary variables, in the SAS data table. The random walk Metropolis (RWM) sampler without the **TRANSFORM** option has no additional variables to save. With the **TRANSFORM** option, the SAS data table also includes the transformed version of each parameter and the log posterior of the transformed parameters.

SAMPLER=RWM <(rwm-options)>**SAMPLING=RWM <(rwm-options)>**

samples from the posterior distribution by using the random walk Metropolis scheme. You can specify the following *rwm-options*:

ACCTOL=value**ATOL=value**

specifies the tolerance ϵ for the acceptance rate during the tuning process of the random walk Metropolis (RWM) sampler. For more information, see the section “[Scale Tuning](#)” on page 20 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” By default, ACCTOL=0.075.

INITSCALE=value**SCALE=value**

specifies the initial scale parameter(s) c^{cur} of the RWM proposal distribution. For more information, see the section “[Scale Tuning](#)” on page 20 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” By default, INITSCALE=2.38.

NTUNE=number**NTU=number**

specifies the number of iterations, n_{tune} , to perform for each tuning stage of the random walk Metropolis sampler. For more information, see the section “[Tuning Random Walk Metropolis Algorithms](#)” on page 19 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” By default, NTUNE=500.

NTUNESTAGE=number

specifies the number of tuning stages, n_{stage} . For more information, see the section “[Tuning Random Walk Metropolis Algorithms](#)” on page 19 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” By default, NTUNESTAGE=24.

TARGETRATE=value**RATE=value****DELTA=value**

specifies the target acceptance rate δ of the random walk Metropolis sampler. For more information, see the section “[Tuning Random Walk Metropolis Algorithms](#)” on page 19 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” By default, TARGETRATE=0.234.

TRANSFORM**TRANS**

transforms all parameters to an unconstrained space and implements the random walk Metropolis sampler on the unconstrained space. For more information, see the section “[Parameter Transformation](#)” on page 25 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).”

TUNEWEIGHT=value**WEIGHT=value****WT=value**

specifies the tuning weight w to use during the tuning phase of the random walk Metropolis sampler to tune the proposal covariance matrix. For more information, see the section “[Covariance Tuning](#)” on page 20 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” By default, TUNEWEIGHT=0.75.

SAMPLERSETTINGS**SAMSETTINGS****SAMSET**

produces a summary of the MCMC sampler settings to be used to sample from the posterior distribution, including tuning settings.

SAMPLERSUMMARY**SAMSUMMARY****SAMSUM**

produces a summary of the MCMC sampler to be used to sample from the posterior distribution, including, for example, Metropolis acceptance rates.

SEED=number

specifies an integer seed in the range 1 to $2^{31} - 1$ to use for the random number generator in the simulation. Specifying a seed enables you to reproduce identical Markov chains for the same specification. If you omit this option, or if you specify a non-positive seed, the seed specified in the PROC SMC statement is used.

STATISTICS < (*stat-option*) >=ALL | NONE | keyword | (*keyword-list*)

STATISTIC < (*stat-option*) >=ALL | NONE | keyword | (*keyword-list*)

STATS < (*stat-option*) >=ALL | NONE | keyword | (*keyword-list*)

STAT < (*stat-option*) >=ALL | NONE | keyword | (*keyword-list*)

specifies which posterior summary statistics to produce. If the value of the NCHAIN= option is greater than 1, then instead of the posterior summary statistics being computed separately for each Markov chain, by default the posterior summary statistics are computed by using all chains. For more information, see the section “[Using Multiple Chains](#)” on page 37 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” You can specify the following *stat-option*:

BYCHAIN

produces posterior summary statistics tables for each Markov chain. If NCHAIN=1, then the BYCHAIN option does nothing.

To produce all statistics, specify STATISTICS=ALL. To produce no statistics, specify STATISTICS=NONE. To produce some but not all statistics, or to change certain settings of these statistics, specify one or more of the following keywords. If you specify multiple keywords, separate them by using spaces.

CORR

COR

produces the posterior correlation matrix.

COV

produces the posterior covariance matrix.

INTERVAL < (*interval-option*) >

INTERVALS < (*interval-option*) >

INT < (*interval-option*) >

produces equal-tail posterior credible intervals and highest posterior density (HPD) credible intervals. For more information, see the sections “[Interval Estimation](#)” on page 10 and “[Summary Statistics](#)” on page 35 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” You can specify the following *interval-option*:

ALPHA=*numeric-list*

ALPHAS=*numeric-list*

computes posterior credible intervals at the levels that you specify in the *numeric-list*. Values in the *numeric-list* must be between 0 and 1, and they can be separated either by spaces or by commas. Repeated values are removed. Each value in the *numeric-list* produces a pair of 100(1-*value*)% equal-tail and HPD intervals for each parameter. By default, ALPHA=0.05, which yields the 95% credible intervals for each parameter.

SUMMARIES < (*summary-option*) >

SUMMARY < (*summary-option*) >

SUM < (*summary-option*) >

produces the means, standard deviations, and percentiles for the posterior sample. For more information, see the section “[Summary Statistics](#)” on page 35 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” You can specify the following *summary-option*:

PERCENTILES=*numeric-list*

PERCENTILE=*numeric-list*

PERCENT=*numeric-list*

PERC=*numeric-list*

PCT=*numeric-list*

computes the percentiles of the posterior sample that you specify in the *numeric-list*. Values in the *numeric-list* must be between 0 and 100, and they can be separated either by spaces or by commas. Repeated values are removed. By default, PERCENTILES=(2.5 25 50 75 97.5), which yields the 2.5th, 25th, 50th, 75th, and 97.5th percentiles, respectively, for each parameter.

The posterior mean and median are two point estimates that you can use in the [EVALUATE](#), [FILTER](#), [FORECAST](#), and [SMOOTH](#) statements (see the PARM= option for each of those statements). Therefore, the 50th percentile of the posterior sample is always computed whether it is specified in the *numeric-list* or not.

By default, STATISTICS=SUMMARIES.

THIN=*k*

THINNING=*k*

thins the Markov chain by using only one of every *k* iterations. For more information, see the section “[Burn-In, Thinning, and Markov Chain Samples](#)” on page 27 in Chapter 2, “[Introduction to Bayesian Analysis Procedures](#).” By default, THIN=1.

MODEL Statement

MODEL *dependent-variable* ~ *distribution* ;

The MODEL statement specifies the measurement distribution of the dependent variable given the parameters, the state variables, and the independent variables; that is, $\mathbf{Y}_t \sim g_{\theta}(\cdot | \mathbf{X}_{t-r:t}, \mathbf{Z}_{t-s:t}, \mathbf{Y}_{t-p:t-1})$, $s \geq 0$, $r \geq 0$, $p \geq 1$. For more information about the measurement distribution in the state space model, see the section “[Sequential Monte Carlo Methods and State Space Models](#)” on page 1961. The MODEL statement is ignored if you specify the SUBMITMODEL statement. The MODEL statement has the following requirements if you omit the SUBMITMODEL statement:

- The MODEL statement is required. Each dependent variable must have a corresponding AUXMODEL statement.
- Multiple MODEL statements are permitted. When you specify multiple MODEL statements, be careful about the order of the MODEL statements if there exists dependency between dependent variables.

The MODEL statement must have the following components in the order shown:

1. *Dependent variable*: A single dependent variable from the input data table.
2. *Tilde*: A tilde (~) symbol between the dependent variable and the distribution.

3. *Distribution*: A distribution that is specified in the form *distribution-name(distribution-arguments)*. The available *distribution-name* and *distribution-arguments* in the MODEL statements are displayed in Table 27.4. For the description of each distribution, see the section “[Standard Distributions](#)” on page 1991.

Table 27.4 Distribution Names and Arguments

Distribution Name	Distribution Arguments	Definitions
BETA	a, b	Beta distribution with arguments shape parameter a and shape parameter b
CAUCHY	l, s	Cauchy distribution with arguments location l and scale s
GAMMA	a, b	Gamma distribution with arguments shape a and scale b
LOGN	m, s	Log-normal distribution with arguments mean m and standard deviation s
NORMAL N	m, s	Normal distribution with arguments mean m and standard deviation s
POISSON	λ	Poisson distribution with argument mean λ
T	m, s, ν	Student's t distribution with arguments mean m , standard deviation s , and degrees of freedom ν
UNIFORM	l, u	Uniform distribution with arguments min l and scale u

The *distribution-arguments* are specified by expressions that are enclosed in parentheses and separated by commas. Such expressions must follow any SAS programming statements. To avoid the possible computation errors, you should make some adjustments to the expressions. For more information about the adjustments, see the section “[Distribution Argument Restriction](#)” on page 1990. The number of expressions is equal to the number of arguments of the given distribution. For the MODEL statement, the variables that can appear in the expressions must be selected from the following list:

- the model parameters
- the current and lagged state variables
- the current and lagged independent variables
- the lagged dependent variables
- the current dependent variables whose MODEL statements are specified in the preceding MODEL statements
- the actual time index, `_time`

For more information about the actual time index, see the section “[Time Index](#)” on page 1995. For more information about the parameters, the state variables, and the dependent/independent variables, see the sections “[PARAMETERS Statement](#)” on page 1937, “[STATEVAR Statement](#)” on page 1945, and “[VAR Statement](#)” on page 1960, respectively.

Moreover, the MODEL statements must satisfy the following conditions:

- The maximum lag order of all the state variables in the *distribution-arguments* of all MODEL statements must be less than or equal to r , where r is defined in the section “[Method 1: Maximum Lag Order of State Variables, \$r\$](#) ” on page 1986.
- The maximum lag order of all the dependent variables in the *distribution-arguments* of all MODEL statements must be less than or equal to p , where p is defined in the section “[Method 1: Maximum Lag Order of Dependent Variables, \$p\$](#) ” on page 1986.
- The maximum lag order of all the independent variables in the *distribution-arguments* of all MODEL statements must be less than or equal to s , where s is defined in the section “[Method 1: Maximum Lag Order of Independent Variables, \$s\$](#) ” on page 1986.
- The dependent variables in all MODEL statements must not have duplicates; that is, each dependent variable should appear only once as the *dependent variable* in all MODEL statements.

For example, the following statement defines the measurement distribution $y_t = \beta \exp(\frac{x_t}{2})\epsilon_t$, $\epsilon_t \stackrel{\text{iid}}{\sim} N(0, 1)$:

```
model y ~ normal(0, beta*exp(x/2));
```

where y is the current dependent variable, β is the parameter, and x is the current state variable.

The second example supposes that the measurement distributions of the state-space model are

$$y_{1,t} = \alpha y_{1,t-1} + \exp(\frac{x_t}{2})\xi_t, \quad \xi_t \stackrel{\text{iid}}{\sim} N(0, 1)$$

$$y_{2,t} = \phi y_{1,t} + \gamma \exp(\frac{x_{t-1}}{2})\eta_t, \quad \eta_t \stackrel{\text{iid}}{\sim} N(0, 1), \quad \xi_t \perp \eta_t$$

Then the following statements define these measurement distributions:

```
model y1 ~ normal(alpha*y1.l1, exp(x1/2));
model y2 ~ normal(phi*y1, gamma*exp(x1.l1/2));
```

where α , ϕ , and γ are parameters and $y1$ and $y2$ are current dependent variables. The first-order lagged state variable $x.l1$ is constructed by appending the suffix “.l1” to the current state variable x . The first-order lagged dependent variables $y1.l1$ is constructed by appending the suffix “.l1” to the current dependent variable $y1$ (see the section “[Method 1: Lagged Variables](#)” on page 1985).

PARAMETERS Statement

PARAMETERS *parameter-specification* < , . . . , *parameter-specification* > < / *options* > ;

PARMS *parameter-specification* < , . . . , *parameter-specification* > < / *options* > ;

The PARAMETERS (or PARMS) statement lists the names of the model parameters and specifies the initial value of each parameter. Whether the PARAMETERS statement is required depends on whether the SUBMITMODEL statement is specified: If you specify the SUBMITMODEL statement, the PARAMETERS statement is ignored; if you omit the SUBMITMODEL statement, the PARAMETERS statement is required.

A *parameter-specification* has the following general form, where *name* identifies the parameter and *value* provides a single initial value for the parameter:

name = value

Multiple *parameter-specifications* must be separated by commas or spaces. You can specify the following *options* after a forward slash (/):

LOWER=(*number1 number2 ...*)

LOWER=(*number*)

specifies the lower bounds of the specified parameters. The list can contain exactly one number, which is taken to be the lower bound of all the listed parameters in the statement, or it must contain as many values as the number of parameters specified. A missing value, denoted by a period (.), is a permissible value, which signifies that the parameter has no lower bound.

UPPER=(*number1 number2 ...*)

UPPER=(*number*)

specifies the upper bounds of the specified parameters. The list can contain exactly one number, which is taken to be the upper bound of all the listed parameters in the statement, or it must contain as many values as the number of parameters specified. A missing value, denoted by a period (.), is a permissible value, which signifies that the parameter has no upper bound.

The parameter names are case-insensitive, and the following conditions must be satisfied:

- The parameter names must not have duplicates.
- The parameter names must not contain the dot (“.”) symbol.
- “_t” or “_time” is a reserved name in PROC SMC. “_t” or “_time” (case-insensitive) must not be used as a parameter name.
- “dft_” is a reserved prefix in PROC SMC. The variable and parameter names must not start with “dft_” (case-insensitive).

For example, the following PARMS statement specifies three parameters and sets their initial values:

```
parms phi=0.9 beta=1 gamma=0.4;
```

PRIOR Statement

PRIOR *parameter-list* ~ *distribution* ;

The PRIOR statement specifies the prior distribution and range of the model parameters. You must specify a single parameter or a list of parameters, a tilde (~), and then a distribution with its hyperparameters. Multiple PRIOR statements are permitted. The PRIOR statement is ignored if you specify the SUBMITMODEL statement.

With respect to each PRIOR statement, the syntax must have the following components in the order shown:

1. *List of parameters*: A list of parameters that have the same prior distribution.
2. *Tilde*: A tilde (~) symbol between the list of parameters and the distribution.
3. *Distribution with hyperparameters*: A distribution that is specified in the form *distribution-name*(*distribution-arguments*). The available *distribution-name* and *distribution-arguments* in the prior statements are displayed in [Table 27.5](#).

Table 27.5 Distribution Names and Arguments

Distribution Name	Distribution Arguments	Definitions
BETA	a, b	Beta distribution with arguments shape parameter a and shape parameter b
CAUCHY	l, s	Cauchy distribution with arguments location l and scale s
GAMMA	a, b	Gamma distribution with arguments shape a and scale b
IGAMMA	a, b	Inverse gamma distribution with arguments shape a and scale b
LOGN	m, s	Log-normal distribution with arguments mean m and standard deviation s
NORMAL N	m, s	Normal distribution with arguments mean m and standard deviation s
T	m, s, ν	Student's t distribution with arguments mean m , standard deviation s , and degrees of freedom ν
UNIFORM	l, u	Uniform distribution with arguments min l and scale u

The *distribution-arguments* are specified by numbers that are enclosed in parentheses and separated by commas.

The constant hyperparameters of a prior distribution are specified by constant numbers in parentheses. For example, the following statements specify the prior distributions of ϕ , var_1 , and var_2 , where the latter two parameters have the same prior distribution:

```
prior phi ~ uniform(-1, 1);
prior var_1 var_2 ~ igamma(0.01, 0.01);
```

The range of each model parameter defines its upper and lower bounds when you draw them from the random walk proposal in the PMCMC method. If any model parameter is not specified in any PRIOR statement, then the contribution of that parameter to the logarithmic prior density function, $\ln p(\theta)$, is zero (see the section “[Particle Marginal Metropolis-Hastings Sampler](#)” on page 1974), and the range of that parameter is defined by LOWER and UPPER options in the PARAMETERS statement (see the section “[PARAMETERS Statement](#)” on page 1937). For any model parameter that you specify in the PRIOR statement, its range is defined by the intersection of the range specified in the PARAMETERS statement and the default range of the prior distribution. In addition, the range of that parameter defined in the PARAMETERS statement must be a subset of the default range of its prior distribution. For example, the following statements cause an error because $0 < 0.2$:

```
parameter phi = 0.5 / lower = 0 upper = 1;
prior phi ~ uniform(0.2, 1);
```

SCORE Statement

SCORE *options* ;

The SCORE statement specifies options that are related to scoring data. You can specify the following *options*:

INMODEL=*libref.data-table*

specifies the input data table that contains model information. The data table must be an output data table that is produced by the OUTMODEL= option in a previous call of the SMC procedure. When you specify this option, the ID, MODEL, and LEARN statements are ignored. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1903.

OUTMODEL=*libref.data-table*

writes the model information and the learning results to the specified output data table. The output data table consists of binary large object columns to store the binary data. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters because the data type of each column is binary. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “Using CAS Sessions and CAS Engine Librefs” on page 1903.

SMOOTH Statement

SMOOTH <*options*> ;

The SMOOTH statement specifies options that are related to the smoothing problem, which is to find the probability distribution of the state, conditional on all observations (see the section “[SMC Smoothing](#)” on page 1969). If the PMCMC method is specified in the LEARN statement, the model parameters in the requested smoothing method are set to the posterior mean of the corresponding model parameters. If the LEARN statement is omitted, the parameters with initial values specified in the PARAMETERS statement are used for the smoothing problem. You can specify the following *options*:

ALGORITHM=*algorithm*

ALG=*algorithm*

specifies the particle filter algorithm to use in the smoothing process. You can specify the following *algorithms*:

APF<(ADP)> specifies the auxiliary particle filter (APF) algorithm. The ADP suboption specifies the fully adapted auxiliary particle filter algorithm.

BF specifies the bootstrap filter (BF) algorithm.

SIR<(TH | THRESH | THRESHOLD=*number*)> specifies the sequential importance resampling (SIR) algorithm. The optional TH= option specifies the threshold (a value between 0 and 1) of the resampling step in the SIR algorithm. The resampling step

occurs when the effective sample size is less than the product of the threshold and the number of particles. By default, TH=0.8.

By default, ALGORITHM=SIR.

METHOD=FIXEDINTERVAL | FIXEDLAG<(number)>

specifies the type of smoothing method. You can specify the following *values*:

FIXEDINTERVAL specifies the fixed-interval smoothing method.

FIXEDLAG<(number)> specifies the fixed-lag smoothing method. The optional *number* in parentheses specifies the number of lags to use in the fixed-lag smoothing method. By default, *number*=25.

By default, METHOD=FIXEDLAG<(number)>.

NPARTICLE=number

specifies the number of particles to use for the smoothing problem. If this option is omitted, the smoothing method uses the value of the NPARTICLE= option in the PROC SMC statement.

OUT<(PERCENTILES=numeric-list)>=libref.data-table

OUT<(PERCENTILE=numeric-list)>=libref.data-table

OUT<(PERCENT=numeric-list)>=libref.data-table

OUT<(PERC=numeric-list)>=libref.data-table

OUT<(PCT=numeric-list)>=libref.data-table

writes the summary of the smoothing estimates to the specified output data table. The weighted average, weighted standard deviation, minimum value, first quantile, second quantile, third quantile, maximum value, and percentile points of each state variable at each time step are displayed. The optional PERCENTILES=*numeric-list* specifies the percentile points in the summary table of the smoothing estimates, where each *value* in the *numeric-list* must be between 0 and 100 and values are separated by commas or spaces. By default, PERCENTILES=2.5, 97.5, which yields the 2.5th and 97.5th percentile points, respectively. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1903.

OUTSIM=libref.data-table

writes the smoothing estimates to the specified output data table. The particle values with the corresponding normalized weights at each time step are displayed. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 1903.

PARM=MEAN | MEDIAN

specifies which parameter values from the posterior distribution to use for the smoothing distribution when you also specify the LEARN statement. If the LEARN statement is omitted, this option is ignored. You can specify one of the following values:

MEAN	constructs the smoothing distribution by using the estimated posterior means of the parameters.
MEDIAN	constructs the smoothing distribution by using the estimated posterior medians of the parameters.

By default, PARM=MEAN.

STATE Statement

STATE *state-variable* $\sim$ *distribution* *</ options>* ;

The STATE statement specifies the transition distributions of the state variable given the parameters, the lagged state variables, the lagged and current independent variables; that is, $\mathbf{X}_t \sim f_{\theta}(\cdot | \mathbf{X}_{t-r:t-1}, \mathbf{Z}_{t-s:t}, \mathbf{Y}_{t-p:t-1})$, $t > 1, s \geq 0, r \geq 1, p \geq 1$. For more information about the transition equation in the state space model, see the section “[Sequential Monte Carlo Methods and State Space Models](#)” on page 1961. The STATE statement is ignored if you specify the SUBMITMODEL statement. The STATE statement has the following requirements if you omit the SUBMITMODEL statement:

- The STATE statement is required. Each state variable must have a corresponding STATE statement.
- Multiple STATE statements are permitted. When you specify multiple STATE statements, be careful about the order if there is any dependency between state variables.

The STATE statement must have the following components in the order shown:

1. *State variable*: A single state variable that is specified in the [STATEVAR](#) statement.
2. *Tilde*: A tilde ($\sim$) symbol between the state variable and the distribution.
3. *Distribution*: A distribution that is specified in the form *distribution-name*(*distribution-arguments*). The available *distribution-name* and *distribution-arguments* in the STATE statements are displayed in [Table 27.6](#). For the description of each distribution, see the section “[Standard Distributions](#)” on page 1991.

Table 27.6 Distribution Names and Arguments

Distribution Name	Distribution Arguments	Definitions
BETA	a, b	Beta distribution with arguments shape parameter a and shape parameter b
CAUCHY	l, s	Cauchy distribution with arguments location l and scale s
DEGENERATE	c	Degenerate distribution with argument c
GAMMA	a, b	Gamma distribution with arguments shape a and scale b
LOGN	m, s	Log-normal distribution with arguments mean m and standard deviation s

Table 27.6 continued

Distribution Name	Distribution Arguments	Definitions
NORMAL N	m, s	Normal distribution with arguments mean m and standard deviation s
POISSON	λ	Poisson distribution with argument mean λ
T	m, s, ν	Student's t distribution with arguments mean m , standard deviation s , and degrees of freedom ν
UNIFORM	l, u	Uniform distribution with arguments min l and scale u

The *distribution-arguments* are specified by expressions that are enclosed in parentheses and separated by commas. Such expressions must follow any SAS programming statements. To avoid the possible computation errors, you should make some adjustments to the expressions. For more information about the adjustments, see the section “[Distribution Argument Restriction](#)” on page 1990. The number of expressions is equal to the number of arguments of the given distribution. For the STATE statement, the variables that can appear in the expressions must be selected from the following list:

- the model parameters
- the lagged state variables
- the lagged dependent variables
- the lagged and current independent variables
- the state variables that have been specified in the preceding STATE statements
- the actual time index, `_time`

For more information about the actual time index, see the section “[Time Index](#)” on page 1995. For more information about the parameters, the state variables, and the dependent/independent variables, see the sections “[PARAMETERS Statement](#)” on page 1937, “[STATEVAR Statement](#)” on page 1945, and “[VAR Statement](#)” on page 1960, respectively.

You can specify the following *option* after a forward slash (/):

PROPOSAL=*proposal-dist*

IMPORTANCE=*proposal-dist*

specifies the proposal (importance) transition distribution given the parameters, the lagged state variables, and the current dependent and independent variables for $t > 1$; that is, $\mathbf{X}_t \sim q_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t}, \mathbf{Z}_{t-s:t})$, $t > 1$, $s \geq 1$, $r \geq 1$, $p \geq 0$. If this option is not specified, then the corresponding state variable uses the original transition distribution as its proposal transition distribution. In the SIR or APF algorithm, each state variable is sampled from its proposal transition distributions. Subsequently, the joint densities of both the original and proposal transition distributions of all the state variables are evaluated within the importance weight calculation. In the BF algorithm, the proposal transition distribution of each state variable is always the same as its original transition distribution. For more information about the proposal distribution, see the sections “[Sequential Importance Resampling Algorithm](#)” on page 1964 and “[Auxiliary Particle Filter](#)” on page 1966. The format

of the *proposal-dist* is *proposal-dist-name(proposal-arguments)*. The available *proposal-dist-name* and *proposal-arguments* in the STATE statements are also displayed in [Table 27.6](#).

The expressions for *proposal-arguments* are enclosed in parentheses and separated by commas. Such expressions must follow any SAS programming statements. To avoid the possible computation errors, you should make some adjustments to the expressions. For more information about the adjustments, see the section “[Distribution Argument Restriction](#)” on page 1990. The number of expressions is equal to the number of arguments of the given distribution type. The variables used in the expressions for *proposal-arguments* must be selected from the following list:

- the model parameters
- the lagged state variables
- the lagged and current dependent variables
- the lagged and current independent variables
- the state variables that have been specified in the preceding STATE statements
- the actual time index, *_time*

Moreover, the STATE statements must satisfy the following conditions:

- The maximum lag order of all the state variables in the *distribution-arguments* of all STATE statements must be less than or equal to *r*, where *r* is defined in the section “[Method 1: Maximum Lag Order of State Variables, *r*](#)” on page 1986.
- The maximum lag order of all the dependent variables in the *distribution-arguments* of all the STATE statements, including the PROPOSAL= option, must be less than or equal to *p*, where *p* is defined in the section “[Method 1: Maximum Lag Order of Dependent Variables, *p*](#)” on page 1986.
- The maximum lag order of all the independent variables in the *distribution-arguments* of all the STATE statements, including the PROPOSAL= option, must be less than or equal to *s*, where *s* is defined in the section “[Method 1: Maximum Lag Order of Independent Variables, *s*](#)” on page 1986.
- The state variables appear as the *variable-name* in all STATE statements must not have duplicates; that is, each state variable should appear only once as the *variable-name* in all STATE statements.

For example, suppose the transition equations are

$$x_{1,t} = x_{1,t-1} + \gamma \xi_t, \quad \xi_t \stackrel{\text{iid}}{\sim} N(0, 1),$$

$$x_{2,t} = \phi x_{2,t-1} + \beta \eta_t, \quad \eta_t \stackrel{\text{iid}}{\sim} N(0, 1), \quad \xi_t \perp \eta_t$$

Then the following statements define these initialization equations:

```
state x1 ~ normal(x1.l1, gamma);
state x2 ~ normal(phi*x2.l1, beta);
```

where phi, gamma, and beta are parameters and x1 and x2 are current state variables. The first-order lagged state variables x1.l1 and x2.l1 are constructed by appending the suffix “.l1” to the current state variables x1 and x2 (see the section “[Method 1: Lagged Variables](#)” on page 1985).

If $x_{1,t}$ has a proposal transition equation $x_{1,1} = y + \gamma \epsilon_t, \epsilon_t \stackrel{\text{iid}}{\sim} N(0, \gamma)$, the transition equations can be defined by

```
state x1 ~ normal(x1.1, gamma) / proposal = normal(y, gamma);
state x2 ~ normal(phi*x2.1, beta);
```

where the state variable x1 has a proposal transition distribution that incorporates the current dependent variable y and the state variable x2 uses the original transition as its proposal transition distribution.

STATEVAR Statement

STATEVAR *variable-list* ;

The STATEVAR statement specifies the names of the state variables in the SMC procedure. Whether the STATEVAR statement is required depends on whether the SUBMITMODEL statement is specified: If you specify the SUBMITMODEL statement, the STATEVAR statement is ignored; if you omit the SUBMITMODEL statement, the STATEVAR statement is required. You can specify one or more state variables in a space-separated *variable-list*. Each state variable must have corresponding INITSTATE and STATE statements.

The state variable names are case-insensitive, and the following conditions must be satisfied:

- The state variable names must not have duplicates.
- The state variable names must not contain the dot (“.”) symbol.
- “_t” or “_time” is a reserved name in PROC SMC. “_t” or “_time” (case-insensitive) must not be used as any state variable name.
- “dft_” is a reserved prefix in PROC SMC. The state variable names must not start with “dft_” (case-insensitive).

For example, the following statement specifies the state variables x1 and x2:

```
statevar x1 x2;
```

SUBMITMODEL Statement

SUBMITMODEL *dependent-variables* <=*independent-variables*> < / *options* > ;

The SUBMITMODEL statement indicates the start of your user-defined program statements between the SUBMITMODEL and ENDSUBMIT statements or specifies a file that contains your user-defined program statements in the FILE= option. When you specify the SUBMITMODEL statement, the AUXMODEL, INITSTATE, MODEL, PARAMETERS, PRIOR, STATE, STATEVAR, and VAR statements are ignored.

PROC SMC loads the predefined functions or subroutines from the current CMPLIB session and combines them with the functions or subroutines defined in the SUBMITMODEL statement. For more information about the combination of the CMPLIB session and SUBMITMODEL statement, see the section “[Method 2](#)” on page 1987.

The SUBMITMODEL defines the user-defined functions or subroutines by using either the FILE= option or the user-defined program statements that appear between the SUBMITMODEL and ENDSUBMIT

statements. If you specify the FILE= option, you cannot add lines of code for the user-defined program in the SUBMITMODEL statement. If you omit the FILE= option in the SUBMITMODEL statement, then PROC SMC executes all lines of code that are specified between the SUBMITMODEL and ENDSUBMIT statements. For more information, see the section “[ENDSUBMIT Statement](#)” on page 1921.

To define a state space model, you define FCMP functions and subroutines in the user-defined program. For more information, see the “FCMP Procedure” chapter in the *Base SAS Procedures Guide*. Each function or subroutine must be named using the format `<model-name>_<keyword>`, where *model-name* must be identical to the name specified in the NAME= option and *keyword* identifies the function or subroutine. The total length of the name should not exceed 32 characters. Each function or subroutine must have a specific signature, which consists of the number of arguments, sequence and types of arguments, and return value type. The summary of all the recognized function and subroutine names and their expected behavior is presented in [Table 27.7](#). Moreover, the type, definition, and size of each argument in the functions and subroutines are summarized in [Table 27.8](#). Consider the following points when you define a distribution model:

- When you define a function or subroutine, the name, type, and order of those arguments must follow the corresponding signature syntax and semantics. For more information about the signature syntax and semantics, see the section “[Signature Syntax and Semantics of User-Defined Functions and Subroutines](#)” on page 1950.
- When the SMC procedure invokes any function or subroutine, it provides the necessary input values according to the specified signature, and it expects the function or subroutine to prepare the output and return it according to the specification of the return values in the signature.
- You can use most of the SAS programming statements and SAS functions that you can use in a DATA step to define the FCMP functions and subroutines. However, there are a few differences in the capabilities of the DATA step and the FCMP procedure. To learn more, see the documentation of the FCMP procedure in the *Base SAS Procedures Guide*.
- The dimensions of the state variable and parameter array must match the values specified in the NSTATE= and NPARAM= options in the SUBMITMODEL statement. The dimensions of the dependent and independent variable array must match the number of variables specified in the *dependent-variables* and *independent-variables* in the SUBMITMODEL statement. The dimensions of the lagged variables must match the XLAG=, YLAG=, and ZLAG= option values. For more information, see [Table 27.8](#).
- Not all the functions and subroutines are required. Whether you need to define a particular function or subroutine depends on the SMC algorithms and other statements (see the section “[Signature Syntax and Semantics of User-Defined Functions and Subroutines](#)” on page 1950).
- The results of the subroutine should be returned in the parameter arguments of the subroutine.

You can specify the following options in the SUBMITMODEL statement after a forward slash (/):

FILE=SAS-file-ref | 'File-path'

specifies a file that contains your user-defined program. If you specify this option, you cannot specify the ENDSUBMIT statement.

You can specify the file either by including a *SAS-file-ref* that is defined in a prior SAS FILENAME statement or by including a quoted string (a 'File-path') that identifies the host-specific file path.

The following rules apply when you specify the FILE= option:

- The text file that you specify must contain only the program statements that you want to submit and none of the PROC SMC statements. You cannot include an ENDSUBMIT statement in the file.
- The text file that you specify must not contain any SAS macro statements or macro variable references. The file content is submitted as specified.

NAME=*symbol-name*

specifies the name of the model of interest. The model should be defined using the user-defined program (see the section “[Method 2](#)” on page 1987).

NPARM=*number*

specifies the number of parameters. The *number* should be a nonnegative integer.

NSTATE<(*numeric-list*)>=*number*

specifies the number of state variables. The *number* should be a nonnegative integer. The optional *numeric-list* in parentheses specifies the number of levels of all category variables. Each value in the *numeric-list* must be a positive integer, and values can be separated by commas or spaces. The number of values in the *numeric-list* must be less than or equal to the number of state variables. For each categorical state variable, its level values start from 0. For example, if a categorical state variable has three levels, its value is 0, 1, or 2.

In the underlying SMC algorithms of the SMC procedure, the category state variables are positioned before the noncategorical state variables in the state variable vector. For example, suppose that there are d_x state variables and d_x is defined by the NSTATE= option. If there are d_c ($0 \leq d_c \leq d_x$) values in the *numeric-list*, then the first d_c state variables are category variables and the remaining $d_x - d_c$ state variables are noncategorical variables.

XLAG=(*xlag-options*)

specifies the lag orders of the state variables in the distribution functions. For the XLAG= option in the SUBMITMODEL statement, the value of INIT= suboption must be greater than or equal to $\max(r_1, r_2 - 1, r_3 - 1)$, where r_1, r_2, r_3 are specified by the MEAS=, STATE=, and AUX= suboptions, respectively.

You can specify one or more of the following *xlag-options*:

AUX=*number***AUXILIARY=***number*

specifies the maximum lag order of the state variables in the auxiliary distribution function (*name_EVALNEXTMEAS*). If the APF algorithm is not specified in one or more of the EVALUATE, FILTER, FORECAST, LEARN, or LEARN statements, the AUX= suboption is ignored. By default, AUX=1.

INIT=*number***INITIALIZATION=***number*

specifies the maximum lag order of the state variables in the initialization distribution functions (*name_SAMPINIT* or *name_EVALINIT*) and proposal initialization distribution functions (*name_SAMPINITP* or *name_EVALINITP*). By default, INIT=0.

MEAS=number

MEASUREMENT=number

MODEL=number

specifies the maximum lag order of the state variables in the measurement distribution functions (*name_EVALMEAS* or *name_SAMPMEAS*). By default, MEAS=0.

STATE=number

TRAN=number

TRANSITION=number

specifies the maximum lag order of the state variables in the transition distribution functions (*name_SAMPTRAN* or *name_EVALTRAN*) and proposal transition distribution functions (*name_SAMPTRANP* or *name_EVALTRANP*). By default, STATE=1.

YLAG=(ylag-options)

specifies the lag orders of the dependent in the distribution functions. You can specify one or more of the following *ylag-options*:

AUX=number

AUXILIARY=number

specifies the maximum lag order of the dependent variables in the auxiliary distribution function (*name_EVALNEXTMEAS*). If the APF algorithm is not specified in one or more of the EVALUATE, FILTER, FORECAST, LEARN, or LEARN statements, the AUX= suboption is ignored. By default, AUX=0.

INIT=number

INITIALIZATION=number

specifies the maximum lag order of the dependent variables in the initialization distribution functions (*name_SAMPINIT* or *name_EVALINIT*) and proposal initialization distribution functions (*name_SAMPINITP* or *name_EVALINITP*). By default, INIT=0.

MEAS=number

MEASUREMENT=number

MODEL=number

specifies the maximum lag order of the dependent variables in the measurement distribution functions (*name_EVALMEAS* or *name_SAMPMEAS*). By default, MEAS=0.

STATE=number

TRAN=number

TRANSITION=number

specifies the maximum lag order of the dependent variables in the transition distribution functions (*name_SAMPTRAN* or *name_EVALTRAN*) and proposal transition distribution functions (*name_SAMPTRANP* or *name_EVALTRANP*). By default, STATE=0.

ZLAG=(*zlag-options*)

specifies the lag orders of the independent in the distribution functions. You can specify one or more of the following *zlag-options*:

AUX=number**AUXILIARY=number**

specifies the maximum lag order of the independent variables in the auxiliary distribution function (*name_EVALNEXTMEAS*). If the APF algorithm is not specified in one or more of the EVALUATE, FILTER, FORECAST, LEARN, or LEARN statements, the AUX= suboption is ignored. By default, AUX=0.

INIT=number**INITIALIZATION=number**

specifies the maximum lag order of the independent variables in the initialization distribution functions (*name_SAMPINIT* or *name_EVALINIT*) and proposal initialization distribution functions (*name_SAMPINITP* or *name_EVALINITP*). By default, INIT=0.

MEAS=number**MEASUREMENT=number****MODEL=number**

specifies the maximum lag order of the independent variables in the measurement distribution functions (*name_EVALMEAS* or *name_SAMPMEAS*). By default, MEAS=0.

STATE=number**TRAN=number****TRANSITION=number**

specifies the maximum lag order of the independent variables in the transition distribution functions (*name_SAMPTRAN* or *name_EVALTRAN*) and proposal transition distribution functions (*name_SAMPTRANP* or *name_EVALTRANP*). By default, STATE=0.

Table 27.7 shows functions and subroutines that define a state space model, and the subsections after the table provide more details.

Table 27.7 Functions and Subroutines That Define a State Space Model

Name	Type	Expected to Return
<i>name</i> _EVALINIT	Function	LOGPDF of the initialization distribution
<i>name</i> _EVALINITP	Function	LOGPDF of the proposal initialization distribution
<i>name</i> _EVALMEAS	Function	LOGPDF of the measurement distribution
<i>name</i> _EVALNEXTMEAS	Function	LOGPDF of the auxiliary distribution
<i>name</i> _EVALPRIO	Function	LOGPDF of the prior distribution
<i>name</i> _EVALTRAN	Function	LOGPDF of the transition distribution
<i>name</i> _EVALTRANP	Function	LOGPDF of the proposal transition distribution
<i>name</i> _LOWERBOUNDS	Subroutine	Lower bounds of the parameters
<i>name</i> _SAMPINIT	Subroutine	A sample from the initialization distribution
<i>name</i> _SAMPINITP	Subroutine	A sample from the proposal initialization distribution
<i>name</i> _SAMPMEAS	Subroutine	A sample from the measurement distribution
<i>name</i> _SAMPPRIO	Subroutine	Initial values for the parameters
<i>name</i> _SAMPTRAN	Subroutine	A sample from the transition distribution
<i>name</i> _SAMPTRANP	Subroutine	A sample from the proposal transition distribution
<i>name</i> _UPPERBOUNDS	Subroutine	Upper bounds of the parameters

Signature Syntax and Semantics of User-Defined Functions and Subroutines

Each function or subroutine has a fixed sequence and type of arguments. The name of each argument is also fixed. All the arguments of the functions and subroutines are listed in Table 27.8, where n is specified by the NPARM= option, d_x is defined by the NSTATE= option, d_y is the number of dependent variables, d_z is defined by the number of independent variables, r is specified by the maximum value in the XLAG=(*xlag-options*) option, p is specified by the maximum value in the YLAG=(*ylag-options*) option, and s is specified by the maximum value in the ZLAG=(*zlag-options*) option. Moreover, *_time* refers to the actual time index of the observations (see the section “Time Index” on page 1995).

For an array argument array-argument[*] that is one of theta[*], x[*], y[*], and z[*], the i th ($i \geq 1$) element, array-argument[i], refers to the i th element of the corresponding variable or parameter vector. For a lagged variable array argument lag-array-argument[*] that is one of xlag[*], ylag[*], and zlag[*], lag-array-argument[($j - 1$) * $d + i$] ($i, j \geq 1$) refers to the j th order of lag for the i th element of the corresponding variable whose dimension is denoted by d . For more information about the array or lagged array arguments for the parameter, state variables, dependent variables, and independent variables, see the sections “Method 2: Parameters” on page 1988, “Method 2: State Variables” on page 1988, “Method 2: Dependent Variables” on page 1988, “Method 2: Independent Variables” on page 1989, and “Method 2: Lagged Variables” on page 1988.

Table 27.8 List of Arguments in Functions and Subroutines

Name	Type	Definition	Size
theta[*]	Input/Output array	Parameters	n
x[*]	Input/Output array	Current state variables	d_x
xlag[*]	Input/Output array	Lagged state variables	$d_x * r$
y[*]	Input/Output array	Current dependent variables	d_y
ylag[*]	Input array	Lagged dependent variables	$d_y * p$
z[*]	Input array	Current independent variables	d_z
zlag[*]	Input array	Lagged independent variables	$d_z * s$
_time	Input scalar	Actual time index	1

The details of the argument, signature syntax, and semantics of each function or subroutine are listed as follows:

*name_***EVALINIT**

defines a function that returns the log of the probability density function (LOGPDF) of the initialization distribution, $\mu_{\theta}(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})$.

- *Type*: FUNCTION
- *Requirement*: Required only when the APF or SIR algorithm is specified and the *name_SAMPINITP* function is specified
- *Number of arguments*: 7
- *Sequence and type of arguments*:

x[*]	Input numeric array of the current state variables at the initial time step
xlag[*]	Input numeric array of the lagged state variables before the initial time step
ylag[*]	Input numeric array of the lagged dependent variables before the initial time step
z[*]	Input numeric array of the current independent variables at the initial time step
zlag[*]	Input numeric array of the lagged independent variables before the initial time step
theta[*]	Input numeric array of the parameters
_time	Input numeric value of the current actual time index

Here is a sample structure of this function for a model named ‘TOY’:

```
function TOY_EVALINIT(x[*],xlag[*],ylag[*],z[*],zlag[*],theta[*],_time);
/*Code to compute LOGPDF based on initialization distribution*/
LOGPDF = <computed logpdf>;
return (LOGPDF);
endsub;
```

name_EVALINITP

defines a function that returns the LOGPDF of the proposal initialization distribution, $q_{\theta}^1(\mathbf{X}_{1-\tau:1}|\mathbf{Y}_{1-p:1}, \mathbf{Z}_{1-s:1})$.

- *Type*: FUNCTION
- *Requirement*: Required only when the APF or SIR algorithm is specified and the *name_SAMPINITP* function is specified
- *Number of arguments*: 8
- *Sequence and type of arguments*:

<code>x[*]</code>	Input numeric array of the current state variables at the initial time step
<code>xlag[*]</code>	Input numeric array of the lagged state variables before the initial time step
<code>y[*]</code>	Input numeric array of the current dependent variables at the initial time step
<code>ylag[*]</code>	Input numeric array of the lagged dependent variables before the initial time step
<code>z[*]</code>	Input numeric array of the current independent variables at the initial time step
<code>zlag[*]</code>	Input numeric array of the lagged independent variables before the initial time step
<code>theta[*]</code>	Input numeric array of the parameters
<code>_time</code>	Input numeric value of the current actual time index

Here is a sample structure of this function for a model named ‘TOY’:

```
function TOY_EVALINITP(x[*],xlag[*],y[*],ylag[*],z[*],zlag[*],theta[*],_time);
/*Code to compute LOGPDF based on proposal initialization distribution*/
LOGPDF = <computed logpdf>;
return (LOGPDF);
endsub;
```

name_EVALMEAS

defines a function that returns the LOGPDF of the measurement distribution, $g_{\theta}(\mathbf{Y}_t|\mathbf{X}_{t-r:t}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$.

- *Type*: FUNCTION
- *Requirement*: Always required
- *Number of arguments*: 8
- *Sequence and type of arguments*:

<code>x[*]</code>	Input numeric array of the current state variables
<code>xlag[*]</code>	Input numeric array of the lagged state variables
<code>y[*]</code>	Input numeric array of the current dependent variables
<code>ylag[*]</code>	Input numeric array of the lagged dependent variables
<code>z[*]</code>	Input numeric array of the current independent variables
<code>zlag[*]</code>	Input numeric array of the lagged independent variables

theta[*] Input numeric array of the parameters
 _time Input numeric value of the current actual time index

Here is a sample structure of this function for a model named ‘TOY’:

```
function TOY_EVALMEAS(x[*],xlag[*],y[*],ylag[*],z[*],zlag[*],theta[*],_time);
  /*Code to compute LOGPDF based on measurement distribution*/
  LOGPDF = <computed logpdf>;
  return (LOGPDF);
endsub;
```

*name_***EVALNEXTMEAS**

defines a function that returns the LOGPDF of the auxiliary distribution, $\hat{p}_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$.

- *Type:* FUNCTION
- *Required:* Required only when the APF algorithm is specified in one or more of the EVALUATE, FILTER, FORECAST, LEARN, and SMOOTH statements.
- *Number of arguments:* 7
- *Sequence and type of arguments:*

xlag[*] Input numeric array of the lagged state variables
 y[*] Input numeric array of the current dependent variables
 ylag[*] Input numeric array of the lagged dependent variables
 z[*] Input numeric array of the current independent variables
 zlag[*] Input numeric array of the lagged independent variables
 theta[*] Input numeric array of the parameters
 _time Input numeric value of the current actual time index

Here is a sample structure of this function for a model named ‘TOY’:

```
function TOY_EVALNEXTMEAS(xlag[*],y[*],ylag[*],z[*],zlag[*],theta[*],_time);
  /*Code to compute LOGPDF based on the approximated density function*/
  LOGPDF = <computed logpdf>;
  return (LOGPDF);
endsub;
```

*name_***EVALPRIO**

defines a function that defines the LOGPDF of the prior distribution, $p(\theta)$.

- *Type:* FUNCTION
- *Required:* Required only when the PMCMC method is specified in the LEARN statement
- *Number of arguments:* 1
- *Sequence and type of arguments:*

theta[*] Input numeric array of the parameters

Here is a sample structure of this function for a model named ‘TOY’:

```
function TOY_EVALPRIO(theta[*]);
/*Code to compute LOGPDF based on the prior distribution*/
LOGPDF = <computed logpdf>;
return (LOGPDF);
endsub;
```

*name_***EVALTRAN**

defines a function that returns LOGPDF of the transition distribution, $f_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$.

- *Type*: FUNCTION
- *Requirement*: Required only when the APF or SIR algorithm is specified and the *name_SAMPTRANP* subroutine is specified
- *Number of arguments*: 7
- *Sequence and type of arguments*:

x[*] Input numeric array of the current state variables
xlag[*] Input numeric array of the lagged state variables
ylag[*] Input numeric array of the lagged dependent variables
z[*] Input numeric array of the current independent variables
zlag[*] Input numeric array of the lagged independent variables
theta[*] Input numeric array of the parameters
_time Input numeric value of the current actual time index

Here is a sample structure of this function for a model named ‘TOY’:

```
function TOY_EVALTRAN(x[*],xlag[*],ylag[*],z[*],zlag[*],theta[*],_time);
/*Code to compute LOGPDF based on the transition distribution*/
LOGPDF = <computed logpdf>;
return (LOGPDF);
endsub;
```

*name_***EVALTRANP**

defines a function that returns the LOGPDF of the proposal transition distribution, $q_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t}, \mathbf{Z}_{t-s:t})$.

- *Type*: FUNCTION
- *Requirement*: Required only when the APF or SIR algorithm is specified and the *name_SAMPTRANP* subroutine is specified
- *Number of arguments*: 8
- *Sequence and type of arguments*:

<code>x[*]</code>	Input numeric array of the current state variables
<code>xlag[*]</code>	Input numeric array of the lagged state variables
<code>y[*]</code>	Input numeric array of the current dependent variables
<code>ylag[*]</code>	Input numeric array of the lagged dependent variables
<code>z[*]</code>	Input numeric array of the current independent variables
<code>zlag[*]</code>	Input numeric array of the lagged independent variables
<code>theta[*]</code>	Input numeric array of the parameters
<code>_time</code>	Input numeric value of the current actual time index

Here is a sample structure of this function for a model named ‘TOY’:

```
function TOY_EVALTRANP(x[*],xlag[*],y[*],ylag[*],z[*],zlag[*],theta[*],_time);
  /* Code to compute LOGCDF based on the proposal transition distribution*/
  LOGPDF = <computed logpdf>;
  return (LOGPDF);
endsub;
```

*name_***LOWERBOUNDS**

defines a subroutine that returns lower bounds for the parameters. To indicate the output numeric array, the line “outargs theta;” must appear after the line “subroutine *name_*LOWERBOUNDS(theta[*]);”.

- *Type*: SUBROUTINE
- *Requirement*: Not always required
- *Number of arguments*: 1
- *Sequence and type of arguments*:

<code>theta[*]</code>	Output numeric array of the parameters. <code>theta[i]</code> assigns the lower bound for the <i>i</i> th parameter.
-----------------------	--

If this subroutine is not defined, then the SMC procedure assumes a lower bound of $-\infty$ for each parameter. If a lower bound of l_i is returned for a parameter p_i , then PROC SMC assumes that $l_i < p_i$ (strict inequality). If a missing value or no value is returned for one parameter, then PROC SMC assumes that there is no lower bound for that parameter (this is equivalent to a lower bound of $-\infty$).

Here is a sample structure of this subroutine for a model named ‘TOY’ that has three parameters:

```
subroutine TOY_LOWERBOUNDS(theta[*]);
  outargs theta;
  theta[1] = <lower bound for the first parameter>;
  /*the second parameter is missing */
  theta[3] = <lower bound for the third parameter>;
endsub;
```

name_SAMPINIT

defines a subroutine that returns the initial state variables drawn from the initialization distribution, $\mu_{\theta}(\mathbf{X}_{1-\tau:1}|\mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})$. To indicate the output numeric arrays, the line “outargs x, xlag;” must appear after the line “subroutine *name_SAMPINIT*(x[*],xlag[*],ylag[*],z[*],zlag[*],theta[*],_time);”.

- *Type*: SUBROUTINE
- *Requirement*: Required only when either of the following conditions is satisfied:
 - The BF algorithm is specified.
 - The APF or SIR algorithm is specified and the *name_SAMPINITP* subroutine is not specified.
- *Number of arguments*: 7
- *Sequence and type of arguments*:

x[*]	Output numeric array of the current state variables at the initial time step. x[i] assigns the initial value of the <i>i</i> th state variable.
xlag[*]	Output numeric array of the lagged state variables before the initial time step xlag[(<i>j</i> – 1) * <i>d_x</i> + <i>i</i>] (<i>i, j</i> ≥ 1) assigns the initial value of the <i>j</i> th order of lag for the <i>i</i> th state variable.
ylag[*]	Input numeric array of the lagged dependent variables before the initial time step
z[*]	Input numeric array of the current independent variables at the initial time step
zlag[*]	Input numeric array of the lagged independent variables before the initial time step
theta[*]	Input numeric array of the parameters
_time	Input numeric value of the current actual time index

Here is a sample structure of this subroutine for a model named ‘TOY’ that has three state variables:

```
subroutine TOY_SAMPINIT(x[*],xlag[*],ylag[*],z[*],zlag[*],theta[*],_time);
  outargs x, xlag;
  /*Code to generate x and xlag based on the sampling initial distribution*/
  x[1] = <generated first state variable>;
  x[2] = <generated second state variable>;
  x[3] = <generated third state variable>;
endsub;
```

name_SAMPINITP

defines a subroutine that returns the initial state variables drawn from the proposal initialization distribution, $q_{\theta}^1(\mathbf{X}_{1-\tau:1}|\mathbf{Y}_{1-p:1}, \mathbf{Z}_{1-s:1})$. To indicate the output numeric arrays, the line “outargs x, xlag;” must appear after the line “subroutine *name_SAMPINITP*(x[*],xlag[*],y[*],ylag[*],z[*],zlag[*],theta[*],_time);”.

- *Type*: SUBROUTINE
- *Required*: Required only when the APF or SIR algorithm is specified and the proposal initialization distribution, $q_{\theta}^1(\mathbf{X}_{1-\tau:1}|\mathbf{Y}_{1-p:1}, \mathbf{Z}_{1-s:1})$, is different from the initialization distribution, $\mu_{\theta}(\mathbf{X}_{1-\tau:1}|\mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})$
- *Number of arguments*: 8
- *Sequence and type of arguments*:

<code>x[*]</code>	Output numeric array of the current state variables at the initial time step. <code>x[i]</code> assigns the initial value of the i th state variable.
<code>xlag[*]</code>	Output numeric array of the lagged state variables before the initial time step. <code>xlag[($j - 1$) * d_x + i]</code> ($i, j \geq 1$) assigns the initial value of the j th order of lag for the i th state variable.
<code>y[*]</code>	Input numeric array of the lagged dependent variables at the initial time step
<code>ylag[*]</code>	Input numeric array of the lagged dependent variables before the initial time step
<code>z[*]</code>	Input numeric array of the current independent variables at the initial time step
<code>zlag[*]</code>	Input numeric array of the lagged independent variables before the initial time step
<code>theta[*]</code>	Input numeric array of the parameters
<code>_time</code>	Input numeric value of the current actual time index

Here is a sample structure of this subroutine for a model named ‘TOY’ that has three state variables:

```
subroutine TOY_SAMPINITP(x[*],xlag[*],y[*],ylag[*],z[*],zlag[*],theta[*],_time);
  outargs x, xlag;
  /*Code to generate x and xlag based on the sampling initial distribution*/
  x[1] = <generated first state variable>;
  x[2] = <generated second state variable>;
  x[3] = <generated third state variable>;
endsub;
```

name_ **SAMPMEAS**

defines a subroutine that returns the current dependent variables drawn from the measurement distribution, $g_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$. To indicate the output numeric array, the line “outargs y;” must appear after the line “subroutine *name_*SAMPMEAS(`x[*]`,`xlag[*]`,`y[*]`,`ylag[*]`,`z[*]`,`zlag[*]`,`theta[*]`,`_time`);”.

- *Type*: SUBROUTINE
- *Requirement*: Required when the FORECAST statement is specified
- *Number of arguments*: 8
- *Sequence and type of arguments*:

<code>x[*]</code>	Input numeric array of the current state variables
<code>xlag[*]</code>	Input numeric array of the lagged state variables
<code>y[*]</code>	Output numeric array of the current dependent variables. <code>y[i]</code> assigns the value of the i th current dependent variable.
<code>ylag[*]</code>	Input numeric array of the lagged dependent variables
<code>z[*]</code>	Input numeric array of the current independent variables
<code>zlag[*]</code>	Input numeric array of the lagged independent variables
<code>theta[*]</code>	Input numeric array of the parameters
<code>_time</code>	Input numeric value of the current actual time index

Here is a sample structure of this subroutine for a model named ‘TOY’ that has one dependent variable:

```

subroutine TOY_SAMPMEAS(x[*],xlag[*],y[*],ylag[*],z[*],zlag[*],theta[*],_time);
  outargs y;
  /*Code to generate x based on the sampling observation distribution*/
  y[1] = <the first generated dependent variable>;
endsub;

```

name_SAMPPRIO

defines a subroutine that returns the initial values of the parameters. To indicate the output numeric array, the line “outargs theta;” must appear after the line “subroutine *name_SAMPPRIO*(theta[*]);”.

- *Type*: Subroutine
- *Requirement*: Always required
- *Number of arguments*: 1
- *Sequence and type of arguments*:

theta[*] Output numeric array of the parameters. theta[i] assigns the initial value of the *i*th parameter.

Here is a sample structure of this subroutine for a model named ‘TOY’ that has three parameters:

```

subroutine TOY_SAMPPRIO(theta[*]);
  outargs theta;
  /*Code to initialize parameters*/
  theta[1] = <initial value of the first parameter>;
  theta[2] = <initial value of the second parameter>;
  theta[3] = <initial value of the third parameter>;
endsub;

```

name_SAMPTRAN

defines a subroutine that returns the current state variables drawn from the transition distribution, $f_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$. To indicate the output numeric array, the line “outargs x;” must appear after the line “subroutine *name_SAMPTRAN*(x[*],xlag[*],ylag[*],z[*],zlag[*],theta[*],_time);”.

- *Type*: SUBROUTINE
- *Requirement*: Required only when one of the following conditions is satisfied:
 - The BF algorithm is specified.
 - The APF or SIR algorithm is specified and the *name_SAMPTRANP* subroutine is not specified.
 - The FORECAST statement is specified.
- *Number of arguments*: 7
- *Sequence and type of arguments*:

<code>x[*]</code>	Output numeric array of the current state variables. <code>x[i]</code> assigns the value of the <i>i</i> th current state variable.
<code>xlag[*]</code>	Input numeric array of the lagged state variables
<code>ylag[*]</code>	Input numeric array of the lagged dependent variables
<code>z[*]</code>	Input numeric array of the current independent variables
<code>zlag[*]</code>	Input numeric array of the lagged independent variables
<code>theta[*]</code>	Input numeric array of the parameters
<code>_time</code>	Input numeric value of the current actual time index

Here is a sample structure of this subroutine for a model named ‘TOY’ that has three state variables:

```

subroutine TOY_SAMPTRAN(x[*],xlag[*],ylag[*],z[*],zlag[*],theta[*],_time);
  outargs x;
  /*Code to generate x based on the sampling transition distribution*/
  x[1] = <the first generated state variable>;
  x[2] = <the second generated state variable>;
  x[3] = <the third generated state variable>;
endsub;

```

name_SAMPTRANP

defines a subroutine that returns the current state variables drawn from the proposal transition distribution, $q_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t}, \mathbf{Z}_{t-s:t})$. To indicate the output numeric array, the line “outargs x;” must appear after the line “subroutine *name_SAMPTRANP*(`x[*]`,`xlag[*]`,`y[*]`,`ylag[*]`,`z[*]`,`zlag[*]`,`theta[*]`,`_time`);”.

- *Type*: SUBROUTINE
- *Requirement*: Required only when the APF or SIR algorithm is specified and the proposal transition distribution, $q_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t}, \mathbf{Z}_{t-s:t})$, is different from the transition distribution, $f_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$.
- *Number of arguments*: 9
- *Sequence and type of arguments*:

<code>x[*]</code>	Output numeric array of the current state variables. <code>x[i]</code> assigns the value of the <i>i</i> th current state variable.
<code>xlag[*]</code>	Input numeric array of the lagged state variables
<code>y[*]</code>	Input numeric array of the current dependent variables
<code>ylag[*]</code>	Input numeric array of the lagged dependent variables
<code>z[*]</code>	Input numeric array of the current independent variables
<code>zlag[*]</code>	Input numeric array of the lagged independent variables
<code>theta[*]</code>	Input numeric array of the parameters
<code>_time</code>	Input numeric value of the current actual time index

Here is a sample structure of this subroutine for a model named ‘TOY’ that has three state variables:

```

subroutine TOY_SAMPTRANP (x[*],xlag[*],y[*],ylag[*],z[*],zlag[*],theta[*],_time);
  outargs x;
  /*Code to generate x based on the sampling transition distribution*/
  x[1] = <the first generated state variable>;
  x[2] = <the second generated state variable>;
  x[3] = <the third generated state variable>;
endsub;

```

*name_*UPPERBOUNDS

defines a subroutine that returns upper bounds for the parameters. To indicate the output numeric array, the line “outargs theta;” must appear after the line “subroutine *name_*UPPERBOUNDS(theta[*]);”.

- *Type*: Subroutine
- *Requirement*: Not always required
- *Number of arguments*: 1
- *Sequence and type of arguments*:

theta[*] Output numeric array of the parameters. theta[i] assigns the upper bound for the *i*th parameter.

Here is a sample structure of this subroutine for a model named ‘TOY’ that has three parameters:

```

subroutine TOY_UPPERBOUNDS (theta[*]);
  outargs theta;
  theta[1] = <upper bound for the first parameter>;
  theta[2] = <upper bound for the second parameter>;
  theta[3] = <upper bound for the third parameter>;
endsub;

```

If this subroutine is not defined, then the SMC procedure assumes that there is no upper bound for any of the parameters. If an upper bound of u_i is returned for a parameter p_i , then PROC SMC assumes that $p_i < u_i$ (strict inequality). If a missing value or no value is returned for one parameter, then PROC SMC assumes that there is no upper bound for that parameter (this is equivalent to an upper bound of ∞).

VAR Statement

VAR *variable-list* ;

The VAR statement specifies the names of the dependent variables and the independent (exogenous) variables in the SMC procedure. One or more variables can be specified in a space-separated *variable-list*, and the order does not matter. The variables must be selected from the input data table (see the **DATA=** option in the **PROC SMC** statement). The requirement of the VAR statement depends on whether the SUBMITMODEL statement is specified: If the SUBMITMODEL is specified, the VAR statement is ignored; if the SUBMITMODEL is not specified, the VAR statement is required.

The variables in the VAR statement must contain all dependent variables that are specified before the tilde (~) symbol in the MODEL statements, and the remaining variables in the VAR statement are viewed as independent variables in the SMC procedure.

The dependent and independent variable names are case-insensitive, and the following conditions must be satisfied:

- The dependent and independent variable names must not have duplicates.
- The dependent and independent variable names must not contain the dot (“.”) symbol.
- “_t” and “_time” is a reserved name in PROC SMC. “_t” or “_time” (case-insensitive) must not be used as any dependent and independent variable name.
- “dft_” is a reserved prefix in PROC SMC. The dependent and independent variable names must not start with “dft_” (case-insensitive).

For example, the following statements specify the variables y1, y2, and z1:

```
var y1 y2 z1;
model y1 ~ normal(0, exp(x1/2));
model y2 ~ normal(phi*x2, gamma);
```

where y1 and y2 are dependent variables and z1 is the independent variable.

Details: The SMC Procedure

Sequential Monte Carlo Methods and State Space Models

This section is a brief review of the sequential Monte Carlo (SMC) methods (also known as particle filtering methods). These methods provide simulation-based approximate solutions to the state space model (SSM), which is also known as the hidden Markov model (HMM), especially for the nonlinear or non-Gaussian SSM. In some literature, the HMM is referred to as the discrete-state SSM (that is, the state can take only discrete values), whereas the SSM is referred to as the continuous-state SSM (that is, the state can take only continuous values). In this chapter, the HMM is equivalent to the SSM; that is, the state can take discrete or continuous values or even a mix of discrete and continuous values. For more information, see Doucet and Johansen (2011); Doucet, Godsill, and Andrieu (2000); Cappé, Godsill, and Moulines (2007).

The SSM consists of a discrete time process $\{\mathbf{X}_t, \mathbf{Y}_t, \mathbf{Z}_t\}$, where $\{\mathbf{X}_t\}$ is an unobserved Markov process; conditional on $\{\mathbf{X}_t\}$, the observable process $\{\mathbf{Y}_t\}$ is a sequence of independent random variables. $\mathbf{X}_t$ are called the state variables, and $\mathbf{Y}_t$ are called the dependent variables. In many cases, the SSM also has independent variables that are denoted by $\mathbf{Z}_t$. The independent variables, also called the exogenous variables, are determined outside the SSM. Hereafter, θ denotes the parameters, any discrete-time sequence $\mathbf{S}_i, \mathbf{S}_{i+1}, \dots, \mathbf{S}_j (i \leq j)$ is denoted by $\mathbf{S}_{i:j}$, and T denotes the time step of the last observation. There is no restriction on the dimensionality of $\mathbf{X}_t$, $\mathbf{Y}_t$, and $\mathbf{Z}_t$; that is, they can be scalars, vectors, or matrices.

In general, the SSM can be expressed in three distribution functions:

- initialization distribution function
- transition distribution function

- measurement distribution function

In the distribution functions, a sequence that is denoted by $\mathbf{S}_{i:j}$ with $i > j$ might sometimes appear as an argument, and that sequence should be ignored in the function. For ease of representation, the lag orders of the three kinds of variables $\{\mathbf{X}_t, \mathbf{Y}_t, \mathbf{Z}_t\}$ in the distribution functions are constantly set to r , p , and s , respectively. However, in practice, the lag orders for each kind of variable can be different in different distribution functions. Therefore, in all the necessary distribution functions, r can be seen as the maximum lag order of all the state variables, p can be seen as the maximum lag order of all the dependent variables, s can be seen as the maximum lag order of the independent variables, and τ can be seen as the maximum lag order of the state variables that must be generated in the initialization (or proposal initialization) distribution. The maximum lag order of all the state variables for the measurement distribution is r_1 and the counterpart for the transition (or proposal transition) distribution is r_2 , then $\tau = \max(r_1, r_2 - 1)$. For each of the three kinds of variables of any distribution function, only the corresponding lagged variables are necessary, even though the maximum lag order of those variables is used in the function listed later. For example, suppose that $r_1 = 3$ and $r_2 = 5$. Then, r is set to 5. $\mathbf{X}_{t-3:t}$, $t \geq 1$, are used in the measurement distribution function, and $\mathbf{X}_{t-5:t-1}$, $t > 1$, are used in the transition distribution function. Moreover, $\tau = 4$; that is, only $\mathbf{X}_{-3:1}$ are necessarily drawn from the initialization distribution function because $\mathbf{X}_{-4}$ is not used in all the possible distribution functions in any SMC algorithm.

Besides those three distribution functions, some other distribution functions might be required in a specific SMC algorithm. All the distribution functions that might be necessary in the SMC algorithms are summarized in the following list:

- Initialization distribution function, $\mu_{\theta}(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})$

This is the density function for the state variables at time step 1 and the lagged state variables with lag order up to τ that are denoted by $\mathbf{X}_{1-\tau:1}$, conditional on the lagged dependent variables with lag order up to p that are denoted by $\mathbf{Y}_{1-p:0}$, and the independent variables at time step 1 and the lagged independent variables with lag order up to s that are denoted by $\mathbf{Z}_{1-s:1}$.

- Transition distribution function, $f_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}), t > 1$

This is the density function for the current state variables that are denoted by $\mathbf{X}_t$, conditional on the lagged state variables with lag order up to r that are denoted by $\mathbf{X}_{t-r:t-1}$, p lagged dependent variables that are denoted by $\mathbf{Y}_{t-p:t-1}$, and the current and lagged independent variables with lag order up to s that are denoted by $\mathbf{Z}_{t-s:t}$.

- Measurement distribution function, $g_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}), t \geq 1$

This is the density function for the current dependent variables that are denoted by $\mathbf{Y}_t$, conditional on the current and lagged state variables with lag order up to r that are denoted by $\mathbf{X}_{t-r:t}$, the lagged dependent variables with lag order up to p that are denoted by $\mathbf{Y}_{t-p:t-1}$, and the current and lagged independent variables with lag order up to s that are denoted by $\mathbf{Z}_{t-s:t}$.

- Proposal initialization distribution function, $q_{\theta}^1(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:1}, \mathbf{Z}_{1-s:1})$

This is the proposal density function for the initial state variables at time step 1 and the lagged state variables with lag order up to τ that are denoted by $\mathbf{X}_{1-\tau:1}$, conditional on the current and lagged dependent variables with lag order up to p that are denoted by $\mathbf{Y}_{1-p:1}$, and the current and lagged independent variables with lag order up to s that are denoted by $\mathbf{Z}_{1-s:1}$.

- Proposal transition distribution function, $q_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t}, \mathbf{Z}_{t-s:t}), t > 1$

This is the proposal density function for the current state variables that are denoted by $\mathbf{X}_t$, conditional on the lagged state variables with lag order up to r that are denoted by $\mathbf{X}_{t-r:t-1}$, the current and lagged dependent variables with lag order up to p that are denoted by $\mathbf{Y}_{t-p:t}$, and the current and lagged independent variables with lag order up to s that are denoted by $\mathbf{Z}_{t-s:t}$.

- Auxiliary distribution function, $\hat{p}_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}), t > 1$

This is the auxiliary density function for the current dependent variables that are denoted by $\mathbf{Y}_t$, conditional on the lagged state variables with lag order up to r that are denoted by $\mathbf{X}_{t-r:t-1}$, the lagged dependent variables with lag order up to p that are denoted by $\mathbf{Y}_{t-p:t-1}$, and the current and lagged independent variables with lag order up to s that are denoted by $\mathbf{Z}_{t-s:t}$.

- Prior distribution function, $p(\theta)$

This is the density function for the prior distribution of the parameters.

An SSM has five common problems:

- Filtering problem: What is $p_{\theta}(\mathbf{X}_t | \mathbf{Y}_{1:t}, \mathbf{Z}_{1:t})$, the probability distribution of state $\mathbf{X}_t$ given dependent variables $\mathbf{Y}_{1:t}$ and independent variables $\mathbf{Z}_{1:t}$?
- Smoothing problem: What is $p_{\theta}(\mathbf{X}_t | \mathbf{Y}_{1:T}, \mathbf{Z}_{1:T}), 1 \leq t \leq T$, the probability distribution of state $\mathbf{X}_t$ given dependent variables $\mathbf{Y}_{1:T}$ and independent variables $\mathbf{Z}_{1:T}$?
- Forecasting problem: What is $p_{\theta}(\mathbf{X}_{T+L} | \mathbf{Y}_{1:T}, \mathbf{Z}_{1:T}), L > 0$, the probability distribution of state $\mathbf{X}_{T+L}$ given dependent variables $\mathbf{Y}_{1:T}$ and independent variables $\mathbf{Z}_{1:T}$?
- Evaluating problem: What is $p_{\theta}(\mathbf{Y}_{1:t} | \mathbf{Z}_{1:t})$, the probability (or the likelihood) distribution of dependent variables $\mathbf{Y}_{1:t}$ given independent variables $\mathbf{Z}_{1:t}$?
- Learning problem: How do you estimate the unknown parameters θ given all observed variables $\mathbf{Y}_{1:T}$ and $\mathbf{Z}_{1:T}$?

The following sections demonstrate how to use the SMC methods to solve these problems. First, the SMC filtering, smoothing, forecasting, and evaluating algorithms are discussed using the simple SSM, in which $p = 0$ and no independent variables are incorporated. Moreover, the maximum lag order of all the state variables for the measurement distribution is 0 ($r_1 = 0$), and the counterpart for the transition (or proposal transition) distribution is 1 ($r_2 = 1$). This simple SSM is used in most of the literature and textbooks. The corresponding SMC algorithms for the general SSM that considers $p \geq 0, r_1 \geq 0, r_2 \geq 0$, the existence of independent variables, and $s \geq 0$ is discussed in the section “[SMC Algorithms for the General Case of SSMs](#)” on page 1974.

SMC Filtering

The SMC filtering algorithms recursively provide numerical estimates of the sequence of joint posterior densities $p_{\theta}(\mathbf{X}_{1:t}|\mathbf{Y}_{1:t})$ over time t for the given parameters θ based on the weighted particles $\{\mathbf{X}_{1:t}^{(k)}, \tilde{w}_t^{(k)}\}_{k=1}^N$, where N denotes the number of particles, $\mathbf{X}_{1:t}^{(k)}$ denotes the state variable values of the k th particle sequence, and $\tilde{w}_t^{(k)}$ denotes the normalized weight of the k th particle sequence.

The numerical approximations of the joint posterior densities $p_{\theta}(\mathbf{X}_{1:t}|\mathbf{Y}_{1:t})$ over time are given by

$$\hat{p}_{\theta}(\mathbf{X}_{1:t}|\mathbf{Y}_{1:t}) = \sum_{k=1}^N \tilde{w}_t^{(k)} \delta_{\mathbf{X}_{1:t}^{(k)}}(\mathbf{X}_{1:t}), \quad t = 1, \dots, T$$

where $\delta_{\hat{x}}(x)$ denotes the Dirac measure for $\hat{x}$ such that

$$\delta_{\hat{x}}(x) = \begin{cases} 1 & \text{if } \hat{x} = x \\ 0 & \text{otherwise} \end{cases}$$

The conditional expected value of an arbitrary function $h(\mathbf{X}_{1:t})$ given $\mathbf{Y}_{1:t}$ is approximated by

$$\mathbb{E}_{\theta}[h(\mathbf{X}_{1:t})|\mathbf{Y}_{1:t}] = \sum_{k=1}^N \tilde{w}_t^{(k)} h(\mathbf{X}_{1:t}^{(k)}), \quad t = 1, \dots, T$$

It is also straightforward to approximate the marginal densities by

$$\hat{p}_{\theta}(\mathbf{X}_t|\mathbf{Y}_{1:t}) = \sum_{k=1}^N \tilde{w}_t^{(k)} \delta_{\mathbf{X}_t^{(k)}}(\mathbf{X}_t), \quad t = 1, \dots, T$$

Sequential Importance Resampling Algorithm

The sequential importance sampling (SIS) algorithm offers a solution to the filtering problem. In the SIS algorithm, random particles (samples) are propagated by the importance sampling mechanism, and the target posterior densities are then estimated recursively. However, the variance of the importance weights in the SIS algorithm increases exponentially over time. This issue is described as the degeneracy problem in some literature, and it results in poor approximations of the filtering distribution $p_{\theta}(\mathbf{X}_{1:t}|\mathbf{Y}_{1:t})$ when t is large. In practice, after a few iterations of the algorithm, most of the normalized importance weights are sufficiently close to zero, and their contribution to the final estimate is almost zero. The introduction of a resampling procedure at certain time steps is thus necessary in order for the SIS algorithm to discard the particles with negligible weights and multiply the promising ones. The resulting algorithm is known as the sequential importance resampling (SIR) algorithm or sequential importance sampling and resampling (Doucet, de Freitas, and Gordon 2001; Ristic, Arulampalam, and Gordon 2004; Rubin 1988).

The SIS and SIR algorithms rely on weighted particles $\{\mathbf{X}_{1:t}^{(k)}, \tilde{w}_t^{(k)}\}_{k=1}^N$. The particles $\{\mathbf{X}_{1:t}^{(k)}\}_{k=1}^N$ are propagated from a proposal distribution, and their normalized importance weights $\{\tilde{w}_t^{(k)}\}_{k=1}^N$ are updated such that they approximate the densities $p_{\theta}(\mathbf{X}_{1:t}|\mathbf{Y}_{1:t})$. In practice, the resampling step in the SIR algorithm is not necessary at each time step. Only when the variance of importance weights is greater than a prespecified threshold should the particles be resampled. The effective sample size (ESS) (or effective number of particles)

introduced by Liu and Chen (1995) is a widely used measure of that variance. The ESS at the t th time step is estimated as

$$\widehat{N}_{\text{eff}}(t) = \frac{1}{\sum_{k=1}^N (\tilde{w}_t^{(k)})^2}$$

Resampling is implemented when $\widehat{N}_{\text{eff}}$ is below a threshold N_{thres} that is significantly less than N (such as $\frac{N}{10}$). As for the resampling schemes, there are four popular algorithms: stratified resampling, systematic resampling, residual resampling, and multinomial resampling. Stratified resampling, proposed by Kitagawa (1996), is used in the SMC procedure.

The SIR algorithm proceeds as follows:

1. At time $t = 1$:

- For $k = 1, \dots, N$, sample $\mathbf{X}_1^{(k)}$ from the proposal initialization distribution $q_{\theta}^1(\mathbf{X}_1|\mathbf{Y}_1)$.
- For $k = 1, \dots, N$, calculate the importance weights:

$$w_1(\mathbf{X}_1^{(k)}) = \frac{\mu_{\theta}(\mathbf{X}_1^{(k)})g_{\theta}(\mathbf{Y}_1|\mathbf{X}_1)}{q_{\theta}^1(\mathbf{X}_1|\mathbf{Y}_1)}$$

- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_1^{(k)} = \frac{w_1(\mathbf{X}_1^{(k)})}{\sum_{i=1}^N w_1(\mathbf{X}_1^{(i)})}$$

2. At times $t = 2, \dots, T$:

- Calculate $\widehat{N}_{\text{eff}}(t-1)$, and compare it with N_{thres} .
 - If $\widehat{N}_{\text{eff}} \geq N_{\text{thres}}$: for $k = 1, \dots, N$, set $A_{t-1}^{(k)} = k$, and set $V_{t-1}^{(k)} = \tilde{w}_{t-1}^{(k)}$.
 - Otherwise: for $k = 1, \dots, N$, sample index $A_{t-1}^{(k)}$ based on $\{\tilde{w}_{t-1}^{(k)}\}_{k=1}^N$ using a resampling scheme, and set $V_{t-1}^{(k)} = \frac{1}{N}$.
- For $k = 1, \dots, N$, sample $\mathbf{X}_t^{(k)}$ from the proposal distribution $q_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_t)$, and set $\mathbf{X}_{1:t}^{(k)} = (\mathbf{X}_{1:t-1}^{(A_{t-1}^{(k)})}, \mathbf{X}_t^{(k)})$.
- For $k = 1, \dots, N$, calculate the importance weights:¹

$$w_t(\mathbf{X}_{1:t}^{(k)}) = V_{t-1}^{(k)} \frac{f_{\theta}(\mathbf{X}_t^{(k)}|\mathbf{X}_{t-1}^{(A_{t-1}^{(k)})})g_{\theta}(\mathbf{Y}_t|\mathbf{X}_t^{(k)})}{q_{\theta}(\mathbf{X}_t^{(k)}|\mathbf{X}_{t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_t)}$$

- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_t^{(k)} = \frac{w_t(\mathbf{X}_{1:t}^{(k)})}{\sum_{i=1}^N w_t(\mathbf{X}_{1:t}^{(i)})}$$

¹In some literature, the scaling factor $V_{t-1}^{(k)}$ is replaced by the normalized or non-normalized weights at the previous time step that are adjusted if the resampling step is implemented. $V_{t-1}^{(k)}$ is used here so that the original weights can be restored for the following approximations regardless of the possible resampling step.

Bootstrap Filter

The bootstrap filter (BF) algorithm proposed by Gordon, Salmond, and Smith (1993) is an extreme case of the SIR algorithm. It sets $q_{\theta}^1(\mathbf{X}_1|\mathbf{Y}_1) = \mu_{\theta}(\mathbf{X}_1)$ and $q_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1}, \mathbf{Y}_t) = f_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1})$. The resampling step is carried out at every time step.

The BF algorithm proceeds as follows:

1. At time $t = 1$:

- For $k = 1, \dots, N$, sample $\mathbf{X}_1^{(k)}$ from the initial distribution $\mu_{\theta}(\mathbf{X}_1)$.
- For $k = 1, \dots, N$, calculate the weights:

$$w_1(\mathbf{X}_1^{(k)}) = g_{\theta}(\mathbf{Y}_1|\mathbf{X}_1^{(k)})$$

- For $k = 1, \dots, N$, normalize the weights:

$$\tilde{w}_1^{(k)} = \frac{w_1(\mathbf{X}_1^{(k)})}{\sum_{i=1}^N w_1(\mathbf{X}_1^{(i)})}$$

2. At times $t = 2, \dots, T$:

- For $k = 1, \dots, N$, sample index $A_{t-1}^{(k)}$ based on $\{\tilde{w}_{t-1}^{(k)}\}_{k=1}^N$ using a resampling scheme.
- For $k = 1, \dots, N$, sample $\mathbf{X}_t^{(k)}$ from the transition distribution $f_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1}^{(A_{t-1}^{(k)})})$, and set $\mathbf{X}_{1:t}^{(k)} = (\mathbf{X}_{1:t-1}^{(A_{t-1}^{(k)})}, \mathbf{X}_t^{(k)})$.
- For $k = 1, \dots, N$, calculate the weights:

$$w_t(\mathbf{X}_{1:t}^{(k)}) = g_{\theta}(\mathbf{Y}_t|\mathbf{X}_t^{(k)})$$

- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_t^{(k)} = \frac{w_t(\mathbf{X}_{1:t}^{(k)})}{\sum_{i=1}^N w_t(\mathbf{X}_{1:t}^{(i)})}$$

Auxiliary Particle Filter

The auxiliary particle filter (APF), proposed by Pitt and Shephard (1999), is a popular alternative to the SIR algorithm. At time step t , the APF first resamples weighted particles $\{\mathbf{X}_{t-1}^{(k)}, \tilde{w}_{t-1}^{(k)}\}_{k=1}^N$ to obtain only the ones that are likely to survive after considering the coming observation $\mathbf{Y}_t$. That resampling step is implemented by sampling auxiliary index variables according to an auxiliary distribution that weights particles in terms of their compatibility with the coming observation. Those weights are defined by

$$v_{t-1}^{(k)} = \tilde{w}_{t-1}^{(k)} p_{\theta}(\mathbf{Y}_t|\mathbf{X}_{t-1}^{(k)}), \quad k = 1, \dots, N$$

where the auxiliary density function $p_{\theta}(\mathbf{Y}_t|\mathbf{X}_{t-1})$ can be expanded as follows:

$$p_{\theta}(\mathbf{Y}_t|\mathbf{X}_{t-1}) = \int g_{\theta}(\mathbf{Y}_t|\mathbf{X}_t) f_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1}) d\mathbf{X}_t$$

The auxiliary density function is usually replaced by an approximation $\hat{p}_{\theta}(\mathbf{Y}_t|\mathbf{X}_{t-1})$ because it is not analytically available in most cases. It is suggested in the literature that you set $\hat{p}_{\theta}(\mathbf{Y}_t|\mathbf{X}_{t-1}) = g_{\theta}(\mathbf{Y}_t|m(\mathbf{X}_{t-1}))$, where $m(\mathbf{X}_{t-1})$ is the mean, the median, a draw, or any other meaningful value associated with the transition density $f_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1})$. The resampled particles are then used to sample new particles at time step t with the proposal distribution.

The APF algorithm proceeds as follows:²

1. At time $t = 1$:

- For $k = 1, \dots, N$, sample $\mathbf{X}_1^{(k)}$ from the proposal initialization distribution $q_{\theta}^1(\mathbf{X}_1|\mathbf{Y}_1)$.
- For $k = 1, \dots, N$, calculate the importance weights:

$$w_1(\mathbf{X}_1^{(k)}) = \frac{\mu_{\theta}(\mathbf{X}_1^{(k)})g_{\theta}(\mathbf{Y}_1|\mathbf{X}_1)}{q_{\theta}^1(\mathbf{X}_1|\mathbf{Y}_1)}$$

- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_1^{(k)} = \frac{w_1(\mathbf{X}_1^{(k)})}{\sum_{i=1}^N w_1(\mathbf{X}_1^{(i)})}$$

2. At times $t = 2, \dots, T$:

- For $k = 1, \dots, N$, calculate the weights:

$$v_{t-1}^{(k)} = \tilde{w}_{t-1}^{(k)} \hat{p}_{\theta}(\mathbf{Y}_t|\mathbf{X}_{t-1}^{(k)})$$

- For $k = 1, \dots, N$, normalize the weights:

$$\tilde{v}_{t-1}^{(k)} = \frac{v_{t-1}^{(k)}}{\sum_{i=1}^N v_{t-1}^{(i)}}$$

- For $k = 1, \dots, N$, sample index $A_{t-1}^{(k)}$ with weights $\{\tilde{v}_{t-1}^{(k)}\}_{k=1}^N$ using a resampling scheme.
- For $k = 1, \dots, N$, sample $\mathbf{X}_t^{(k)}$ from the proposal distribution $q_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_t)$, and set $\mathbf{X}_{1:t}^{(k)} = (\mathbf{X}_{1:t-1}^{(A_{t-1}^{(k)})}, \mathbf{X}_t^{(k)})$.
- For $k = 1, \dots, N$, calculate the importance weights:

$$w_t(\mathbf{X}_{1:t}^{(k)}) = \frac{f_{\theta}(\mathbf{X}_t^{(k)}|\mathbf{X}_{t-1}^{(A_{t-1}^{(k)})})g_{\theta}(\mathbf{Y}_t|\mathbf{X}_t^{(k)})}{\hat{p}_{\theta}(\mathbf{Y}_t|\mathbf{X}_{t-1}^{(A_{t-1}^{(k)})})q_{\theta}(\mathbf{X}_t^{(k)}|\mathbf{X}_{t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_t)}$$

- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_t^{(k)} = \frac{w_t(\mathbf{X}_{1:t}^{(k)})}{\sum_{i=1}^N w_t(\mathbf{X}_{1:t}^{(i)})}$$

²In some literature, a second resampling step is implemented at the end of each iteration. In practice, this setting is outperformed by the APF with the single resampling scheme that is listed here.

Fully Adapted Auxiliary Particle Filter

The fully adapted auxiliary particle filter (APF(ADP)), introduced by Pitt and Shephard (1999) and Pitt et al. (2012), is a special case of the APF algorithm. Full adaptation is possible when the transition distribution $f_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1})$ is conjugate in $\mathbf{X}_t$ to the measurement distribution $g_{\theta}(\mathbf{Y}_t|\mathbf{X}_t)$. That is,

$$\frac{g_{\theta}(\mathbf{Y}_t|\mathbf{X}_t)f_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1})}{\int g_{\theta}(\mathbf{Y}_t|\mathbf{X}_t)f_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1})d\mathbf{X}_t}$$

is in the same probability distribution family as the transition distribution $f_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1})$.

When conjugacy holds, the auxiliary density function $p_{\theta}(\mathbf{Y}_t|\mathbf{X}_{t-1}) = \int g_{\theta}(\mathbf{Y}_t|\mathbf{X}_t)f_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1})d\mathbf{X}_t$ is analytically available. In addition, the proposal transition distribution that is chosen as

$$q_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1}, \mathbf{Y}_t) = \frac{g_{\theta}(\mathbf{Y}_t|\mathbf{X}_t)f_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1})}{\int g_{\theta}(\mathbf{Y}_t|\mathbf{X}_t)f_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1})d\mathbf{X}_t}$$

has a closed-form expression and can be sampled from easily.

As a result of conjugacy, the importance weights simplify to 1:

$$w_t(\mathbf{X}_{1:t}^{(k)}) = \frac{f_{\theta}(\mathbf{X}_t^{(k)}|\mathbf{X}_{t-1}^{(A_{t-1}^{(k)})})g_{\theta}(\mathbf{Y}_t|\mathbf{X}_t^{(k)})}{p_{\theta}(\mathbf{Y}_t|\mathbf{X}_{t-1}^{(A_{t-1}^{(k)})})q_{\theta}(\mathbf{X}_t^{(k)}|\mathbf{X}_{t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_t)} = 1$$

The fully adapted auxiliary particle filter has several advantages:

- Because the importance weights simplify to 1, the steps that compute those weights are eliminated from the APF algorithm. This considerably reduces the computing time, especially when the number of particles and/or the number of time points is large.
- Following the guideline for choosing the optimal number of particles provided by Pitt et al. (2012), APF(ADP) requires many fewer particles than BF and APF.
- Pitt et al. (2012) also showed that the estimated log likelihood obtained by APF(ADP) has a much smaller variance than that obtained by BF. This can prevent slow mixing of the Markov chain in the LEARN statement.
- The Markov chain that is estimated in the LEARN statement has a smaller absolute autocorrelation for APF(ADP) than for APF and BF.

Table 27.9 lists examples of conjugate distributions that PROC SMC supports.

Table 27.9 Conjugate Distributions

Measurement Distribution	Transition Distribution
$y_t \sim \text{normal}(\beta_t x_t, \lambda_t^2)$	$x_t \sim \text{normal}(\mu(x_{t-1}), \sigma^2(x_{t-1}))$
$y_t \sim \text{normal}(\mu_t, \frac{1}{x_t})$	$x_t \sim \text{gamma}(a_t x_{t-1}, \frac{\sigma^2}{x_{t-1}})$
$y_t \sim \text{lognormal}(x_t, s_t)$	$x_t \sim \text{normal}(\mu(x_{t-1}), \sigma^2(x_{t-1}))$
$y_t \sim \text{lognormal}(\mu_t, \frac{1}{x_t})$	$x_t \sim \text{gamma}(a_t x_{t-1}, \frac{\sigma^2}{x_{t-1}})$
$y_t \sim \text{gamma}(\alpha_t, x_t)$	$x_t \sim \text{gamma}(a_t x_{t-1}, \frac{\sigma^2}{x_{t-1}})$
$y_t \sim \text{poisson}(a_t x_t)$	$x_t \sim \text{gamma}(b_t x_{t-1}, \frac{\sigma^2}{x_{t-1}})$

SMC Smoothing

The smoothing problem, $p(\mathbf{X}_t | \mathbf{Y}_{1:T})$, $1 \leq t \leq T$, can be solved by marginalizing $p_\theta(\mathbf{X}_{1:T} | \mathbf{Y}_{1:T})$, which is approximated by the SMC filtering algorithms. However, this approximation is poor when $T - t$ is large because the resampling steps cause $p(\mathbf{X}_t | \mathbf{Y}_{1:T})$ to be approximated by only a few different particles. The following sections introduce the alternative algorithms that solve the smoothing problem.

Fixed-Lag Smoothing

Suppose that the number of lags in the fixed-lag smoothing algorithm is λ . This algorithm, proposed by Kitagawa and Sato (2001), relies on the assumption that observations collected at any time step Λ ($\Lambda > t + \lambda$) provide no additional information to $\mathbf{X}_{1:t}$. Therefore, the following approximation is given by implementing an SMC filtering algorithm until time step t' ($t' = \min(t + \lambda, T)$):

$$\hat{p}_\theta(\mathbf{X}_{1:t} | \mathbf{Y}_{1:T}) \approx \hat{p}_\theta(\mathbf{X}_{1:t} | \mathbf{Y}_{1:t'})$$

To clearly describe the smoothing algorithm, $\{\mathbf{S}_t^{(k)}\}_{k=1}^N$ denote the particles for the smoothing estimation at time t and $\{\tilde{w}_t^{(k)}\}_{k=1}^N$ denote the corresponding normalized weights for the particles. As previously mentioned, $\tilde{\mathbf{X}}_{i:j}$ ($i \leq j$), which is equivalent to $\{\tilde{\mathbf{X}}_t\}_{t=i}^j$, denotes a discrete-time sequence that ranges from time step i to time step j . Therefore, given the sequence $\tilde{\mathbf{X}}_{i:j}$, $\tilde{\mathbf{X}}_s$ ($i \leq s \leq j$) denotes the random variable at time step s .

Based on a given SMC filtering algorithm, the fixed-lag smoothing algorithm proceeds as follows:

1. At time $t' = 1$:

- For $k = 1, \dots, N$, sample $\mathbf{X}_{t'}^{(k)}$ and calculate its importance weights $w_{t'}(\mathbf{X}_{t'}^{(k)})$ based on the specific filtering algorithm.
- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_{t'}^{(k)} = \frac{w_{t'}(\mathbf{X}_{t'}^{(k)})}{\sum_{i=1}^N w_{t'}(\mathbf{X}_{t'}^{(i)})}$$

2. At times $t' = 2, \dots, T$:

- For $k = 1, \dots, N$, get the sample index $A_{t'-1}^{(k)}$ based on the specific filtering algorithm.
- For $k = 1, \dots, N$, sample $\mathbf{X}_{t'}^{(k)}$ and set $\tilde{\mathbf{X}}_{1:t'}^{(k)} = (\tilde{\mathbf{X}}_{1:t'-1}^{(A_{t'-1}^{(k)})}, \mathbf{X}_{t'}^{(k)})$, and calculate the importance weights $w_{t'}(\mathbf{X}_{1:t'}^{(k)})$ based on the specific filtering algorithm.
- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_{t'}^{(k)} = \frac{w_{t'}(\mathbf{X}_{1:t'}^{(k)})}{\sum_{i=1}^N w_{t'}(\mathbf{X}_{1:t'}^{(i)})}$$

- If $t' > \lambda$ and $t' < T$, get $t = t' - \lambda$.
 - for $k = 1, \dots, N$, set $\mathbf{S}_t^{(k)} = \tilde{\mathbf{X}}_t^{(k)}$ and $u_t^{(k)} = \tilde{w}_{t'}^{(k)}$
- If $t' = T$, get $t_l = \max(t' - \lambda, 1)$. For $t = t_l, \dots, T$ and $k = 1, \dots, N$,
 - $k = 1, \dots, N$, set $\mathbf{S}_t^{(k)} = \tilde{\mathbf{X}}_t^{(k)}$ and $u_t^{(k)} = \tilde{w}_{t'}^{(k)}$

With the weighted particles $\{\mathbf{S}_t^{(k)}, \tilde{u}_t^{(k)}\}_{k=1}^N$ at each time step t , the smoothing problem is solved by

$$\hat{p}_{\boldsymbol{\theta}}(\mathbf{X}_t | \mathbf{Y}_{1:T}) = \sum_{k=1}^N \tilde{u}_t^{(k)} \delta_{\mathbf{S}_t^{(k)}}(\mathbf{X}_t), 1 \leq t \leq T$$

Moreover, the expected value of an arbitrary function $h(\mathbf{X}_t)$ given $\mathbf{Y}_{1:T}$ is approximated by

$$\mathbb{E}_{\boldsymbol{\theta}}[h(\mathbf{X}_t) | \mathbf{Y}_{1:T}] = \sum_{k=1}^N \tilde{u}_t^{(k)} h(\mathbf{S}_t^{(k)})$$

Fixed-Interval Smoothing

The fixed-interval smoothing algorithm, proposed by Doucet, Godsill, and Andrieu (2000), solves the marginal smoothing problem by backward recursion on the basis of the following formula:

$$p_{\boldsymbol{\theta}}(\mathbf{X}_t | \mathbf{Y}_{1:T}) = p_{\boldsymbol{\theta}}(\mathbf{X}_t | \mathbf{Y}_{1:t}) \int \frac{f_{\boldsymbol{\theta}}(\mathbf{X}_{t+1} | \mathbf{X}_t) p_{\boldsymbol{\theta}}(\mathbf{X}_{t+1} | \mathbf{Y}_{1:T})}{p_{\boldsymbol{\theta}}(\mathbf{X}_{t+1} | \mathbf{Y}_{1:t})} d\mathbf{X}_{t+1}, \quad t = 1, \dots, T$$

Given the weighted particles $\{\mathbf{X}_t^{(k)}, \tilde{w}_t^{(k)}\}_{k=1}^N$ obtained by a filtering algorithm until time step T , the weights in the backward recursions can be calculated as follows:

1. At time $t = T$:
 - For $k = 1, \dots, N$, initialize $\tilde{w}_{T|T}^{(k)} = \tilde{w}_T^{(k)}$
2. At times $t = T - 1, \dots, 1$:
 - For $k = 1, \dots, N$, evaluate the importance weights

$$\tilde{w}_{t|T}^{(k)} = \sum_{j=1}^N \tilde{w}_{t+1|T}^{(j)} \frac{\tilde{w}_t^{(k)} f_{\boldsymbol{\theta}}(\mathbf{X}_{t+1}^{(j)} | \mathbf{X}_t^{(k)})}{\sum_{i=1}^N \tilde{w}_t^{(i)} f_{\boldsymbol{\theta}}(\mathbf{X}_{t+1}^{(j)} | \mathbf{X}_t^{(i)})}$$

The reweighted particles $\{\mathbf{X}_t^{(k)}, \tilde{w}_{t|T}^{(k)}\}_{k=1}^N$ after the backward recursion approximates the smoothing distribution $p_{\theta}(\mathbf{X}_t|\mathbf{Y}_{1:T})$ as

$$\hat{p}_{\theta}(\mathbf{X}_t|\mathbf{Y}_{1:T}) = \sum_{k=1}^N \tilde{w}_{t|T}^{(k)} \delta_{\mathbf{X}_t^{(k)}}(\mathbf{X}_t), 1 \leq t \leq T$$

Moreover, the expected value of an arbitrary function $h(\mathbf{X}_t)$ given $\mathbf{Y}_{1:T}$ is approximated by

$$\mathbb{E}_{\theta}[h(\mathbf{X}_t)|\mathbf{Y}_{1:T}] = \sum_{k=1}^N \tilde{w}_{t|T}^{(k)} h(\mathbf{X}_t^{(k)}), 1 \leq t \leq T$$

SMC Forecasting

At logical time step T , the L -step-ahead forecasting problem is solved by extending the weighted particles $\{\mathbf{X}_{1:T}^{(k)}, \tilde{w}_T^{(k)}\}_{k=1}^N$ obtained using an SMC filtering algorithm. The SMC filtering algorithms usually do not resample at the last time step. An extra resampling step might be implemented at time step T . If so, the normalized weights of all resampled particles denoted by $\{\tilde{w}_T^{(k)}\}_{k=1}^N$ are set to $\frac{1}{N}$. For ease of presentation, the same symbol for the weighted particles is used no matter whether the resampling step is implemented at time step T . In the forecasting stage, no resampling step is needed.

The SMC forecasting algorithm proceeds as follows:

1. For $k = 1, \dots, N$, set $\tilde{w}_{x,T}^{(k)} = \tilde{w}_T^{(k)}$, where $\tilde{w}_T^{(k)}$ is derived from the filtering process.
2. For $t = T + 1$ to $T + L$:
 - For $k = 1, \dots, N$, sample $\mathbf{X}_t^{(k)}$ from the transition distribution $f_{\theta}(\mathbf{X}_t|\mathbf{X}_{t-1}^{(k)})$.
 - For $k = 1, \dots, N$, set $\mathbf{X}_{1:t}^{(k)} = (\mathbf{X}_{1:t-1}^{(k)}, \mathbf{X}_t^{(k)})$, and sample $\mathbf{Y}_t^{(k)}$ from the measurement distribution $g_{\theta}(\mathbf{Y}_t|\mathbf{X}_t^{(k)})$.
 - For $k = 1, \dots, N$, calculate the normalized weights of the state and dependent variables:

$$\tilde{w}_{x,t}^{(k)} = \tilde{w}_{y,t}^{(k)} = \tilde{w}_{x,t-1}^{(k)}$$

The weighted particles for the state and dependent variables are obtained. Here the transition density for forecasting should not rely on the observations after time step T . The approximations of $p_{\theta}(\mathbf{X}_t|\mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T})$ and $p_{\theta}(\mathbf{Y}_t|\mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T})$ for $t = T + 1, \dots, T + L$ are given by

$$\begin{aligned} \hat{p}_{\theta}(\mathbf{X}_t|\mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T}) &= \sum_{k=1}^N \tilde{w}_{x,t}^{(k)} \delta_{\mathbf{X}_t^{(k)}}(\mathbf{X}_t) \\ \hat{p}_{\theta}(\mathbf{Y}_t|\mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T}) &= \sum_{k=1}^N \tilde{w}_{y,t}^{(k)} \delta_{\mathbf{Y}_t^{(k)}}(\mathbf{Y}_t) \end{aligned}$$

Moreover, the conditional expected value of an arbitrary function $h(\mathbf{X}_t)$ or $h(\mathbf{Y}_t)$ given $\mathbf{Y}_{1:T}$ is approximated by

$$\begin{aligned}\mathbb{E}_{\boldsymbol{\theta}}[h(\mathbf{X}_t)|\mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T}] &= \sum_{k=1}^N \tilde{w}_{x,t}^{(k)} h(\mathbf{X}_t^{(k)}), \quad t = T+1, \dots, T+L \\ \mathbb{E}_{\boldsymbol{\theta}}[h(\mathbf{Y}_t)|\mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T}] &= \sum_{k=1}^N \tilde{w}_{y,t}^{(k)} h(\mathbf{Y}_t^{(k)}), \quad t = T+1, \dots, T+L\end{aligned}$$

SMC Evaluating

The marginal likelihood is defined by

$$p_{\boldsymbol{\theta}}(\mathbf{Y}_{1:t}) = \int p_{\boldsymbol{\theta}}(\mathbf{Y}_{1:t}, \mathbf{X}_{1:t}) d\mathbf{X}_{1:t}$$

Monte Carlo methods can directly estimate this integral, but the approximation is usually poor in practice. Alternatively, the marginal likelihood ($t > 1$) is decomposed as

$$p_{\boldsymbol{\theta}}(\mathbf{Y}_{1:t}) = p_{\boldsymbol{\theta}}(\mathbf{Y}_1) \prod_{j=2}^t p_{\boldsymbol{\theta}}(\mathbf{Y}_j | \mathbf{Y}_{1:j-1})$$

For $j = 2, \dots, t$, it is straightforward to have

$$\begin{aligned}p_{\boldsymbol{\theta}}(\mathbf{Y}_j | \mathbf{Y}_{1:j-1}) &= \int p_{\boldsymbol{\theta}}(\mathbf{Y}_j | \mathbf{X}_{j-1}) p_{\boldsymbol{\theta}}(\mathbf{X}_{j-1} | \mathbf{Y}_{1:j-1}) d\mathbf{X}_{j-1} \\ &= \int \int g_{\boldsymbol{\theta}}(\mathbf{Y}_j | \mathbf{X}_j) f_{\boldsymbol{\theta}}(\mathbf{X}_j | \mathbf{X}_{j-1}) p_{\boldsymbol{\theta}}(\mathbf{X}_{j-1} | \mathbf{Y}_{1:j-1}) d\mathbf{X}_{j-1} d\mathbf{X}_j\end{aligned}$$

These terms can be estimated by the SMC algorithms with the weighted particles at time step $j-1$ as

$$\hat{p}_{\boldsymbol{\theta}}(\mathbf{Y}_j | \mathbf{Y}_{1:j-1}) = \sum_{k=1}^N \tilde{w}_{j-1}^{(k)} \int g_{\boldsymbol{\theta}}(\mathbf{Y}_j | \mathbf{X}_j) f_{\boldsymbol{\theta}}(\mathbf{X}_j | \mathbf{X}_{j-1}) d\mathbf{X}_j, \quad j > 1$$

SIR Algorithm

In the SIR algorithm, this approximation can be further simplified by sampling $\mathbf{X}_j^{(k)}$ ($j > 1$) from $q_{\boldsymbol{\theta}}(\mathbf{X}_j | \mathbf{X}_{j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_j)$ for $k = 1, \dots, N$:

$$\hat{p}_{\boldsymbol{\theta}}(\mathbf{Y}_j | \mathbf{Y}_{1:j-1}) = \sum_{k=1}^N V_{j-1}^{(k)} \frac{g_{\boldsymbol{\theta}}(\mathbf{Y}_j | \mathbf{X}_j^{(k)}) f_{\boldsymbol{\theta}}(\mathbf{X}_j^{(k)} | \mathbf{X}_{j-1}^{(A_{j-1}^{(k)})})}{q_{\boldsymbol{\theta}}(\mathbf{X}_j | \mathbf{X}_{j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_j)} = \sum_{k=1}^N w_j(\mathbf{X}_{1:j}^{(k)})$$

Moreover, $p_{\boldsymbol{\theta}}(\mathbf{Y}_1)$ can be written as the following integral with the importance sampling scheme:

$$p_{\boldsymbol{\theta}}(\mathbf{Y}_1) = \int \frac{\mu_{\boldsymbol{\theta}}(\mathbf{X}_1) g_{\boldsymbol{\theta}}(\mathbf{Y}_1 | \mathbf{X}_1)}{q_{\boldsymbol{\theta}}^1(\mathbf{X}_1 | \mathbf{Y}_1)} q_{\boldsymbol{\theta}}^1(\mathbf{X}_1 | \mathbf{Y}_1) d\mathbf{X}_1$$

In the SIR algorithm, $\{\mathbf{X}_1^{(k)}\}_{k=1}^N$ are sampled from $q_{\boldsymbol{\theta}}^1(\mathbf{X}_1|\mathbf{Y}_1)$. Therefore, the basic Monte Carlo approximation of $p_{\boldsymbol{\theta}}(\mathbf{Y}_1)$ is

$$\hat{p}_{\boldsymbol{\theta}}(\mathbf{Y}_1) = \frac{1}{N} \sum_{k=1}^N w_1(\mathbf{X}_1^{(k)})$$

BF Algorithm

In the BF algorithm, this approximation can be simplified by sampling $\mathbf{X}_j^{(k)}$ ($j > 1$) from $f_{\boldsymbol{\theta}}(\mathbf{X}_j^{(k)}|\mathbf{X}_{j-1}^{(A_{j-1}^{(k)})})$ for $k = 1, \dots, N$:

$$\hat{p}_{\boldsymbol{\theta}}(\mathbf{Y}_j|\mathbf{Y}_{1:j-1}) = \sum_{k=1}^N \frac{1}{N} \frac{g_{\boldsymbol{\theta}}(\mathbf{Y}_j|\mathbf{X}_j^{(k)}) f_{\boldsymbol{\theta}}(\mathbf{X}_j^{(k)}|\mathbf{X}_{j-1}^{(A_{j-1}^{(k)})})}{f_{\boldsymbol{\theta}}(\mathbf{X}_j^{(k)}|\mathbf{X}_{j-1}^{(A_{j-1}^{(k)})})} = \frac{1}{N} \sum_{k=1}^N w_j(\mathbf{X}_{1:j}^{(k)})$$

Moreover, the $\hat{p}_{\boldsymbol{\theta}}(\mathbf{Y}_1)$ in the BF algorithm is computed in the same way as the one in the SIR algorithm.

APF Algorithm

In the APF algorithm, because $v_{j-1}^{(k)} = \tilde{w}_{j-1}^{(k)} \hat{p}_{\boldsymbol{\theta}}(\mathbf{Y}_j|\mathbf{X}_{j-1}^{(k)})$, the approximation can be written as

$$\hat{p}_{\boldsymbol{\theta}}(\mathbf{Y}_j|\mathbf{Y}_{1:j-1}) = \sum_{k=1}^N \frac{v_{j-1}^{(k)} \sum_{i=1}^N v_{j-1}^{(i)}}{(\sum_{i=1}^N v_{j-1}^{(i)}) \hat{p}_{\boldsymbol{\theta}}(\mathbf{Y}_j|\mathbf{X}_{j-1}^{(k)})} \int g_{\boldsymbol{\theta}}(\mathbf{Y}_j|\mathbf{X}_j) f_{\boldsymbol{\theta}}(\mathbf{X}_j|\mathbf{X}_{j-1}^{(k)}) d\mathbf{X}_j, \quad j > 1$$

The auxiliary index variables $\{A_{j-1}^{(k)}\}_{k=1}^N$ are sampled according to $\left\{ \frac{v_{j-1}^{(k)}}{\sum_{i=1}^N v_{j-1}^{(i)}} \right\}_{k=1}^N$, and $\mathbf{X}_j^{(k)}$ are sampled from $q_{\boldsymbol{\theta}}(\mathbf{X}_j|\mathbf{X}_{j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_j)$. The weight for each auxiliary index is $\frac{1}{N}$. The preceding approximation is thus simplified as

$$\begin{aligned} \hat{p}_{\boldsymbol{\theta}}(\mathbf{Y}_j|\mathbf{Y}_{1:j-1}) &= \sum_{k=1}^N \frac{1}{N} \left(\sum_{i=1}^N v_{j-1}^{(i)} \right) \frac{g_{\boldsymbol{\theta}}(\mathbf{Y}_j|\mathbf{X}_j^{(k)}) f_{\boldsymbol{\theta}}(\mathbf{X}_j^{(k)}|\mathbf{X}_{j-1}^{(A_{j-1}^{(k)})})}{\hat{p}_{\boldsymbol{\theta}}(\mathbf{Y}_j|\mathbf{X}_{j-1}^{(A_{j-1}^{(k)})}) q_{\boldsymbol{\theta}}(\mathbf{X}_j^{(k)}|\mathbf{X}_{j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_j)} \\ &= \frac{1}{N} \left(\sum_{i=1}^N v_{j-1}^{(i)} \right) \left(\sum_{k=1}^N w_j(\mathbf{X}_{1:j}^{(k)}) \right). \end{aligned}$$

It is further simplified to $\hat{p}_{\boldsymbol{\theta}}(\mathbf{Y}_j|\mathbf{Y}_{1:j-1}) = \sum_{i=1}^N v_{j-1}^{(i)}$ if you use APF(ADP). Moreover, the $\hat{p}_{\boldsymbol{\theta}}(\mathbf{Y}_1)$ in the APF algorithm is computed in the same way as the one in the SIR algorithm.

SMC Learning

In most cases, the learning problem is the most difficult one. One of the SSM parameter estimation methods is the particle Markov chain Monte Carlo (PMCMC) algorithm, which combines the SMC and Markov chain Monte Carlo methods (Andrieu, Doucet, and Holenstein 2010).

Particle Marginal Metropolis-Hastings Sampler

The particle marginal Metropolis-Hastings algorithm directly targets the marginal density $p(\theta | \mathbf{Y}_{1:T})$. This algorithm proceeds as follows:

1. Initialization, $i = 0$:
 - Set $\theta[0]$ to the initial parameter values and run the SMC filtering algorithm with $\theta[i]$ until the time step T . Calculate $\hat{p}_{\theta[i]}(\mathbf{Y}_{1:T})$ using one SMC evaluating scheme.
2. For $i = 1, \dots, M$ (M is the number of samples):
 - Sample θ^* from the random walk Metropolis sampler based on $\theta[m-1]$, and run the SMC filtering algorithm with θ^* until T . Calculate $\hat{p}_{\theta^*}(\mathbf{Y}_{1:T})$ using the SMC evaluating scheme.
 - Calculate the acceptance probability $\alpha_m = \min\left(\frac{\hat{p}_{\theta^*}(\mathbf{Y}_{1:T})p(\theta^*)}{\hat{p}_{\theta[m-1]}(\mathbf{Y}_{1:T})p(\theta[m-1])} \frac{q(\theta[m-1]|\theta^*)}{q(\theta^*|\theta[m-1])}, 1\right)$.
 - Sample u_m uniformly over $[0, 1]$.
 - If $u_m \leq \alpha_m$, then set $\theta[m] = \theta^*$ and $\hat{p}_{\theta[m]}(\mathbf{Y}_{1:T}) = \hat{p}_{\theta^*}(\mathbf{Y}_{1:T})$. Otherwise, set $\theta[m] = \theta[m-1]$ and $\hat{p}_{\theta[m]}(\mathbf{Y}_{1:T}) = \hat{p}_{\theta[m-1]}(\mathbf{Y}_{1:T})$.

The random walk Metropolis sampler is used to draw parameters. Therefore, $q(\theta[m-1]|\theta^*) = q(\theta^*|\theta[m-1])$ holds in the algorithm.

SMC Algorithms for the General Case of SSMs

This section discusses the SMC algorithms for the general case of SSMs, where any of the following conditions might exist:

- There exist some independent variables.
- The maximum lag order of all the state variables for the measurement distribution is greater than or equal to 0.
- The maximum lag order of all the state variables for the transition (or proposal transition) distribution is greater than or equal to 0.
- The maximum lag order of the dependent variables in any distribution is greater than or equal to 0.

The notations τ , r , p , and s are defined in the section “[Sequential Monte Carlo Methods and State Space Models](#)” on page 1961. For convenience, the definition is copied here. The value r can be seen as the maximum lag order of all the state variables; p can be seen as the maximum lag order of all the dependent

variables; s can be seen as the maximum lag order of the independent variables; and τ can be seen as the maximum lag order of the state variables that must be generated in the initialization (or proposal initialization) distribution. For more information about the value of τ , see the sections “[Method 1: Maximum Lag Order of State Variables to Be Generated in Initialization Distribution, \$\tau\$](#) ” on page 1986 (Method 1) and “[Method 2: Maximum Lag Order of State Variables to Be Generated in Initialization Distribution, \$\tau\$](#) ” on page 1989 (Method 2).

SMC Filtering Algorithm

Sequential Importance Resampling

The sequential importance sampling (SIS) algorithm offers a solution to the filtering problem. In the SIS algorithm, random particles (samples) are propagated by the importance sampling mechanism, and the target posterior densities are then estimated recursively. However, the variance of the importance weights in the SIS algorithm increases exponentially over time. This issue is described as the degeneracy problem in some literature, and it results in poor approximations of the filtering distribution $p_{\theta}(\mathbf{X}_{1-\tau:t}|\mathbf{Y}_{1-p:t}, \mathbf{Z}_{1-s:t})$ when t is large. In practice, after a few iterations of the algorithm, most of the normalized importance weights are sufficiently close to zero, and their contribution to the final estimate is almost zero. The introduction of a resampling procedure at certain time steps is thus necessary in order for the SIS algorithm to discard the particles with negligible weights and multiply the promising ones. The resulting algorithm is known as the sequential importance resampling (SIR) algorithm or sequential importance sampling and resampling (Doucet, de Freitas, and Gordon 2001; Ristic, Arulampalam, and Gordon 2004; Rubin 1988).

The SIS and SIR algorithms rely on weighted particles $\{\mathbf{X}_{1-\tau:t}^{(k)}, \tilde{w}_t^{(k)}\}_{k=1}^N$. The particles $\{\mathbf{X}_{1:t}^{(k)}\}_{k=1}^N$ are propagated from a proposal distribution, and their normalized importance weights $\{\tilde{w}_t^{(k)}\}_{k=1}^N$ are updated such that they approximate the densities $p_{\theta}(\mathbf{X}_{1-\tau:t}|\mathbf{Y}_{1-p:t}, \mathbf{Z}_{1-s:t})$. In practice, the resampling step in the SIR algorithm is not necessary at each time step. Only when the variance of importance weights is greater than a pre-specified threshold should the particles be resampled. The effective sample size (ESS) (or effective number of particles) introduced by Liu and Chen (1995) is a widely used measure of that variance. The ESS at t th time step is estimated as

$$\widehat{N}_{\text{eff}}(t) = \frac{1}{\sum_{k=1}^N (\tilde{w}_t^{(k)})^2}$$

Resampling is implemented when $\widehat{N}_{\text{eff}}$ is below a threshold N_{thres} that is significantly less than N (such as $\frac{N}{10}$). As for the resampling schemes, there are four popular algorithms: stratified resampling, systematic resampling, residual resampling, and multinomial resampling. Stratified resampling, proposed by Kitagawa (1996), is used in the SMC procedure.

The SIR algorithm proceeds as follows:

1. At time $t = 1$:

- For $k = 1, \dots, N$, sample $\mathbf{X}_{1-\tau:1}^{(k)}$ from the proposal initialization distribution $q_{\theta}^1(\mathbf{X}_{1-\tau:1}|\mathbf{Y}_{1-p:1}, \mathbf{Z}_{1-s:1})$.
- For $k = 1, \dots, N$, calculate the importance weights:

$$w_1(\mathbf{X}_{1-\tau:1}^{(k)}) = \frac{\mu_{\theta}(\mathbf{X}_{1-\tau:1}^{(k)}|\mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})g_{\theta}(\mathbf{Y}_1|\mathbf{X}_{1-\tau:1}, \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})}{q_{\theta}^1(\mathbf{X}_{1-\tau:1}|\mathbf{Y}_{1-p:1}, \mathbf{Z}_{1-s:1})}$$

- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_1^{(k)} = \frac{w_1(\mathbf{X}_{1-\tau:1}^{(k)})}{\sum_{i=1}^N w_1(\mathbf{X}_{1-\tau:1}^{(i)})}$$

2. At times $t = 2, \dots, T$:

- Calculate $\widehat{N}_{\text{eff}}(t-1)$, and compare it with N_{thres} .
 - If $\widehat{N}_{\text{eff}} \geq N_{\text{thres}}$: for $k = 1, \dots, N$, set $A_{t-1}^{(k)} = k$, and set $V_{t-1}^{(k)} = \tilde{w}_{t-1}^{(k)}$.
 - Otherwise: for $k = 1, \dots, N$, sample index $A_{t-1}^{(k)}$ based on $\{\tilde{w}_{t-1}^{(k)}\}_{k=1}^N$ using a resampling scheme, and set $V_{t-1}^{(k)} = \frac{1}{N}$.
- For $k = 1, \dots, N$, sample $\mathbf{X}_t^{(k)}$ from the proposal distribution $q_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$, and set $\mathbf{X}_{1-\tau:t}^{(k)} = (\mathbf{X}_{1-\tau:t-1}^{(A_{t-1}^{(k)})}, \mathbf{X}_t^{(k)})$.
- For $k = 1, \dots, N$, calculate the importance weights³:

$$w_t(\mathbf{X}_{1-\tau:t}^{(k)}) = V_{t-1}^{(k)} \frac{f_{\theta}(\mathbf{X}_t^{(k)} | \mathbf{X}_{t-r:t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) g_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t}^{(k)}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})}{q_{\theta}(\mathbf{X}_t^{(k)} | \mathbf{X}_{t-r:t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_{t-p:t}, \mathbf{Z}_{t-s:t})}$$

- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_t^{(k)} = \frac{w_t(\mathbf{X}_{1-\tau:t}^{(k)})}{\sum_{i=1}^N w_t(\mathbf{X}_{1-\tau:t}^{(i)})}$$

Bootstrap Filter

The bootstrap filter (BF) algorithm proposed by Gordon, Salmond, and Smith (1993) is an extreme case of the SIR algorithm. It sets $q_{\theta}^1(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:1}, \mathbf{Z}_{1-s:1}) = \mu_{\theta}(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})$ and $q_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t}, \mathbf{Z}_{t-s:t}) = f_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$. The resampling step is carried out at every time step.

The BF algorithm proceeds as follows:

1. At time $t = 1$:

- For $k = 1, \dots, N$, sample $\mathbf{X}_{1-\tau:1}^{(k)}$ from the initial distribution $\mu_{\theta}(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})$.
- For $k = 1, \dots, N$, calculate the weights:

$$w_1(\mathbf{X}_{1-\tau:1}^{(k)}) = g_{\theta}(\mathbf{Y}_1 | \mathbf{X}_{1-\tau:1}^{(k)}, \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})$$

- For $k = 1, \dots, N$, normalize the weights:

$$\tilde{w}_1^{(k)} = \frac{w_1(\mathbf{X}_{1-\tau:1}^{(k)})}{\sum_{i=1}^N w_1(\mathbf{X}_{1-\tau:1}^{(i)})}$$

³In some literature, the scaling factor $V_{t-1}^{(k)}$ is replaced by the normalized or non-normalized weights at the previous time step that are adjusted if the resampling step is implemented. $V_{t-1}^{(k)}$ is used here so that the original weights can be restored for the following approximations regardless of the possible resampling step.

2. At times $t = 2, \dots, T$:

- For $k = 1, \dots, N$, sample index $A_{t-1}^{(k)}$ based on $\{\tilde{w}_{t-1}^{(k)}\}_{k=1}^N$ using a resampling scheme.
- For $k = 1, \dots, N$, sample $\mathbf{X}_t^{(k)}$ from the transition distribution $f_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$, and set $\mathbf{X}_{1-\tau:t}^{(k)} = (\mathbf{X}_{1-\tau:t-1}^{(A_{t-1}^{(k)})}, \mathbf{X}_t^{(k)})$.
- For $k = 1, \dots, N$, calculate the weights:

$$w_t(\mathbf{X}_{1-\tau:t}^{(k)}) = g_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t}^{(k)}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$$

- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_t^{(k)} = \frac{w_t(\mathbf{X}_{1-\tau:t}^{(k)})}{\sum_{i=1}^N w_t(\mathbf{X}_{1-\tau:t}^{(i)})}$$

Auxiliary Particle Filter

The auxiliary particle filter (APF), proposed by Pitt and Shephard (1999), is a popular alternative to the SIR method. At time step t , the APF first resamples weighted particles $\{\mathbf{X}_{t-r:t-1}^{(k)}, \tilde{w}_{t-1}^{(k)}\}_{k=1}^N$ to obtain only the ones that are likely to survive after considering the coming observation $\mathbf{Y}_t$. That resampling step is implemented by sampling auxiliary index variables according to an auxiliary distribution that weights particles in terms of their compatibility with the coming observation. Those weights are defined by

$$v_{t-1}^{(k)} = \tilde{w}_{t-1}^{(k)} p_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}^{(k)}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}), \quad k = 1, \dots, N$$

where the auxiliary density function $p_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$ can be expanded as follows:

$$\begin{aligned} & p_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) \\ &= \int g_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) f_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) d\mathbf{X}_t \end{aligned}$$

The auxiliary density function is usually replaced by an approximation $\hat{p}_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$ because it is not analytically available in most cases. It is suggested in the literature that you set $\hat{p}_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) = g_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}, m(\mathbf{X}_{t-r:t-1}), \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_t)$, where $m(\mathbf{X}_{t-r:t-1})$ is the mean, the median, a draw, or any other meaningful value associated with the transition density $f_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$. The resampled particles are then used to sample new particles at time step t with the proposal distribution.

The APF algorithm proceeds as follows:⁴

1. At time $t = 1$:

- For $k = 1, \dots, N$, sample $\mathbf{X}_{1-\tau:1}^{(k)}$ from the proposal initialization distribution $q_{\theta}^1(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:1}, \mathbf{Z}_{1-s:1})$.
- For $k = 1, \dots, N$, calculate the importance weights:

$$w_1(\mathbf{X}_{1-\tau:1}^{(k)}) = \frac{\mu_{\theta}(\mathbf{X}_{1-\tau:1}^{(k)} | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1}) g_{\theta}(\mathbf{Y}_1 | \mathbf{X}_{1-\tau:1}, \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})}{q_{\theta}^1(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:1}, \mathbf{Z}_{1-s:1})}$$

⁴In some literature, a second resampling step is implemented at the end of each iteration. In practice, this setting is outperformed by the APF with the single resampling scheme that is listed here.

- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_1^{(k)} = \frac{w_1(\mathbf{X}_{1-\tau:1}^{(k)})}{\sum_{i=1}^N w_\tau(\mathbf{X}_{1-\tau:1}^{(i)})}$$

2. At times $t = 2, \dots, T$:

- For $k = 1, \dots, N$, calculate the weights:

$$v_{t-1}^{(k)} = \tilde{w}_{t-1}^{(k)} \hat{p}_\theta(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}^{(k)}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$$

- For $k = 1, \dots, N$, normalize the weights:

$$\tilde{v}_{t-1}^{(k)} = \frac{v_{t-1}^{(k)}}{\sum_{i=1}^N v_{t-1}^{(i)}}$$

- For $k = 1, \dots, N$, sample index $A_{t-1}^{(k)}$ with weights $\{\tilde{v}_{t-1}^{(k)}\}_{k=1}^N$ using a resampling scheme.
- For $k = 1, \dots, N$, sample $\mathbf{X}_t^{(k)}$ from the proposal distribution $q_\theta(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_{t-p:t}, \mathbf{Z}_{t-s:t})$, and set $\mathbf{X}_{1-\tau:t}^{(k)} = (\mathbf{X}_{1-\tau:t-1}^{(A_{t-1}^{(k)})}, \mathbf{X}_t^{(k)})$.
- For $k = 1, \dots, N$, calculate the importance weights:

$$w_t(\mathbf{X}_{1-\tau:t}^{(k)}) = \frac{f_\theta(\mathbf{X}_t^{(k)} | \mathbf{X}_{t-r:t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) g_\theta(\mathbf{Y}_t | \mathbf{X}_{t-r:t}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})}{\hat{p}_\theta(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) q_\theta(\mathbf{X}_t^{(k)} | \mathbf{X}_{t-r:t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_{t-p:t}, \mathbf{Z}_{t-s:t})}$$

- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_t^{(k)} = \frac{w_t(\mathbf{X}_{1-\tau:t}^{(k)})}{\sum_{i=1}^N w_t(\mathbf{X}_{1-\tau:t}^{(i)})}$$

Fully Adapted Auxiliary Particle Filter

The fully adapted auxiliary particle filter (APF(ADP)), introduced by Pitt and Shephard (1999) and Pitt et al. (2012), is special a case of the APF algorithm. Full adaptation is possible when the transition distribution $f_\theta(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$ is conjugate in $\mathbf{X}_t$ to the measurement distribution $g_\theta(\mathbf{Y}_t | \mathbf{X}_{t-r:t}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$. That is,

$$\frac{g_\theta(\mathbf{Y}_t | \mathbf{X}_{t-r:t}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) f_\theta(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})}{\int g_\theta(\mathbf{Y}_t | \mathbf{X}_{t-r:t}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) f_\theta(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) d\mathbf{X}_t}$$

is in the same probability distribution family as the transition distribution $f_\theta(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})$.

When conjugacy holds, the auxiliary density function $p_\theta(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) = \int g_\theta(\mathbf{Y}_t | \mathbf{X}_{t-r:t}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) f_\theta(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) d\mathbf{X}_t$ is analytically available. In addition, the proposal transition distribution that is chosen as

$$q_\theta(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t}, \mathbf{Z}_{t-s:t}) = \frac{g_\theta(\mathbf{Y}_t | \mathbf{X}_{t-r:t}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) f_\theta(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})}{\int g_\theta(\mathbf{Y}_t | \mathbf{X}_{t-r:t}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) f_\theta(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) d\mathbf{X}_t}$$

has a closed-form expression and can be sampled from easily.

As a result of conjugacy, the importance weights simplify to 1:

$$w_t(\mathbf{X}_{1-\tau:t}^{(k)}) = \frac{f_{\theta}(\mathbf{X}_t^{(k)} | \mathbf{X}_{t-r:t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) g_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t}^{(k)}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})}{p_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) q_{\theta}(\mathbf{X}_t^{(k)} | \mathbf{X}_{t-r:t-1}^{(A_{t-1}^{(k)})}, \mathbf{Y}_{t-p:t}, \mathbf{Z}_{t-s:t})} = 1$$

The fully adapted auxiliary particle filter has several advantages:

- Because the importance weights simplify to 1, the steps that compute those weights are eliminated from the APF algorithm. This considerably reduces the computing time, especially when the number of particles and/or the number of time points is large.
- Following the guideline on choosing the optimal number of particles provided by Pitt et al. (2012), APF(ADP) requires many fewer particles than BF and APF.
- Pitt et al. (2012) also showed that the estimated log likelihood obtained by APF(ADP) has a much smaller variance than that obtained by BF. This can prevent slow mixing of the Markov chain in the LEARN statement.
- The Markov chain that is estimated in the LEARN statement has a smaller absolute autocorrelation for APF(ADP) than for APF and BF.

Fixed-Lag Smoothing

Suppose that the number of lags in the fixed-lag smoothing algorithm is λ . This algorithm, proposed by Kitagawa and Sato (2001), relies on the assumption that observations collected at any time step Λ ($\Lambda > t + \lambda$) provide no additional information to $\mathbf{X}_{1-\tau:t}$. Therefore, the following approximation is given by implementing an SMC filtering algorithm until time step t' ($t' = \min(t + \lambda, T)$):

$$\hat{p}_{\theta}(\mathbf{X}_{1-\tau:t} | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T}) \approx \hat{p}_{\theta}(\mathbf{X}_{1-\tau:t} | \mathbf{Y}_{1-p:t'}, \mathbf{Z}_{1-s:t'})$$

To clearly describe the smoothing algorithm, $\{\mathbf{S}_t^{(k)}\}_{k=1}^N$ denote the particles for the smoothing estimation at time t and $\{\tilde{w}_t^{(k)}\}_{k=1}^N$ denote the corresponding normalized weights for the particles. As previously mentioned, $\tilde{\mathbf{X}}_{i:j}$ ($i \leq j$), which is equivalent to $\{\tilde{\mathbf{X}}_t\}_{t=i}^j$, denotes a discrete-time sequence that ranges from time step i to time step j . Therefore, given the sequence $\tilde{\mathbf{X}}_{i:j}$, $\tilde{\mathbf{X}}_s$ ($i \leq s \leq j$) denotes the random variable at time step s .

Based on a given SMC filtering algorithm, the fixed-lag smoothing algorithm proceeds as follows:

1. At time $t' = 1$:

- For $k = 1, \dots, N$, sample $\mathbf{X}_{1-\tau:t'}^{(k)}$ and calculate its importance weights $w_{t'}(\mathbf{X}_{1-\tau:t'}^{(k)})$ based on the specific filtering algorithm.
- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_{t'}^{(k)} = \frac{w_{t'}(\mathbf{X}_{1-\tau:t'}^{(k)})}{\sum_{i=1}^N w_{t'}(\mathbf{X}_{1-\tau:t'}^{(i)})}$$

2. At times $t' = 2, \dots, T$:

- For $k = 1, \dots, N$, get the sample index $A_{t'-1}^{(k)}$ based on the specific filtering algorithm.
- For $k = 1, \dots, N$, sample $\mathbf{X}_{t'}^{(k)}$ and set $\tilde{\mathbf{X}}_{1-\tau:t'}^{(k)} = (\tilde{\mathbf{X}}_{1-\tau:t'-1}^{(A_{t'-1}^{(k)})}, \mathbf{X}_{t'}^{(k)})$, and calculate the importance weights $w_{t'}(\mathbf{X}_{1-\tau:t'}^{(k)})$ based on the specific filtering algorithm.
- For $k = 1, \dots, N$, normalize the importance weights:

$$\tilde{w}_{t'}^{(k)} = \frac{w_{t'}(\mathbf{X}_{1-\tau:t'}^{(k)})}{\sum_{i=1}^N w_{t'}(\mathbf{X}_{1-\tau:t'}^{(i)})}$$

- If $t' > \lambda$ and $t' < T$, get $t = t' - \lambda$.
 - If $t = 1$: for $t_s = 1 - \tau, \dots, t$,
 - * for $k = 1, \dots, N$, set $\mathbf{S}_{t_s}^{(k)} = \tilde{\mathbf{X}}_{t_s}^{(k)}$ and $\tilde{u}_{t_s}^{(k)} = \tilde{w}_{t'}^{(k)}$.
 - Otherwise: for $k = 1, \dots, N$, set $\mathbf{S}_t^{(k)} = \tilde{\mathbf{X}}_t^{(k)}$ and $\tilde{u}_t^{(k)} = \tilde{w}_{t'}^{(k)}$.
- If $t' = T$, get $t_l = \max(t' - \lambda, 1)$. For $t = t_l, \dots, T$,
 - If $t = 1$: for $t_s = 1 - \tau, \dots, t$,
 - * for $k = 1, \dots, N$, set $\mathbf{S}_{t_s}^{(k)} = \tilde{\mathbf{X}}_{t_s}^{(k)}$ and $\tilde{u}_{t_s}^{(k)} = \tilde{w}_{t'}^{(k)}$.
 - Otherwise: for $k = 1, \dots, N$, set $\mathbf{S}_t^{(k)} = \tilde{\mathbf{X}}_t^{(k)}$ and set $\tilde{u}_t^{(k)} = \tilde{w}_{t'}^{(k)}$.

With the weighted particles $\{\mathbf{S}_t^{(k)}, \tilde{u}_t^{(k)}\}_{k=1}^N$ at each time step t , the smoothing problem is solved by

$$\hat{p}_{\boldsymbol{\theta}}(\mathbf{X}_t | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T}) = \sum_{k=1}^N \tilde{u}_t^{(k)} \delta_{\mathbf{S}_t^{(k)}}(\mathbf{X}_t), 1 - \tau \leq t \leq T$$

Moreover, the expected value of an arbitrary function $h(\mathbf{X}_t)$ given $\mathbf{Y}_{1-p:T}$ and $\mathbf{Z}_{1-s:T}$ is approximated by

$$\mathbb{E}_{\boldsymbol{\theta}}[h(\mathbf{X}_t) | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T}] = \sum_{k=1}^N \tilde{u}_t^{(k)} h(\mathbf{S}_t^{(k)})$$

Fixed-Interval Smoothing

The fixed-interval smoothing algorithm, proposed by Doucet, Godsill, and Andrieu (2000), solves the marginal smoothing problem by backward recursion on the basis of the following formula:

$$p_{\boldsymbol{\theta}}(\mathbf{X}_t | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T}) = p_{\boldsymbol{\theta}}(\mathbf{X}_t | \mathbf{Y}_{1-p:t}, \mathbf{Z}_{1-s:t}) \int \frac{f_{\boldsymbol{\theta}}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t}) p_{\boldsymbol{\theta}}(\mathbf{X}_{t+1} | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T})}{p_{\boldsymbol{\theta}}(\mathbf{X}_{t+1} | \mathbf{Y}_{1-p:t}, \mathbf{Z}_{1-s:t})} d\mathbf{X}_{t+1}$$

Given the weighted particles $\{\mathbf{X}_t^{(k)}, \tilde{w}_t^{(k)}\}_{k=1}^N$ obtained by a filtering algorithm until time step T , the weights in the backward recursions can be calculated as follows:

1. At time $t = T$:

- For $k = 1, \dots, N$, initialize $\tilde{w}_{T|T}^{(k)} = \tilde{w}_T^{(k)}$.

2. At times $t = T - 1, \dots, 1$:

- For $k = 1, \dots, N$, evaluate the importance weights

$$\tilde{w}_{t|T}^{(k)} = \sum_{j=1}^N \tilde{w}_{t+1|T}^{(j)} \frac{\tilde{w}_t^{(k)} f_{\theta}(\mathbf{X}_{t+1}^{(j)} | \mathbf{X}_t^{(k)}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})}{\sum_{i=1}^N \tilde{w}_t^{(i)} f_{\theta}(\mathbf{X}_{t+1}^{(j)} | \mathbf{X}_t^{(i)}, \mathbf{Y}_{t-p:t-1}, \mathbf{Z}_{t-s:t})}$$

The reweighted particles $\{\mathbf{X}_t^{(k)}, \tilde{w}_{t|T}^{(k)}\}_{k=1}^N$ after the backward recursion approximates the smoothing distribution $p_{\theta}(\mathbf{X}_t | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T})$ as

$$\hat{p}_{\theta}(\mathbf{X}_t | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T}) = \sum_{k=1}^N \tilde{w}_{t|T}^{(k)} \delta_{\mathbf{X}_t^{(k)}}(\mathbf{X}_t), \quad 1 - \tau \leq t \leq T$$

Moreover, the expected value of an arbitrary function $h(\mathbf{X}_t)$ given $\mathbf{Y}_{1-p:T}$ and $\mathbf{Z}_{1-s:T}$ is approximated by

$$\mathbb{E}_{\theta}[h(\mathbf{X}_t) | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T}] = \sum_{k=1}^N \tilde{w}_{t|T}^{(k)} h(\mathbf{X}_t^{(k)}), \quad 1 - \tau \leq t \leq T$$

SMC Forecasting

At time step T , the L -step-ahead forecasting problem is solved by extending the weighted particles $\{\mathbf{X}_{1-\tau:T}^{(k)}, \tilde{w}_T^{(k)}\}_{k=1}^N$ obtained using an SMC filtering algorithm. The SMC filtering algorithms usually do not resample at the last time step. An extra resampling step might be implemented at time step T . If so, the normalized weights of all resampled particles denoted by $\{\tilde{w}_T^{(k)}\}_{k=1}^N$ are set to $\frac{1}{N}$. For ease of presentation, the same symbol for the weighted particles is used no matter whether the resampling step is implemented at time step T . In the forecasting stage, no resampling step is needed.

The SMC forecasting algorithm proceeds as follows:

1. For $k = 1, \dots, N$, set $\tilde{w}_{x,T}^{(k)} = \tilde{w}_T^{(k)}$, where $\tilde{w}_T^{(k)}$ is derived from the filtering process, and set $\mathbf{Y}_{1-p:T}^{(k)} = \mathbf{Y}_{1-p:T}$.
2. For $t = T + 1$ to $T + L$:
 - For $k = 1, \dots, N$, sample $\mathbf{X}_t^{(k)}$ from the transition distribution $f_{\theta}(\mathbf{X}_t | \mathbf{X}_{t-r:t-1}^{(k)}, \mathbf{Y}_{t-p:t-1}^{(k)}, \mathbf{Z}_{t-s:t})$, and set $\mathbf{X}_{1-\tau:t}^{(k)} = (\mathbf{X}_{1-\tau:t-1}^{(k)}, \mathbf{X}_t^{(k)})$.
 - For $k = 1, \dots, N$, sample $\mathbf{Y}_t^{(k)}$ from the measurement distribution $g_{\theta}(\mathbf{Y}_t | \mathbf{X}_{t-r:t}^{(k)}, \mathbf{Y}_{t-p:t-1}^{(k)}, \mathbf{Z}_{t-s:t})$, and set $\mathbf{Y}_{1-p:t}^{(k)} = (\mathbf{Y}_{1-p:t-1}^{(k)}, \mathbf{Y}_t^{(k)})$.
 - For $k = 1, \dots, N$, calculate the normalized weights of the state and dependent variables:

$$\tilde{w}_{x,t}^{(k)} = \tilde{w}_{y,t}^{(k)} = \tilde{w}_{x,t-1}^{(k)}$$

With the weighted particles for the state variables, $\{\mathbf{X}_t^{(k)}, \tilde{w}_{x,t}^{(k)}\}_{t=T+1}^{T+L}$, and the weighted particles for the dependent variables, $\{\mathbf{Y}_t^{(k)}, \tilde{w}_{y,t}^{(k)}\}_{t=T+1}^{T+L}$, are obtained. The approximations of $p_{\theta}(\mathbf{X}_t | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:t})$ and

$p_{\theta}(\mathbf{Y}_t | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:T+L})$ for $t = T + 1, \dots, T + L$ are given by

$$\begin{aligned}\hat{p}_{\theta}(\mathbf{X}_t | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:t}) &= \sum_{k=1}^N \tilde{w}_{x,t}^{(k)} \delta_{\mathbf{X}_t^{(k)}}(\mathbf{X}_t) \\ \hat{p}_{\theta}(\mathbf{Y}_t | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:t}) &= \sum_{k=1}^N \tilde{w}_{y,t}^{(k)} \delta_{\mathbf{Y}_t^{(k)}}(\mathbf{Y}_t)\end{aligned}$$

Moreover, the conditional expected value of an arbitrary function $h(\mathbf{X}_t)$ or $h(\mathbf{Y}_t)$ given $\mathbf{Y}_{1-p:T}$ and $\mathbf{Z}_{1-s:t}$ is approximated by

$$\begin{aligned}\mathbb{E}_{\theta}[h(\mathbf{X}_t) | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:t}] &= \sum_{k=1}^N \tilde{w}_{x,t}^{(k)} h(\mathbf{X}_t^{(k)}), \quad t = T + 1, \dots, T + L \\ \mathbb{E}_{\theta}[h(\mathbf{Y}_t) | \mathbf{Y}_{1-p:T}, \mathbf{Z}_{1-s:t}] &= \sum_{k=1}^N \tilde{w}_{y,t}^{(k)} h(\mathbf{Y}_t^{(k)}), \quad t = T + 1, \dots, T + L\end{aligned}$$

SMC Evaluating

The marginal likelihood is defined by

$$p_{\theta}(\mathbf{Y}_{1:t} | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:t}) = \int p_{\theta}(\mathbf{Y}_{1:t}, \mathbf{X}_{1-\tau:t} | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:t}) d\mathbf{X}_{1-\tau:t}$$

Monte Carlo methods can directly estimate this integral, but the approximation is usually poor in practice. Alternatively, the marginal likelihood ($t > 1$) is decomposed as

$$p_{\theta}(\mathbf{Y}_{1:t} | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:t}) = p_{\theta}(\mathbf{Y}_1 | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1}) \prod_{j=2}^t p_{\theta}(\mathbf{Y}_j | \mathbf{Y}_{1-p:j-1}, \mathbf{Z}_{1-s:j})$$

For $j = 2, \dots, t$, it is straightforward to have

$$\begin{aligned}& p_{\theta}(\mathbf{Y}_j | \mathbf{Y}_{1-p:j-1}, \mathbf{Z}_{1-s:j}) \\ &= \int p_{\theta}(\mathbf{Y}_j | \mathbf{X}_{j-r:j-1}, \mathbf{Y}_{1-p:j-1}, \mathbf{Z}_{1-s:j}) p_{\theta}(\mathbf{X}_{j-r:j-1} | \mathbf{Y}_{1-p:j-1}, \mathbf{Z}_{1-s:j}) d\mathbf{X}_{j-r:j-1} \\ &= \int \int g_{\theta}(\mathbf{Y}_j | \mathbf{X}_{j-r:j}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j}) f_{\theta}(\mathbf{X}_j | \mathbf{X}_{j-r:j-1}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j}) \\ &\quad p_{\theta}(\mathbf{X}_{j-r:j-1} | \mathbf{Y}_{1-p:j-1}, \mathbf{Z}_{1-s:j}) d\mathbf{X}_{j-r:j-1} d\mathbf{X}_j\end{aligned}$$

These terms can be estimated by the SMC algorithms with the weighted particles at time step $j - 1$ ($j > 1$) as

$$\begin{aligned}& \hat{p}_{\theta}(\mathbf{Y}_j | \mathbf{Y}_{1-p:j-1}, \mathbf{Z}_{1-s:j}) \\ &= \sum_{k=1}^N \tilde{w}_{j-1}^{(k)} \int g_{\theta}(\mathbf{Y}_j | \mathbf{X}_{j-r:j-1}^{(k)}, \mathbf{X}_j, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j}) f_{\theta}(\mathbf{X}_j | \mathbf{X}_{j-r:j-1}^{(k)}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j}) d\mathbf{X}_j\end{aligned}$$

SIR Algorithm

In the SIR algorithm, this approximation can be further simplified by sampling $\mathbf{X}_j^{(k)}$ ($j > 1$) from $q_{\theta}(\mathbf{X}_j | \mathbf{X}_{j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_{j-p:j}, \mathbf{Z}_{j-s:j})$ and setting $\mathbf{X}_{1-\tau:j}^{(k)} = (\mathbf{X}_{1-\tau:j-1}^{(A_{j-1}^{(k)})}, \mathbf{X}_j^{(k)})$ for $k = 1, \dots, N$:

$$\begin{aligned} & \hat{p}_{\theta}(\mathbf{Y}_j | \mathbf{Y}_{1-p:j-1}, \mathbf{Z}_{1-s:j}) \\ &= \sum_{k=1}^N V_{j-1}^{(k)} \frac{g_{\theta}(\mathbf{Y}_j | \mathbf{X}_{j-r:j}^{(k)}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j}) f_{\theta}(\mathbf{X}_j^{(k)} | \mathbf{X}_{j-r:j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j})}{q_{\theta}(\mathbf{X}_j | \mathbf{X}_{j-r:j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_{j-p:j}, \mathbf{Z}_{j-s:j})} \\ &= \sum_{k=1}^N w_j(\mathbf{X}_{1-\tau:j}^{(k)}) \end{aligned}$$

Moreover, $p_{\theta}(\mathbf{Y}_1 | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})$ can be written as the following integral with the importance sampling scheme:

$$\begin{aligned} & p_{\theta}(\mathbf{Y}_1 | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1}) \\ &= \int \frac{\mu_{\theta}(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1}) g_{\theta}(\mathbf{Y}_1 | \mathbf{X}_{1-r:1}, \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})}{q_{\theta}^1(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:1}, \mathbf{Z}_{1-s:1})} q_{\theta}^1(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:1}, \mathbf{Z}_{1-s:1}) d\mathbf{X}_{1-\tau:1} \end{aligned}$$

In the SIR algorithm, $\{\mathbf{X}_{1-\tau:1}^{(k)}\}_{k=1}^N$ are sampled from $q_{\theta}^1(\mathbf{X}_{1-\tau:1} | \mathbf{Y}_{1-p:1}, \mathbf{Z}_{1-s:1})$. Therefore, the basic Monte Carlo approximation of $p_{\theta}(\mathbf{Y}_1 | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})$ is

$$\hat{p}_{\theta}(\mathbf{Y}_1 | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1}) = \frac{1}{N} \sum_{k=1}^N w_1(\mathbf{X}_{1-\tau:1}^{(k)})$$

BF Algorithm

In the BF algorithm, this approximation can be simplified by sampling $\mathbf{X}_j^{(k)}$ ($j > 1$) from $f_{\theta}(\mathbf{X}_j^{(k)} | \mathbf{X}_{j-r:j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j})$ and setting $\mathbf{X}_{1-\tau:j}^{(k)} = (\mathbf{X}_{1-\tau:j-1}^{(A_{j-1}^{(k)})}, \mathbf{X}_j^{(k)})$ for $k = 1, \dots, N$:

$$\begin{aligned} & \hat{p}_{\theta}(\mathbf{Y}_j | \mathbf{Y}_{1-p:j-1}, \mathbf{Z}_{1-s:j}) \\ &= \sum_{k=1}^N \frac{1}{N} \frac{g_{\theta}(\mathbf{Y}_j | \mathbf{X}_{j-r:j}^{(k)}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j}) f_{\theta}(\mathbf{X}_j^{(k)} | \mathbf{X}_{j-r:j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j})}{f_{\theta}(\mathbf{X}_j^{(k)} | \mathbf{X}_{j-r:j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j})} \\ &= \frac{1}{N} \sum_{k=1}^N w_j(\mathbf{X}_{1-\tau:j}^{(k)}) \end{aligned}$$

Moreover, the $\hat{p}_{\theta}(\mathbf{Y}_1 | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})$ in the BF algorithm is computed in the same way as the one in the SIR algorithm.

APF Algorithm

In the APF algorithm, $v_{j-1}^{(k)} = \tilde{w}_{j-1}^{(k)} \hat{p}_{\theta}^A(\mathbf{Y}_j | \mathbf{X}_{j-r:j-1}^{(k)}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j})$. Then the approximation can be written as

$$\begin{aligned} & \hat{p}_{\theta}(\mathbf{Y}_j | \mathbf{Y}_{1-p:j-1}, \mathbf{Z}_{1-s:j}), \quad j > 1 \\ &= \sum_{k=1}^N \frac{v_{j-1}^{(k)} \int g_{\theta}(\mathbf{Y}_j | \mathbf{X}_{j-r:j-1}^{(k)}, \mathbf{X}_j, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j}) f_{\theta}(\mathbf{X}_j | \mathbf{X}_{j-r:j-1}^{(k)}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j}) d\mathbf{X}_j}{\hat{p}_{\theta}^A(\mathbf{Y}_j | \mathbf{X}_{j-r:j-1}^{(k)}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j})} \\ &= \sum_{k=1}^N \left(\frac{v_{j-1}^{(k)} \sum_{i=1}^N v_{j-1}^{(i)}}{(\sum_{i=1}^N v_{j-1}^{(i)}) \hat{p}_{\theta}^A(\mathbf{Y}_j | \mathbf{X}_{j-r:j-1}^{(k)}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j})} \right. \\ & \quad \left. \int g_{\theta}(\mathbf{Y}_j | \mathbf{X}_{j-r:j-1}^{(k)}, \mathbf{X}_j, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j}) f_{\theta}(\mathbf{X}_j | \mathbf{X}_{j-r:j-1}^{(k)}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j}) d\mathbf{X}_j \right) \end{aligned}$$

The auxiliary index variables $\{A_{j-1}^{(k)}\}_{k=1}^N$ are sampled according to $\left\{ \frac{v_{j-1}^{(k)}}{\sum_{i=1}^N v_{j-1}^{(i)}} \right\}_{k=1}^N$. After the sampling, the weight for each auxiliary index is $\frac{1}{N}$. The approximation can be further simplified by sampling $\mathbf{X}_j^{(k)}$ ($j > 1$) from $q_{\theta}(\mathbf{X}_j | \mathbf{X}_{j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_{j-p:j}, \mathbf{Z}_{j-s:j})$ and setting $\mathbf{X}_{1-\tau:j}^{(k)} = (\mathbf{X}_{1-\tau:j-1}^{(A_{j-1}^{(k)})}, \mathbf{X}_j^{(k)})$ for $k = 1, \dots, N$:

$$\begin{aligned} & \hat{p}_{\theta}(\mathbf{Y}_j | \mathbf{Y}_{1-p:j-1}, \mathbf{Z}_{1-s:j}) \\ &= \sum_{k=1}^N \frac{1}{N} \left(\sum_{i=1}^N v_{j-1}^{(i)} \right) \frac{g_{\theta}(\mathbf{Y}_j | \mathbf{X}_{j-r:j}^{(k)}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j}) f_{\theta}(\mathbf{X}_j^{(k)} | \mathbf{X}_{j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j})}{\hat{p}_{\theta}^A(\mathbf{Y}_j | \mathbf{X}_{j-r:j-1}^{(k)}, \mathbf{Y}_{j-p:j-1}, \mathbf{Z}_{j-s:j}) q_{\theta}(\mathbf{X}_j^{(k)} | \mathbf{X}_{j-r:j-1}^{(A_{j-1}^{(k)})}, \mathbf{Y}_{j-p:j}, \mathbf{Z}_{j-s:j})} \\ &= \frac{1}{N} \left(\sum_{i=1}^N v_{j-1}^{(i)} \right) \left(\sum_{k=1}^N w_j(\mathbf{X}_{1-\tau:j}^{(k)}) \right). \end{aligned}$$

It is further simplified to $\hat{p}_{\theta}(\mathbf{Y}_j | \mathbf{Y}_{1-p:j-1}, \mathbf{Z}_{1-s:j}) = \sum_{i=1}^N v_{j-1}^{(i)}$ if you use APF(ADP). Moreover, the $\hat{p}_{\theta}(\mathbf{Y}_1 | \mathbf{Y}_{1-p:0}, \mathbf{Z}_{1-s:1})$ in the APF is computed in the same way as the one in the SIR algorithm.

SMC Learning

The SMC learning algorithm of the general SSM is the same as the SMC learning algorithm of the simple SSM that is illustrated in the section “**SMC Learning**” on page 1974.

Defining a State Space Model

In order to define an SSM, you must provide parameters, variables, and multiple distribution functions (see the section “[Sequential Monte Carlo Methods and State Space Models](#)” on page 1961). The SMC procedure defines an SSM by using either of two methods: Method 1 and Method 2.

Method 1

In the SMC procedure, Method 1 defines an SSM by using the combinations of AUXMODEL, INITSTATE, MODEL, PARAMETER, PRIOR, STATE, STATEVAR, and VAR statements. The following sections define the components of an SSM by using Method 1.

Method 1: Parameters

The parameters are specified in the PARAMETER statement. Each name that you specify in the PARAMETER statement is a parameter.

- *Parameter value:* The initial parameter values are specified in the PARAMETER statement.
- *Parameter bound:* The parameter bounds, which might be needed in the parameter estimation, are specified in the PARAMETER statement and the PRIOR statements.

Method 1: Lagged Variables

The lagged state, dependent, and independent variables can appear in the *distribution-arguments* of the AUXMODEL, MODEL, INITSTATE, and STATE statements. Moreover, the lagged state variables can also appear as the *variable-name* in the INITSTATE statements. The lagged variables are constructed by concatenating the variable name, the suffix “.L” (or “.I”), and the string “i” for the order of lag i :

- $rv.Li$ or $rv.Ii$: the i th lag of the variable rv ($i \geq 1$)

Method 1: State Variables

Each variable that you specify in the STATEVAR statement is a state variable.

Method 1: Dependent Variables

Each variable that satisfies the following three conditions is a dependent variable:

- The variable is specified in the VAR statement.
- The variable appears before the tilde ($\sim$) symbol in the MODEL statement.
- The variable corresponds to one variable from the input data table.

Method 1: Independent Variables

Each variable that satisfies the following three conditions is an independent variable:

- The variable is specified in the VAR statement.
- The variable is not a dependent variable.
- The variable corresponds to one variable from the input data table.

Method 1: Maximum Lag Order of State Variables, r

Suppose the maximum lag order of the i th state variable in the *distribution-arguments* of all the MODEL statements is denoted by r_{1i} . Suppose the maximum lag order of the i th state variable in the *distribution-arguments* of all the STATE statements including the PROPOSAL= option is denoted by r_{2i} . Assuming that the number of state variables is d_x , the maximum lag order of the state variables, r , is equal to $\max(\{r_{1i}\}_{i=1}^{d_x}, \{r_{2i}\}_{i=1}^{d_x})$.

Method 1: Maximum Lag Order of State Variables to Be Generated in Initialization Distribution, τ

Suppose the maximum lag order of all the state variables for the measurement distribution is r_1 and the counterpart for the transition (or proposal transition) distribution is r_2 ; that is, $r_1 = \max(\{r_{1i}\}_{i=1}^{d_x})$ and $r_2 = \max(\{r_{2i}\}_{i=1}^{d_x})$, where d_x , r_{1i} , and r_{2i} are defined in the section “Method 1: Maximum Lag Order of State Variables, r ” on page 1986. Suppose the maximum lag order of the i th state variable that must be generated in the initialization (or proposal initialization) distribution is denoted by τ_i and $\tau_i = \max(r_{1i}, r_{2i} - 1)$. Then $\tau = \max(\{\tau_i\}_{i=1}^{d_x})$.

Method 1: Maximum Lag Order of Dependent Variables, p

The maximum lag order of the dependent variables, p , is equal to the maximum lag order of all the dependent variables in the *distribution-arguments* of all the MODEL statements and the STATE statements including the PROPOSAL= option.

Method 1: Maximum Lag Order of Independent Variables, s

The maximum lag order of the independent variables, s , is equal to the maximum lag order of all the independent variables in the *distribution-arguments* of all the MODEL statements and the STATE statements including the PROPOSAL= option.

Method 1: Number of Skipped Observations, κ

Suppose that the maximum lag order of all the dependent variables for the measurement distribution is denoted by p_1 , and the counterparts for the transition (or proposal transition) distribution and the initialization (or proposal initialization) distribution are denoted by p_2 and p_3 , respectively. Moreover, the corresponding maximum lag orders of all the independent variables for the measurement distribution, the transition (or proposal transition) distribution, and the initialization (or proposal initialization) distribution are denoted by s_1 , s_2 , and s_3 , respectively. The SMC algorithms skip some observations and begin at a certain time step in the data table such that there are enough lagged observations to be used. The number of skipped observations, κ , is equal to $\max(p_2 - 1, s_2 - 1, p_1, p_3, s_1, s_3)$. In other words, the $(\kappa + 1)$ th observation corresponds to the logical time index $_t = 1$ in the SMC algorithms.

Method 1: Distribution Functions

How to define each distribution function is summarized in [Table 27.10](#).

Table 27.10 Distribution Functions

Distribution Function	Statement	Option
Initialization	INITSTATE	
Proposal initialization	INITSTATE	PROPOSAL=
Transition	STATE	
Proposal transition	STATE	PROPOSAL=
Measurement	MODEL	
Auxiliary	AUXMODEL	
Prior	PRIOR	

Method 2

In the SMC procedure, Method 2 defines an SSM by using the options in the SUBMITMODEL statement and the user-defined program. Functions and subroutines are defined in the user-defined program that appears between the SUBMITMODEL and ENDSUBMIT statements or in the file that is specified in the FILE= option in the SUBMITMODEL statement. Moreover, functions or subroutines can also be loaded from a given CMPLIB session that stores the corresponding functions or subroutines. For example, you can use the following statements to update the CMPLIB sessions:

```
proc cas;
  action sessionProp.setSessOpt / cmplib="casuser._smc_";
  run;
quit;
```

Subsequently, the predefined functions and subroutines in the session `casuser._smc_` are loaded.

To add functions and subroutines to a CMP session, you can use the **addRoutines** action. For example, the following statements store a subroutine, `toy_SAMPPRIO`, in a table in the session `casuser._smc_`:

```
proc cas;
  sessionProp.setSessOpt / cmplib="casuser._smc_";
  fcompact.addRoutines / package = "pkg", saveTable = True,
    funcTable = {name="_smc_" caslib="CASUSER" replace=1},
    routineCode =
      ' subroutine toy_sampprio(theta[*]);
        outargs theta;
        theta[1] = 0.95;
        theta[2] = 0.43;
        theta[3] = 1;
      endsub; ';
quit;
```

When you define a function or subroutine, the name, type, and order of those arguments must follow the corresponding signature syntax and semantics. For more information about the signature syntax and semantics of each function or subroutine, see the section “[Signature Syntax and Semantics of User-Defined Functions and Subroutines](#)” on page 1950.

The subroutines and functions that are loaded from the CMPLIB session are combined with the ones defined between the SUBMITMODEL and ENDSUBMIT statements or the ones defined in the file that you specify in the FILE= option in the SUBMITMODEL statement. Moreover, the subroutines and functions defined between the SUBMITMODEL and ENDSUBMIT statements or in the file that you specify in the FILE= option in the SUBMITMODEL overwrite the identical ones stored in the CMPLIB session.

The following sections define the components of an SSM by using Method 2.

Method 2: Model Name

The model name is specified in the NAME= option in the SUBMITMODEL statement, and the name is used in the name_KEYWORD functions and subroutines defined in the user-defined program.

Method 2: Parameters

The number of parameters, n , is specified in the NPARAM= option in the SUBMITMODEL statement. The parameters appear as an array argument, theta[*], of the functions and subroutines in the user-defined program. The i th element of theta[*], theta[i], denotes the i th parameter. For example, theta[2] denotes the second parameter.

- *Parameter value:* The initial parameter values are specified in the name_SAMPPRIO subroutine.
- *Parameter bound:* The parameter bounds are specified in the name_UPPERBOUNDS and name_LOWERBOUNDS subroutines.

Method 2: Lagged Variables

The lagged state, dependent, and independent variables appear as array arguments of the functions and subroutines in the user-defined program. Specifically, the lagged state variables appear as xlag[*], the lagged dependent variables appear as ylag[*], and the lagged independent variables appear as zlag[*].

In the lagged variable array argument, variables that have a lower lag order have smaller indices. Specifically, $xlag[(j - 1) * d_x + i]$ ($i, j \geq 1$) refers to the j th order of lag for the i th state variable; $ylag[(j - 1) * d_y + i]$ ($i, j \geq 1$) refers to the j th order of lag for the i th dependent variable; and $zlag[(j - 1) * d_z + i]$ ($i, j \geq 1$) refers to the j th order of lag for the i th independent variable. For example, suppose that a model has three state variables ($d_x = 3$) and the maximum lag order of the state variables is 2 ($r = 2$). In the functions and subroutines, the three first-lag state variables are denoted by xlag[1], xlag[2], and xlag[3], respectively, and the three second-order lag state variables are denoted by xlag[4], xlag[5], and xlag[6], respectively.

Method 2: State Variables

The state variables appear in an array argument, x[*], of the functions and subroutines in the user-defined program. The i th element of x[*], x[i], denotes the i th state variable. For example, x[3] denotes the third parameter.

Method 2: Dependent Variables

The dependent variables are specified in the *dependent-variables* in the SUBMITMODEL statement. The specified dependent variables match the array argument, y[*], of the functions and subroutines in the user-defined program such that The i th element of y[*], y[i], denotes the i th dependent variable in the *dependent-variables*. For example, y[1] corresponds to the first variable in the *dependent-variables*.

Method 2: Independent Variables

The independent variables are specified in the optional *independent-variables* in the SUBMITMODEL statement. The specified independent variables match the array argument, $z[*]$, of the functions and subroutines in the user-defined program such that The i th element of $z[*]$, $z[i]$, denotes the i th variable in the *independent-variables*. For example, $z[2]$ corresponds to the second variable in the *independent-variables*.

Method 2: Maximum Lag Order of State Variables, r

The maximum lag order of the state variables, r , is specified by the maximum value in the $XLAG=(xlag-options)$ option in the SUBMITMODEL statement.

Method 2: Maximum Lag Order of State Variables to Be Generated in Initialization Distribution, τ

The maximum lag order of the state variables to be generated in the initialization (or proposal initialization) distribution, τ , is specified by the INIT= suboption in the $XLAG=(xlag-options)$ option of the SUBMITMODEL statement.

Method 2: Maximum Lag Order of Dependent Variables, p

The maximum lag order of the dependent variables, p , is specified by the maximum value in the $YLAG=(ylag-options)$ option in the SUBMITMODEL statement.

Method 2: Maximum Lag Order of Independent Variables, s

The maximum lag order of the independent variables, s , is specified by the maximum value in the $ZLAG=(zlag-options)$ option in the SUBMITMODEL statement.

Method 2: Number of Skipped Observations, κ

Suppose that the maximum lag orders of all the dependent variables for the measurement, transition (or proposal transition), initialization (or proposal initialization), and auxiliary distributions are denoted by p_1 , p_2 , p_3 , and p_4 , respectively. The values p_1 , p_2 , p_3 , and p_4 are specified, respectively, by the MEAS=, TRAN=, INIT=, and AUX= suboptions of the $YLAG=(ylag-options)$ option in the SUBMITMODEL statement. Moreover, the corresponding maximum lag orders of all the independent variables for the measurement distribution, transition (or proposal transition) distribution, initialization (or proposal initialization), and auxiliary distributions are denoted by s_1 , s_2 , s_3 , and s_4 , respectively. The values s_1 , s_2 , s_3 , and s_4 are specified, respectively, by the MEAS=, TRAN=, INIT=, and AUX= suboptions of the $ZLAG=(zlag-options)$ option in the SUBMITMODEL statement.

The SMC algorithms skip some observations and begin at a certain time step in the data table such that there are enough lagged observations to be used. The number of skipped observations, κ , is equal to $\max(p_2 - 1, s_2 - 1, p_1, p_3, p_4, s_1, s_3, s_4)$. In other words, the $(\kappa + 1)$ th observation corresponds to the time index $_t = 1$ in the SMC algorithms.

Method 2: Distribution Function

For Method 2, how to define each distribution function is summarized in Table 27.11.

Table 27.11 Method 2: Distribution Functions

Distribution Function	Function and Subroutine
Initialization	<i>name_EVALINIT</i> , <i>name_SAMPINIT</i>
Proposal initialization	<i>name_EVALINITP</i> , <i>name_SAMPINITP</i>
Transition	<i>name_EVALTRAN</i> , <i>name_SAMPTRAN</i>
Proposal transition	<i>name_EVALTRANP</i> , <i>name_SAMPTRANP</i>
Measurement	<i>name_EVALMEAS</i> , <i>name_SAMPMEAS</i>
Auxiliary	<i>name_EVALNEXTMEAS</i>
Prior	<i>name_EVALPRIO</i>

Method 2: Category State Variables

The category state variables are supported only by Method 2. For more information about the category state variables, see the section “*NSTATE*<(numeric-list)>=*number*” on page 1947.

Distribution Argument Restriction

In the AUXMODEL, MODEL, INITSTATE, and STATE statements, the *distribution-arguments* are specified by expressions that must follow any SAS programming statements. In practice, the evaluation of the *distribution-arguments* can have computation errors even though they are specified correctly. The reason why the computation errors exist is that the SMC methods are based on simulations and the state variables can have extreme values. In most cases, the errors result from two circumstances: the support restriction of a specific function and the parameter restriction of a specific distribution. For example, the following statements contain the expressions that can cause computation errors of the function support restriction:

```
state x1 ~ normal(x1.11, 1);
state x2 ~ normal(x2.11, 1);
state x3 ~ normal(log(x1), sqrt(x2));
```

where x1, x2, and x3 are state variables. The LOG and SQRT functions both require a positive argument. However, x1 or x2 is drawn from a normal distribution, so there is likely to be a negative x1 or x2 value in the simulation within the SMC method. To avoid the computation error, you can add the IFN function to the third statement as follows:

```
state x3 ~ normal(log(ifn(x1>0.01,x1,0.01)), sqrt(ifn(x2>0.01,x2,0.01)));
```

All the arguments to the IFN function are evaluated before the function is called, and the results of the evaluation are then passed to the function. The following statement can still have computation errors even though it appears to have the same logic as the previous statement:

```
state x3 ~ normal(ifn(x1>0.01,log(x1),log(0.01)), sqrt(ifn(x2>0.01,x2,0.01)));
```

The following statements contain the expressions that can cause computation errors of the parameter restriction:

```
state x1 ~ normal(x1.11, 1);
state x2 ~ lognormal(x1, 1);
state x3 ~ poisson(x1);
```

where x_1 , x_2 , and x_3 are state variables. The Poisson distribution asks for a nonnegative parameter, but a negative x_1 value can be drawn from a specific distribution. Moreover, an overflow error can occur when you draw a new sample from the lognormal distribution if the x_1 value is quite large. To avoid the computation error, you can add the IFN function as follows:

```
state x2 ~ lognormal(ifn(x1<500,x1,500), 1);
state x3 ~ poisson(ifn(x1<0,0,x1));
```

Whether the adjustment is necessary or what the format of the adjustment is must depend on the *distribution-arguments* of a specific distribution.

Standard Distributions

This section lists all distributions that PROC SMC recognizes.

Table 27.12 Cauchy Distribution

Distribution	cauchy (l, s)
Parameter	Location parameter: l ; scale parameter: s
Density	$\frac{1}{\pi} \left(\frac{s}{s^2 + (\theta - l)^2} \right)$
Parameter restriction	$s > 0$
Range	$\theta \in (-\infty, \infty)$
Mean	Not defined
Variance	Not defined
Mode	l

Table 27.13 Beta Distribution

Distribution	beta (a, b)
Density	$\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} \theta^{a-1} (1-\theta)^{b-1}$
Parameter	Shape parameters: a and b
Parameter restriction	$a > 0, b > 0$
Range	$\begin{cases} [0, 1] & \text{when } a = 1, b = 1 \\ [0, 1) & \text{when } a = 1, b \neq 1 \\ (0, 1] & \text{when } a \neq 1, b = 1 \\ (0, 1) & \text{otherwise} \end{cases}$
Mean	$\frac{a}{a+b}$

Table 27.13 *continued*

Variance	$\frac{ab}{(a+b)^2(a+b+1)}$	
	$\frac{a-1}{a+b-2}$	$a > 1, b > 1$
	0 and 1	$a < 1, b < 1$
Mode	0	$\begin{cases} a < 1, b \geq 1 \\ a = 1, b > 1 \end{cases}$
	1	$\begin{cases} a \geq 1, b < 1 \\ a > 1, b = 1 \end{cases}$
	does not exist uniquely	$a = b = 1$

Table 27.14 **Gamma Distribution**

Distribution	gamma (a, b)
Parameter	Shape parameter: a ; scale parameter: b
Density	$\frac{1}{b^a \Gamma(a)} \theta^{a-1} e^{-\theta/b}$
Parameter restriction	$a > 0, b > 0$
Range	$\theta \in [0, \infty)$ if $a = 1$; $(0, \infty)$ otherwise
Mean	ab
Variance	ab^2
Mode	$(a-1)b$ if $a \geq 1$

Table 27.15 **Inverse Gamma Distribution**

Distribution	igamma (a, b)
Parameter	Shape parameter: a ; scale parameter: b
Density	$\frac{b^a}{\Gamma(a)} \theta^{-(a+1)} e^{-b/\theta}$
Parameter restriction	$a > 0, b > 0$
Range	$\theta \in (0, \infty)$
Mean	$\frac{b}{a-1}$ if $a > 1$
Variance	$\frac{b^2}{(a-1)^2(a-2)}$
Mode	$\frac{b}{a+1}$
Relationship to the gamma distribution	$\theta \sim \text{gamma}(a, 1/b) \Leftrightarrow 1/\theta \sim \text{igamma}(a, b)$

Table 27.16 Lognormal Distribution

Distribution	lognormal (m, s)
Parameter	Mean parameter: m ; standard deviation parameter: s
Density	$\frac{1}{\theta s \sqrt{2\pi}} \exp\left(-\frac{(\log \theta - m)^2}{2s^2}\right)$
Parameter restriction	$s > 0$
Range	$\theta \in (0, \infty)$
Mean	$\exp(m + s^2/2)$
Variance	$\exp(2(m + s^2)) - \exp(2m + s^2)$
Mode	$\exp(m - s^2)$

Table 27.17 Normal Distribution

Distribution	normal (m, s)
Parameter	Mean parameter: m ; standard deviation parameter: s
Density	$\frac{1}{s \sqrt{2\pi}} \exp\left(-\frac{(\theta - m)^2}{2s^2}\right)$
Parameter restriction	$s > 0$
Range	$\theta \in (-\infty, \infty)$
Mean	m
Variance	s^2
Mode	m

Table 27.18 Poisson Distribution

Distribution	poisson (λ)
Density	$\frac{\lambda^\theta}{\theta!} \exp(-\lambda)$
Parameter	Mean parameter: λ
Parameter restriction	$\lambda \geq 0$
Range	$\theta \in \begin{cases} \{0, 1, \dots\} & \text{if } \lambda > 0 \\ \{0\} & \text{if } \lambda = 0 \end{cases}$
Mean	λ
Variance	λ , if $\lambda > 0$
Mode	$\text{round}(\lambda)$

Table 27.19 *t* Distribution

Distribution	$\mathbf{t}(m, s, \nu)$
Density	$\frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})s\sqrt{\nu\pi}}(1 + \frac{(\theta-m)^2}{\nu s^2})^{-\frac{\nu+1}{2}}$
Parameter	Mean parameter: m ; standard deviation parameter: s ; degrees of freedom parameter: ν
Parameter restriction	$s > 0, \nu > 0$
Range	$\theta \in (-\infty, \infty)$
Mean	m if $\nu > 1$
Variance	$\frac{\nu}{\nu-2}s^2$ if $\nu > 2$
Mode	m

Table 27.20 Uniform Distribution

Distribution	$\mathbf{uniform}(l, u)$
Density	$\frac{1}{u-l}$
Parameter	Left location parameter: l ; right location parameter: u
Parameter restriction	$u > l$
Range	$\theta \in [l, u]$
Mean	$\frac{l+u}{2}$
Variance	$\frac{(u-l)^2}{12}$
Mode	Does not exist

Table 27.21 Degenerate Distribution

Distribution	$\mathbf{degenerate}(c)$
Density	1 if $\theta = c$
Parameter	Constant value: c
Parameter restriction	Does not exist
Range	$\theta = c$
Mean	c
Variance	0
Mode	c

Missing Values

Missing values of the dependent and independent variables are treated as follows:

- The independent variables cannot have missing values.
- Missing values in the dependent variables are not supported. But at the end of the data table, for the purpose of forecasting, the dependent variables can be set to missing values when the independent variables are provided.

Time Index

There are two types of time index:

- *actual time index*
This is the time index of the observations (dependent or independent variables). The actual time index of the i th observation (dependent or independent variable) vector is i ($i \geq 1$). For example, if all observations of the same time step are stored in a row and there are 365 rows, then the actual time indices for the observations are 1, 2, ..., 365. The actual time index is used as a variable or an argument, denoted by `_time`, in the AUXMODEL, INITSTATE, MODEL, STATE, and SUBMITMODEL statements.
- *logical time index*
This is the time index used in the SMC algorithms. The first time step that is incorporated in the SMC algorithms is indexed as 1. This index is denoted by t in these algorithms. For more information about the SMC algorithms, see the sections “[SMC Evaluating](#)” on page 1972, “[SMC Filtering](#)” on page 1964, “[SMC Forecasting](#)” on page 1971, “[SMC Smoothing](#)” on page 1969, and “[SMC Algorithms for the General Case of SSMS](#)” on page 1974. The logical time index is output as `_t` in the data table that corresponds to the OUT= or OUTSIM= option in the EVALUATE, FILTER, FORECAST, and SMOOTH statements.

The actual time index and logical time index do not necessarily have the same value. For example, if the observations contain N_{ob} time steps and the first two observations must be skipped (see the sections “[Method 1: Number of Skipped Observations, \$\kappa\$](#) ” on page 1986 and “[Method 2: Number of Skipped Observations, \$\kappa\$](#) ” on page 1989), the actual time indices of all observations are 1, 2, 3, ..., N_{ob} and the logical time indices of all observations are $-1, 0, 1, \dots, N_{\text{ob}} - 2$.

Data Table Output

The SMC procedure can create the data tables that are specified in the OUT= and OUTSIM= options in the FILTER, FORECAST, and SMOOTH statements; the OUT= option in the EVALUATE statement; the OUTMODEL= option in the SCORE statement; and the OUTPOST= option in the METHOD=PMCMC(OUTPOST=) option in the LEARN statement. The information in each table is described in the following sections.

OUT= Data Table Generated from the EVALUATE Statement

The output data table contains the following variables:

Time ID Variable	value of the variable that is specified in the TIME= option in the ID statement
_t	value of the logical time index in the evaluation algorithms. For more information about the logical time index, see the section “ Time Index ” on page 1995.
LogLikelihood	log likelihood up to each time step

OUT= Data Table Generated from the FILTER Statement

The output data table contains the following variables:

Time ID Variable	value of the variable that is specified in the TIME= option in the ID statement
_t	value of the logical time index in the filtering algorithms. For more information about the logical time index, see the section “ Time Index ” on page 1995.
State ID	index of the state variable in the filtering algorithms at a given time step.
mean	weighted mean of the corresponding noncategorical state variable at a given time step in the filtering estimates. This variable does not exist if there is no noncategorical state variable.
stdDev	weighted sample standard deviation of the corresponding noncategorical state variable at a given time step in the filtering estimates. This variable does not exist if there is no noncategorical state variable.
min	minimum value of the corresponding noncategorical state variable at a given time step in the filtering estimates. This variable does not exist if there is no noncategorical state variable.
Q1	first quantile of the corresponding noncategorical state variable at a given time step in the filtering estimates. This variable does not exist if there is no noncategorical state variable.
Q2	second quantile of the corresponding noncategorical state variable at a given time step in the filtering estimates. This variable does not exist if there is no noncategorical state variable.
Q3	third quantile of the corresponding noncategorical state variable at a given time step in the filtering estimates. This variable does not exist if there is no noncategorical state variable.

max	maximum value of the corresponding noncategorical state variable at a given time step in the filtering estimates. This variable does not exist if there is no noncategorical state variable.
P _j	j th ($j = 1, \dots, J$) percentile points of the corresponding noncategorical state variable at a given time step. The percentile points are specified by the PERCENT= <i>number-list</i> suboption of the OUT= option in the FILTER statement, and J is the number of values in the <i>number-list</i> . These variables do not exist if there is no noncategorical state variable.
Cat _l	the relative frequency of the l th ($l = 1, \dots, L$) category for the corresponding category state variable at a given time step, where L is the largest value in the <i>number-list</i> suboption of the NSTATE= <i>number-list</i> option in the SUBMITMODEL statement. The relative frequency equals the probability that the category state variable is in the l th category. These variables do not exist if there is no category state variable.

OUTSIM= Data Table Generated from the FILTER Statement

The output data table contains the following variables:

Time ID Variable	value of the variable that is specified in the TIME= option in the ID statement
_t	value of the logical time index in the filtering algorithms. For more information about the logical time index, see the section “ Time Index ” on page 1995.
Particle ID	index of the particle (sample) at a given time step in the filtering algorithm
Weight	normalized weight of the corresponding particle (sample) at a given time step in the filtering algorithm
State _k	value of the k th state variable, $k = 1, \dots, d_x$, of the corresponding particle (sample), where d_x is the number of state variables that are specified in the STATEVAR statement that is specified by the NSTATE= option in the SUBMITMODEL statement or the number of state variables that are specified in the STATEVAR statement.

OUT= Data Table Generated from the SMOOTH Statement

The output data table contains the following variables:

Time ID Variable	value of the variable that is specified in the TIME= option in the ID statement
_t	value of the logical time index in the smoothing algorithms. For more information about the logical time index, see the section “ Time Index ” on page 1995.
State ID	index of the state variable in the smoothing algorithms at a given time step
mean	weighted mean of the corresponding noncategorical state variable at a given time step in the smoothing estimates. This variable does not exist if there is no noncategorical state variable.
stdDev	weighted sample standard deviation of the corresponding noncategorical state variable at a given time step in the smoothing estimates. This variable does not exist if there is no noncategorical state variable.

min	minimum value of the corresponding noncategorical state variable at a given time step in the smoothing estimates. This variable does not exist if there is no noncategorical state variable.
Q1	first quantile of the corresponding noncategorical state variable at a given time step in the smoothing estimates. This variable does not exist if there is no noncategorical state variable.
Q2	second quantile of the corresponding noncategorical state variable at a given time step in the smoothing estimates. This variable does not exist if there is no noncategorical state variable.
Q3	third quantile of the corresponding noncategorical state variable at a given time step in the smoothing estimates. This variable does not exist if there is no noncategorical state variable.
max	maximum value of the corresponding noncategorical state variable at a given time step in the smoothing estimates. This variable does not exist if there is no noncategorical state variable.
P _j	j th ($j = 1, \dots, J$) percentile points of the corresponding state variable at a given time step. The percentile points are specified by the PERCENT= <i>number-list</i> suboption of the OUT= option in the SMOOTH statement, and J is the number of values in the <i>number-list</i> . These variables do not exist if there is no noncategorical state variable.
Cat _l	the relative frequency of the l th ($l = 1, \dots, L$) category for the corresponding category state variable at a given time step, where L is the largest value in the <i>number-list</i> suboption of the NSTATE= <i>number-list</i> option in the SUBMITMODEL statement. The relative frequency equals the probability that the category state variable is in the l th category. These variables do not exist if there is no category state variable.

OUTSIM= Data Table Generated from the SMOOTH Statement

The output data table contains the following variables:

Time ID Variable	value of the variable that is specified in the TIME= option in the ID statement
_t	value of the logical time index in the smoothing algorithms. For more information about the logical time index, see the section “ Time Index ” on page 1995.
Particle ID	index of the particle (sample) in the smoothing algorithm
Weight	normalized weight of the corresponding particle (sample) at a given time step in the smoothing algorithm
State _k	value of the k th state variable, $k = 1, \dots, d_x$, of the corresponding particle (sample), where d_x is the number of state variables that are specified in the STATEVAR statement or the number of state variables that is specified by the NSTATE= option in the SUBMITMODEL statement.

OUT= Data Table Generated from the FORECAST Statement

The output data table contains the following variables:

Time ID Variable	value of the variable that is specified in the TIME= option in the ID statement for the time step before the forecasting process
_t	value of the logical time index in the forecasting algorithms. For more information about the logical time index, see the section “ Time Index ” on page 1995.
Step	value h for the h -step-ahead forecast
Variable	name of the state variable or the dependent variable
Variable ID	index of the state variable or the dependent variable
mean	weighted mean of the corresponding noncategorical state variable at a given time step in the forecasting estimates. This variable does not exist if there is no noncategorical state variable.
stdDev	weighted sample standard deviation of the corresponding noncategorical state variable at a given time step in the forecasting estimates. This variable does not exist if there is no noncategorical state variable.
min	minimum value of the corresponding noncategorical state variable at a given time step in the forecasting estimates. This variable does not exist if there is no noncategorical state variable.
Q1	first quantile of the corresponding noncategorical state variable at a given time step in the forecasting estimates. This variable does not exist if there is no noncategorical state variable.
Q2	second quantile of the corresponding noncategorical state variable at a given time step in the forecasting estimates. This variable does not exist if there is no noncategorical state variable.
Q3	third quantile of the corresponding noncategorical state variable at a given time step in the forecasting estimates. This variable does not exist if there is no noncategorical state variable.
max	maximum value of the corresponding noncategorical state variable at a given time step in the forecasting estimates. This variable does not exist if there is no noncategorical state variable.
P_j	j th ($j = 1, \dots, J$) percentile points of the corresponding noncategorical state variable at a given time step. The percentile points are specified by the PERCENT= <i>number-list</i> suboption of the OUT= option in the FORECAST statement, and J is the number of values in the <i>number-list</i> . These variables do not exist if there is no noncategorical state variable.
Cat_l	the relative frequency of the l th ($l = 1, \dots, L$) category for the corresponding category state variable, where L is the largest value in the <i>number-list</i> suboption of the NSTATE= <i>number-list</i> option in the SUBMITMODEL statement. The relative frequency equals the probability that the category state variable is in the l th category. These variables do not exist if there is no category state variable.

OUTSIM= Data Table Generated from the FORECAST Statement

The output data table contains the following variables:

Time ID Variable	value of the variable that is specified in the TIME= option in the ID statement
Step	value of h for the h -step-ahead forecast
Particle ID	index of the particle (sample) in the forecast
Variable	name of the state variable or the dependent variable
Variable ID	index of the state variable or the dependent variable
Weight	normalized weight of the corresponding particle (sample) in the forecast
Value	value of the state variable or the dependent variable in the forecast

OUTMODEL= Data Table Generated from the SCORE Statement

The output data table consists of binary large object columns to store the binary data, which should be used only by the IN= option in the SCORE statement. **NOTE:** The number of columns and the definition of columns might be changed without notice in future releases. Do not edit the content of this output data table. If you run the PRINT procedure on this data table, you get a row of zeros or meaningless characters because the data type of each column is binary.

OUTPOST= Data Table Generated from the METHOD=PMCMC(OUTPOST=) Option in the LEARN Statement

The output data table contains the following variables:

Chain	index of the chain for the sample in the MCMC method
Iteration	index of the iteration number for the sample in the MCMC method
Theta_ i	value for the i th parameter, $i = 1, \dots, n$, where n is the number of parameters that are specified in the PARAMETER statement or specified by the NPARM= option in the SUBMITMODEL statement.
LogLike	log likelihood of the corresponding sample
LogPost	log posterior (the sum of log likelihood and log prior) of the corresponding sample

ODS Table Names

PROC SMC assigns a name to each table that it creates. You can use these names to refer to the tables when you use the Output Delivery System (ODS) to select tables and create output data tables. These names are listed in [Table 27.22](#).

Table 27.22 ODS Tables Produced in the SMC Procedure

ODS Table Name	Description	Suboption
ODS Tables Created by the Model Information		
InitialParmInfo	Initial parameter information	Default
NObs	Observation information	Default
StateSpaceModelInfo	Model specification information	Default
ODS Tables Created by the Suboptions of METHOD=PMCMC in the LEARN Statement		
AccRates	Metropolis acceptance rates	SAMSUM
AutoCorr	Autocorrelation statistics for each parameter	DIAG=AUTOCORR
AutoCorrByChain	Autocorrelation statistics for each parameter in each Markov chain	DIAG(BYCHAIN)=AUTOCORR
DiagSettings	Settings used for MCMC diagnostics	DIAG(SETTINGS)=
DiagSummaries	ESS and MCSE diagnostics for each parameter	Default
DiagSummariesByChain	ESS and MCSE diagnostics for each parameter in each Markov chain	DIAG(BYCHAIN)=SUMMARIES
Geweke	Geweke diagnostics for each parameter	DIAG=GEWEKE
GewekeByChain	Geweke diagnostics for each parameter in each Markov chain	DIAG(BYCHAIN)=GEWEKE
Heidelberger	Heidelberger-Welch diagnostics for each parameter	DIAG=HEIDEL
HeidelbergerByChain	Heidelberger-Welch diagnostics for each parameter in each Markov chain	DIAG(BYCHAIN)=HEIDEL
PostCorr	Posterior correlation matrix	STATS=CORR
PostCorrByChain	Posterior correlation matrix for each Markov chain	STATS(BYCHAIN)=CORR
PostCov	Posterior covariance matrix	STATS=COV
PostCovByChain	Posterior covariance matrix for each Markov chain	STATS(BYCHAIN)=COV
PostIntervals	Equal-tail and highest posterior density intervals for each parameter	STATS=INTERVALS
PostIntervalsByChain	Equal-tail and highest posterior density intervals for each parameter in each Markov chain	STATS(BYCHAIN)=INTERVALS
PostSummaries	Posterior mean, standard deviation, and percentiles for each parameter	Default

Table 27.22 *continued*

ODS Table Name	Description	Suboption
PostSummariesByChain	Posterior mean, standard deviation, and percentiles for each parameter in each Markov chain	STATS(BYCHAIN)=SUMMARIES
Raftery	Raftery-Lewis diagnostics for each parameter	DIAG=RAFTERY
RafteryByChain	Raftery-Lewis diagnostics for each parameter in each Markov chain	DIAG(BYCHAIN)=RAFTERY
SamplerSettings	Full MCMC sampler specification	SAMSET

Examples: SMC Procedure

Example 27.1: Stochastic Susceptible-Infected-Recovered Model with a Constant Transmission Rate

This example illustrates how to define a stochastic susceptible-infected-recovered (SSIR) model with a constant transmission rate in the SMC procedure and then estimate the parameters using the PMCMC method.

Consider the following SSIR model within the framework of the state space model:

- Initialization distribution:

$$ID_1 = Y_1$$

$$IU_1 \sim \text{uniform}(0.75 \frac{ID_1}{p}, 1.75 \frac{ID_1}{p})$$

$$RC_1 = 0$$

$$S_1 = N - ID_1 - IU_1$$

$$\xi_1 \sim \text{Poisson}(\frac{r}{ND} S_1 (ID_1 + IU_1))$$

- Transition distribution:

$$RC_t = RC_{t-1} + \frac{1}{D}(ID_{t-1} + IU_{t-1})$$

$$ID_t = (1 - \frac{1}{D})ID_{t-1} + Y_{t-1}$$

$$IU_t = (1 - \frac{1}{D})IU_{t-1} + \xi_{t-1} - Y_{t-1}$$

$$S_t = S_{t-1} - \xi_{t-1}$$

$$\xi_t \sim \text{Poisson}(\frac{r}{ND} S_t (ID_t + IU_t))$$

- Measurement distribution:

$$Y_t \sim \text{binomial}(\text{int}(IU_t), p)$$

Here ξ_t , a Poisson distributed instance, denotes the number of new infections at time $t + 1$; S_t denotes the number of susceptible individuals at time t ; Y_t is the number of new observed infections at time t ; RC_t is the cumulative number of recovered infections until time t ; ID_t is the number of documented active infectious individuals at time t ; and IU_t is the number of undocumented active infectious individuals at time t . Moreover, N denotes the population, r denotes the basic reproduction number, p is the diagnosis rate, D denotes the average time to removal after infection, $\frac{1}{D}$ denotes the recovery rate, and $\frac{r}{D}$ is the transmission rate. In this SSIR model, there are three parameters: r , D , and p ; and there are five state variables: ξ , S , ID , IU , and RC .

The prior specification for the parameters are given as follows:

$$\begin{aligned} r &\sim \text{uniform}(2.6, 3.3) \\ D &\sim \text{gamma}(325.5, 0.0285714286) \\ p &\sim \text{uniform}(0.1, 0.4) \end{aligned}$$

The initial values and bounds for the parameters are given by

$$\begin{aligned} r &= 2.9, \quad r_l = 2.6, \quad r_u = 3.3 \\ D &= 9.3, \quad D_l = 6.5, \quad D_u = 11 \\ p &= 0.25, \quad p_l = 0.1, \quad p_u = 0.4 \end{aligned}$$

where the bounds of r and p are identical to the supports of their prior distributions, whereas the bounds of D are different from the support of its prior distribution, which is $(0, \infty)$. To achieve this, the bounds can be specified in the `PARAMETER` statement as a supplement to the supports of the prior distributions.

The following statements simulate 89 observations based on the given stochastic volatility model. The first 75 observations are used as a training data set, and the remaining 14 observations are used as a test data set.

```
*macro variables;
%let N=20000000; *population;
%let Y_1 = 100;
%let IU_1 = 500;
%let RC_1 = 0;
%let D = 8.7;
%let r = 3.1;
%let p = 0.25;
data sir_all;
  call streaminit(1);
  t = 1;
  ID = &Y_1;
  IU = &IU_1;
  RC = &RC_1;
  S = &N - ID - IU;
  xi = RAND('POISSON', &r/(&N*&D)*S*(ID+IU));
  Y = &Y_1;
  sum = S + IU + ID + RC;
```

```

output;

  ID = (1-1/&D)*ID + Y;
  S = S - xi;
  xi = RAND('POISSON', &r/(&N*&D)*S*(ID+IU));
  Y = RAND('BINOMIAL', &p, int(IU));
  sum = S + IU + ID + RC; *sum is always equal to N;
  output;
end;
run;

```

The following DATA steps load the first 75 observations of the data set `sir_all` into the data set `sir_train` and then load that data set into a data table in your session that is associated with the `mylib` libref. The DATA steps assume that your libref is named `mylib`, but you can substitute any appropriately defined libref. The last 14 observations of the data set `sir_all` are loaded into the data set `sir_test`.

```

data sir_train;
  set sir_all;
  if (t le 75) then output;
run;

data sir_test;
  set sir_all;
  if (t > 75) then output;
run;

data mylib.sir_train;
  set sir_train;
run;

```

The following statements use PROC SMC to define the preceding SSIR model and then use the PMCMC method to estimate the three parameters for the simulated data set. The posterior medians will be used as the parameters in the smoothing and forecasting process.

```

  series x=t y=Q2 /legendlabel='Smoothing Median'
    lineattrs=(color=blue pattern=shortdash);
  yaxis label='RC, Smoothing';
  xaxis label='Day';
run;

```

Output 27.1.8 Smoothing Estimates vs. Actual Values, RC

The median smoothing estimates of all the state variables are close to the actual values of the simulated data set. The following statements load the forecasting result for each state variable into the Work library and then sort each data set by the time ID:

```
data fc_4; set mylib.fc(where=(VariableID=4)); run;
proc sort data=fc_4; by _t; run;

data fc_6; set mylib.fc(where=(VariableID=6)); run;
proc sort data=fc_6; by _t; run;
```

The following statements create a relevant data table, `combine_xi_forecast`, in the `Work` library to record the forecasting estimates and actual values of the number of new infectious individuals the next day. Then they draw a plot to compare the forecasting estimates to the actual values at each time step. The plot is shown in [Output 27.1.9](#), where the shadow band indicates the range between the 2.5th and 97.5th percentiles of the forecasting estimates.

```
data combine_xi_forecast;
  set fc_4 (keep=P_1 P_2 Q2);
  set sir_test (keep=t xi);
run;

proc sgplot data=combine_xi_forecast;
  band x=t upper=P_2 lower=P_1 /transparency=.3;
  scatter x=t y=xi /legendlabel='Actual Value'
    markerattrs=(color=red size=6 symbol=circlefilled);
  series x=t y=Q2 /legendlabel='Forecasting Median'
    markers markerattrs=(color=blue size=6 symbol=triangle)
    lineattrs=(color=blue pattern=solid);
  yaxis label='xi, Forecasting';
  xaxis integer label='Day';
run;
```

Output 27.1.9 Forecasting Estimates vs. Actual Values, xi

The following statements create a relevant data table, `combine_Y_forecast`, in the `Work` library to record the forecasting estimates and actual values of the new confirmed cases. Then they draw a plot to compare the forecasting estimates to the actual values at each time step. The plot is shown in [Output 27.1.10](#), where the shadow band indicates the range between the 2.5th and 97.5th percentiles of the forecasting estimates.

```
data combine_Y_forecast;
    set fc_6 (keep=P_1 P_2 Q2);
    set sir_test (keep=t Y);
run;

proc sgplot data=combine_Y_forecast;
    band x=t upper=P_2 lower=P_1 / transparency=.3;
    scatter x=t y=Y / legendlabel='Actual Value'
        markerattrs=(color=red size=6 symbol=circlefilled);
    series x=t y=Q2 / legendlabel='Forecasting Median'
        markers markerattrs=(color=blue size=6 symbol=triangle)
        lineattrs=(color=blue pattern=solid);
    yaxis label='Number of the New Observed Infections, Forecast';
    xaxis integer label='Day';
run;
```

Output 27.1.10 Forecasting Estimates vs. Actual Values, New Case

Example 27.2: Stochastic Susceptible-Infected-Recovered Model with a Time-Varying Transmission Rate

Although the stochastic susceptible-infected-recovered (SSIR) model with the constant transmission rate, as shown in the section “[Example 27.1: Stochastic Susceptible-Infected-Recovered Model with a Constant Transmission Rate](#)” on page 2002, is simple and easy to understand, it is not realistic because the transition rate is often time-varying as a result of the intervention, seasonality, and other complex reasons. This example illustrates how to define an SSIR model with a time-varying transmission rate in the SMC procedure and then estimate the parameters using the PMCMC method.

Consider the following SSIR model within the framework of the state space model:

- Initialization distribution:

$$\begin{aligned}
 ID_1 &= Y_1 \\
 IU_1 &\sim \text{uniform}(0.75 \frac{ID_1}{p}, 1.75 \frac{ID_1}{p}) \\
 RC_1 &= 0 \\
 S_1 &= N - ID_1 - IU_1 \\
 \ln(\beta_1) &\sim \text{uniform}(\ln(\frac{2.75}{D}), \ln(\frac{3.3}{D})) \\
 R_{e,1} &= \exp(\ln(\beta_1)) \frac{S_1 D}{N} \\
 \xi_1 &= \exp(\ln(\beta_1)) S_1 \frac{IU_1 + ID_1}{N}
 \end{aligned}$$

- Transition distribution:

$$\begin{aligned}
 S_t &= S_{t-1} - \xi_{t-1} \\
 RC_t &= RC_{t-1} + \frac{1}{D} (ID_{t-1} + IU_{t-1}) \\
 ID_t &= (1 - \frac{1}{D}) ID_{t-1} + Y_{t-1} \\
 IU_t &= (1 - \frac{1}{D}) IU_{t-1} + \xi_{t-1} - Y_{t-1} \\
 \ln(\beta_t) &\sim \text{normal}(u_1 + u_2 t + \rho \ln(\beta_{t-1}) - u_1 - u_2(t-1), \sqrt{\sigma^2(1 - \rho^2)}) \\
 R_{e,t} &= \exp(\ln(\beta_t)) \frac{S_t D}{N} \\
 \xi_t &= \exp(\ln(\beta_t)) S_t \frac{IU_t + ID_t}{N}
 \end{aligned}$$

- Measurement distribution:

$$Y_t \sim \text{binomial}(\text{int}(IU_t), p)$$

Here ξ_t , a Poisson distributed instance, denotes the number of new infections at time $t + 1$; S_t denotes the number of susceptible individuals at time t ; Y_t is the number of new observed infections at time t ; RC_t is the cumulative number of recovered infections until time t ; ID_t is the number of documented active infectious individuals at time t ; IU_t is the number of undocumented active infectious individuals at time t ; β_t is the transmission rate at time t ; and $R_{e,t}$ is the effective reproduction number at time t . Moreover, N denotes the population; p is the diagnosis rate; D denotes the average time to removal after infection; and $\frac{1}{D}$ denotes the recovery rate. The natural logarithm of the transmission rate follows an AR(1) model with coefficients u_1 and u_2 , correlation parameter ρ , and variance $\sigma^2(1 - \rho^2)$.

In this SSIR model, there are six parameters: D , u_1 , u_2 , p , ρ , and σ ; and there are seven state variables: S , RC , ID , IU , $\ln(\beta)$, R_e , and ξ . Actually, the model can be represented without R_e because no state variables or dependent variables depend on it. However, R_e is worth investigating: $R_e < 1$ indicates containment of the disease. Moreover, the equation of ξ_t can be included in the equations of other state variables. For example, $S_t = S_{t-1} - \xi_{t-1}$ can be written as follows:

$$S_t = S_{t-1} - \exp(\ln(\beta_{t-1})) S_{t-1} \frac{IU_{t-1} + ID_{t-1}}{N}$$

The equation $IU_t = (1 - \frac{1}{D})IU_{t-1} + \xi_{t-1} - Y_{t-1}$ can be written in the same way. The reason that ξ is still kept as a state variable is because the estimated number or interval of new infections is also useful for public health organizations in a pandemic.

A scenario with a basic reproduction number that is a decreasing function of the time is considered in the data generating process. The function is defined as

$$R_{0,t} = R_{0,0} \exp(-\eta t) + (1 - \exp(-\eta t))\bar{R}_0$$

where $R_{0,t}$ denotes the basic reproduction number at time t , η denotes the decreasing rate, and $\bar{R}_0$ denotes the long run value to which $R_{0,t}$ converges when t is large. Note that the preceding function form is unknown to the modeler; the AR(1) process for the natural logarithm of the transmission rate is used to approximate the true unknown function form of $R_{0,t}$.

The following statements simulate 82 observations in which the first 75 observations are used as a training data set and the remaining 7 observations are used as a test data set:

```
*macro variables;
%let N=20000000; * 20 million people ;
%let ID_0 = 100;
%let IU_0 = 800;
%let RC_0 = 0;
%let D = 8.7;
%let R_0 = 3.1;
%let eta = 0.045;
%let p = 0.25;
data sir_data;
  t = 1;
  S = &N - &ID_0 - &IU_0;
  RC = &RC_0;
  IU = &IU_0;
  ID = &ID_0;
  R = &R_0;
  beta = R*1/&D;
  logbeta = log(beta);
  R_eff = R*S/&N;
  Y = ID;
  xi = beta*S*(IU + ID)/&N;
  sum = S + IU + ID + RC;
  output;
  call streaminit(1);
  do t = 2 to 82;
    Slag = S;
    S = S - xi;
    RC = RC + 1/&D*(IU + ID);
    IU = (1-1/&D)*IU + xi - Y;
    ID = (1-1/&D)*ID + Y;
    Y = RAND('BINomial', &p, int(IU));
    R = &R_0*exp(-&eta*t) + 1-exp(-&eta*t);
    beta = R*1/&D;
    logbeta = log(beta);
    R_eff = R*S/&N;
    xi = beta*S*(IU + ID)/&N;
```

```

        sum = S + IU + ID + RC;
    output;
end;
run;

```

The following DATA steps load the first 75 observations of the data set `sir_data` into the data set `sir_train` and then load that data set into a data table in your session that is associated with the `mylib` libref. The DATA steps assume that your libref is named `mylib`, but you can substitute any appropriately defined libref. The last 7 observations are loaded into the data set `sir_test`.

```

data sir_train;
    set sir_data;
    if (t le 75) then output;
run;

data sir_test;
    set sir_data;
    if (t > 75) then output;
run;

data mylib.sir_train;
    set sir_train;
run;

```

The following statements use PROC SMC to define the preceding SSIR model and then use the PMCMC method to estimate the three parameters for the simulated data set. The posterior medians will be used as the parameters in the smoothing and forecasting process.

xaxis integer label='Day';
run;

```

Output 27.2.4 Smoothing Estimates vs. Actual Values, logbeta

The following statements create a relevant data table, `combine_REFF`, in the `Work` library to record the smoothing estimates and actual values of R_e . Then they draw a plot to compare the smoothing estimates to the actual values at each time step. The plot is shown in [Output 27.2.5](#), where the shadow band indicates the range between the 2.5th and 97.5th percentiles of the smoothing estimates.

```

data combine_REFF;
  set smo_s6 (keep=P_1 P_2 Q2);
  set sir_train (keep=t R_EFF);
run;

proc sgplot data=combine_REFF;
  band x=t upper=P_2 lower=P_1 /transparency=.3;
  series x=t y=R_EFF /legendlabel='Actual Value' lineattrs=(color=red);

```

```
series x=t y=Q2 /legendlabel='Smoothing Median'
  lineattrs=(color=blue pattern=shortdash);
yaxis label='R_EFF, Smoothing';
xaxis integer label='Day';
run;
```

Output 27.2.5 Smoothing Estimates vs. Actual Values, Reff

The following statements load the forecasting estimates for R_e , ξ , and Y into the Work library and then sort each data set by the time ID:

```
data fc_6; set mylib.fc(where=(VariableID=6)); run;
proc sort data=fc_6; by _t; run;

data fc_7; set mylib.fc(where=(VariableID=7)); run;
proc sort data=fc_7; by _t; run;

data fc_8; set mylib.fc(where=(VariableID=8)); run;
proc sort data=fc_8; by _t; run;
```

The following statements create a relevant data table, combine_REFF_forecast, in the Work library to record the forecasting estimates and actual values of R_e . Then they draw a plot to compare the forecasting estimates

to the actual values at each time step. The plot is shown in [Output 27.2.6](#), where the shadow band indicates the range between the 2.5th and 97.5th percentiles of the forecasting estimates.

```
data combine_REFF_forecast;
  set fc_6 (keep=P_1 P_2 Q2);
  set sir_test (keep=t R_EFF);
run;

proc sgplot data=combine_REFF_forecast;
  band x=t upper=P_2 lower=P_1 /transparency=.3;
  scatter x=t y=R_EFF /legendlabel='Actual Value'
    markerattrs=(color=red size=6 symbol=circlefilled);
  series x=t y=Q2 /legendlabel='Forecasting Median'
    markers markerattrs=(color=blue size=6 symbol=triangle)
    lineattrs=(color=blue pattern=solid);
  yaxis label='R_EFF, Forecasting';
  xaxis integer label='Day';
run;
```

Output 27.2.6 Forecasting Estimates vs. Actual Values, Reff

The following statements create a relevant data table, `combine_xi_forecast`, in the `Work` library to record the forecasting estimates and actual values of ξ . Then they draw a plot to compare the forecasting estimates to

the actual values at each time step. The plot is shown in [Output 27.2.7](#), where the shadow band indicates the range between the 2.5th and 97.5th percentiles of the forecasting estimates.

```
data combine_xi_forecast;
  set fc_7 (keep=P_1 P_2 Q2);
  set sir_test (keep=t xi);
run;

proc sgplot data=combine_xi_forecast;
  band x=t upper=P_2 lower=P_1 /transparency=.3;
  scatter x=t y=xi /legendlabel='Actual Value'
    markerattrs=(color=red size=6 symbol=circlefilled);
  series x=t y=Q2 /legendlabel='Forecasting Median'
    markers markerattrs=(color=blue size=6 symbol=triangle)
    lineattrs=(color=blue pattern=solid);
  yaxis label='xi, Forecasting';
  xaxis integer label='Day';
run;
```

Output 27.2.7 Forecasting Estimates vs. Actual Values, xi

The following statements create a relevant data table, `combine_Y_forecast`, in the `Work` library to record the forecasting estimates and actual values of Y . Then they draw a plot to compare the forecasting estimates to

the actual values at each time step. The plot is shown in [Output 27.2.8](#), where the shadow band indicates the range between the 2.5th and 97.5th percentiles of the forecasting estimates.

```
data combine_Y_forecast;
  set fc_8 (keep=P_1 P_2 Q2);
  set sir_test (keep=t Y);
run;

proc sgplot data=combine_Y_forecast;
  band x=t upper=P_2 lower=P_1 /transparency=.3;
  scatter x=t y=Y /legendlabel='Actual Value'
    markerattrs=(color=red size=6 symbol=circlefilled);
  series x=t y=Q2 /legendlabel='Forecasting Median'
    markers markerattrs=(color=blue size=6 symbol=triangle)
    lineattrs=(color=blue pattern=solid);
  yaxis label='Y, Forecasting';
  xaxis integer label='Day';
run;
```

Output 27.2.8 Forecasting Estimates vs. Actual Values, Y

As shown in this example, by introducing the AR(1) process for the transition rate, this simple and powerful model successfully captures the dynamics in the epidemic spread, even when the true DGP follows a different

stochastic process. This model is applied to the real-data example in the section “[Example 27.3: Estimating the Effective Reproduction Number of COVID-19 Cases in Pennsylvania](#)” on page 2025.

Example 27.3: Estimating the Effective Reproduction Number of COVID-19 Cases in Pennsylvania

This example illustrates how to estimate the time-varying effective reproduction number of COVID-19 using the stochastic susceptible-infected-recovered (SSIR) model introduced in the section “[Example 27.2: Stochastic Susceptible-Infected-Recovered Model with a Time-Varying Transmission Rate](#)” on page 2014. The daily confirmed number of COVID-19 cases in Pennsylvania reported by the Center for Systems Science and Engineering at Johns Hopkins University (JHU CSSE) (Dong, Du, and Gardner 2020) is used.

The following DATA step inputs the number of new COVID-19 cases confirmed in Pennsylvania into the data set `penn_state_data`:

```
data penn_state_data;
    input date: anydtdte. cases newcase;
    format date DATE.;
    label date="Date" cases="cumulative cases" newcase="new case";
datalines;
22-Mar-20  509  110
23-Mar-20  698  189
24-Mar-20  946  248
25-Mar-20 1260  314
26-Mar-20 1795  535
27-Mar-20 2345  550

... more lines ...

;
```

The following statements plot the number of new cases confirmed in Pennsylvania from March 22 to September 28, 2020. The output is shown in [Output 27.3.1](#).

```
proc sgplot data=penn_state_data;
    series x=date y=newcase /
        markers markerattrs=(color=red size=5 symbol=circlefilled)
        lineattrs=(color=red);
    yaxis label='New Case';
    xaxis label='Date';
run;
```

Output 27.3.1 New Cases, Pennsylvania

The data start from March 22, 2020, because it is the first day when Pennsylvania had more than 100 new cases and more than 500 cumulative cases. The transition and measurement distributions for the SSIR model are exactly the same as the ones in the section “[Example 27.2: Stochastic Susceptible-Infected-Recovered Model with a Time-Varying Transmission Rate](#)” on page 2014. However, the initialization distribution must be adjusted because the first day of the data (March 22, 2020) is not the day when the first case was reported in Pennsylvania.

Consider the following initialization distribution:

$$\begin{aligned}
 ID_1 &\sim \text{uniform}(450, 550) \\
 IU_1 &\sim \text{uniform}\left(0.98\frac{110}{p} - 110, 3\frac{ID_1}{p} - 110\right) \\
 RC_1 &= 0 \\
 S_1 &= N - ID_1 - IU_1 \\
 \ln(\beta_1) &\sim \text{uniform}\left(\ln\left(\frac{2.75}{D}\right), \ln\left(\frac{3.3}{D}\right)\right) \\
 R_{e,1} &= \exp(\ln(\beta_1))\frac{S_1 D}{N} \\
 \xi_1 &= \exp(\ln(\beta_1))S_1\frac{IU_1 + ID_1}{N}
 \end{aligned}$$

Here all the denotations are defined in the same way as in the section “[Example 27.2: Stochastic Susceptible-Infected-Recovered Model with a Time-Varying Transmission Rate](#)” on page 2014. The cumulative number of reported cases until March 22, 2020, is 509, and the number of new cases that day is 110. Thus, it is reasonable to set initialization distributions for ID_1 and IU_1 as earlier. In the initialization distribution for IU_1 , $\frac{110}{p}$ can be seen as the expected value of the number of undocumented infectious individuals before that day; 110 is subtracted because the 110 cases are confirmed that day.

The following statements add a logical time ID (“t”) and split the data set such that the first 181 observations are used as the training set and the last 14 observations are used as the test set:

```

data penn_state_data;
  set penn_state_data;
  t = _N_;
run;

data penn_state_train;
  set penn_state_data;
  if (t le 181) then output;
run;

data penn_state_test;
  set penn_state_data;
  if (t > 181) then output;
run;

```

The following DATA step loads the training set into a data table in your session that is associated with the mylib libref. The DATA step assumes that your libref is named mylib, but you can substitute any appropriately defined libref.

```

data mylib.train;
  set penn_state_train;
run;

```

The following statements use PROC SMC to define the SSIR model and then use the PMCMC method to estimate the three parameters for the simulated data set. Moreover, the population of Pennsylvania is set as a macro variable. The median of the posterior parameter samples will be used as the parameters in the smoothing and forecasting process.

```

The following statements load the smoothing result for the effective reproduction number (VariableID = 6) into the Work library and then sort that data set by the logical time ID:

```
data smo_s6; set mylib.sm(where=(VariableID=6)); run;
proc sort data=smo_s6; by _t; run;
```

The following statements create a relevant data table, combine_REFF, in the Work library to record the smoothing estimates and actual values of the effective reproduction number. Then they draw a plot to compare the smoothing estimates to the actual values at each time step. The output is shown in [Output 27.3.5](#), where the shadow band in the plot indicates the range between the 2.5th and 97.5th percentiles of the smoothing estimates and the horizontal reference line denotes the line $y = 1$.

```
data combine_REFF;
  set smo_s6 (keep=P_1 P_2 Q2 _t);
  set penn_state_train (keep=date);
run;

proc sgplot data=combine_REFF;
  band x=date upper=P_2 lower=P_1 /transparency=.3;
  series x=date y=Q2 /legendlabel='Smoothing Median'
    lineattrs=(color=blue pattern=shortdash);
  yaxis label='R_EFF, Smoothing';
  xaxis label='Date';
  refline 1 / axis=y label='1' lineattrs=(thickness=3);
run;
```

Output 27.3.5 Smoothing Estimates vs. Actual Values, R_e

The following statements load the forecasting result for each state variable into the Work library and then sort each data set by the time ID:

```
data fc_8; set mylib.fc(where=(VariableID=8)); run;
proc sort data=fc_8; by _t; run;
```

The following statements create a relevant data table, `combine_Y_forecast`, in the Work library to record the forecasting estimates and actual values of new cases. Then they draw a plot to compare the forecasting estimates to the actual values at each time step. The plot is shown in [Output 27.3.6](#), where the shadow band indicates the range between the 2.5th and 97.5th percentiles of the forecasting estimates.

```
data combine_Y_forecast;
  set fc_8 (keep=P_1 P_2 Q2);
  set penn_state_test (keep=date t newcase);
run;

proc sgplot data=combine_Y_forecast;
  band x=date upper=P_2 lower=P_1 /transparency=.3;
  series x=date y=newcase /legendlabel='Actual Value'
    markers markerattrs=(color=red size=5 symbol=circlefilled)
    lineattrs=(color=red);
```

```

series x=date y=Q2 /legendlabel='Forecasting Median'
      markers markerattrs=(color=blue size=5 symbol=trianglefilled)
      lineattrs=(color=blue pattern=shortdash);
yaxis label='New Case, Forecasting';
xaxis label='Date';
run;

```

Output 27.3.6 Forecasting Estimates vs. Actual Values, Y

Example 27.4: Estimating the Dynamic Bayesian Network

This example illustrates how to estimate a dynamic Bayesian network (DBN). A heating, ventilation, and air conditioning (HVAC) system is used as a prototype network of DBN.

In this HVAC system, there are four state variables:

- OutSensorStatus: category variable, outer sensor status (WORK=1 or FAIL=0)
- InSensorStatus: category variable, inner sensor status (WORK=1 or FAIL=0)
- OutTemp: continuous variable, actual outer temperature
- InTemp: continuous variable, actual inner temperature

There are three observation variables:

- OutTempRead: dependent continuous variable, outer temperature reading
- InTempRead: dependent continuous variable, inner temperature reading
- HVAC: independent category variable, HVAC mode (heating, cooling or normal)

The HVAC system can be represented by the following state space model (or the DBN model), where the subscript t denotes the time index:

- Initialization distributions:

$$\text{OutSensorStatus}_1 \sim \text{Bernoulli}(0.5)$$

$$\text{InSensorStatus}_1 \sim \text{Bernoulli}(0.5)$$

$$\text{OutTemp}_1 \sim N(\text{OutTempRead}_1, 4)$$

$$\text{InTemp}_1 \sim N(\text{InTempRead}_1, 4)$$

- Transition distributions:

$$\Pr(\text{OutSensorStatus}_t = j | \text{OutSensorStatus}_{t-1} = i) = P_{ij}, \quad i, j \in \{0, 1\}$$

$$\Pr(\text{InSensorStatus}_t = j | \text{InSensorStatus}_{t-1} = i) = Q_{ij}, \quad i, j \in \{0, 1\}$$

$$\text{OutTemp}_t = \text{OutTemp}_{t-1} + \frac{45\pi}{287} \cos\left(\frac{2\pi}{287}(t-2) - \frac{\pi}{2}\right) + \epsilon_t, \epsilon_t \sim N(0, \text{Var}_{\text{OT}})$$

$$\text{InTemp}_t = a_i \text{InTemp}_{t-1} + b_i \text{OutTemp}_{t-1} + \eta_{i,t}, \eta_{i,t} \sim N(0, \text{Var}_{i,\text{IT}}), i = \text{HVAC}_{t-1}$$

- Measurement distributions:

$$\text{OutTempRead}_t = \begin{cases} \text{OutTemp}_t + \xi_{2,t}, \xi_{2,t} \stackrel{\text{iid}}{\sim} N(0, \text{Var}_1), & \text{if } \text{OutSensorStatus}_t = 1 \\ \text{OutTempRead}_{t-1} + \xi_{1,t}, \xi_{1,t} \stackrel{\text{iid}}{\sim} N(0, \text{Var}_0), & \text{if otherwise} \end{cases}$$

$$\text{InTempRead}_t = \begin{cases} \text{InTemp}_t + \xi_{2,t}, \xi_{2,t} \stackrel{\text{iid}}{\sim} N(0, \text{Var}_1), & \text{if } \text{InSensorStatus}_t = 1 \\ \text{InTempRead}_{t-1} + \xi_{1,t}, \xi_{1,t} \stackrel{\text{iid}}{\sim} N(0, \text{Var}_0), & \text{otherwise} \end{cases}$$

Here $\text{Bernoulli}(p)$ denotes the Bernoulli distribution whose probability of success is p (success: 1; failure: 0), and $N(\mu, \sigma^2)$ denotes the normal distribution, whose mean is μ and variance is σ^2 . Figure 27.11 shows the relationships within the HVAC system.

Figure 27.11 DBN States and Their Transitions

There are 16 parameters. The initial values, bounds, and actual values that the simulation data set uses for the parameters are listed in Table 27.23. Each of the variance parameters technically has an upper bound of ∞ , but they are constrained to have an upper bound of 0.99. This represents prior information that the variances cannot be larger than 0.99, which makes sense for this example because it is known that the true values of these parameters are all less than 0.99. Also, adding these constraints makes the model significantly easier to fit.

Table 27.23 Parameter Information

Parameter	Initial Value	Range	Actual Value
$\theta_1 = P_{0,0}$	0.65	(0.01, 0.99)	0.85
$\theta_2 = P_{1,0}$	0.3	(0.01, 0.99)	0.15
$\theta_3 = Q_{0,0}$	0.65	(0.01, 0.99)	0.85

    output;
    OTReadlag = OTRead;
    ITReadlag = ITRead;
    OSlag = OS;
    ISlag = IS;
  end;

```

```

        OTlag = OT;
        ITlag = IT;
        HVAClag = HVAC;
    end;
run;

```

The following DATA step loads the data set hvacSystem into a data table in your session that is associated with the mylib libref. The DATA step assumes that your libref is named mylib, but you can substitute any appropriately defined libref.

```

data mylib.hvacSystem;
    set hvacSystem;
run;

```

In the SMC procedure, two categorical variables must be positioned before the two noncategorical ones in the state variable vector $\{x_i\}_{i=1}^4$. For the four state variables, x_1 denotes OutSensorStatus; x_2 denotes InSensorStatus; x_3 denotes OutTemp; and x_4 denotes InTemp.

For the two dependent variables, OutTempRead is denoted by y_1 and InTempRead is denoted by y_2 . The independent variable, HVAC, is denoted by z_1 .

The following statements use the SUBMITMODEL statement in the SMC procedure to define the HVAC system and then use the PMCMC method to estimate the 16 parameters for the simulated data set. The median of the posterior parameter samples will be used as the parameter in the smoothing process. Moreover, in the SUBMITMODEL statement, θ_i is represented as theta[i] for $i = 1, \dots, 16$; x_i is represented by x[i] for $i = 1, \dots, 4$; y_i is represented by y[i] for $i = 1, 2$; and z_1 is represented by z[1]. You must specify the *dependent-variables* in the SUBMITMODEL statement in the same order as $\{y_i\}_{i=1}^2$. This example can take around 14 hours or longer to run, depending on which hardware you run it on. The TRANSFORM option for the PMCMC method in the LEARN statement significantly improves the efficiency of the sampler for this model, especially when you combine it with the constraints on the variance parameters.

```

The following statements load the smoothing estimates for each state variable into the Work library and then sort each data set by the time ID:

```
data smo_s1; set mylib.sm(where=(variableID=1)); run;
proc sort data=smo_s1; by timeID; run;

data smo_s2; set mylib.sm(where=(variableID=2)); run;
proc sort data=smo_s2; by timeID; run;

data smo_s3; set mylib.sm(where=(variableID=3)); run;
proc sort data=smo_s3; by timeID; run;
```

```
data smo_s4; set mylib.sm(where=(variableID=4)); run;
proc sort data=smo_s4; by timeId; run;
```

The following statements create a relevant data table, `combine_s3`, in the `Work` library to record the smoothing estimates and actual values of `OutTemp`. Then they draw a plot to compare the smoothing estimates to the actual values at each time step. The plot is shown in [Output 27.4.4](#), where the shadow band indicates the range from the 2.5th to the 97.5th percentiles of the smoothing estimates.

```
data combine_s3;
  set smo_s3;
  set hvacSystem;
run;

proc sgplot data=combine_s3;
  band x=t upper=P_2 lower=P_1 /transparency=.3;
  series x=Time y=OT /legendlabel='Actual Value' lineattrs=(color=red);
  series x=Time y=Q2/ legendlabel='Smoothing Median'
    lineattrs=(color=blue pattern=shortdash);
run;
```

Output 27.4.4 Smoothing Estimates vs. Actual Values, `OutTemp`

The following statements create a relevant data table, `combine_s4`, in the Work library to record the smoothing estimates and actual values of `InTemp`. Then they draw a plot to compare the smoothing estimates to the actual values at each time step. The plot is shown in [Output 27.4.5](#), where the shadow band indicates the range from the 2.5th to the 97.5th percentiles of the smoothing estimates.

```
data combine_s4;
  set smo_s4;
  set hvacSystem;
run;

proc sgplot data=combine_s4;
  band x=t upper=P_2 lower=P_1 /transparency=.3;
  series x=Time y=IT /legendlabel='Actual Value' lineattrs=(color=red);
  series x=Time y=Q2/ legendlabel='Smoothing Median'
    lineattrs=(color=blue pattern=shortdash);
run;
```

Output 27.4.5 Smoothing Estimates vs. Actual Values, `InTemp`

[Output 27.4.4](#) and [Output 27.4.5](#) show both the outer temperature and inner temperature are accurately estimated by the model.

For the category variables, `OutSensorStatus` and `InSensorStatus`, the smoothing estimates of the frequency

of the work status (WORK: 1) are used to compare the actual values. The following statements create a relevant data table, `combine_s1`, in the Work library to record the smoothing estimates and actual values of the category variable `OutSensorStatus`. Then they draw a plot to compare the smoothing estimates to the actual values at each time step. The plot, which is shown in [Output 27.4.6](#), indicates that the hidden outer sensor status is successfully decoded by the model.

```
data combine_s1;
  set smo_s1;
  set hvacSystem;
run;

proc sgplot data=combine_s1;
  series x=Time y=OS;
  series x=Time y=cat_2;
run;
```

Output 27.4.6 Smoothing Estimates vs. Actual Values, `OutSensorStatus`

The following statements create a relevant data table, `combine_s2`, in the Work library to record the smoothing estimates and actual values of the category variable `InSensorStatus`. Then they draw a plot to compare the smoothing estimates to the actual values at each time step. The plot, which is shown in [Output 27.4.7](#), indicates that the hidden inner sensor status is successfully decoded by the model.

```

data combine_s2;
  set smo_s2;
  set hvacSystem;
run;

proc sgplot data=combine_s2;
  series x=Time y=IS;
  series x=Time y=cat_2;
run;

```

Output 27.4.7 Smoothing Estimates vs. Actual Values, InSensorStatus

Example 27.5: The Fully Adapted Auxiliary Particle Filter Using a Gaussian ARCH Model

This example illustrates the advantages of the fully adapted auxiliary particle filter by using a Gaussian ARCH model.

Consider the following model:

- initialization distribution:

$$x_0 \sim \text{degenerate}(0)$$

- transition distribution:

$$x_t | x_{t-1} \sim \text{normal}(0, \beta_0 + \beta_1 x_{t-1}^2)$$

- measurement distribution:

$$y_t | x_t \sim \text{normal}(x_t, \lambda^2)$$

For each distribution, $\beta_0 > 0$, $\beta_1 > 0$ and $\lambda^2 > 0$.

The fully adapted auxiliary and proposal transition distributions are derived respectively as

$$y_t | x_{t-1} \sim \text{normal}(0, \beta_0 + \beta_1 x_{t-1}^2 + \lambda_t^2)$$

$$x_t | x_{t-1}, y_t \sim \text{normal} \left(\frac{(\beta_0 + \beta_1 x_{t-1}^2) y_t}{\beta_0 + \beta_1 x_{t-1}^2 + \lambda_t^2}, \frac{(\beta_0 + \beta_1 x_{t-1}^2) \lambda_t^2}{\beta_0 + \beta_1 x_{t-1}^2 + \lambda_t^2} \right)$$

First, the decrease in computing time of the APF(ADP) algorithm compared to the APF algorithm is illustrated using the EVALUATE statement. Data sets that have varying numbers of observations are generated. PROC SMC then runs for each data set with varying numbers of particles, and the run time is recorded.

The following statements generate a data set that has a specified number of observations by using the parameter values $\lambda^2 = 0.00027$, $\beta_0 = 0.0000495$, and $\beta_1 = 0.89275$:

```
%let lambda_sq = 0.00027;
%let beta0=0.0000495;
%let beta1=0.89275;
%macro generate_data(nobs=);
  proc iml;
    call randseed(123);
    x = j(&nobs,1,.);
    y = j(&nobs,1,.);
    timeID = j(&nobs,1,.);
    x[1]=0;
    call randgen(rny,"Normal");
    y[1]=x[1]+sqrt(&lambda_sq)*rny;
    timeID[1]=1;
```

```

do t=2 to &nobs;
  call randgen(rnx,"Normal");
  x[t]=sqrt(&beta0+&beta1*x[t-1]*x[t-1])*rnx;
  call randgen(rny,"Normal");
  y[t]=x[t]+sqrt(&lambda_sq)*rny;
  timeID[t]=t;
end;
create arch var {TimeID x y};
append ;
close arch;
quit;
%mend generate_data;

```

The following macro repeatedly generates data sets and runs PROC SMC with the fully adapted auxiliary and proposal distributions by using the APF(ADP) and APF algorithms. The average run time and total run time over the 100 replications of the log-likelihood computation are recorded.

```

%macro runby_npart_nobs(nobs=,N=,alg=,algn=,nb=,);
  %generate_data(nobs=&nobs);
  data mylib.arch;
    set arch;
  run;
  %do r=1 %to 100;
    %let _timer_start = %sysfunc(datetime());
    proc smc data=mylib.arch seed = 123;
      id time = timeID;
      var y;
      statevar x;
      parameters lambda_sq=&lambda_sq beta0=&beta0 beta1=&beta1;
      initstate x ~ degenerate(0) ;
      state x ~ normal(0, sqrt(beta0+beta1*x.ll*x.ll))/proposal=
        normal((beta0+beta1*x.ll*x.ll)*y/(beta0+beta1*x.ll*x.ll+lambda_sq),
          sqrt(lambda_sq*(beta0+beta1*x.ll*x.ll)/
            (beta0+beta1*x.ll*x.ll+lambda_sq)));
      model y ~ normal(x, sqrt(lambda_sq));
      auxmodel y ~ normal(0, sqrt(beta0+beta1*x.ll*x.ll+lambda_sq));
      evaluate nparticle = &N alg=&alg out=mylib.eval;
    run;
    data duration&nb.&r.;
      duration = datetime() - &_timer_start;
    run;
  %end;

  data duration&nb;
    set
      %do r=1 %to 100;
        duration&nb.&r.
      %end;
  ;

  proc univariate data=duration&nb noprint;
    output out= durationsum&algn.&nb. mean=MEAN&algn. sum=SUM&algn.;
  run;

```

```

data durationsum&align.&nb.;
  set durationsum&align.&nb;
  N = &N;
  T = &nobs;
run;
%mend runby_npart_nobs;

```

The previous macro is then run with $T = 200, 500$, and 1000 and with $N = 500, 1000, 2500$, and 5000 :

```

%macro runit;
  %let value_nobs = 200 500 1000;
  %let value_npart = 500 1000 2500 5000;
  %local iter iter_nobs iter_npart next_value_nobs next_value_npart;
  %let iter=1; %let iter_nobs=1; %let iter_npart=1;
  %do %while (%scan(&value_nobs, &iter_nobs) ne );
    %let next_value_nobs = %scan(&value_nobs, &iter_nobs);
    %do %while (%scan(&value_npart, &iter_npart) ne );
      %put &iter_nobs &iter_npart &iter;
      %let next_value_npart = %scan(&value_npart, &iter_npart);
      %runby_npart_nobs (nobs=&next_value_nobs, N=&next_value_npart,
        alg=%str(APF(ADP)), align=apf_adp, nb=&iter);
      %runby_npart_nobs (nobs=&next_value_nobs, N=&next_value_npart,
        alg=APF, align=apf, nb=&iter);
      data durationallsum&iter;
        merge durationsumapf_adp&iter. (in=a) durationsumapf&iter. (in=b);
        by T N;
        if (a=b);
      run;
      %if &iter =1 %then %do;
        %let dataread=durationallsum&iter;
      %end;
      %else %do;
        %let dataread= durationallsum durationallsum&iter;
      %end;
      data durationallsum;
        set &dataread;
      run;
      %let iter_npart = %eval(&iter_npart + 1);
      %let iter = %eval(&iter + 1);
    %end;
    %let iter_nobs = %eval(&iter_nobs + 1);
    %let iter_npart=1;
  %end;
%mend runit;
%runit;

```

The following statements plot the average log-likelihood computation run time over 100 replications. The results are shown in [Figure 27.12](#).

run;

```

Figure 27.13 Total Log-Likelihood Computation Run Time over 100 Replications

Figure 27.12 and Figure 27.13 show that the APF(ADP) algorithm is faster than the APF algorithm with fully adapted auxiliary and proposal distributions, especially when the number of particles and/or the number of time points is large. A similar conclusion can be made about the FILTER, FORECAST, LEARN, and SMOOTH statements.

In addition to being faster, the APF(ADP) algorithm results in a smaller variance for the estimated log likelihood and a smaller optimal number of particles compared to APF and BF. The next code aims to illustrate this.

The following statements simulate 500 observations on the basis of the defined ARCH model and load the data set arch into a data table in your session that is associated with the mylib libref:

```
%let lambda_sq = 0.00027;
%let beta0=0.0000495;
%let beta1=0.89275;
proc iml;
  call randseed(123);
  x = j(500,1,.);
  y = j(500,1,.);
  timeID = j(500,1,.);
  x[1]=1;
  call randgen(rny,"Normal");
  y[1]=x[1]+sqrt(&lambda_sq)*rny;
  timeID[1]=1;
  do t=2 to 500;
    call randgen(rnx,"Normal");
    x[t]=sqrt(&beta0+&beta1*x[t-1]*x[t-1])*rnx;
    call randgen(rny,"Normal");
    y[t]=x[t]+sqrt(&lambda_sq)*rny;
    timeID[t]=t;
  end;
  create arch var {TimeID x y};
  append ;
  close arch;
quit;

data mylib.arch;
  set arch;
run;
```

Following the guideline for choosing the optimal number of particles provided by Pitt et al. (2012), the next group of statements estimate the log likelihood 100 times for a given number of particles and filtering algorithm, and then they compute the standard deviation of the log likelihood over the 100 replications:

```
%macro repeat_run(npart=,alg=,algn=,nb=);
  %do i=1 %to 100;
    proc smc data=mylib.arch seed = &i;
      id time = timeID;
      var y;
      statevar x;
      parameters lambda_sq=&lambda_sq beta0=&beta0 beta1=&beta1;
      initstate x ~ degenerate(1) ;
      state x ~ normal(0, sqrt(beta0+beta1*x.l1*x.l1))
    end;
  end;
```

```

        %if %length(&alg) gt 3 %then /proposal=
        normal((beta0+beta1*x.ll*x.ll)*y/(beta0+beta1*x.ll*x.ll+lambda_sq),
        sqrt(lambda_sq*(beta0+beta1*x.ll*x.ll)/(beta0+beta1*x.ll*x.ll+lambda_sq)));;
model y ~ normal(x, sqrt(lambda_sq));
auxmodel y ~ normal(0, sqrt(beta0+beta1*x.ll*x.ll+lambda_sq));
evaluate nparticle = &npart alg=&alg out=mylib.eval&nb.&i.;
run;
data eval&nb.&i.(keep = LogLikelihood);
    set mylib.eval&nb.&i. end=eof;
    if eof=1;
run;
%end;
data evalall&nb;
    set
    %do i=1 %to 100;
        eval&nb.&i.
    %end;
;

proc univariate data= evalall&nb vardef=n noprint;
    output out= evalallsum&algn.&nb. mean=MEAN std=STDDEV var=VARIANCE n=R;
run;

data evalallsum&algn.&nb.;
    set evalallsum&algn.&nb(drop=R);
    N = &npart;
    algorithm = "&alg";
run;
%mend repeat_run;

```

The following statements run the macro with $N = 15, 20, 25, 50, 75, 90, 100, 200, 300, 400$, and 500 particles for the APF(ADP), APF, and BF algorithms:

```

%macro runit2;
    %let value = 15 20 25 50 75 90 100 200 300 400 500;
    %local iter next_value;
    %let iter=1;
    %do %while (%scan(&value, &iter) ne );
        %let next_value = %scan(&value, &iter);
        %repeat_run(npart=&next_value, alg=%str(APF(ADP)), algn=1, nb=&iter);
        %repeat_run(npart=&next_value, alg=APF, algn=2, nb=&iter);
        %repeat_run(npart=&next_value, alg=BF, algn=3, nb=&iter);
        data evalallsum&iter;
            set evalallsum1&iter evalallsum2&iter evalallsum3&iter;
        run;
        %if &iter =1 %then %do;
            %let dataread=evalallsum&iter;
        %end;
        %else %do;
            %let dataread= evalallsum evalallsum&iter;
        %end;

        data evalallsum;
            set &dataread;
    %end;
%macro runit2;

```

```

run;
%let iter = %eval(&iter + 1);
%end;
%mend runit2;
%runit2;

```

The log-likelihood standard deviation across the different number of particles and filtering algorithms is then plotted using the following code. The results are shown in [Figure 27.14](#). Following Pitt et al. (2012), a reference line corresponding to a standard deviation of 0.92 is added to help determine the optimal number of particles.

```

data evalallsum;
  set evalallsum;
  ref = 0.92;
run;

proc sort data=evalallsum;
  by algorithm N;
run;

proc sgpanel data=evalallsum;
  title ;
  panelby algorithm / layout=panel columns=3 rows=1 uniscale=all;
  series x=N y=STDDEV/markers markerattrs=(color=blue size=7 symbol=plus)
         legendlabel='StdDev ';
  series x=N y=ref / legendlabel='Cutoff';
  rowaxis thresholdmin=1 thresholdmax=1 label='Standard Deviation' max=25;
  colaxis label='Number of Particles'
         valueshint
         values=(0 15 20 25 50 75 90 100 200 300 400 500);
  keylegend/position=bottom;
run;

```

Figure 27.14 Log-Likelihood Variability and Optimal Number of Particles

Figure 27.14 shows that the variability in the log likelihood is significantly smaller for APF(ADP) than for APF and BF. Moreover, the optimal numbers of particles that are determined as the number of particles corresponding to a standard deviation of 0.92 (intersection of the red reference line and standard deviation line) are 20, 450, and 450 for APF(ADP), APF, and BF, respectively. Because APF(ADP) requires fewer particles in order to reach the optimal standard deviation, this further improves the speed of computation.

A final advantage of APF(ADP) over APF and BF is its lower Markov chain autocorrelation. To illustrate this, particle Markov chain Monte Carlo (MCMC) is run using the arch data set and the APF(ADP), APF, and BF algorithms.

The parameters β_0 and β_1 are transformed so that the new parameters θ_0 and θ_1 are unconstrained: $\theta_0 = \log(\beta_0)$ and $\theta_1 = \log(\beta_1)$. The following prior distributions are specified:

$$\theta_0 \sim \text{normal}(-10, 4)$$

$$\theta_1 \sim \text{normal}(-0.13, 2.8)$$

$$\lambda^2 \sim \text{inverse gamma}(0.01, 0.01)$$

The following macro runs particle MCMC and saves the acceptance rate and diagnostics summary tables for a given filtering algorithm and number of particles:

```

%macro run_learn(npart=, alg=, algn=);
  ods output DiagSummaries= DiagSummary_&algn.
    AccRates=AccRates_&algn.;
  proc smc data=mylib.arch seed =123;
    id time = timeID;
    var y;
    statevar x;
    parameters lambda_sq=0.005 theta0=-6 theta1=-0.3;
    initstate x ~ degenerate(1) ;
    state x ~ normal(0, sqrt(exp(theta0)+exp(theta1)*x.l1*x.l1))
      %if %length(&alg) gt 3 %then /proposal=
        normal((exp(theta0)+exp(theta1)*x.l1*x.l1)*y/(exp(theta0)
          +exp(theta1)*x.l1*x.l1+lambda_sq),
        sqrt(lambda_sq*(exp(theta0)+exp(theta1)*x.l1*x.l1)/(exp(theta0)+
          exp(theta1)*x.l1*x.l1+lambda_sq)));;
    model y ~ normal(x, sqrt(lambda_sq));
    auxmodel y ~ normal(0, sqrt(exp(theta0)+exp(theta1)*x.l1*x.l1+lambda_sq));
    prior lambda_sq ~ igamma(0.01,0.01);
    prior theta0 ~ normal(-10,4);
    prior theta1 ~ normal(-0.13,2.8);
    learn nparticle = &npart algorithm=&alg
      method = PMCMC(nsampl = 50000 nbi=10000 samsum samset seed = 1
        thin=1 outpost = mylib.outle_&algn.
        statistics=(corr cov interval(alpha = (0.01))
        summary(perc = (0.5 2.5 25 50 75 97.5 99)))
        diagnostics(settings)=all sampler = rwm(ntu=700 ntunestage=48)) ;
  run;

  data AccRates_&algn.;
    set AccRates_&algn.;
    Algorithm = "&alg";
    N = &npart;
  run;
%mend run_learn;

```

The macro is then run for the APF(ADP), APF, and BF algorithms by using the optimal number of particles determined previously. A computing time variable is defined as (Number of particles) * (Autocorrelation time)/1000.

```

%run_learn(npart=20,alg=%str(APF(ADP)),algn=apf_adp);
%run_learn(npart=450,alg=APF,algn=apf);
%run_learn(npart=450,alg=BF,algn=bf);

data AccRates;
  set AccRates_apf_adp AccRates_bf AccRates_apf;
run;

data DiagSummary_bf;
  set DiagSummary_bf;
  ComputingTime = 450*CorrTime/1000;
run;
proc transpose data=DiagSummary_bf out=DiagSummary_bf_w;
  id Parameter;

```

```

run;
data DiagSummary_bf_w; set DiagSummary_bf_w;
  order=2; Algorithm='BF'; N = 450;run;

data DiagSummary_apf;
  set DiagSummary_apf;
  ComputingTime = 450*CorrTime/1000;
run;
proc transpose data=DiagSummary_apf out=DiagSummary_apf_w;
  id Parameter;
run;
data DiagSummary_apf_w; set DiagSummary_apf_w;
  order=1; Algorithm='APF'; N = 450;run;

data DiagSummary_fapf;
  set DiagSummary_fapf;
  ComputingTime = 20*CorrTime/1000;
run;
proc transpose data=DiagSummary_fapf out=DiagSummary_fapf_w;
  id Parameter;
run;
data DiagSummary_fapf_w; set DiagSummary_fapf_w;
  order=3; Algorithm='APF(ADP)'; N = 20;run;

data DiagSummary;
  set DiagSummary_fapf_w DiagSummary_bf_w DiagSummary_apf_w;
run;

```

The following statements print the acceptance rates for each algorithm, as shown in [Output 27.5.1](#). The acceptance rates of the three algorithms are around the 0.234 optimal value for the random walk Metropolis sampler, despite APF(ADP) using far fewer particles.

```

proc sort data=AccRates; by descending N;run;
proc print data=AccRates noobs;
  var Algorithm N AccRate;
run;

```

Output 27.5.1 Acceptance Rates

Algorithm	N	AccRate
BF	450	0.260185
APF	450	0.253605
APF(ADP)	20	0.208684

The following statements print the autocorrelation time and the indicator variable that demonstrates whether autocorrelation remains in the chain, as shown in [Output 27.5.2](#) and [Output 27.5.3](#), respectively:

```

data CorrTime;
  set DiagSummary;
  where _NAME_ = 'CorrTime';
run;
proc sort data=CorrTime; by order;run;
proc print data=CorrTime noobs;
  var Algorithm N lambda_sq theta0 theta1;

```

```

run;
data AutoCorrRemains;
  set DiagSummary;
  where _NAME_ = 'AutoCorrRemains';
run;
proc sort data=AutoCorrRemains; by order;run;
proc print data=AutoCorrRemains noobs;
  var Algorithm N lambda_sq theta0 theta1;
run;

```

Output 27.5.2 Autocorrelation Time

Algorithm	N	lambda_sq	theta0	theta1
APF	450	6.3872	478.600	496.600
BF	450	6.1982	491.500	488.600
APF(ADP)	20	29.9046	43.622	45.618

Output 27.5.3 Autocorrelation Remains

Algorithm	N	lambda_sq	theta0	theta1
APF	450	0	1	1
BF	450	0	1	1
APF(ADP)	20	0	0	0

Output 27.5.2 and Output 27.5.3 show that significant autocorrelation still remains in the Markov chain for θ_0 and θ_1 when the APF and BF algorithms are used, indicating that you need to run the Markov chain longer or increase the tuning time of the proposal distribution.

Finally, the following statements print the computing time, which is shown in Output 27.5.4:

```

data ComputingTime;
  set DiagSummary;
  where _NAME_ = 'ComputingTime';
run;
proc sort data=ComputingTime; by order;run;
proc print data=ComputingTime noobs;
  var Algorithm N lambda_sq theta0 theta1;
run;

```

Output 27.5.4 Computing Time

Algorithm	N	lambda_sq	theta0	theta1
APF	450	2.87424	215.370	223.470
BF	450	2.78919	221.175	219.870
APF(ADP)	20	0.59809	0.872	0.912

Output 27.5.4 shows that APF(ADP) has a lower computing time, defined as (Number of particles) * (Autocorrelation time)/1000, than APF and BF for all the parameters in the model. Clearly, the APF(ADP) algorithm with 20 particles is more efficient than the APF or BF algorithm with 450 particles.

Overview: TSINFO Procedure

The TSINFO procedure evaluates a variable in an input data table for its suitability as a time ID variable in SAS procedures and solutions that are used for time series analysis. PROC TSINFO assesses how well a time interval specification fits SAS date values, SAS datetime values, or observation numbers that are used to index a time series. The time interval used in this analysis can be either specified explicitly as input or inferred based on values of the time ID variable. The TSINFO procedure produces diagnostic information in the form of data tables and ODS tables. These diagnostic results summarize characteristics of the time ID variable that can help determine its use as an index in other time series procedures and solutions.

PROC TSINFO is intended for use as a tool to either identify the time interval of a variable or prepare problematic data sets for use in subsequent time series analyses. In particular, this procedure can be used to investigate inconsistencies between time ID values and the ID statement options that are used in other SAS procedures and solutions.

PROC TSINFO Compared with the TIMEID Procedure

The TSINFO procedure is the next generation of the TIMEID procedure (a SAS/ETS procedure) for time series information analysis. PROC TSINFO was developed specifically for SAS Viya. The syntax of PROC TSINFO is similar to the syntax of PROC TIMEID, from which it borrows the underlying methodology and goals. PROC TSINFO is designed to run on a cluster of machines that distribute the data and computations to multiple threads, and it requires your data tables to be available on a SAS Cloud Analytic Services (CAS) server.

Table 28.1 shows the differences between the TSINFO and TIMEID procedures.

Table 28.1 PROC TSINFO versus PROC TIMEID

Feature	TSINFO	TIMEID
Threading	Multithreaded	Single-threaded
Input data	CAS tables	SAS data sets
Requires sorted input data?	No	Yes, by BY variables and ID variable bottom-up

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the `mylib` CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the `CASHOST` and `CASPORT` of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the `TERMINATE` option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS statement and the LIBNAME statement, see *SAS Cloud Analytic Services: User's Guide*. For general information about CAS and CAS sessions, see *SAS Cloud Analytic Services: Fundamentals*.

Getting Started: TSINFO Procedure

When a data table contains a time ID variable that has corrupted, missing, or duplicate values, PROC TSINFO can help isolate and identify these problematic observations. For larger data tables whose quality is unknown, it can be useful to get a general overview of the relative number of observations that have problematic time ID values. When prior knowledge of the time interval that separates observations is incomplete, PROC TSINFO can be used to infer the interval.

The following example uses the Sashelp.Air data set to illustrate how to analyze some time series information. The following DATA step loads the Air data set from the Sashelp directory to a table named mylib.air in your CAS session. This DATA step assumes that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.air(replace=yes);
  set sashelp.air;
  do class=1 to 10;
    output;
  end;
run;
```

The following statements use the TSINFO procedure to infer the interval of the time series:

```
proc tsinfo data=mylib.air outintervaldetails=mylib.interval1
  nthreads=2;
  id date align=BEGIN;
  by class;
run;
```

PROC TSINFO requires the following inputs:

- The input table, specified in the DATA= option in the PROC statement
- BY variables (class), specified in the BY statement
- The variable that contains the timestamps in the ID statement

Syntax: TSINFO Procedure

The following statements are available in the TSINFO procedure:

```
PROC TSINFO < options > ;
BY variables ;
ID variable < options > ;
```

The PROC TSINFO and ID statements are required. The following sections describe the PROC TSINFO statement and then describe the other statements in alphabetical order.

Functional Summary

Table 28.2 summarizes the statements and options that are used with the TSINFO procedure.

Table 28.2 PROC TSINFO Functional Summary

Description	Statement	Option
Data Options		
Specifies the input data table	PROC TSINFO	DATA=
Specifies the detailed output interval data table	PROC TSINFO	OUTINTERVALDETAILS=
Specifies the number of threads to be used in the procedure	PROC TSINFO	NTHREADS=
Time ID Options		
Specifies the alignment of time ID values	ID	ALIGN=
Specifies the ending time ID value	ID	END=
Specifies the starting time ID value	ID	START=

PROC TSINFO Statement

```
PROC TSINFO options ;
```

The PROC TSINFO statement invokes the TSINFO procedure.

You must specify the following data tables:

DATA=*libref.data-table*

specifies the SAS input data table that contains the input data for the procedure. If the DATA= option is not specified, the most recently created SAS data set is used. *libref.data-set* is a two-level name, where *libref* refers to the library and session identifier, and *data-table* specifies the name of the input data table.

OUTINTERVALDETAILS =libref.data-table

names the output data table to contain the time ID interval information for each BY group in the DATA= data set. For more information, see the section “[OUTINTERVALDETAILS= Data Set](#)” on page 2065. *libref.data-table* is a two-level name, where *libref* refers to the library and session identifier, and *data-table* specifies the name of the input data table.

You can also specify the following *option*:

NTHREADS=number

specifies the number of threads to use in the computation.

By default, NTHREADS=1.

BY Statement

BY variables ;

You can use a BY statement to obtain separate analyses for groups of observations that are defined by the *variables*, which can be either character or numeric.

When a BY statement is included, the procedure expects the input data to be sorted in the order of the BY variables.

ID Statement

ID variable </options> ;

The ID statement names a numeric *variable* that identifies observations in the input and output data. The ID variable values are assumed to be SAS date or datetime values.

You can specify the following *options* to determine how to space the time ID values and align them relative to a SAS date or datetime interval:

ALIGN=BEGINNING | MIDDLE | ENDING | INFER

specifies the alignment of the identifying SAS date or datetime that is used to represent intervals. The value of the ALIGN= option is used in the analysis of the time ID variable. You can specify the following values:

BEGINNING BEG B	uses the beginning date in the interval as the identifying date for the interval.
MIDDLE MID M	uses the middle date in the interval as the identifying date for the interval.
ENDING END E	uses the end date in the interval as the identifying date for the interval.
INFER	infers that the alignment of values within time intervals from the time ID values.

By default, ALIGN=BEGIN.

END=*value*

specifies a SAS date, datetime, or time value that represents when the SAS date or datetime values end. If the largest *variable* value is less than *value*, then this option has no effect.

START=*value*

specifies a SAS date, datetime, or time value that represents the *variable* value at which the SAS date or datetime values begins.

Details: TSINFO Procedure

Time ID Diagnostics

For a specified time interval, PROC TSINFO decomposes the raw time ID values in an input data table into the following three quantities, whose values are represented by nonnegative integers at each unique time ID value in the input series:

intervalcounts	the number of observations that share each time interval in the data set.
offsets	the numerical difference between a time ID value and the aligned value for that time interval. The unit of measure that is used to express this distance is days for date values and seconds for datetime values. The offset is computed for each time ID value, t_i , by using the following SAS expression:

$$\text{offset}_i = t_i - \text{INTNX}(\text{interval}, t_i, 0, \text{alignment})$$

spans	the number of intervals between each time ID value and the previous time ID value. The spans value is equivalent to the number returned by the following SAS expression:
-------	--

$$\text{spans}_i = \text{INTCK}(\text{interval}, t_{i-1}, t_i)$$

Inferring Time Intervals and Alignments

A time interval is inferred from the time ID values in the input data. The technique that is used to infer a time interval involves searching for the interval that fits the greatest number of time ID values. First, time ID values are sampled from the input data to generate a set of candidate intervals. Then the candidate interval that is consistent with greatest number of time ID values is chosen to represent the time series.

When the **ALIGN=INFER** option is specified, the convention that is used to specify time interval alignment is inferred from the time ID variable values by using a similar technique. When both the time interval and its alignment are to be inferred, each of the possible alignments (**BEGIN**, **MIDDLE**, and **END**) is considered in the search. Precedence in the search is given to intervals that use the **BEGIN** alignment.

Data Table Output

The TSINFO procedure creates an ODS output data table. This data table contains the variables that are specified in the BY statement along with variables that characterize the time ID values. The information in this data table summarizes time ID diagnostic information across all BY groups in the table that is specified in the DATA= option.

OUTINTERVALDETAILS= Data Set

The OUTINTERVALDETAILS= data set contains statistics about the time interval that is specified in the ID statement or inferred from the time ID values for each BY group. The following variables represent these statistics:

TIMEID	time ID variable name
START	starting time ID interval
END	ending time ID interval
INTERVAL	time interval that was specified or is recommended
INTNAME	time interval base name that was specified or is recommended
MULTIPLIER	time interval multiplier that was specified or is recommended
SHIFT_INDEX	time interval shift index that was specified or is recommended
ALIGNMENT	time interval alignment that was specified or is recommended
SEASONALITY	seasonality determined from the specified or recommended time interval
FORMAT	format of the time ID variable

The START and END variables are reported using the interval and alignment values that are either specified in the ID statement or inferred from the time ID values.

Printed Output

The TSINFO procedure always prints a summary of the processing that is performed on the time series data. The following variables represent these statistics:

Interval	inferred interval
Count	number of times inferred
Conditional	number of times conditional
Alignment	inferred alignment
Nseason	number of season cycles

Examples: TSINFO Procedure

Example 28.1: Examining a Monthly Time ID Variable and Inferring a Date Interval

This example illustrates how a time ID variable can be inferred from data when a sufficient number of observations are present.

The following DATA step loads the Air data set onto the CAS server. These statements assume that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.air(replace=yes);  
    set sashelp.air;  
run;
```

The following TSINFO procedure statements generate an ODS display of the time series that characterizes interval counts, alignment, and seasonality in the time ID variable:

```
proc tsinfo data=mylib.air outintervaldetails=mylib.interval2 nthreads=2;  
    id date align=B;  
run;
```

There are 144 observations in the mylib.Air data table. The 144 observations are enough to determine that the Date time ID variable is represented by the MONTH interval.

Example 28.2: Examining Multiple BY Groups

This example illustrates how a time ID variable can be examined independently over each BY group and summarized over all observations in the data table that is specified in the DATA= option.

The following DATA step creates the BY-group variable, class, and loads the Air data set onto the CAS server:

```
data mylib.air(replace=yes);  
    set sashelp.air;  
    do class=1 to 10;  
        output;  
    end;  
run;
```

The following TSINFO procedure statements generate data tables that summarize data that have 10 BY groups:

```
proc tsinfo data=mylib.air outintervaldetails=mylib.interval2 nthreads=2;  
    id date align=B;  
    by class;  
run;
```

The summarized information shows that BY groups 1 to 10 in the mylib.interval2 data table contain the interval fit information of the time ID values and shows the number of counts, alignment, and seasonality for each by group. All BY groups conform exactly to the MONTH interval. The information can be useful in diagnosing time series that contain many time intervals.

Overview: TSMODEL Procedure

The TSMODEL procedure is a SAS procedure that executes user-defined programs on time series data. The procedure analyzes timestamped transactional data with respect to time and accumulates the data into a time series format.

The TSMODEL procedure forms time series from input timestamped transactional data and writes the accumulated time series variables to an output table. Time series are delineated based on the distinct values of the variables that are listed in the BY statement.

Timestamped transactional data are recorded at no fixed interval. Analysts often want to use time series analysis techniques that require fixed-time intervals. Therefore, the transactional data must be accumulated to form a fixed-interval time series, such as daily, weekly, or monthly.

The TSMODEL procedure forms time series vectors from timestamped data and then provides these vectors as array variables for subsequent processing by your program statements. Your program statements are processed independently for each BY group. The TSMODEL procedure is similar to the SAS DATA step for time series data. The SAS DATA step processes data by each row, whereas PROC TSMODEL processes time series vectors for the BY groups.

Because PROC TSMODEL runs on SAS Cloud Analytic Services (CAS), it can process the time series data in parallel. Time series for the BY groups are divided across the nodes of the CAS session, and then threads are used on each node to process the node's BY groups concurrently.

All results of the time series analysis can be saved to output tables.

Comparison of the TSMODEL and TIMESERIES Procedures

The TSMODEL procedure has similarities to the TIMESERIES procedure in SAS/ETS. The TIMESERIES procedure enables you to perform a variety of standard time series analysis techniques with its various statements, whereas the TSMODEL procedure enables you to define your own analyses via user-defined program statements that you include in the procedure's statement block. The TSMODEL procedure provides no built-in time series analysis capabilities. You must provide a program to analyze the time series data. For more information about PROC TIMESERIES, see *SAS/ETS User's Guide*.

Comparison of the TSMODEL and TIMEDATA Procedures

The syntax of the TSMODEL procedure is similar to the syntax of the TIMEDATA procedure in SAS/ETS software. For more information about PROC TIMEDATA, see *SAS/ETS User's Guide*.

PROC TSMODEL requires that you specify CAS tables for all input data and all output data. Unlike PROC TIMEDATA, no actual processing of the time series data occurs in PROC TSMODEL. Data in PROC TSMODEL are processed in the CAS session that is associated with the CAS librefs that you specify in the PROC TSMODEL statement.

Like PROC TIMEDATA, PROC TSMODEL supports auxiliary input tables, which you specify in the AUXDATA= option. However, PROC TSMODEL requires that either all or none of the BY variables are

present in an AUXDATA= table. No partial BY group matching for the AUXDATA= tables is supported at this time.

A simple example provides insight about the relative ease of moving from PROC TIMEDATA to PROC TSMODEL. Consider the following PROC TIMEDATA example, which rescales the Sale and Price variables for each of the Product BY groups:

```
proc timedata data=mylib.pricex
    outsum=mylib.pricexsum
    outarray=mylib.pricexoa
    outscalar=mylib.pricexos;
by Product;
id date interval=month start='01jan1998'd end='01dec2002'd;
var Sale / accumulate=total;
var Price / accumulate=avg;
outarray relsale relprice;
outscalar sbase pbase;
sbase=Sale[1];
pbase=Price[1];
do i=1 to _length_;
    if Sale[i] ne . then do;
        relsale[i] = Sale[i]/sbase;
    end;
    if Price[i] ne . then do;
        relprice[i]=Price[i]/pbase;
    end;
end;
run;
```

When you convert the preceding statements to use PROC TSMODEL, the code looks like this:

```
proc tsmodel data=mylib.pricex
    outsum=mylib.pricexsum
    outarray=mylib.pricexoa
    outscalar=mylib.pricexos;
by Product;
id date interval=month start='01jan1998'd end='01dec2002'd;
var Sale /accumulate=total;
var Price /accumulate=avg;
outarray relsale relprice;
outscalar sbase pbase;
submit;
sbase=Sale[1];
pbase=Price[1];
do i=1 to _length_;
    if Sale[i] ne . then do;
        relsale[i] = Sale[i]/sbase;
    end;
    if Price[i] ne . then do;
        relprice[i]=Price[i]/pbase;
    end;
end;
endsubmit;
quit;
```

Examine these two examples closely to see the differences. At first glance, the differences might not be very

obvious. Although the differences in code syntax are subtle, the underlying differences in the procedure processing are profound.

One important difference between PROC TIMEDATA and PROC TSMODEL is that PROC TSMODEL requires you to use the SUBMIT and ENDSUBMIT statements to begin and end the set of programming statements that you want to execute on the time series BY groups. You can include SAS macro statements in the statements in your SUBMIT/ENDSUBMIT block. Table 29.1 shows the differences between the processing of programming statements in PROC TSMODEL compared to PROC TIMEDATA.

Table 29.1 Comparison of PROC TSMODEL and PROC TIMEDATA

Processing Step	PROC TSMODEL	PROC TIMEDATA
Statement parsing	Any parse-time errors are reported only after the ENDSUBMIT statement. Those errors come from the parsing and compilation of your code in your CAS session. SAS line numbers for incorrect statements are not reported in the SAS log.	Statements are parsed as the procedure works its way through its statement block. Any parse-time errors are interspersed with the program statements in the SAS log.
PROC FCMP subroutines and functions	Does not support as many built-in PROC FCMP functions and subroutines.	Supports built-in PROC FCMP functions and subroutines.
RUN_MACRO	Not supported because it cannot be performed by the CAS server when it executes your program statements in the context of your CAS session.	Can call the PROC FCMP subroutine RUN_MACRO to run a SAS macro, which can then call a SAS procedure.
ID statement with a SAS date or datetime variable	An ID variable is required because the value of the ID variable is needed to determine the time index of each row within the BY group. The accumulation frequency that you specify in the INTERVAL= option in the ID statement is required.	An ID statement is not required.
Accumulation modes	ACCUMULATE=NONE, FIRST, LAST, NOBS, and MEDIAN are not supported.	ACCUMULATE=NONE, FIRST, LAST, NOBS, and MEDIAN are supported.
Output data	Can be printed and plotted through other SAS procedures.	Supports PRINT and PLOT options to display data.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);  
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;  
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “[Introduction to Shared Concepts](#)” on page 54 in Chapter 4, “[Shared Concepts](#).”

Getting Started: TSMODEL Procedure

This section outlines the use of the TSMODEL procedure and describes some of the analysis techniques that you can perform on timestamped transactional data.

Suppose that a bank wants to analyze the transactions that are associated with each of its customers over time. Further, suppose that the table `mylib.transactions` contains four variables that are related to these transactions: `Customer`, `Date`, `Withdrawals`, and `Deposits`. The following examples illustrate possible ways to analyze these transactions by using the TSMODEL procedure.

The following statements accumulate the timestamped transactional data to form a daily time series based on the accumulated daily totals of each type of transaction (`Withdrawals` and `Deposits`). These statements assume that your CAS engine libref is named `mylib`, but you can substitute any appropriately defined CAS engine libref.

```
proc tsmodel data=mylib.transactions
    out=mylib.timeseries(replace=yes)
    outarray=mylib.arrays(replace=yes);
  by Customer;
  id Date interval=day accumulate=total;
  var withdrawals deposits;
  outarrays Balance;
  submit;
  Balance[1] = deposits[1] - withdrawals[1];
  do t = 2 to _LENGTH_;
    Balance[t] = Balance[t-1] + (deposits[t] - withdrawals[t]);
  end;
  endsubmit;
quit;
```

The `OUT=` option requests that the resulting time series data for each customer be stored in the table `mylib.timeseries`. The `OUTARRAY=` option requests that the resulting time series data along with a newly created variable, `Balance`, be stored in the table `mylib.arrays`. Both tables are created in the CAS session's current library.

The `INTERVAL=DAY` option requests that the transactions be accumulated on a daily basis within each `Customer` according to the values of the `ID` variable `Date`. The `ACCUMULATE=TOTAL` option requests that the sum of the transactions be calculated. After the transactional data are accumulated into a time series format, the example code computes a daily balance for each customer. Many of the procedures provided with SAS software can be used to perform further processing on the resulting time series data. The tables that are produced by PROC TSMODEL can also be used as input to subsequent PROC TSMODEL steps.

The TSMODEL procedure prints a summary of the time series processing that is performed, as shown in Figure 29.1.

Figure 29.1 Summary of Time Series Processing
The TSMODEL Procedure

Processing Summary	
CAS table	TRANSACTIONS
Number of analysis variables	2
Number of rows read	600
Number of groups read	3
Memory for group packages (KB)	1
Time to load groups (seconds)	0.0079259872
Minimum time ID	05NOV2007
Maximum time ID	22NOV2007
Minimum time periods	18
Maximum time periods	18
Number of nodes run	1
Number of nodes with data	1
Number of nodes with groups	1
Number of threads budgeted	32
Minimum thread group count	0
Maximum thread group count	1
Minimum threads active	32
Maximum threads active	32
Number of groups processed by submitted code	3
Number of groups failing	0
Elapsed time to process groups (seconds)	0.0168471336
Number of output table rows produced	54
Number of array table rows produced	54

You might want to plot the generated Balance series for some particular customer. The following code produces a graph for the customer named 'Bill'; the graph is shown in [Figure 29.2](#).

```
proc sgplot data=mylib.arrays (where=(customer='Bill')) ;
    series x=Date y=balance;
run;
```

Figure 29.2 Balance for Bill

Syntax: TSMODEL Procedure

The following statements are available in the TSMODEL procedure:

```

PROC TSMODEL options ;
  BY variables ;
  ID variable INTERVAL=interval < options > ;
  OUTARRAYS array-name-list ;
  OUTSCALARS scalar-name-list ;
  INSCALARS scalar-name-list ;
  VAR variable-list / options ;
  REQUIRE package-list ;
  PRINT print-options ;
  SUBMIT < FILE= SAS-file-ref | 'File-path' > < submit-options > ;
  Programming statements ;
  ENDSUBMIT ;

```

The PROC TSMODEL and ID statements are required.

The following sections present a summary of the statements and options that are used in PROC TSMODEL, a description of the TSMODEL statement, and then descriptions of the other statements.

Functional Summary

Table 29.2 summarizes the statements and options that control the TSMODEL procedure.

Table 29.2 Functional Summary

Description	Statement	Option
Statements		
Specifies BY-group processing	BY	
Specifies variables to analyze	VAR	
Specifies the time ID variable	ID	
Specifies the arrays to output	OUTARRAYS	
Specifies the scalars to output	OUTSCALARS

Specifies the maximum number of threads to use for multithreaded processing	PROC TSMODEL	NTHREADS=
Specifies the format for the time ID variable	ID	FORMAT=
Specifies the file that contains the user-defined program	SUBMIT	FILE=
Specifies variable values available to the user-defined program	SUBMIT	DYNAMICS=

PROC TSMODEL Statement

PROC TSMODEL *options* ;

The PROC TSMODEL statement invokes the TSMODEL procedure. You can specify the following *options*:

AUXDATA=*libref.data-table*

names a table that contains auxiliary input data for the procedure to use for supplying time series variables. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the **DATA=** option and the section “Using CAS Sessions and CAS Engine Librefs” on page 2071. For more information, see the section “Auxiliary Tables” on page 2097.

DATA=*libref.data-table*

names the input data table for PROC TSMODEL to use. The default is the most recently created data table. *libref.data-table* is a two-level name, where

<i>libref</i>	refers to a collection of information that is defined in the LIBNAME statement and includes the library, which includes a path to the data, and a session identifier, which defaults to the active session but which can be explicitly defined in the LIBNAME statement. For more information about <i>libref</i> , see the section “ Using CAS Sessions and CAS Engine Librefs ” on page 2071.
<i>data-table</i>	specifies the name of the input data table.

ERRORSTOP=YES | NO

specifies whether the program stops running when an error occurs during execution of package functions or object methods. When ERRORSTOP=YES, the program stops running when an error is encountered while a package function or object method is being executed. When ERRORSTOP=NO, the program continues running despite errors.

By default, ERRORSTOP=NO.

If you specify the BY statement, then the ERRORSTOP= option applies independently to each BY group. When ERRORSTOP=YES, if one BY group encounters an error and stops execution, this does not cause the other BY groups or the procedure to stop running.

INOBJ=(*object-name=libref.data-table ...*)

specifies pairs, each of which binds a repeater object specified by *object-name* with an input table specified by *libref.data-table*. You can specify one or more object-table pairs as needed to associate the repeater objects that you declare in your user-defined program with their input tables. You must specify a binding for any repeater object that you declare in your program; otherwise, a parse-time error is generated when you submit the program and no execution occurs. Consider the following SAS code:

```
inobj=(inest=mylib.outest
       inspec=mylib.outspec)
```

This code binds the repeater objects named INEST and INSPEC to the tables mylib.outest and mylib.outspec, respectively. In addition to the columns that are required to satisfy the built-in table schema of a particular repeater object, each specified table must have all or none of the BY variables of the primary DATA= table. When the INOBJ= table has none of the BY variables, all the table rows are input.

Repeater objects are defined in various packages that use PROC TSMODEL as a method to input data that are required for each application. For more information about creating repeater objects for a package, see *SAS Visual Forecasting: Time Series Packages*. For more information about package access, see the section “[REQUIRE Statement](#)” on page 2091.

INSCALAR=libref.data-table

specifies a table to supply scalar dynamic variables to be included and made accessible to your program code as it executes.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the input data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 2071.

When you specify BY variables for the DATA= table, the INSCALAR= table must contain those BY variables. If you do not specify BY variables, then the INSCALAR= table is read unqualified for the BY variables across the CAS workers in the CAS session. In this case, only a single value for each variable is needed, and only a single row is required in the table. If the table contains multiple rows in this case, an error is generated when the procedure is called. If you specify this option, then you must also specify one or more INSCALARS statements to specify the variables that you want to include for your program to access.

If BY variables are specified in a BY statement, then the table specified in the INSCALAR= option must contain all the specified BY variables or none of them. If BY variables are present in the INSCALAR= table, then the values for the variables specified in the INSCALARS statement are input subject to BY-group processing. If BY variables are not present in the INSCALAR= table, then only a single value of each variable specified in the INSCALARS statement is input for all BY groups. It is an error for the INSCALARS= table to contain more than one value (row) for the variables if the table is not subject to BY-group processing. If the INSCALARS= table is subject to BY-group processing and multiple values (rows) are present for any BY group, then the value can be input from any row, leading to inconsistent results. For consistent results, you should prepare the INSCALAR= tables such that only a single value is input for each BY group.

LEAD=*n*

specifies the number of periods ahead to extend time series arrays for the variables in both the VAR and OUTARRAYS statements that are output to the table. You can specify this option to accommodate a forecast lead or horizon when you are preparing time series data for forecasting.

The value of *n* is relative to the ending value of the input time ID for each BY group as specified by the [TRIMID=](#) option in the ID statement; it is not relative to the last nonmissing observation of a particular series. By default, LEAD=0.

LOGCONTROL=(*severity=IGNORE* | *KEEP* < *severity=IGNORE* | *KEEP* . . . >)

specifies pairs that define error severity and associated message disposition for the [OUTLOG=](#) option. You can specify multiple LOGCONTROL= options.

You can specify zero or more pairs. In these pairs, *severity* can take one of the following values:

NONE	specifies messages that have no severity classification.
NOTE	specifies messages whose severity classification is NOTE.
WARNING	specifies messages whose severity classification is WARNING.
ERROR	specifies messages whose severity classification is ERROR.

You can specify the following values to indicate the associated message disposition:

IGNORE	ignores messages of the specified severity.
KEEP	retains messages of the specified severity.

This option is applied only when you specify an OUTLOG= option; otherwise, it has no effect. By default, LOGCONTROL=(ERROR=KEEP) when the OUTLOG= option is specified. This default value retains only messages whose severity classification is ERROR and discards all others. However, the default behavior no longer applies when you specify the LOGCONTROL= option. For example, if you specify LOGCONTROL=(NONE=KEEP), then only messages that have no severity classification are retained and all others (that is, those whose classification is NOTE, WARNING, or ERROR) are discarded.

NTHREADS=*n*

specifies the number of threads that are used per worker node in a CAS session. Threads are used to both preprocess and analyze input data in parallel. You must specify a value *n* that is greater than or equal to 0. If you specify 0, the number of threads is set to the maximum number of licensed cores. By default, NTHREADS=0.

OUT=libref.data-table

names the output table to contain the time series variables that are specified in the subsequent VAR statements.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 2071.

If BY variables are specified, they are also included in this output table. The ID variable’s fixed-interval time ID sequence is included in the OUT= table. The time series variables are accumulated based on the INTERVAL= option and the variable’s ACCUMULATE= option. The OUT= table is particularly useful when you want to further analyze, model, or forecast the resulting time series with other SAS procedures.

OUTARRAY=libref.data-table

names the output table to contain the time series vectors that are specified in the VAR and OUTARRAYS statements. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 2071.

This table also contains the variables that are specified in the BY, ID, and VAR statements in addition to the arrays that are specified in the OUTARRAYS statements.

OUTLOG=libref.data-table

names the output table to contain textual messages that are collected from the execution of the BY-group processing.

Messages captured for the BY group are subject to prefiltering by their severity based on the setting of the LOGCONTROL= option. If PUTTOLOG=YES is specified, then messages from the PUT programming statement are also included in this table. This table has rows only for BY groups that generate text messages. Messages that are related to the PROC TSMODEL syntax are not included in this table. Normally, this table contains no rows.

OUTOBJ=(object-name=libref.data-table ...)

specifies pairs, each of which binds a collector object specified by *object-name* with an output table specified by *libref.data-table*.

libref.data-table is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 2071.

You can specify one or more object-table pairs as needed to associate the collector objects that you declare in your user-defined program with their output tables. You must specify a binding for any collector object that you declare in your program; otherwise, a parse-time error is generated when you submit the program and no execution occurs. Consider the following SAS code:

```
outobj=(oss=mylib.saleoss1
        pest=mylib.salepest1
        ofor=mylib.salefor1
        oind=mylib.saleind1
        ostat=mylib.salestat1)
```

This code binds the collector objects named OSS, PEST, OFOR, OIND, and OSTAT to the tables named SALEOSS1, SALEPEST1, SALEFOR1, SALEIND1, and SALESTAT1, respectively.

Collector objects are defined in various packages that can be run by PROC TSMODEL. For more information about using packages, see *SAS Visual Forecasting: Time Series Packages*. For more information about package access, see the section “[REQUIRE Statement](#)” on page 2091.

OUTSCALAR=libref.data-table

names the output table to contain the scalar names that are specified in the OUTSCALARS statements. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 2071.

This table also contains the variables that are specified in the BY statement and the scalars that are specified in the OUTSCALARS statements.

OUTSUM=libref.data-table

names the output table to contain the descriptive statistics. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the [DATA=](#) option and the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 2071.

The descriptive statistics are based on the accumulated time series when you specify the ACCUMULATE= option, the SETMISSING= option, or both options in the ID or VAR statement. The accumulated time series also contains the time horizon that is extended by the value that you specify in the LEAD= option. The OUTARRAY= table shows the data table that is used to calculate the statistics. The results table contains the statistics only for the variables in the OUTARRAYS and VAR statements. It is particularly useful when you want to analyze large numbers of series and you need a summary of the variables.

PUTTOLOG=YES | NO

specifies whether to capture messages from the PUT programming statement to the BY group's row in the table that is specified in the **OUTLOG=** option. You can specify the following values:

NO does not capture messages.

YES captures messages.

This option is applied only when you specify the **OUTLOG=** option; otherwise, it has no effect. This option should be used only to aid in debugging your user-defined programs on small amounts of data. This option can produce large amounts of output that increases processing time and memory usage in your CAS session processes and should be used with caution. By default, **PUTTOLOG=NO**.

SEASONALITY=number

specifies the length of the seasonal cycle. For example, **SEASONALITY=3** means that every group of three time periods forms a seasonal cycle. By default, the length of the seasonal cycle is 1 (no seasonality) or the length that is implied by the **INTERVAL=** option in the **ID** statement. For example, **INTERVAL=MONTH** implies that the length of the seasonal cycle is 12. For more information about seasonality, see the section “Seasonality in Models” in Chapter 17, “Forecasting Details” (*SAS Visual Forecasting: Time Series Packages*).

BY Statement

BY variables ;

You can include a **BY** statement with **PROC TSMODEL** to obtain separate processing for groups of observations that are defined by the **BY variables**. The rows in each distinct **BY** group are used to accumulate the time series vectors from the timestamped row data according to a desired frequency (which is specified in the **INTERVAL=** option) and the accumulation mode (which is specified in the **ACCUMULATE=** option).

For more information about table output and **BY** group processing, see the section “[Table Output](#)” on page 2100.

ID Statement

ID variable INTERVAL=interval < options > ;

The **ID** statement names a numeric *variable* that identifies the temporal order (time sequence) of observations in the input and output tables. The values of variables are assumed to be SAS date, SAS datetime, or observation values. In addition, the **ID** statement specifies the frequency to be associated with the time series. The **ID** statement *options* also specify a global treatment for how the time series variables are accumulated from the **BY** group's rows and how the time **ID** values are aligned to form the time series. The specified information affects all variables that are specified in subsequent **VAR** statements. The **ID** statement and the **INTERVAL=** option are required to specify the desired accumulation frequency.

You must specify the following option:

INTERVAL=*interval*

specifies the frequency of the accumulated time series. For example, if the input table consists of quarterly observations, then specify **INTERVAL=QTR**.

Interval names are constructed from a basic interval type with an optional multiplier and shift. The general form of an interval name is as follows:

type< *multiplier*>.< *shift*>

The interval *type* for SAS date values are summarized as follows:

YEAR

specifies yearly intervals. Abbreviations are YEAR, YEARS, YEARLY, YR, ANNUAL, ANNUALLY, and ANNUALS. The starting subperiod *shift* is in months ([MONTH](#)).

YEARV

specifies ISO 8601 yearly intervals. The ISO 8601 year starts on the Monday immediately preceding January 4 (or on January 4 if it is a Monday). Note that it is possible for the ISO 8601 year to start in December of the preceding year. Also, some ISO 8601 years contain a leap week. For more information about ISO weeks, see Technical Committee ISO/TC 154 (Processes, Data Elements, and Documents in Commerce, Industry, and Administration) (2004). The starting subperiod *shift* is in ISO 8601 weeks ([WEEKV](#)).

R445YR

is the same as YEARV except that the starting subperiod *shift* is in retail 4-4-5 months ([R445MON](#)).

R454YR

is the same as YEARV except that the starting subperiod *shift* is in retail 4-5-4 months ([R454MON](#)). For more information about the retail 4-5-4 calendar, see National Retail Federation (2007).

R544YR

is the same as YEARV except that the starting subperiod *shift* is in retail 5-4-4 months ([R544MON](#)).

SEMIYEAR

specifies semiannual intervals (every six months). Abbreviations are SEMIYEAR, SEMIYEARS, SEMIYEARLY, SEMIYR, SEMIANNUAL, and SEMIANN.

The starting subperiod *shift* is in months ([MONTH](#)). For example, SEMIYEAR.3 intervals are March–August and September–February.

QTR

specifies quarterly intervals (every three months). Abbreviations are QTR, QUARTER, QUARTERS, QUARTERLY, QTRLY, and QTRS. The starting subperiod *shift* is in months ([MONTH](#)).

R445QTR

specifies retail 4-4-5 quarterly intervals (every 13 ISO 8601 weeks). Some fourth quarters contain a leap week. The starting subperiod *shift* is in retail 4-4-5 months ([R445MON](#)).

R454QTR

specifies retail 4-5-4 quarterly intervals (every 13 ISO 8601 weeks). Some fourth quarters contain a leap week. For more information about the retail 4-5-4 calendar, see National Retail Federation (2007). The starting subperiod *shift* is in retail 4-5-4 months ([R454MON](#)).

R544QTR

specifies retail 5-4-4 quarterly intervals (every 13 ISO 8601 weeks). Some fourth quarters contain a leap week. The starting subperiod *shift* is in retail 5-4-4 months ([R544MON](#)).

MONTH

specifies monthly intervals. Abbreviations are MONTH, MONTHS, MONTHLY, and MON. The starting subperiod *shift* is in months (MONTH). For example, MONTH2.2 intervals are February–March, April–May, June–July, August–September, October–November, and December–January of the following year.

R445MON

specifies retail 4-4-5 monthly intervals. The 3rd, 6th, 9th, and 12th months are five ISO 8601 weeks long with the exception that some 12th months contain leap weeks. All other months are four ISO 8601 weeks long. R445MON intervals begin with the 1st, 5th, 9th, 14th, 18th, 22nd, 27th, 31st, 35th, 40th, 44th, and 48th weeks of the ISO year. The starting subperiod *shift* is in retail 4-4-5 months ([R445MON](#)).

R454MON

specifies retail 4-5-4 monthly intervals. The 2nd, 5th, 8th, and 11th months are five ISO 8601 weeks long. All other months are four ISO 8601 weeks long with the exception that some 12th months contain leap weeks. R454MON intervals begin with the 1st, 5th, 10th, 14th, 18th, 23rd, 27th, 31st, 36th, 40th, 44th, and 49th weeks of the ISO year. For more information about the retail 4-5-4 calendar, see National Retail Federation (2007). The starting subperiod *shift* is in retail 4-5-4 months ([R454MON](#)).

R544MON

specifies retail 5-4-4 monthly intervals. The 1st, 4th, 7th, and 10th months are five ISO 8601 weeks long. All other months are four ISO 8601 weeks long with the exception that some 12th months contain leap weeks. R544MON intervals begin with the 1st, 6th, 10th, 14th, 19th, 23rd, 27th, 32nd, 36th, 40th, 45th, and 49th weeks of the ISO year. The starting subperiod *shift* is in retail 5-4-4 months ([R544MON](#)).

SEMIMONTH

specifies semimonthly intervals. SEMIMONTH breaks each month into two periods, starting on the 1st and 16th days. Abbreviations are SEMIMONTH, SEMIMONTHS, SEMIMONTHLY, and SEMIMON. The starting subperiod *shift* is in SEMIMONTH periods. For example, SEMIMONTH2.2 specifies intervals from the 16th of one month through the 15th of the next month.

TENDAY

specifies 10-day intervals. TENDAY breaks the month into three periods, the 1st through the 10th day of the month, the 11th through the 20th day of the month, and the remainder of the month. (TENDAY is a special interval typically used for reporting automobile sales data.) The starting subperiod *shift* is in TENDAY periods. For example, TENDAY4.2 defines 40-day periods that start at the second TENDAY period.

WEEK

specifies weekly intervals of seven days. Abbreviations are WEEK, WEEKS, and WEEKLY. The starting subperiod *shift* is in days (DAY), with the days of the week numbered as 1=Sunday, 2=Monday, 3=Tuesday, 4=Wednesday, 5=Thursday, 6=Friday, and 7=Saturday. For example, WEEK.7 means weekly with Saturday as the first day of the week.

WEEKV

specifies ISO 8601 weekly intervals of seven days. Each week starts on Monday. The starting subperiod *shift* is in days (DAY). Note that WEEKV differs from WEEK in that WEEKV.1 starts on Monday, WEEKV.2 starts on Tuesday, and so on.

WEEKDAY**WEEKDAYdW****WEEKDAYddW****WEEKDAYdddW**

specifies daily intervals with weekend days included in the preceding weekday. Note that for a five-day work week that starts on Monday, the appropriate interval is WEEKDAY5.2. Abbreviations are WEEKDAY and WEEKDAYS. The starting subperiod *shift* is in weekdays (WEEKDAY).

The WEEKDAY interval is the same as DAY except that weekend days are absorbed into the preceding weekday. Thus, there are five WEEKDAY intervals in a calendar week: Monday, Tuesday, Wednesday, Thursday, and the three-day period Friday-Saturday-Sunday.

The default weekend days are Saturday and Sunday, but any one to six weekend days can be listed after the WEEKDAY string and followed by a W. Weekend days are specified as '1' for Sunday, '2' for Monday, and so forth. For example, WEEKDAY67W specifies a Friday-Saturday weekend. WEEKDAY1W specifies a six-day work week with a Sunday weekend. WEEKDAY17W is the same as WEEKDAY.

DAY

specifies daily intervals. Abbreviations are DAY, DAYS, and DAILY. The starting subperiod *shift* is in days (DAY).

The interval *type* for SAS datetime values are summarized as follows:

DTSAS-date-interval

specifies a SAS datetime interval that corresponds to the SAS date interval but operates on SAS datetime values. The SAS datetime interval is created by adding the prefix "DT" to the SAS date interval name. For example, DTMONTH.

HOURL

specifies hourly intervals. Aliases are HOUR, DTHOUR, HOURS, DTHOURS, HOURLY, DTHOURLY, HR, and DTHR. The starting subperiod *shift* is in hours (HOUR).

MINUTE

specifies minute intervals. Aliases are MINUTE, DTMINUTE, MINUTES, DTMINUTES, MIN, and DTMIN. The starting subperiod *shift* is in minutes (MINUTE).

SECOND

specifies second intervals. Aliases are SECOND, DTSECOND, SECONDS, DTSECONDS, SEC, and DTSEC. The starting subperiod *shift* is in seconds (SECOND).

The interval *type* for SAS observation values is summarized as follows:

OBS

n

specifies that observation numbers identify the time periods. You can specify INTERVAL=*n* as an alias for INTERVAL=OBS*n*.

If the SEASONALITY= option is not specified in the PROC TSMODEL statement, then the length of the seasonal cycle is implied by the INTERVAL= option. For example, INTERVAL=QTR implies a seasonal cycle of length 4. For more information about seasonality, see the section “Seasonality in Models” in Chapter 17, “Forecasting Details” (*SAS Visual Forecasting: Time Series Packages*).

You can also specify the following *options*:

ACCUMULATE=option

specifies how to accumulate the table observations within each time period into a single value. The frequency (width of each time interval) is specified in the INTERVAL= option. The ID *variable* contains the time ID values. The value of the time ID *variable* identifies the time period of the observation. The accumulated values for each time period form the time series, which is used in subsequent analysis.

The ACCUMULATE= option is necessary when multiple input observations identify the same time period. An example of this is timestamped transactional data.

The following *options* determine how to accumulate the observations within each time period based on the ID variable and the frequency specified by the INTERVAL= option. Each value indicates how the accumulated value is calculated:

TOTAL SUM	calculates as the total sum of the nonmissing values.
AVERAGE AVG	calculates as the average of the nonmissing values.
MINIMUM MIN	calculates as the minimum of the nonmissing values.
MAXIMUM MAX	calculates as the maximum of the nonmissing values.
N	calculates as the number of nonmissing observations.
NMISS	calculates as the number of missing observations.
STDDEV STD	calculates as the standard deviation of the nonmissing values.
CSS	calculates as the corrected sum of squares of the nonmissing values.
USS	calculates as the uncorrected sum of squares of the nonmissing values.

By default, `ACCUMULATE=TOTAL`.

The `SETMISSING=` option is useful for specifying how to treat missing values in the accumulated time series variable. If missing values should be interpreted as 0, then specify `SETMISSING=0`. For more information about accumulation, see the section “[Accumulation](#)” on page 2094.

ALIGN=option

controls the alignment of SAS date or datetime values that are used to identify the time period of output observations. Although any date or datetime value within the time period can identify the time period, the `ALIGN=` option requests that the representative date or datetime for the time period be calculated as the beginning date or datetime of the time period, the ending date or datetime of the time period, or the middle date or datetime of the time period. In addition to aligning the time ID values consistently for observations that are supplied by the user, the `ALIGN=` option specifies the method for calculating the time ID values for observations in the forecast and backcast time periods, which often are not supplied by the user. You can specify the following options:

- BEGINNING | BEG | B** represents each time period using the beginning SAS date or datetime value of the time period.
- ENDING | END | E** represents each time period using the ending SAS date or datetime value of the time period.
- MIDDLE | MID | M** represents each time period using the middle SAS date or datetime value of the time period. The middle is calculated as the average of the beginning and ending values.

By default, `ALIGN=BEGINNING`.

DISTRIBUTE=option

specifies the method that is used to distribute the input time series observations in the input tables across the CAS worker nodes in the CAS session. This process, which is known as “autopartitioning,” is performed in order to form complete time series that are suitable for processing. You can specify the following *options*:

- AUTO** automatically selects the best approach, using either the `PREACCUMULATE` or `SHUFFLE` *option*, to distribute the input time series observations across the CAS worker nodes in the CAS session. The selection occurs on the basis of both the accumulation time interval that you specify in the `INTERVAL=` option and the level of scattering of the time series observations across the CAS worker nodes.
- PREACCUMULATE | PREACC** generates partially accumulated time series (that is, those that have a fixed length and a fixed interval) on each CAS worker node in the CAS session and then distributes their observations to their destination CAS worker nodes. These partially accumulated time series are accumulated again upon arrival at their destination CAS worker nodes in order to form complete time series. This option can usually reduce the amount of time that is required in order to distribute time series observations across the CAS worker nodes, especially in the case in which you specify an accumulation interval in the `INTERVAL=` option that is larger than the natural frequency of the input data. However, this option can require additional memory in order to generate the partially accumulated time series on the CAS worker nodes.

SHUFFLE

distributes the raw time series observations to their destination CAS worker nodes in the CAS session before accumulating them into complete time series. This option is recommended when you specify an accumulation time interval in the **INTERVAL=** option that is close to the natural frequency of the input data. This option requires less memory than the **PREACCUMULATE** option because it does not have to generate partially accumulated time series in the memory of each CAS worker node. However, this option can lead to a longer run time than the **PREACCUMULATE** option when it is used outside the recommended setting.

By default, **DISTRIBUTE=AUTO**.

END=*value*

specifies a SAS date or datetime value that represents the end of the data. If the last time ID variable value is less than *value*, then the series is extended with missing values. If the last time ID variable value is greater than *value*, then the series is truncated. For example, **END=“&sysdate”D** uses the automatic macro variable **SYSDATE** to extend or truncate the series to the current date. You can specify the **START=** and **END=** options to ensure that the data that are associated within each **BY** group contain the same number of observations.

FORMAT=*format*

specifies the SAS format for the time ID values. If this option is omitted, then the default format is inferred from the **INTERVAL=** option. You can specify **FORMAT=_DATA_** to force the SAS format of the time ID variable to be automatically propagated to the time ID values.

NLFORMAT=*option*

enables the selection of the best international SAS format for the time ID values on the basis of the accumulation time interval that you specify in the **INTERVAL=** option. This option is ignored when you specify the **FORMAT=** option. You can specify the following *options*:

NO selects the best English-language-based SAS format for the time ID values.

YES selects the best international SAS format for the time ID values.

By default, **NLFORMAT=NO**.

SETMISSING=*option*

specifies how to interpret missing values (either actual or accumulated) in the accumulated time series. You can use the following *options* to determine how to interpret missing values:

n interprets a missing value as having the value *n*. You can specify any number for *n*, but not a missing value. If a missing value indicates a 0 value, specify **SETMISSING=0**. You typically use **SETMISSING=0** for transactional data because no recorded data usually implies no activity.

MISSING interprets a missing value as a missing value. Use this option if a missing value indicates an unknown value.

AVERAGE | AVG interprets a missing value as the average value of all accumulated nonmissing values in the span of the series.

MINIMUM MIN	interprets a missing value as the minimum value of all accumulated nonmissing values in the span of the series.
MEDIAN MED	interprets a missing value as the median value of all accumulated nonmissing values in the span of the series.
MAXIMUM MAX	interprets a missing value as the maximum value of all accumulated nonmissing values in the span of the series.
FIRST	interprets a missing value as the first nonmissing value of all accumulated nonmissing values in the span of the series.
LAST	interprets a missing value as the last nonmissing value of all accumulated nonmissing values in the span of the series.
PREVIOUS PREV	interprets a missing value as the previous period's accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.
NEXT	interprets a missing value as the next period's accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.

By default, SETMISSING=MISSING.

START=*value*

specifies a SAS date or datetime value that represents the beginning of the data. If the first time ID variable value is greater than *value*, then missing values are added at the beginning of the series. If the first time ID variable value is less than *value*, then the series is truncated. You can specify the START= and END= options to ensure that data associated with each BY group contain the same number of observations.

TRIMID=*method*

specifies the method for trimming the data in the BY groups when time series vectors are input to the user-defined program. The output time ID variable span that is calculated by the *method* is dependent on the input time ID variable span, irrespective of missing values of the time series variables. Depending on the *method* and the input time ID variable data, leading or trailing missing values can be added to the time series variables.

After the output time ID variable span is calculated by the *method*, the ending value of the output time ID variable will be recalculated according to the value of the LEAD= option (if one is specified).

You can specify one of the following *methods*:

- NONE** uses the same starting and ending values of the output time ID variable for all BY groups. The span of the output time ID variable includes all values that are input as a time ID value for all BY groups. The time series variables are extended with leading or trailing missing values as required.
- LEFT** uses the identifying date for the first time period that is input for the BY group as the starting value of the output time ID variable for each BY group. The time series values in each BY group are not extended with leading missing values. The ending value of the time ID variable is the same for all BY groups. The time series variables are extended with trailing missing values as required.

- RIGHT** uses the identifying date for the last time period that is input for the BY group as the ending value of the output time ID variable for each BY group. The time series values in each BY group are not extended with trailing missing values. The starting value of the time ID variable is the same for all BY groups. The time series variables are extended with leading missing values as required.
- BOTH** uses the span of the input time ID variable for the BY group as the span of the output time ID variable for each BY group. The time series values in each BY group are not extended with leading or trailing missing values.

By default, TRIMID=NONE.

Note that when you do not specify the **START=** and **END=** options in the **ID** statement, the TSMODEL procedure is required to make an additional pass through the primary data set that you specified in the **DATA=** option in order to determine its time index span. This is required so that the total number of accumulation time intervals can be computed using the accumulation frequency that you specified in the **INTERVAL=** option. In this scenario, the TSMODEL procedure will read all rows from the primary data set exactly twice. Moreover, this effect will be captured in the numeric value associated with the row labeled 'Number of rows read' of the time series processing summary table that is generated at the end of the execution of the TSMODEL procedure, as is illustrated in [Figure 29.1](#) and [Output 29.1.1](#).

INSCALARS Statement

INSCALARS *scalar-name-list* ;

INSCALAR *scalar-name-list* ;

The INSCALARS statement specifies which scalar variables to automatically include for your program to use. These variables can be numeric or character. Each variable that you name in an INSCALARS statement must be defined in the table specified in the **INSCALAR=** option in the PROC TSMODEL statement. You must specify at least one INSCALARS statement if you specify the INSCALAR= option in the PROC TSMODEL statement. You can specify multiple INSCALARS statements. For more information, see the **INSCALAR=** option.

OUTARRAYS Statement

OUTARRAYS *array-name-list* ;

OUTARRAY *array-name-list* ;

The OUTARRAYS statement specifies a list of array names; each name specifies a numeric output array variable to be stored in the table that is specified in the **OUTARRAY=** option in the PROC TSMODEL statement. You can specify multiple OUTARRAYS statements.

Your program statements can create and use any number of arrays. The array variables that are specified in the OUTARRAYS statement are created automatically for you, and their lengths are predetermined by the length of the time ID vector for the BY group. The arrays are initialized to missing values at the start of each BY group. Although you can define and use many arrays in your program, only arrays that are listed in the OUTARRAYS statement are included in the table that is specified in the OUTARRAY= option.

OUTSCALARS Statement

OUTSCALARS *scalar-name-list* ;

OUTSCALAR *scalar-name-list* ;

The OUTSCALARS statement specifies a list of scalar names; each name specifies a numeric or character output scalar variable to be stored in the table that is specified in the **OUTSCALAR=** option in the PROC TSMODEL statement. You can specify multiple OUTSCALARS statements.

Your program statements can create and use any number of scalars. Only scalars that are listed in the OUTSCALARS statement are predefined and included in the table that is specified in the OUTSCALAR= option. The scalars are initialized to missing values at the start of each BY group. Each scalar name can specify numeric or character scalar variables which are defined as follows:

var-list defines the variables in the *var-list* as numeric scalars.

var-list \$*n* defines the variables in the *var-list* as character scalars with length *n*.

The following statement defines scalar variables *rc*, *holdout*, and *nchanges* as numeric scalars, and defines *selected* as character with length 32.

```
outscalar rc selected $32 holdout nchanges;
```

PRINT Statement

PRINT *print-options* ;

The PRINT statement allows you to display results that are saved to tables that you specify in the PROC TSMODEL statement options. You can include multiple PRINT statements in your PROC TSMODEL statement block. Each PRINT statement is processed independently in the order that you specify them.

The PRINT OUTLOG statement has the following form:

PRINT OUTLOG < **WHERE** *where-clause* > ;

PRINT OUTLOG displays information from the OUTLOG= table to the SAS LOG. If you specify a BY statement, then the messages that are stored to the OUTLOG table are printed in BY group order followed with a BY line separator. You can specify an optional WHERE clause to select the rows from the OUTLOG table that you want to print. The WHERE clause must reference columns of the OUTLOG= table.

Following are four examples of PRINT OUTLOG statements that you might specify:

```
print outlog;
print outlog where regionName eq 'Region1';
print outlog where _errno_ ne 0;
print outlog where _log_ contains "sale";
```

The first PRINT statement prints all OUTLOG= table rows to the SAS LOG, the second selects rows where the *regionName* column has the value 'Region1', the third selects rows where the *_errno_* column has a non-zero value, and the last selects rows where the *_log_* column text contains the word 'sale'.

VAR Statement

VAR *variable-list* < / *options* > ;

The VAR statement lists the numeric variables in the DATA= table or AUXDATA= tables whose values are to be accumulated to form the time series.

An input table variable can be specified in only one VAR statement. You can specify any number of VAR statements. You can also specify the following *options* in the VAR statements:

ACCUMULATE=*option*

specifies how to accumulate the table observations within each time period for the variables in the *variable-list*. If you do not specify this option, accumulation is determined by the **ACCUMULATE=** option in the ID statement.

SETMISS=*option* | *number*

SETMISSING=*option* | *number*

specifies how to interpret missing values (either actual or accumulated) in the accumulated time series for variables in the *variable-list*. If you do not specify this option, missing values are set based on the **SETMISSING=** option in the ID statement.

REQUIRE Statement

REQUIRE *package-1* < *package-2* ... *package-n* > ;

REQUIRE *package* (*class-1* ... *class-n*) ;

The REQUIRE statement specifies which time series and time frequency analysis packages to make available for your user-defined program. These packages include functions, subroutines, and objects that you can utilize from your program to perform sophisticated time series processing. These packages provide functionality that ranges from a simple function to count missing observations in an array to very sophisticated objects that perform automatic time series modeling and forecasting.

The first form of the REQUIRE statement enables you to specify a list of package names that are available for use. If you use this form, you must specify at least one package name. You can specify multiple packages in the same REQUIRE statement.

The second form of the REQUIRE statement enables you to selectively identify which objects in *package* you intend to use. Packages might contain a number of different objects, and it can be more efficient to register only the ones that you plan to use.

You can specify multiple REQUIRE statements. All packages that are specified in REQUIRE statements are loaded prior to parsing your program statements so that any references are defined at the time your code is parsed. If you specify an invalid package name, then an error is returned prior to parsing your program statements. For more information about the packages that are available in SAS Visual Forecasting, see *SAS Visual Forecasting: Time Series Packages*. For more information about the packages that are available in SAS Econometrics, see *SAS Econometrics: Econometrics Procedures*.

SUBMIT Statement

SUBMIT < FILE= SAS-file-ref | 'File-path' > < submit-options > ;

The SUBMIT statement indicates the start of your user-defined program statements or specifies the location of a file that contains your user-defined program statements.

If the SUBMIT statement does not specify a file, then all lines of code that are specified between the SUBMIT statement and the ENDSUBMIT statement are executed on the time series BY groups that arise from your timestamped input data. Compilation errors are reported back to the SAS log, and no further processing occurs.

Notice the placement of the SUBMIT and ENDSUBMIT in the example in the “[Comparison of the TSMODEL and TIMEDATA Procedures](#)” on page 2068. The use of SUBMIT and ENDSUBMIT statements to delineate of the program block is a major difference between PROC TSMODEL and PROC TIMEDATA.

You can specify the following *submit-options*:

FILE=SAS-file-ref | 'File-path'

specifies a file that contains your user-defined program. If you specify this option, you must not specify the ENDSUBMIT statement.

You can specify the file either by including a *SAS-file-ref* that is defined in a prior SAS FILENAME statement or by including a quoted string that identifies the host-specific file path.

The following rules apply when you include the FILE= option:

- The text file you specify must contain only the program statements that you want to submit and none of the PROC TSMODEL statements. You must not include an ENDSUBMIT statement in the file.
- The text file you specify must not contain any SAS macro statements or macro variable references. The file content is submitted as specified.
- You are free to use any mechanism of your choosing to generate the program statements in the text file. You can use a SAS DATA step with PUT statements, PROC LUA, PROC STREAM, and so on to generate the file from within a SAS program. You can use your favorite editor to generate the text file and then specify it in the SUBMIT statement if the content is static. For more information, see [Getting Started with SAS Viya for Lua](#).

DYNAMICS=(var-1=[number | “string”] < var-2=[number | “string”]. . . >)

defines variables (constants) outside of the scope of the submitted code. These variables function as global arguments to the submitted code. In conjunction with the INSCALARS statement, these values can be used and evaluated within the submitted code. You can specify both numeric and character variable types. The type of the variable is determined by the right-hand side of the variable’s declaration. For example, consider the following DYNAMICS= option:

```
DYNAMICS=(SOF='MAPE' HOLDOUT=10)
```

The variable SOF is defined as a character variable, and its static value is 'MAPE'. The variable HOLDOUT is defined as a numeric variable, and its static value is 10.

ENDSUBMIT Statement

ENDSUBMIT ;

The ENDSUBMIT statement is required to terminate the user-defined program statements in the PROC TSMODEL statement block whenever you specify the SUBMIT statement without the FILE= option. Do not specify the ENDSUBMIT statement if you specify the **FILE=** option in the SUBMIT statement. If you do not specify the FILE= option and you fail to include an ENDSUBMIT statement to accompany your SUBMIT statement, then the PROC TSMODEL step ends with an error.

SAS Programming Statements

Programming statements ;

You can use all the programming statements that are allowed in PROC FCMP except the following:

- CALL RUN_MACRO subroutine
- CALL READ_ARRAY subroutine
- CALL WRITE_ARRAY subroutine

Details: TSMODEL Procedure

The TSMODEL procedure forms time series data from transactional data, which are analyzed according to the following steps if the relevant option listed on the right is specified:

- | | |
|---------------------------------|---|
| 1. accumulation | ACCUMULATE= option in the ID or VAR statement |
| 2. missing value interpretation | SETMISSING= option in the ID or VAR statement |
| 3. program execution | user-defined program statements |
| 4. descriptive statistics | OUTSUM= option |

Accumulation

If you specify the `ACCUMULATE=` option in the `ID` or `VAR` statement, observations in the table that is specified in the `DATA=` option in the `PROC TSMODEL` statement are accumulated within each time period. The frequency (width of each time interval) is specified by the `INTERVAL=` option in the `ID` statement. The `ID` variable contains the time `ID` values. Each time `ID` value is a SAS date or datetime that identifies the time period that contains the date or datetime. Accumulation is useful when the input table contains transactional data, whose observations are not spaced with respect to any particular time interval. The accumulated values form the time series, which is used in subsequent analyses.

For example, suppose an input table contains the following observations:

19MAR1999	10
19MAR1999	30
11MAY1999	50
12MAY1999	20
23MAY1999	20

If `INTERVAL=MONTH` is specified in the `ID` statement, then all the preceding observations fall within a three-month period of time between March 1999 and May 1999. The observations are accumulated within each time period as follows:

- If the `ACCUMULATE=TOTAL` option is specified, the resulting time series is

01MAR1999	40
01APR1999	.
01MAY1999	90

- If the `ACCUMULATE=AVERAGE` option is specified, the resulting time series is

01MAR1999	20
01APR1999	.
01MAY1999	30

- If the `ACCUMULATE=MINIMUM` option is specified, the resulting time series is

01MAR1999	10
01APR1999	.
01MAY1999	20

- If the `ACCUMULATE=MAXIMUM` option is specified, the resulting time series is

01MAR1999	30
01APR1999	.
01MAY1999	50

- If the `ACCUMULATE=STDDEV` option is specified, the resulting time series is

01MAR1999	14.14
01APR1999	.
01MAY1999	17.32

As you can see from the preceding examples, the accumulated time series can have missing values even though the input table observations contain no missing values.

Missing Value Interpretation

Once the data has been accumulated to form a time series based on the `INTERVAL=` and the `ACCUMULATE=` options, missing value interpretation is performed. Sometimes missing values should be interpreted as unknown values. In other situations, missing values are known, such as when missing values are created from accumulation and no observation should be interpreted as no value—that is, 0. In the former case, you can specify the `SETMISSING=` option to interpret how to treat missing values. In the latter case, you can specify `SETMISSING=0` in order to treat missing observations as no (zero) values. In other cases, missing values should be interpreted as global values, such as minimum or maximum values of the accumulated series. The accumulated and interpreted time series is used in subsequent analyses.

Summary Statistics

You can compute summary statistics from the working series by specifying the `OUTSUM=` option in the `PROC TSMODEL` statement.

SAS Programming Statements

The user-defined program for `PROC TSMODEL` can contain most of the SAS programming statements and functions available in the `DATA` step or in the `FCMP` procedure. However, there are a few differences as noted in “[SAS Programming Statements](#)” on page 2093. For more information, see the “`FCMP` Procedure” chapter in the *Base SAS Procedures Guide*.

All variables that are specified in the `ID` and `VAR` statements are assigned as predefined arrays for subsequent processing. In addition, all array names that are specified in the `OUTARRAYS` statements and all the scalars names that are specified in the `OUTSCALARS` statements are assigned as predefined symbols for subsequent processing.

Predefined Symbols

In addition to the predefined arrays that are specified in the OUTARRAYS statements and the predefined scalars that are specified in the OUTSCALARS statements, the TSMODEL procedure creates predefined symbols that are automatically available for use in the programming statements. The name and description of the predefined symbols are shown in the following subsections; these names must not be used as variable names in any input data set.

Predefined Scalar Values

<code>_FORMAT_</code>	time format, which is either implied by the <code>INTERVAL=</code> option or specified in the <code>FORMAT=</code> option in the ID statement
<code>_HORIZON_</code>	the time ID value that is one period beyond <code>_TEND_</code>
<code>_INTERVAL_</code>	time interval, which is specified in the <code>INTERVAL=</code> option in the ID statement
<code>_LEAD_</code>	forecast horizon or lead, which is specified in the <code>LEAD=</code> option in the PROC TSMODEL statement
<code>_LENGTH_</code>	length of the time series that is associated with the current BY group
<code>_SEASONALITY_</code>	length of the seasonal cycle, which is specified in the <code>SEASONALITY=</code> option in the PROC TSMODEL statement or implied by the <code>INTERVAL=</code> option in the ID statement. For more information about seasonality, see the section “Seasonality in Models” in Chapter 17, “Forecasting Details” (<i>SAS Visual Forecasting: Time Series Packages</i>).
<code>_SERIES_</code>	series index or BY-group counter. When PROC TSMODEL runs in a parallel processing environment, the index value is relative to the machine that processes the series or BY group. Therefore, values of <code>_SERIES_</code> might not be unique and could also vary for multiple executions of the procedure.
<code>_TEND_</code>	the last time ID value over all the BY groups. <code>_TEND_</code> is independent of the value of the <code>TRIMID=</code> option in the ID statement, but the value of <code>_TEND_</code> is the same as the ending value of the output time ID variable span if you specify <code>TRIMID=NONE</code> .
<code>_TSTART_</code>	the first time ID value over all the BY groups. <code>_TSTART_</code> is independent of the value of the <code>TRIMID=</code> option in the ID statement, but the value of <code>_TSTART_</code> is the same as the starting value of the output time ID variable span if you specify <code>TRIMID=NONE</code> .

Predefined Array Values

<code>_SEASON_</code>	season index values
<code>_CYCLE_</code>	life-cycle index values

Auxiliary Tables

The TSMODEL procedure can use auxiliary tables to contribute input variables to the run of the procedure step. This functionality creates a virtual data source that allows some of the input variables to physically reside in different tables. Some input variables can reside in the primary table, which is specified in the DATA= option, and other input variables can reside in the tables that are specified in one or more AUXDATA= options. This functionality enables sharing of common time series data across multiple projects.

You can specify more than one auxiliary data source to be used to input time series vectors across a particular BY-group hierarchy. To simplify data management, you can isolate variables that have naturally different levels of BY-group qualification into separate tables and use separate AUXDATA= options to supply them.

AUXDATA Functionality

There are two classes of time series table sources:

- a primary table from the DATA= option
- auxiliary data sources from AUXDATA= options

The AUXDATA= option specifies an auxiliary table that provides time series variables that are required for processing but are not included in the table that is specified in the DATA= option.

You can specify multiple AUXDATA= options in the PROC TSMODEL statement. Each AUXDATA= option establishes an auxiliary table source to supply variables that are declared in subsequent statements in the procedure step. If no auxiliary data sources are required, then the AUXDATA= option can be omitted.

Variables referenced in the TSMODEL procedure fall into three classes:

- variables that must be physically present in the primary table, which is specified in the DATA= option
- variables that must be physically present in each auxiliary table that is specified in an AUXDATA= option
- variables that can reside in either the primary or an auxiliary table

The ID variable for PROC TSMODEL must be present in the primary table and all the auxiliary tables that you specify. Variables that you specify in the BY statement must be present in the primary table. The auxiliary tables must contain all of those BY variables or none of them. Partial matching of a leftmost subset of the BY variables is not supported for the auxiliary tables.

The time series variables that you specify in VAR statements can be input from either the primary table or an auxiliary table. Variable resolution proceeds in reverse order from the last AUXDATA= option in the PROC TSMODEL statement to the first. If the variable in question is not found in any of those, the variable must be present in the primary table for the procedure step to be successful.

AUXDATA Alignment across BY Groups

All variables in the BY statement must be physically present in the primary table. However, it is not necessary to have the BY variables present in any of the auxiliary tables. All or none of the BY variables can be present in any auxiliary table.

For example, suppose you have a hierarchy of (REGION, PRODUCT) in the primary table Sales, which holds the time series variables for monthly sales metrics. Suppose you have an auxiliary table called Promotions that has no BY variables and contains analysis variables for promotions, and another table called Returns that contains time series analysis variables for (REGION, PRODUCT) level groupings. In this scenario, each (REGION, PRODUCT) group in the Sales table always includes the time series variables from the Promotions table, and the analysis variables for the matching (REGION, PRODUCT) BY groups from the Returns table. So if ('SOUTH', 'EDSEL') is a BY group from the primary table, any matching rows from the Returns table are used to define the time series variables that are contributed from that table. The time series variables that are contributed by the Promotions table are always included in every BY group from the Sales table.

AUXDATA Alignment over the Time Dimension

The series from each BY group of the primary table defines a reference time span for the auxiliary tables. Only the intersection of the time span for each auxiliary series with the reference span is input. Leading or trailing missing values are added to the auxiliary series as required to create a time series that has the same span as the reference span. The leading or trailing missing values, if any, are then interpreted according to the value of the SETMISSING= option. For more information, see the SETMISSING= option in the ID statement and the SETMISSING= option in the VAR statement.

When time series are input from a single primary table, the values for all observations of all the time series are contained in the primary table, and no time series needs to be extended with leading or trailing missing values. However, when time series are input from both the primary table and an auxiliary table, the time series from the auxiliary table are truncated or extended as required if the span of the auxiliary series is not identical to the reference span.

For the preceding (REGION, PRODUCT) example, which includes a primary table and two auxiliary tables, consider how differences in the reference span from each BY group affect the time series input from the auxiliary tables in the following cases. In these cases:

- The DATA line show a series that contains observations in the table specified in the DATA= option.
- The AUXDATA line show a series that contains observations in the table specified in an AUXDATA= option.
- t_P^b denotes the beginning time ID of the primary (DATA) series.
- t_P^e denotes the ending time ID of the primary (DATA) series.
- t_A^b denotes the beginning time ID of the AUXDATA series.
- t_A^e denotes the ending time ID of the AUXDATA series.
- $[t_P^b, t_P^e]$ denotes the time span for the primary (DATA) series (also known as the reference time span).
- $[t_A^b, t_A^e]$ denotes the time span for the AUXDATA series.

Case 1:

In this case, $[t_P^b, t_P^e] \subseteq [t_A^b, t_A^e]$: the auxiliary time span includes the reference span as a subset. Values in the AUXDATA series to the left of t_P^b and values to the right of t_P^e are truncated from the AUXDATA series. AUXDATA series values in $[t_P^b, t_P^e]$ are input as their actual values. Any actual missing values are interpreted according to the value of the SETMISSING= option.

Case 2:

In this case, $[t_P^b, t_P^e] = [t_P^b, t_A^b) \cup [t_A^b, t_P^e]$: the reference time span leads the auxiliary time span with a non-empty intersection. AUXDATA series values in $[t_P^b, t_A^b)$ are extended with missing values, and then those missing values are interpreted according to the value of the SETMISSING= option. AUXDATA series values in $[t_A^b, t_P^e]$ are input as their actual values. Any actual missing values are interpreted according to the value of the SETMISSING= option. AUXDATA series values in $(t_P^e, t_A^e]$ are truncated.

Case 3:

In this case, $[t_P^b, t_P^e] = [t_P^b, t_A^e] \cup (t_A^e, t_P^e]$: the reference time span lags the auxiliary time span with a non-empty intersection. AUXDATA series values in $[t_P^b, t_A^e]$ are input as their actual values. Any actual missing values are interpreted according to the value of the SETMISSING= option. AUXDATA series values in $(t_A^e, t_P^e]$ are extended with missing values, and then those missing values are interpreted according to the value of the SETMISSING= option. AUXDATA series values in $(t_A^b, t_P^b]$ are truncated.

Case 4:

In this case, $[t_A^b, t_A^e] \subset [t_P^b, t_P^e]$: the auxiliary time span is a subset of the reference time span. *AUXDATA* series values in $[t_P^b, t_A^b)$ and values in $(t_A^e, t_P^e]$ are extended with missing values, and then those missing values are interpreted according to the value of the SETMISSING= option. *AUXDATA* series values in $[t_A^b, t_A^e]$ are input as their actual values. Any actual missing values are interpreted according to the value of the SETMISSING= option.

Case 5:

In this case, $[t_P^b, t_P^e] \cap [t_A^b, t_A^e] = \emptyset$: the auxiliary time span does not intersect the reference time span at all. *AUXDATA* series values in $[t_P^b, t_P^e]$ are set to missing values, and then those missing values are interpreted according to the value of the SETMISSING= option.

Table Output

The TSMODEL procedure can create the **OUT=**, **OUTARRAY=**, **OUTSCALAR=**, **OUTSUM=**, **OUTLOG=**, and **OUTOBJ=** tables. These tables always contain the variables that are specified in the BY statement. If a BY-group analysis step fails, then the values of this step are not recorded or are set to missing in the related output tables. Appropriate error or warning messages (or both) are recorded in the OUTLOG= table, subject to the value of the LOGCONTROL= option.

It is important to note that output tables created by PROC TSMODEL are naturally partitioned by the BY variables because of the way the BY groups are input into CAS session processes to form the time series data frames. The entire time series data for each BY group is input completely in a particular CAS session process. Consequently, all the time series processing for a particular BY group occurs in the context of a single CAS session node. Subsequent use of PROC TSMODEL to process the output tables makes use of this table-level partitioning.

The BY group partitioning of the output tables should not be confused with BY-group sort order or time ID sort order when the output tables are read by the CAS libname engine back into the SAS DATA step code for subsequent processing. If BY-group order is needed, or if time ID sort order within the BY groups is needed, you must specify PROC SORT steps in your SAS code to order the data set. For example, consider

the PROC TSMODEL step in the example “[Comparison of the TSMODEL and TIMEDATA Procedures](#)” on page 2068. In order to process the OUTSUM=, OUTSCALAR=, and OUTARRAY= tables in a SAS DATA step that expects the BY-group rows to be contiguous, you must specify BY Product in the SORT procedure to sort the tables mylib.Pricexsum and mylib.Pricexos. The table mylib.Pricexoa is a time series table, and you must specify BY Product Date in the SORT procedure to sort the data so that they are suitable for normal SAS time series processing. Failure to sort output tables that are generated by PROC TSMODEL can lead to errors when the tables are used as input in other procedures or steps.

OUT= Table

The **OUT=** table contains the variables that are specified in the BY, ID, or VAR statements. The ID variable values are aligned and extended based on the ALIGN=, INTERVAL=, and LEAD= options. The values of the variables specified in the VAR statements are accumulated based on the ACCUMULATE= option, and missing values are interpreted based on the SETMISSING= option.

OUTARRAY= Table

The **OUTARRAY=** table contains the variables that are specified in the BY, ID or VAR statements. If the ID statement is specified, then the ID variable values are aligned and extended based on the ALIGN= and INTERVAL= options. The values of the variables specified in the VAR statements are accumulated based on the ACCUMULATE= option, and missing values are interpreted based on the SETMISSING= option. In addition, the OUTARRAY= table contains the variables that are specified in the OUTARRAYS statements and the following variables:

STATUS	status flag that indicates whether the requested analyses were successful
TIMEID	time ID values
SEASON	season index values
CYCLE	life-cycle index values
Array-Variable-Names	variables that are specified in the OUTARRAYS statement

The OUTARRAY= table contains the arrays that are related to the (accumulated) time series.

OUTSCALAR= Table

The **OUTSCALAR=** table contains the variables that are specified in the BY statement. In addition, the table contains the variables that are specified in the OUTSCALARS statements and the following variables:

STATUS	status flag that indicates whether the requested analyses were successful
Scalar-Variable-Names	variables that are specified in the OUTSCALARS statement

The OUTSCALAR= table contains the scalars that are related to the (accumulated) time series.

OUTSUM= Table

The **OUTSUM=** table contains the variables that are specified in the BY statement and the variables in the following list. This table also records the descriptive statistics for each variable that is specified in a VAR statement. Variables that are related to descriptive statistics are based on the ACCUMULATE= and SETMISSING= options in the ID and VAR statements.

NAME	variable name
STATUS	status flag that indicates whether the requested analyses were successful
START	the starting date of each series
END	the ending date of each series
STARTOBS	the beginning observation number of each series
ENDOBS	the ending observation number of each series
NOBS	number of observations
N	number of nonmissing observations
NMISS	number of missing observations
MINIMUM	minimum value
MAXIMUM	maximum value
AVG	average value
STDDEV	standard deviation

OUTLOG= Table

The **OUTLOG=** table contains the variables that are specified in the BY statement and the variables in the following list. The **OUTLOG=** table records textual messages that arise from the processing of the BY group's time series data. Messages are filtered based on the value of the **LOGCONTROL=** option. In addition to the BY variables, the **OUTLOG=** table includes the following columns:

ERRNO	a numeric variable that stores the _ERRNO_ variable for the BY group. The value of _ERRNO_ might be set by the user-defined program directly or might be set implicitly by calling a function or method that sets the _ERRNO_ value.
LOGLEN	a numeric variable that stores the length of the _LOG_ variable text (byte count).
LOG	a character variable that stores the messages that are logged from the execution of the user-defined program on the BY group's time series data. All messages from the BY group are concatenated into the variable. End-of-line characters separate the individual messages. If PUTTOLOG=YES is specified in the PROC TSMODEL statement, the _LOG_ variable also contains messages from any PUT programming statements that are specified.

STATUS Variable Values

The `_STATUS_` variable that appears in the `OUTARRAY=`, `OUTSCALAR=` and `OUTSUM=` tables contains a value that specifies whether the analysis has been successful or not. The `_STATUS_` variable can take the following values:

0	Analysis was successful.
3000	Accumulation failed.
4000	Missing value interpretation failed.
6000	Series is all missing.
9000	Descriptive statistics could not be computed.

Printed Output

The `TSMODEL` procedure always prints a summary of the processing that is performed on the time series data. This is extremely useful for gauging the work that is performed by the CAS server when it executes `PROC TSMODEL`. Printing of other results is best accomplished by the use of targeted data queries to subset and display the information from the tables that are produced by the `TSMODEL` procedure. For example, you might want to print the `OUTARRAY=` results only for BY groups that have a particular `_STATUS_` value in the `OUTSUM=` table.

Examples: TSMODEL Procedure

Example 29.1: Accumulating Transactional Data into Time Series Data

This example uses the `TSMODEL` procedure to accumulate timestamped transactional data that have been recorded at no particular frequency into time series data at a specific frequency.

Suppose that the input table `mylib.retail` contains variables `Store` and `Timestamp` and numerous other numeric transaction variables. The BY variable `Store` contains values that divide the transactions into groups (BY groups). The time ID variable `Timestamp` contains SAS date values that are recorded at no particular frequency. The other variables, `Item1–Item8`, contain the numeric transaction values to be analyzed. The following statements form monthly time series from the transactional data.

These statements assume that your libref is named `mylib`, but you can substitute any appropriately defined libref.

```
proc tsmodel data=mylib.retail
    out=mylib.mseries(replace=yes);
by store;
id timestamp interval=month
    accumulate=avg
    setmiss=0
    start='01jan1998'd
```

```

            end   ='31dec2000'd;
    var item1-item8;
run;

```

The ACCUMULATE=AVG option in the ID statement accumulates the transactions that are recorded with each time period based on the average values. The SETMISS=0 option in the ID statement sets the accumulated time series values for time periods that have no transactions to 0 instead of to missing. The START='01JAN1998'D and END='31DEC2000'D options request that only transactions recorded between the first day of 1998 and the last day of 2000 be considered and, if needed, extended to include this range.

The monthly time series data are stored in the table mylib.mseries. Each BY group that is associated with the BY variable Store contains an observation for each of the 36 months that are associated with the years 1998, 1999, and 2000. Each observation contains the values Store, Timestamp, and each of the analysis variables Item1–Item8 in the input table.

The TSMODEL procedure prints a summary of the time series processing that is performed, as shown in Output 29.1.1.

Output 29.1.1 Summary of Accumulation Processing
The TSMODEL Procedure

Processing Summary	
CAS table	RETAIL
Number of analysis variables	8
Number of rows read	400
Number of groups read	4
Memory for group packages (KB)	1
Time to load groups (seconds)	0.0077979565
Minimum time ID	NOV1998
Maximum time ID	DEC2000
Minimum time periods	36
Maximum time periods	36
Number of nodes run	1
Number of nodes with data	1
Number of nodes with groups	1
Number of threads budgeted	32
Minimum thread group count	0
Maximum thread group count	1
Minimum threads active	32
Maximum threads active	32
Number of groups processed by submitted code	4
Number of groups failing	0
Elapsed time to process groups (seconds)	0.0124080181
Number of output table rows produced	144

After each set of transactions has been accumulated to form a corresponding time series, the accumulated time series can be analyzed using various time series analysis techniques. For example, exponentially weighted moving averages can be used to smooth each series.

If the time ID variable Timestamp contains SAS datetime values instead of SAS date values, the INTERVAL=, START=, and END= options must be changed accordingly and the following statements could be used:

```

proc tsmodel data=mylib.retail
  out=mylib.tseries(replace=yes);
  by store;
  id timestamp interval=dtmonth
      accumulate=avg
      setmiss=0
      start='01jan1998:00:00:00'dt
      end   ='31dec2000:00:00:00'dt;
  var item1-item8;
run;

```

The monthly time series data are stored in the table mylib.tseries, and the time ID values use a SAS datetime representation.

Example 29.2: User-Defined Program Statements

The following SAS macro statements create a user-defined subroutine and a user-defined function. Mylog is a subroutine that log-transforms a time series. Mymean is a function that computes the mean of a time series.

```

%macro fcmpcode;
  subroutine mylog(actual[*], transform[*]);
    outargs transform;
    actlen  = DIM(actual);
    do t = 1 to actlen;
      transform[t] = log(actual[t]);
    end;
  endsub;

  function mymean(z[*]);
    nz  = DIM(z);
    sum = 0;
    nnmiss = 0;
    do t = 1 to nz;
      if z[t] ne . then do;
        sum = sum + z[t];
        nnmiss = nnmiss + 1;
      end;
    end;
    if nnmiss eq 0 then return(.);

    return(sum/nnmiss);
  endsub;
%mend;

```

The following DATA step loads data set Sashehelp.Air, which contains airline data into the table mylib.air. These statements assume that your libref is named mylib, but you can substitute any appropriately defined libref.

```
data mylib.air(replace=yes);
  set sashelp.air;
run;
```

The input table mylib.air contains the variables Air and Date. The time series is recorded monthly.

The following statements form quarterly time series from the monthly series based on the median value of the total of the transactions recorded within each month. The OUTARRAYS statement specifies the Logair and Logairc arrays as output. The OUTSCALARS statement specifies the Meanlog scalars as output. The other arrays and scalars are not part of the output. The subsequent program statements create the output arrays and scalars.

```
proc tsmodel data=mylib.air
  outarray=mylib.arrays(replace=yes)
  outscalar=mylib.scalars(replace=yes)
  outsum=mylib.airsum(replace=yes);
  id date interval=qtr acc=total;
  var air;
  outarrays logair logairc;
  outscalars meanlog;
  submit;
    %fcmpcode;
    call mylog(air,logair);
    meanlog = mymean(air);
    do t = 1 to dim(air);
      logairc[t] = logair[t] - meanlog;
    end;
  endsubmit;
quit;
```

The following PROC PRINT step displays the OUTSUM= table, as shown in [Output 29.2.1](#).

```
proc print data=mylib.airsum; run;
```

Output 29.2.1 Summary Statistics for mylib.Air

Obs	_NAME_	NOBS	N	NMISS	MIN	MAX	MEAN	STDDEV

Example 29.3: Using Auxiliary Tables

This example demonstrates the use of the `AUXDATA=` option in the `PROC TSMODEL` statement. The data set `Sashelp.Gulfoil` contains oil and gas production data from the Gulf of Mexico. The following `DATA` step loads data set `Sashelp.Gulfoil` into the table `mylib.gulfoil`.

These statements assume that your libref is named `mylib`, but you can substitute any appropriately defined libref.

```
data mylib.gulfoil(replace=yes);
    set sashelp.gulfoil;
run;
```

The variable `RegionName` define a time series hierarchy of interest. Suppose you want to generate two new series that contain the region's total share of oil and gas production for each month in the `mylib.gulfoil` table.

You first use `PROC TSMODEL` to perform temporal aggregation (accumulation) of the time series:

```
proc tsmodel data=mylib.gulfoil
    outarray=mylib.allreg(replace=yes);
    id date interval=month accumulate=total;
    var oil gas;
    outarray alloil allgas;
    submit;
        do t=1 to _length_;
            alloil[t]=oil[t];
            allgas[t]=gas[t];
        end;
    endsubmit;
quit;
```

In the preceding `PROC TSMODEL` statements, the Oil and Gas variables are accumulated across all regions because no `BY` statement is specified. In the following `DATA` step, the variables are dropped from the `mylib.allreg` table to avoid conflict with the original time series variables in the `mylib.gulfoil` table:

```
data mylib.allreg;
    set mylib.allreg;
    drop oil gas;
run;
```

You can then use `PROC TSMODEL` with the `AUXDATA=` option to compute the share of oil and gas production that is contributed by each region for each month. `PROC TSMODEL` reads a monthly time series for each `RegionName` group for the variables Oil and Gas from `mylib.Gulfoil`. Two new series are produced in the variables `Oilshare` and `Gasshare`, which contain the region's share of the oil and gas production, respectively. Those share variables are specified in the `OUTARRAY` statement for inclusion in the table (`mylib.shares`), which is specified in the `OUTARRAY=` option. The time series that are acquired for the variables `alloil` and `allgas` are common across all of the `RegionName` `BY` groups.

```
proc tsmodel data=mylib.gulfoil
    auxdata=mylib.allreg
    outarray=mylib.shares;
    by regionname;
    outarray oilshare gasshare;
```

```

var oil gas alloil allgas;
id date interval=month accumulate=total;
submit;
  do i=1 to _length_;
    oilshare[i] = oil[i] / alloil[i];
    gasshare[i] = gas[i] / allgas[i];
  end;
endsubmit;
quit;

```

The following code demonstrates that the computed shares sum to 1 for each time index in the resulting Oilshare and Gasshare series. PROC TSMODEL is used to accumulate the shares for these respective variables from the table mylib.shares, and the accumulated share series at the RegionName level are stored to the table mylib.rshares with variable names Oilsum and Gassum, respectively. The tables mylib.shares and mylib.rshares are shown in [Output 29.3.1](#).

```

proc tsmode data=mylib.shares
  outscalar=mylib.rshares(replace=yes)
  outsum=mylib.rsum(replace=yes);
id date interval=month accumulate=total;
var oilshare gasshare;
outscalar oilsum gassum;
submit;
  oilsum = 0;
  gassum = 0;
  do t=1 to _length_;
    oilsum = oilsum + oilshare[t];
    gassum = gassum + gasshare[t];
  end;
endsubmit;
quit;

proc print data=mylib.rshares; run;
proc print data=mylib.rsum; run;

```

Output 29.3.1 Validation of Oil and Gas Shares by Region

Obs _STATUS_ oilsum gassum													
1	0	123	123										

Obs	_NAME_	NOBS	N	NMISS	MIN	MAX	MEAN	STDDEV	SUM	_STATUS_	START	END	STARTOBS	ENDOBS
1	oilshare	123	123	0	1	1	1	0	123	0	JAN1996	MAR2006	1	123
2	gasshare	123	123	0	1	1	1	0	123	0	JAN1996	MAR2006	1	123

You might also want to plot the share series. The following code produces a graph that overlays the region level share series for oil production as shown in [Output 29.3.2](#).

```

proc sgplot data=mylib.shares;
  series x=Date y=OilShare/group=RegionName;
run;

```

Output 29.3.2 Region Share of Oil Production

Overview: UCM Procedure

The UCM procedure analyzes and forecasts equally spaced univariate time series data by using an unobserved components model (UCM). The UCMs are also called *structural models* in the time series literature. A UCM decomposes the response series into components such as trend, seasonals, cycles, and the regression effects due to predictor series. The components in the model are supposed to capture the salient features of the series that are useful in explaining and predicting its behavior. Harvey (1989) and Pelagatti (2015) are good references for time series modeling that use the UCMs. Harvey calls the components in a UCM the “stylized facts” about the series under consideration. Traditionally, the ARIMA models and, to some limited extent, the exponential smoothing models have been the main tools in the analysis of this type of time series data. It is fair to say that the UCMs capture the versatility of the ARIMA models while possessing the interpretability of the smoothing models. A thorough discussion of the correspondence between the ARIMA models and the UCMs, and the relative merits of UCM and ARIMA modeling, is given in Harvey (1989). The UCMs are also very similar to another set of models, called the *dynamic models*, that are popular in the Bayesian time series literature (West and Harrison 1999). In SAS Econometrics, you can use PROC CSSM for multivariate and more general univariate UCMs (see Chapter 14, “CSSM Procedure”), PROC ARIMA for ARIMA modeling (see Chapter 7, “ARIMA Procedure” (*SAS/ETS User’s Guide*)), and PROC ESM for exponential smoothing modeling (see Chapter 14, “ESM Procedure” (*SAS/ETS User’s Guide*)).

You can use the UCM procedure to fit a wide range of UCMs that can incorporate complex trend, seasonal, and cyclical patterns and can include multiple predictors. It provides a variety of diagnostic tools to assess the fitted model and to suggest the possible extensions or modifications. The components in the UCM provide a succinct description of the underlying mechanism governing the series. You can print, save, or plot the estimates of these component series. Along with the standard forecast and residual plots, the study of these component plots is an essential part of time series analysis using the UCMs. Once a suitable UCM is found for the series under consideration, it can be used for a variety of purposes. For example, it can be used for the following:

- forecasting the values of the response series and the component series in the model
- obtaining a model-based seasonal decomposition of the series
- obtaining a “denoised” version and interpolating the missing values of the response series in the historical period
- obtaining the full sample or “smoothed” estimates of the component series in the model

PROC UCM in SAS Econometrics Compared with PROC UCM in SAS/ETS

The UCM procedure in SAS Econometrics software is the CAS version of the UCM procedure in SAS/ETS software. This means that it requires SAS Cloud Analytic Services (CAS) in order to run. Except for this difference, both procedures are essentially identical in their modeling capabilities. Because it works in the cloud environment, PROC UCM in SAS Econometrics enables you to efficiently handle large numbers of BY groups by exploiting all available cores and concurrent threads to process them in parallel. These two procedures share virtually identical syntax and should produce virtually identical output. However, some important differences between them arise mainly because CAS tables do not use observation order and because some of the rarely needed and experimental features in PROC UCM in SAS/ETS are excluded from this release of PROC UCM in SAS Econometrics:

- The **ID** statement is required; it is optional in PROC UCM in SAS/ETS.
- All the input and output data sets, such as the input data set in the **DATA=** option in the PROC UCM statement, must be CAS tables.
- In the **NLOPTIONS** statement, you can currently specify only the **TECH=** and **MAXITER=** options; the other options remain at their default settings.
- The InitialParameters ODS table, which displays initial estimates of the free parameters and is part of the default output in PROC UCM in SAS/ETS, is not available. This table is rarely needed.
- The **PERFORMANCE** statement, which is unnecessary in CAS, is not available.
- The **BOOTSTRAP** option in the **FORECAST** statement, which generates the bootstrap prediction standard errors, is not available.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);  
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS and LIBNAME statements, see the section “[Introduction to Shared Concepts](#)” on page 54 in Chapter 4, “[Shared Concepts](#).”

Getting Started: UCM Procedure

The analysis of time series using the UCMs involves recognizing the salient features present in the series and modeling them suitably. The UCM procedure provides a variety of models for estimating and forecasting the commonly observed features in time series. These models are discussed in detail later in the section “[An Introduction to Unobserved Component Models](#)” on page 2156. First the procedure is illustrated using an example.

A Seasonal Series with Linear Trend

The airline passenger series, given as Series G in Box and Jenkins (1976), is often used in time series literature as an example of a nonstationary seasonal time series. This series is a monthly series consisting of the number of airline passengers who traveled during the years 1949 to 1960. Its main features are a steady rise in the number of passengers from year to year and the seasonal variation in the numbers during any given year. It also exhibits an increase in variability around the trend. A log transformation is used to stabilize this variability. The following DATA step prepares the log-transformed passenger series analyzed in this example:

```
data seriesG;
  set sashelp.air;
  logair = log( air );
run;
```

The following statements produce a time series plot of the series by using the TIMESERIES procedure (see Chapter 38, “TIMESERIES Procedure” (*SAS/ETS User’s Guide*)). The trend and seasonal features of the series are apparent in the plot in [Figure 30.1](#).

```
proc timeseries data=seriesG plot=series;
  id date interval=month;
  var logair;
```

```
run;
```

Figure 30.1 Series Plot of Log-Transformed Airline Passenger Series

In this example this series is modeled using an unobserved component model called the basic structural model (BSM). The BSM models a time series as a sum of three stochastic components: a trend component μ_t , a seasonal component γ_t , and random error ϵ_t . Formally, a BSM for a response series y_t can be described as

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

Each of the stochastic components in the model is modeled separately. The random error ϵ_t , also called the *irregular component*, is modeled simply as a sequence of independent, identically distributed (iid) zero-mean Gaussian random variables. The trend and the seasonal components can be modeled in a few different ways. The model for trend used here is called a *locally linear time trend*. This trend model can be written as follows:

$$\begin{aligned}\mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim \text{iid } N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim \text{iid } N(0, \sigma_\xi^2)\end{aligned}$$

These equations specify a trend where the level μ_t as well as the slope β_t is allowed to vary over time. This variation in slope and level is governed by the variances of the disturbance terms η_t and ξ_t in their respective

equations. Some interesting special cases of this model arise when you manipulate these disturbance variances. For example, if the variance of ξ_t is 0, the slope will be constant (equal to β_0); if the variance of η_t is also 0, μ_t will be a deterministic trend given by the line $\mu_0 + \beta_0 t$. The seasonal model that this example uses is called a trigonometric seasonal. The stochastic equations that govern a trigonometric seasonal are explained in the section “[Modeling Seasons](#)” on page 2158. However, it is worth noting here that this seasonal model reduces to the familiar regression with deterministic seasonal dummies if the variance of the disturbance terms in its equations is 0. The following statements specify a BSM that has these three components:

```
/* Load data into mylib */
data mylib.seriesG;
    set seriesG;
run;

proc ucm data=mylib.seriesG;
    id date interval=month;
    model logair;
    irregular;
    level;
    slope;
    season length=12 type=trig print=smooth;
    estimate;
    forecast lead=24 print=decomp;
run;
```

The PROC UCM statement signifies the start of the UCM procedure; the input SAS table, mylib.seriesG, which contains the dependent series, is specified there. The ID statement is used to specify a date, datetime, or time identification variable, which is called date in this example, to label the observations. The INTERVAL=MONTH option in the ID statement indicates that the measurements were collected on a monthly basis. The model specification begins with the MODEL statement, where the response series is specified (logair in this case). Then the components in the model are specified using separate statements that enable you to control their individual properties. The irregular component ϵ_t is specified using the IRREGULAR statement, and the trend component μ_t is specified using the LEVEL and SLOPE statements. The seasonal component γ_t is specified using the SEASON statement. The specifics of the seasonal characteristics, such as the season length, its stochastic evolution properties, and so on, are specified using the options in the SEASON statement. The seasonal component that this example uses has a season length of 12, corresponding to monthly seasonality, and is of the trigonometric type. The various types of seasonal components are explained in the section “[Modeling Seasons](#)” on page 2158.

The parameters of this model are the variances of the disturbance terms in the evolution equations of μ_t , β_t , and γ_t and the variance of the irregular component ϵ_t . These parameters are estimated by maximizing the likelihood of the data. The ESTIMATE statement options can be used to specify the span of data that are used in parameter estimation and to display and save the results of the estimation step and the model diagnostics. You can use the estimated model to obtain the forecasts of the series as well as the components. The options in the individual component statements can be used to display the component forecasts; for example, the PRINT=SMOOTH option in the SEASON statement displays smoothed forecasts of the seasonal component γ_t . The series forecasts and forecasts of the sum of components can be produced using the FORECAST statement. The PRINT=DECOMP option in the FORECAST statement prints the smoothed trend μ_t and the trend plus seasonal component ($\mu_t + \gamma_t$).

The parameter estimates for this model are displayed in [Figure 30.2](#).

Figure 30.2 BSM for the Logair Series**The UCM Procedure**

Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.00023436	0.0001	2.17	0.0298
Level	Error Variance	0.00029828	0.0001	2.82	0.0048
Slope	Error Variance	8.47913E-13	0.0000	0.00	0.9989
Season	Error Variance	0.00000356	0.0000	2.69	0.0072

The estimates suggest that except for the slope component, the disturbance variances of all the components are significant—that is, all these components are *stochastic*. The slope component, however, appears to be deterministic because its error variance is quite insignificant. It might then be useful to check if the slope component can be dropped from the model—that is, if $\beta_0 = 0$. This can be checked by examining the significance analysis table of the components given in Figure 30.3.

Figure 30.3 Component Significance Analysis for the Logair Series

Significance Analysis of Components (Based on the Final State)			
Component	DF	Chi-Square	Pr > ChiSq
Irregular	1	0.08	0.7747
Level	1	117867	<.0001
Slope	1	43.78	<.0001
Season	11	507.75	<.0001

This table provides the significance of the components in the model at the end of the estimation span. If a component is deterministic, this analysis is equivalent to checking whether the corresponding regression effect is significant. However, if a component is stochastic, then this analysis pertains only to the portion of the series near the end of the estimation span. In this example the slope appears quite significant and should be retained in the model, possibly as a deterministic component. Note that, on the basis of this table, the irregular component's contribution appears insignificant toward the end of the estimation span; however, since it is a stochastic component, it cannot be dropped from the model on the basis of this analysis alone. The slope component can be made deterministic by holding the value of its error variance fixed at 0. This is done by modifying the SLOPE statement as follows:

```
slope variance=0 noest;
```

After a tentative model is fit, its adequacy can be checked by examining different goodness-of-fit measures and other diagnostic tests and plots that are based on the model residuals. Once the model appears satisfactory, it can be used for forecasting. An interesting feature of the UCM procedure is that, apart from the series forecasts, you can request the forecasts of the individual components in the model. The plots of component forecasts can be useful in understanding their contributions to the series. The following statements illustrate some of these features:

```

proc ucm data=mylib.seriesG;
  id date interval = month;
  model logair;
  irregular;
  level plot=smooth;
  slope variance=0 noest;
  season length=12 type=trig
    plot=smooth;
  estimate;
  forecast lead=24 plot=decomp;
run;

```

The table given in [Figure 30.4](#) shows the goodness-of-fit statistics that are computed by using the one-step-ahead prediction errors (see the section “[Statistics of Fit](#)” on page 2195). These measures indicate a good agreement between the model and the data. Additional diagnostic measures are also printed by default but are not shown here.

Figure 30.4 Fit Statistics for the Logair Series
The UCM Procedure

Fit Statistics Based on Residuals	
Mean Squared Error	0.00147
Root Mean Squared Error	0.03830
Mean Absolute Percentage Error	0.54132
Maximum Percent Error	2.19097
R-Square	0.99061
Adjusted R-Square	0.99046
Random Walk R-Square	0.87288
Amemiya's Adjusted R-Square	0.99017
Number of non-missing residuals used for computing the fit statistics = 131	

The first plot, shown in [Figure 30.5](#), is produced by the PLOT=SMOOTH option in the LEVEL statement, it shows the smoothed level of the series.

Figure 30.5 Smoothed Trend in the Logair Series

The second plot (Figure 30.6), produced by the PLOT=SMOOTH option in the SEASON statement, shows the smoothed seasonal component by itself.

Figure 30.6 Smoothed Seasonal in the Logair Series

The plot of the sum of the trend and seasonal component, produced by the PLOT=DECOMP option in the FORECAST statement, is shown in [Figure 30.7](#). You can see that, at least visually, the model seems to fit the data well. In all these decomposition plots the component estimates are extrapolated for two years in the future based on the LEAD=24 option specified in the FORECAST statement.

Figure 30.7 Smoothed Trend plus Seasonal in the Logair Series

Syntax: UCM Procedure

The UCM procedure uses the following statements:

```

PROC UCM < options > ;
  AUTOREG < options > ;
  BLOCKSEASON options ;
  BY variables ;
  CYCLE < options > ;
  DEPLAG options ;
  ESTIMATE < options > ;
  FORECAST < options > ;
  ID variable options ;

```

The **PROC UCM**, **ID**, and **MODEL** statements are required. In addition, the model must contain at least one component with nonzero disturbance variance.

Functional Summary

The statements and options controlling the UCM procedure are summarized in [Table 30.1](#). Most commonly needed scenarios are listed; see the individual statements for additional details. You can use the **PRINT=** and **PLOT=** options in the individual component statements for printing and plotting the corresponding component forecasts.

Table 30.1 Functional Summary

Description	Statement	Option
Data Set Options		
Specify the input SAS table	PROC UCM	DATA=
Write parameter estimates to an output SAS table	ESTIMATE	OUTEST=
Write series and component forecasts to an output SAS table	FORECAST	OUTFOR=

Table 30.1 *continued*

Description	Statement	Option
Model Specification		
Specify the dependent variable and simple predictors	MODEL	
Specify predictors with time-varying coefficients	RANDOMREG	
Specify a nonlinear predictor	SPLINEREG	
Specify the irregular component	IRREGULAR	
Specify the random walk trend	LEVEL	
Specify the locally linear trend	LEVEL and SLOPE	
Specify a cycle component	CYCLE	
Specify a dummy seasonal component	SEASON	TYPE=DUMMY
Specify a trigonometric seasonal component	SEASON	TYPE=TRIG
Drop some harmonics from a trigonometric seasonal component	SEASON	DROPH=
Specify a list of harmonics to keep in a trigonometric seasonal component	SEASON	KEEPH=
Specify a spline-season component	SPLINESEASON	
Specify a block-season component	BLOCKSEASON	
Specify an autoreg component	AUTOREG	
Specify the lags of the dependent variable	DEPLAG	
Specify a transfer function component	TF	
Controlling the Likelihood Optimization Process		
Request optimization of the profile likelihood	ESTIMATE	PROFILE
Request optimization of the usual likelihood	ESTIMATE	NOPROFILE
Specify the optimization technique	NLOPTIONS	TECH=
Limit the number of iterations	NLOPTIONS	MAXITER=
Outlier Detection		
Turn on the search for additive outliers		Default
Turn on the search for level shifts	LEVEL	CHECKBREAK
Specify the significance level for outlier tests	OUTLIER	ALPHA=
Limit the number of outliers	OUTLIER	MAXNUM=
Limit the number of outliers to a percentage of the series length	OUTLIER	MAXPCT=
Controlling the Series Span		
Exclude some initial observations from analysis during the parameter estimation	ESTIMATE	SKIPFIRST=
Exclude some observations at the end from analysis during the parameter estimation	ESTIMATE	BACK=
Exclude some initial observations from analysis during forecasting	FORECAST	SKIPFIRST=

Global Printing and Plotting Options		
Turn off all the printing for the procedure	PROC UCM	NOPRINT
Turn on all the printing options for the procedure	PROC UCM	PRINTALL
Turn off all the plotting for the procedure	PROC UCM	PLOTS=NONE
Turn on all the plotting options for the procedure	PROC UCM	PLOTS=ALL
Turn on a variety of plotting options for the procedure	PROC UCM	PLOTS=
ID		
Specify a variable that provides the time index for the series values	ID	

PROC UCM Statement

PROC UCM <options> ;

The PROC UCM statement invokes the UCM procedure. You can specify the following options:

DATA=*libref.data-table*

specifies the name of the SAS table that contains the time series. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section “Using CAS Sessions and CAS Engine Librefs” on page 2114.

NOPRINT

turns off all printing for the procedure. Subsequent print options in the procedure are ignored.

PLOTS<(global-plot-options)> <= plot-request <(options)>>

PLOTS<(global-plot-options)> <= (plot-request <(options)> <...plot-request <(options)>>>

controls the plots that are produced using ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses around it.

Here are some examples:

```
plots=none
plots=all
plots=residuals(acf loess)
plots(noclm)=(smooth(decomp) residual(panel loess))
```

For general information about ODS Graphics, see Chapter 24, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

```
proc ucm;
  model y = x;
  irregular;
  level;
run;

proc ucm plots=all;
  model y = x;
  irregular;
  level;
run;
```

The first PROC UCM step does not specify the PLOTS= option, so the default plot that displays the series forecasts in the forecast region is produced. The PLOTS=ALL option in the second PROC UCM step produces all the plots that are appropriate for the specified model.

In addition to the PLOTS= option in the PROC UCM statement, you can produce plots by using the PLOT= option in other statements of the UCM procedure. This way of producing plots provides finer

control over the plot production. If you do not specify any specific plot request, then PROC UCM produces the plot of series forecasts in the forecast horizon by default.

Global Plot Options

The *global-plot-options* apply to all relevant plots generated by the UCM procedure. You can specify the following *global-plot-option*:

NOCLM

suppresses the confidence limits in all the component and forecast plots.

Specific Plot Options

The following list describes the specific plots that you can specify and their options:

ALL

produces all plots appropriate for the particular analysis.

FILTER (< filter-plot-options >)

produces time series plots of the filtered component estimates. You can specify the following *filter-plot-options*:

ALL

produces all the filtered component estimate plots appropriate for the particular analysis.

CYCLE

produces time series plots of the filtered cycle component estimates for all cycle components in the model, if there are any.

DECOMP

produces time series plots of the filtered estimates of the series decomposition.

LEVEL

produces a time series plot of the filtered level component estimate, provided that the model contains the level component.

SEASON

produces time series plots of the filtered season component estimates for all seasonal components in the model, if there are any.

SLOPE

produces a time series plot of the filtered slope component estimate, provided that the model contains the slope component.

RESIDUAL (< residual-plot-options >)

produces the residuals plots. You can specify the following *residual-plot-options*:

ALL

produces all the residual diagnostics plots appropriate for the particular analysis.

ACF

produces the autocorrelation plot of residuals.

CUSUM

produces the plot of cumulative residuals against time.

CUSUMSQ

produces the plot of cumulative squared residuals against time.

HISTOGRAM

produces the histogram of residuals.

LOESS

produces a scatter plot of residuals against time, which has an overlaid loess fit.

PACF

produces the partial-autocorrelation plot of residuals.

PANEL

produces a summary panel of the residual diagnostics that consists of the following:

- histogram of residuals
- normal quantile plot of residuals
- residual-autocorrelation plot
- residual-partial-autocorrelation plot

QQ

produces a normal quantile plot of residuals.

RESIDUAL

produces a needle plot of residuals against time.

WN

produces the plot of Ljung-Box white-noise test p -values at different lags (in log scale).

SMOOTH (< smooth-plot-options >)

produces time series plots of the smoothed component estimates. You can specify the following *smooth-plot-options*:

ALL

produces all the smoothed component estimate plots appropriate for the particular analysis.

CYCLE

produces time series plots of the smoothed cycle component estimates for all cycle components in the model, if there are any.

DECOMP

produces time series plots of the smoothed estimates of the series decomposition.

LEVEL

produces a time series plot of the smoothed level component estimate, provided that the model contains the level component.

SEASON

produces time series plots of the smoothed season component estimates for all season components in the model, if there are any.

SLOPE

produces a time series plot of the smoothed slope component estimate, provided that the model contains the slope component.

NONE

suppresses all plots.

PRINTALL

turns on all the printing options for the procedure. Any subsequent NOPRINT options in the procedure are ignored.

AUTOREG Statement

AUTOREG <options> ;

The AUTOREG statement specifies an autoregressive component in the model. An autoregressive component is a special case of cycle that corresponds to the frequency of 0 or π . It is modeled separately for easier interpretation. A stochastic equation for an autoregressive component r_t can be written as follows:

$$r_t = \rho r_{t-1} + v_t, \quad v_t \sim \text{iid } N(0, \sigma_v^2)$$

The damping factor ρ can take any value in the interval $(-1, 1)$, including -1 but excluding 1 . If $\rho = 1$, the autoregressive component cannot be distinguished from the random walk level component. If $\rho = -1$, the autoregressive component corresponds to a seasonal component with a season length of 2, or a nonstationary cycle with period 2. If $|\rho| < 1$, then the autoregressive component is stationary. The following example illustrates the AUTOREG statement. This statement includes an autoregressive component in the model. The damping factor ρ and the disturbance variance σ_v^2 are estimated from the data.

autoreg;

You can specify the following *options*:

NOEST=RHO**NOEST=VARIANCE****NOEST=(RHO VARIANCE)**fixes the values of ρ and σ_v^2 to those specified in the **RHO=** and **VARIANCE=** options.**PLOT=FILTER****PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

plots the filtered or smoothed estimate of the autoreg component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

prints the filtered or smoothed estimate of the autoreg component.

RHO=valuespecifies an initial value for the damping factor ρ during the parameter estimation process. The value of ρ must be in the interval $(-1, 1)$, including -1 but excluding 1 .**VARIANCE=value**specifies an initial value for the disturbance variance σ_v^2 during the parameter estimation process. Any nonnegative value, including 0 , is an acceptable starting value.

BLOCKSEASON Statement

BLOCKSEASON NBLOCKS=integer BLOCKSIZE=integer < options > ;

The **BLOCKSEASON** or **BLOCKSEASONAL** statement is used to specify a seasonal component γ_t that has a special block structure. The seasonal γ_t is called a *block seasonal* of block size m and number of blocks k if its season length, s , can be factored as $s = m * k$ and its seasonal effects have a block form—that is, the first m seasonal effects are all equal to some number τ_1 , the next m effects are all equal to some number τ_2 , and so on.

This type of seasonal structure can be appropriate in some cases; for example, consider a series that is recorded on an hourly basis. Further assume that, in this particular case, the hour-of-the-day effect and the day-of-the-week effect are additive. In this situation the hour-of-the-week seasonality, having a season length of 168 , can be modeled as a sum of two components. The hour-of-the-day effect is modeled using a simple seasonal of season length 24 , while the day-of-the-week is modeled as a block seasonal component that has the days of the week as blocks. This day-of-the-week block seasonal component has seven blocks, each of size 24 .

A block seasonal specification requires, at the minimum, the block size m and the number of blocks in the seasonal k . These are specified using the **BLOCKSIZE=** and **NBLOCKS=** option, respectively. In addition, you might need to specify the position of the first observation of the series by using the **OFFSET=** option if it is not at the beginning of one of the blocks. In the example just considered, this corresponds to a situation where the first series measurement is not at the start of the day. Suppose that the first measurement of the series corresponds to the hour between 6:00 and 7:00 a.m., which is the seventh hour within that day or at the seventh position within that block. This is specified as **OFFSET=7**.

The other options in this statement are very similar to the options in the SEASON statement; for example, a block seasonal can also be of one of the two types, DUMMY and TRIG. There can be more than one block seasonal component in the model, each specified using a separate BLOCKSEASON statement. No two block seasonals in the model can have the same NBLOCKS= and BLOCKSIZE= specifications. The following example illustrates the use of the BLOCKSEASON statement to specify the additive, hour-of-the-week seasonal model:

```
season length=24 type=trig;
blockseason nblocks=7 blocksize=24;
```

You must specify the following *options*:

BLOCKSIZE=integer

specifies the block size, m . The block size can be any integer greater than or equal to 2. Typical examples of block sizes are 24, corresponding to the hours of the day when a day is being used as a block in hourly data, or 60, corresponding to the minutes in an hour when an hour is being used as a block in data recorded by minutes, and so on.

NBLOCKS=integer

specifies the number of blocks, k . The number of blocks can be any integer greater than or equal to 2.

You can also specify the following *options*:

NOEST

fixes the value of the disturbance variance parameter to the value specified in the **VARIANCE=** option.

OFFSET=integer

specifies the position of the first measurement within the block, if the first measurement is not at the start of a block. The OFFSET= value must be between 1 and the block size. By default, OFFSET=1. The first measurement refers to the start of the estimation span and the forecast span. If these spans differ, their starting measurements must be separated by an integer multiple of the block size.

PLOT=FILTER

PLOT=SMOOTH

PLOT=F_ ANNUAL

PLOT=S_ ANNUAL

PLOT=(< plot-request > ... < plot-request >)

plots the season component. When you specify only one *plot-request*, you can omit the parentheses around it. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the season component γ_t . You can use the F_ ANNUAL and S_ ANNUAL options to get the plots of “annual” variation in the filtered and smoothed estimates of γ_t . The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here “month” and “year” are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years. The first period in each block is plotted over the years.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**prints the filtered or smoothed estimate of the block seasonal component γ_t .**TYPE=DUMMY | TRIG**

specifies the type of the block seasonal component. By default, TYPE=DUMMY.

VARIANCE=valuespecifies an initial value for the disturbance variance, σ_ω^2 , in the γ_t equation at the start of the parameter estimation process. Any nonnegative value, including 0, is an acceptable starting value.

BY Statement

BY variables ;

You can use a BY statement in the UCM procedure to process a data set in groups of observations defined by the BY variables. The model that you specify using the MODEL statement and other component statements is applied to all the groups defined by the BY variables. The variables are one or more variables in the input SAS table.

CYCLE Statement

CYCLE < options > ;

The CYCLE statement is used to specify a cycle component, ψ_t , in the model. The stochastic equation governing a cycle component of period p and damping factor ρ is

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} \nu_t \\ \nu_t^* \end{bmatrix}$$

where ν_t and ν_t^* are independent, zero-mean, Gaussian disturbances with variance σ_ν^2 and $\lambda = 2 * \pi / p$ is the angular frequency of the cycle. Any p strictly greater than 2 is an admissible value for the period, and the damping factor ρ can be any value in the interval (0, 1), including 1 but excluding 0. The cycles with frequency 0 and π , which correspond to the periods equal to infinity and 2, respectively, can be specified using the AUTOREG statement. The values of ρ less than 1 give rise to a stationary cycle, while $\rho = 1$ gives rise to a nonstationary cycle. As a default, values of ρ , p , and σ_ν^2 are estimated from the data. However, if necessary, you can fix the values of some or all of these parameters.

There can be multiple cycles in a model, each specified using a separate CYCLE statement. The examples that follow illustrate the use of the CYCLE statement.

The following statements add two cycles in the model. The parameters of each of these cycles are estimated from the data.

```
cycle;
cycle;
```

The following statement adds a nonstationary cycle in the model. The cycle period p and the disturbance variance σ_v^2 are estimated from the data.

```
cycle rho=1 noest=rho;
```

In the following statement, a nonstationary cycle with a fixed period of 12 is specified. Moreover, a starting value is supplied for σ_v^2 .

```
cycle period=12 rho=1 variance=4 noest=(rho period);
```

You can specify the following *options*:

NOEST=PERIOD

NOEST=RHO

NOEST=VARIANCE

NOEST=(< RHO > < PERIOD > < VARIANCE >)

fixes the values of the component parameters to those specified in the **RHO=**, **PERIOD=**, and **VARIANCE=** options. This option enables you to fix any combination of parameter values.

ORDER=integer

enables you to specify a higher-order cycle. A higher-order cycle (a cycle whose order is greater than 1) is a generalization of the stochastic cycle described at the beginning of this section, which can be thought of as a first-order cycle. Higher-order cycles are well explained in Trimbur (2005) and Pelagatti (2015, sect. 3.3.3). A cycle whose order is greater than 2 is rarely needed, and specifying cycles of large orders (for example, an order greater than 4) can lead to computational instability. See [Example 30.9](#) for an example of the use of higher-order cycles.

PERIOD=value

specifies an initial value for the cycle period during the parameter estimation process. Period value must be strictly greater than 2.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

plots the filtered or smoothed estimate of the cycle component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

prints a filtered or smoothed estimate of the cycle component ψ_t .

RHO=value

specifies an initial value for the damping factor in this component during the parameter estimation process. Any value in the interval (0, 1), including 1 but excluding 0, is an acceptable initial value for the damping factor.

VARIANCE=value

specifies an initial value for the disturbance variance parameter, σ_v^2 , to be used during the parameter estimation process. Any nonnegative value, including 0, is an acceptable starting value.

DEPLAG Statement

DEPLAG LAGS=order < PHI=value ... > NOEST > ;

The DEPLAG statement is used to specify the lags of the dependent variable to be included as predictors in the model. The following examples illustrate the use of the DEPLAG statement.

If the dependent series is denoted by y_t , the following statement specifies the inclusion of $\phi_1 y_{t-1} + \phi_2 y_{t-2}$ in the model. The parameters ϕ_1 and ϕ_2 are estimated from the data.

```
deplag lags=2;
```

The following statement includes $\phi_1 y_{t-1} + \phi_2 y_{t-4} - \phi_1 \phi_2 y_{t-5}$ in the model. The values of ϕ_1 and ϕ_2 are fixed at 0.8 and -1.2, respectively.

```
deplag lags=(1) (4) phi=0.8 -1.2 noest;
```

The dependent lag parameters are not constrained to lie in any particular region. In particular, this implies that a UCM that contains only an irregular component and dependent lags, resulting in a traditional autoregressive model, is not constrained to be a stationary model. In the DEPLAG statement, if an initial value is supplied for any one of the parameters, the initial values must also be supplied for all other parameters.

You must specify the following option:

LAGS=order

LAGS=(lag, ..., lag) ... (lag, ..., lag)

specifies lags of the dependent variable. $\text{LAGS}=(l_1, l_2, \dots, l_k)$ defines a model with specified lags of the dependent variable included as predictors. LAGS=order is equivalent to $\text{LAGS}=(1, 2, \dots, \text{order})$.

A concatenation of parenthesized lists specifies a factored model. For example, $\text{LAGS}=(1)(12)$ specifies that the lag values, 1, 12, and 13, corresponding to the following polynomial in the backward shift operator, be included in the model:

$$(1 - \phi_{1,1}B)(1 - \phi_{2,1}B^{12})$$

Note that, in this case, the coefficient of the 13th lag is constrained to be the product of the coefficients of the 1st and 12th lags.

You can also specify the following *options*:

NOEST

fixes the values of the parameters to those specified in **PHI=** option.

PHI=value ...

lists starting values for the coefficients of the lagged dependent variable. The order of the values listed corresponds with the order of the lags specified in the **LAGS=** option.

ESTIMATE Statement

ESTIMATE <options> ;

The ESTIMATE statement is an optional statement used to control the overall model-fitting environment. Using this statement, you can control the span of observations used to fit the model by using the **SKIPFIRST=** and **BACK=** options. This can be useful in model diagnostics. You can request a variety of goodness-of-fit statistics and other model diagnostic information including different residual diagnostic plots. Note that the ESTIMATE statement is not used to control the nonlinear optimization process itself. That is done using the **NLOPTIONS** statement, where you can control the number of iterations, choose between the different optimization techniques, and so on. You can save the estimated parameters and other related information in a SAS table by using the **OUTEST=** option. You can request the optimization of the profile likelihood, the likelihood obtained by concentrating out a disturbance variance, for parameter estimation by using the **PROFILE** option. The following example illustrates the use of this statement:

```
estimate skipfirst=12 back=24;
```

This statement requests that the initial 12 measurements and the last 24 measurements be excluded during the model-fitting process. The actual observation span used to fit the model is decided as follows: Suppose that n_0 and n_1 are the observation numbers of the first and last nonmissing values of the response variable, respectively. As a result of specifying **SKIPFIRST=12** and **BACK=24**, the measurements between observation numbers $n_0 + 12$ and $n_1 - 24$ form the estimation span. Of course, the model fitting might not take place if there are insufficient data in the resulting span. The model fitting does not take place if there are regressors in the model that have missing values in the estimation span.

You can specify the following *options*:

BACK=integer

SKIPLAST=integer

indicates that some ending part of the data needs to be ignored during the parameter estimation. This can be useful when you want to study the forecasting performance of a model on the observed data. When **BACK=10**, the last 10 measurements of the response series are skipped during the parameter estimation. By default, **BACK=0**.

EXTRADIFFUSE=k

enables continuation of the diffuse filtering iterations for k additional iterations beyond the first instance where the initialization of the diffuse state would have otherwise taken place. If the specified k is larger than the sample size, the diffuse iterations continue until the end of the sample. Note that one-step-ahead residuals are produced only after the diffuse state is initialized. Delaying the initialization leads to a reduction in the number of one-step-ahead residuals available for computing the residual diagnostic measures. This option is useful when you want to ignore the first few one-step-ahead residuals that often have large variance.

LIKE=DIFFUSE | MARGINAL

specifies the type of likelihood to use for parameter estimation. You can specify the following values:

DIFFUSE	uses diffuse likelihood.
MARGINAL	uses marginal likelihood.

By default, LIKE=DIFFUSE. For more information about likelihood types, see the section “[Likelihood Computation and Model-Fitting Phase](#)” on page 769 in Chapter 14, “[CSSM Procedure](#).” For an example of the use of LIKE=MARGINAL option, see [Example 30.10](#).

NOPROFILE

requests that the usual likelihood be optimized for parameter estimation. For more information, see the section “[Parameter Estimation by Profile Likelihood Optimization](#)” on page 2174.

OUTEST=libref.data-table

specifies an output SAS table for the estimated parameters. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 2114.

PLOT=plot-request**PLOT=(<plot-request> ... <plot-request>)**

produces residual diagnostic plots. You can specify the following *plot-requests*:

ACF

produces a residual-autocorrelation plot.

CUSUM

produces a plot of cumulative residuals against time.

CUSUMSQ

produces a plot of cumulative squared residuals against time.

HISTOGRAM

produces a histogram of residuals.

LOESS

produces a scatter plot of residuals against time, which has an overlaid loess fit.

MODEL

produces a plot of one-step-ahead forecasts in the estimation span.

PACF

produces a residual-partial-autocorrelation plot.

PANEL

produces a summary panel of the residual diagnostics that consists of the following:

- histogram of residuals
- normal quantile plot of residuals
- residual-autocorrelation plot
- residual-partial-autocorrelation plot

QQ

produces a normal quantile plot of residuals.

RESIDUAL

produces a needle plot of residuals against time.

WN

produces a plot of p -values, in log scale, at different lags for the Ljung-Box portmanteau white-noise test statistics.

PRINT=NONE

suppresses all the printed output related to the model fitting, such as the parameter estimates, the goodness-of-fit statistics, and so on.

PROFILE

requests that the profile likelihood, obtained by concentrating out one of the disturbance variances from the likelihood, be optimized for parameter estimation. By default, the profile likelihood is not optimized if any of the disturbance variance parameters is held fixed to a nonzero value. For more information see the section “[Parameter Estimation by Profile Likelihood Optimization](#)” on page 2174.

SKIPFIRST=integer

indicates that some early part of the data needs to be ignored during the parameter estimation. This can be useful if there is a reason to believe that the model being estimated is not appropriate for this portion of the data. When SKIPFIRST=10, the first 10 measurements of the response series are skipped during the parameter estimation. By default, SKIPFIRST=0.

FORECAST Statement

FORECAST <options> ;

The FORECAST statement is an optional statement that is used to specify the overall forecasting environment for the specified model. It can be used to specify the span of observations, the historical period, to be used to compute the forecasts of the future observations. This is done using the SKIPFIRST= and BACK= options. The number of periods to forecast beyond the historical period, and the significance level of the forecast confidence interval, is specified using the LEAD= and ALPHA= options. You can request one-step-ahead series and component forecasts by using the PRINT= option. You can save the series forecasts, and the model-based decomposition of the series, in a SAS table by using the OUTFOR= option. The following example illustrates the use of this statement:

```
forecast skipfirst=12 back=24 lead=30;
```

This statement requests that the initial 12 and the last 24 response values be excluded during the forecast computations. The forecast horizon, specified using the LEAD= option, is 30 periods; that is, multistep forecasting begins at the end of the historical period and continues for 30 periods. The actual observation span that is used to compute the multistep forecasting is determined as follows: Suppose that n_0 and n_1 are the observation numbers of the first and the last nonmissing values of the response variable, respectively. As a result of specifying SKIPFIRST=12 and BACK=24, the historical period, or the forecast span, begins at $n_0 + 12$ and ends at $n_1 - 24$. Multistep forecasts are produced for the next 30 periods—that is, for the

observation numbers $n_1 - 23$ to $n_1 + 6$. Of course, the forecast computations can fail if the model has regressor variables that have missing values in the forecast span. If the regressors contain missing values in the forecast horizon—that is, between the observations $n_1 - 23$ and $n_1 + 6$ —the forecast horizon is reduced accordingly.

You can specify the following *options*:

ALPHA=*value*

specifies the significance level of the forecast confidence intervals; for example, ALPHA=0.05, which is the default, results in a 95% confidence interval.

BACK=*integer*

SKIPLAST=*integer*

specifies the holdout sample for the evaluation of the forecasting performance of the model. For example, BACK=10 results in treating the last 10 observed values of the response series as unobserved. A post-sample-prediction-analysis table is produced for comparing the predicted values with the actual values in the holdout period. By default, BACK=0.

EXTRADIFFUSE=*k*

enables continuation of the diffuse filtering iterations for *k* additional iterations beyond the first instance where the initialization of the diffuse state would have otherwise taken place. If the specified *k* is larger than the sample size, the diffuse iterations continue until the end of the sample. Note that one-step-ahead forecasts are produced only after the diffuse state is initialized. Delaying the initialization leads to reduction in the number of one-step-ahead forecasts. This option is useful when you want to ignore the first few one-step-ahead forecasts that often have large variance.

LEAD=*integer*

specifies the number of periods to forecast beyond the historical period defined by the SKIPFIRST= and BACK= options; for example, LEAD=10 results in the forecasting of 10 future values of the response series. By default, LEAD=12.

OUTFOR=*libref.data-table*

specifies an output SAS table for the forecasts. The output SAS table contains the ID variable, the response and predictor series, the one-step-ahead and out-of-sample response series forecasts, the forecast confidence intervals, the smoothed values of the response series, and the smoothed forecasts produced as a result of the model-based decomposition of the series. *libref.data-table* is a two-level name, where *libref* refers to the library, and *data-table* specifies the name of the output data table. For more information about this two-level name, see the section “[Using CAS Sessions and CAS Engine Librefs](#)” on page 2114.

PLOT=*plot-request*

PLOT=(*< plot-request > ... < plot-request >*)

produces forecast and model decomposition plots. You can specify the following *plot-requests*:

DECOMP

produces smoothed decomposition plots.

DECOMPVAR

produces plots of the variance of smoothed decomposition.

FDECOMP

produces filtered decomposition plots.

FDECOMPVAR

produces plots of the variance of filtered decomposition.

FORECASTS

produces a plot of series forecasts.

TREND

produces a plot of smoothed trend.

By default, a plot of multistep-ahead series forecasts in the post-sample region is produced.

PRINT=*print-request*

PRINT=(*< print-request > ... < print-request >*)

controls the printing of the series forecasts and the printing of smoothed model decomposition estimates. By default, the series forecasts are printed only for the forecast horizon that you specify in the **LEAD**= option; that is, the one-step-ahead predicted values are not printed. You can specify the following *print-requests*:

DECOMP

prints smoothed estimates of the trend, the trend plus regression, the trend plus regression plus cycle, and the sum of all components except the irregular.

FDECOMP

prints filtered estimates of the trend, the trend plus regression, the trend plus regression plus cycle, and the sum of all components except the irregular.

FORECASTS

prints forecasts for the entire forecast span.

NONE

suppress the printing of all the forecast output.

By default, a table of multistep-ahead series forecasts in the post-sample region is produced.

SKIPFIRST=*integer*

specifies that an early portion of the data needs to be ignored during the forecasting calculations. This can be useful if there is a reason to believe that the model that you are using for forecasting is not appropriate for this portion of the data. If you specify an *integer* value of 10, the first 10 measurements of the response series are skipped during the forecasting calculations. By default, SKIPFIRST=0.

ID Statement

ID *variable* INTERVAL=*value* < ALIGN=*value* > ;

The ID statement names a numeric variable that identifies observations in the input and output data sets. This statement is required. The values of the ID *variable* are assumed to be SAS date, time, or datetime values, or the ID *variable* values can signify the observation numbers within a sequence, such as 5 to indicate the fifth observation (for an example of an observation index as an ID variable, see [Example 30.2](#)). In addition, the ID statement specifies the frequency that is associated with the time series. The options also specify how to align the observations to form the time series. The INTERVAL= option is required. The values of the ID *variable* are extrapolated for the forecast observations on the basis of the values that you specify in the INTERVAL= option.

You must specify the following option:

INTERVAL=*value*

specifies the time interval between observations. This option is used in conjunction with the ID *variable* to verify that the input data are in the proper order and have no gaps. The option is also used to extrapolate the ID values past the end of the input data. For an ID variable that signifies the observation number within a sequence, specify INTERVAL=OBS. For more information about the supported intervals, see Chapter 4, “Date Intervals, Formats, and Functions” (*SAS/ETS User’s Guide*).

You can also specify the following option:

ALIGN=*value*

controls the alignment of SAS dates that are used to identify output observations. You can specify the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. The default is BEGINNING. The ALIGN= option is used to align the ID variable with the beginning, middle, or end of the time ID interval that you specify in the INTERVAL= option.

IRREGULAR Statement

IRREGULAR < *options* > ;

The IRREGULAR statement includes an irregular component in the model. There can be at most one IRREGULAR statement in the model specification. The irregular component corresponds to the overall random error ϵ_t in the model. By default, the irregular component is modeled as white noise—that is, as a sequence of independent, identically distributed, zero-mean, Gaussian random variables. However, you can also model it as an autoregressive moving average (ARMA) process. The options for specifying an ARMA model for the irregular component are given in the section “[ARMA Specification](#)” on page 2141.

The options in this statement enable you to specify the model for the irregular component and to output its estimates. Two examples of the IRREGULAR statement follow. In the first example, the statement is in its simplest form, resulting in the inclusion of an irregular component that is white noise with unknown variance:

```
irregular;
```

In the second example, the following statement provides a starting value for the white-noise variance σ_ϵ^2 to be used in the nonlinear parameter estimation process. It also prints smoothed estimates of ϵ_t . The smoothed irregulars are useful in model diagnostics.

```
irregular variance=4 print=smooth;
```

You can specify the following *options*:

NOEST

sets the value of σ_ϵ^2 to the value that you specify in the **VARIANCE=** option. Also see the **NOEST=** option in the section “[ARMA Specification](#)” on page 2141.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(< FILTER > < SMOOTH >)

plots the filtered or smoothed estimate of the irregular component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(< FILTER > < SMOOTH >)

prints the filtered or smoothed estimate of the irregular component.

VARIANCE=value

specifies an initial value for σ_ϵ^2 during the parameter estimation process. Any nonnegative value, including 0, is an acceptable starting value.

ARMA Specification

This section details the options for specifying an ARMA model for the irregular component. The specification of ARMA models requires some notation, which is explained first.

Let B denote the backshift operator—that is, for any sequence ϵ_t , $B\epsilon_t = \epsilon_{t-1}$. The higher powers of B represent larger shifts (for example, $B^3\epsilon_t = \epsilon_{t-3}$). A random sequence ϵ_t follows a zero-mean $\text{ARMA}(p,q) \times (P,Q)_s$ model with nonseasonal autoregressive order p , seasonal autoregressive order P , nonseasonal moving average order q , and seasonal moving average order Q , if it satisfies the following difference equation specified in terms of the polynomials in the backshift operator, where a_t is a white-noise sequence and s is the season length:

$$\phi(B)\Phi(B^s)\epsilon_t = \theta(B)\Theta(B^s)a_t$$

The polynomials ϕ , Φ , θ , and Θ are of orders p , P , q , and Q , respectively, which can be any nonnegative integers. The season length s must be a positive integer. For example, ϵ_t satisfies an $\text{ARMA}(1,1)$ model (that

is, $p = 1, q = 1, P = 0$, and $Q = 0$) if

$$\epsilon_t = \phi_1 \epsilon_{t-1} + a_t - \theta_1 a_{t-1}$$

for some coefficients ϕ_1 and θ_1 and a white-noise sequence a_t . Similarly, ϵ_t satisfies an $\text{ARMA}(1,1) \times (1,1)_{12}$ model if

$$\epsilon_t = \phi_1 \epsilon_{t-1} + \Phi_1 \epsilon_{t-12} - \phi_1 \Phi_1 \epsilon_{t-13} + a_t - \theta_1 a_{t-1} - \Theta_1 a_{t-12} + \theta_1 \Theta_1 a_{t-13}$$

for some coefficients ϕ_1, Φ_1, θ_1 , and Θ_1 and a white-noise sequence a_t . The ARMA process is stationary and invertible if the defining polynomials ϕ, Φ, θ , and Θ have all their roots outside the unit circle—that is, their absolute values are strictly larger than 1.0. It is assumed that the ARMA model specified for the irregular component is stationary and invertible—that is, the coefficients of the polynomials ϕ, Φ, θ , and Θ are constrained so that the stationarity and invertibility conditions are satisfied. The unknown coefficients of these polynomials become part of the model parameter vector that is estimated using the data.

The notation for a closely related class of models, autoregressive integrated moving average (ARIMA) models, is also given here. A random sequence y_t is said to follow an $\text{ARIMA}(p,d,q) \times (P,D,Q)_s$ model if, for some nonnegative integers d and D , the differenced series $\epsilon_t = (1 - B)^d (1 - B^s)^D y_t$ follows an $\text{ARMA}(p,q) \times (P,Q)_s$ model. The integers d and D are called nonseasonal and seasonal differencing orders, respectively. You can specify ARIMA models by using the **DEPLAG** statement for specifying the differencing orders and by using the **IRREGULAR** statement for the ARMA specification. For an example of $\text{ARIMA}(0,1,1) \times (0,1,1)_{12}$ model specification, see [Example 30.8](#). Brockwell and Davis (1991) can be consulted for additional information about ARIMA models.

You can use options of the **IRREGULAR** statement to specify the desired ARMA model and to request printed and graphical output. A few examples of the **IRREGULAR** statement are given next.

The following statement specifies an irregular component that is modeled as an $\text{ARMA}(1,1)$ process. It also requests plotting its smoothed estimate.

```
irregular p=1 q=1 plot=smooth;
```

The following statement specifies an $\text{ARMA}(1,1) \times (1,1)_{12}$ model. It also fixes the coefficient of the first-order seasonal moving average polynomial to 0.1. The other coefficients and the white-noise variance are estimated using the data.

```
irregular p=1 sp=1 q=1 sq=1 s=12 sma=0.1 noest=(sma);
```

You can specify the following ARMA model options:

AR= $\phi_1 \phi_2 \dots \phi_p$

lists the starting values of the coefficients of the nonseasonal autoregressive polynomial

$$\phi(B) = 1 - \phi_1 B - \dots - \phi_p B^p$$

where the order p is specified in the **P=** option. The coefficients ϕ_i must define a stationary autoregressive polynomial.

MA= $\theta_1 \theta_2 \dots \theta_q$

lists the starting values of the coefficients of the nonseasonal moving average polynomial

$$\theta(B) = 1 - \theta_1 B - \dots - \theta_q B^q$$

where the order q is specified in the **Q=** option. The coefficients θ_i must define an invertible moving average polynomial.

NOEST=(**<VARIANCE>** **<AR>** **<SAR>** **<MA>** **<SMA>**)

fixes the values of the ARMA parameters and the value of the white-noise variance to those specified in the **AR=**, **SAR=**, **MA=**, **SMA=**, or **VARIANCE=** option.

P=integer

specifies the order of the nonseasonal autoregressive polynomial. The order can be any nonnegative integer; by default, $P=0$. In practice, the order is a small integer such as 1, 2, or 3.

Q=integer

specifies the order of the nonseasonal moving average polynomial. The order can be any nonnegative integer; by default, $Q=0$. In practice, the order is a small integer such as 1, 2, or 3.

S=integer

specifies the season length used during the specification of the seasonal autoregressive or seasonal moving average polynomial. The season length can be any positive integer; for example, $S=4$ might be an appropriate value for a quarterly series. By default, $S=1$.

SAR= $\Phi_1 \Phi_2 \dots \Phi_P$

lists the starting values of the coefficients of the seasonal autoregressive polynomial

$$\Phi(B^S) = 1 - \Phi_1 B^S - \dots - \Phi_P B^{SP}$$

where the order P is specified in the **SP=** option and the season length s is specified in the **S=** option. The coefficients Φ_i must define a stationary autoregressive polynomial.

SMA= $\Theta_1 \Theta_2 \dots \Theta_Q$

lists the starting values of the coefficients of the seasonal moving average polynomial

$$\Theta(B^S) = 1 - \Theta_1 B^S - \dots - \Theta_Q B^{SQ}$$

where the order Q is specified in the **SQ=** option and the season length s is specified in the **S=** option. The coefficients Θ_i must define an invertible moving average polynomial.

SP=integer

specifies the order of the seasonal autoregressive polynomial. The order can be any nonnegative integer; by default, $SP=0$. In practice, the order is a small integer such as 1 or 2.

SQ=integer

specifies the order of the seasonal moving average polynomial. The order can be any nonnegative integer; by default, $SQ=0$. In practice, the order is a small integer such as 1 or 2.

LEVEL Statement

LEVEL <options> ;

The LEVEL statement is used to include a level component in the model. The level component, either by itself or together with a slope component (see the **SLOPE** statement), forms the trend component, μ_t , of the model. If the slope component is absent, the resulting trend is a random walk (RW) specified by the following equations:

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim \text{iid } N(0, \sigma_\eta^2)$$

If the slope component is present, signified by the presence of a **SLOPE** statement, a locally linear trend (LLT) is obtained. The equations of LLT are as follows:

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim \text{iid } N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim \text{iid } N(0, \sigma_\xi^2) \end{aligned}$$

In either case, the options in the LEVEL statement are used to specify the value of σ_η^2 and to request forecasts of μ_t . The SLOPE statement is used for similar purposes in the case of slope β_t . The following examples illustrate the use of the LEVEL statement. Assuming that a SLOPE statement is not added subsequently, a simple random walk trend is specified by the following statement:

```
level;
```

The following statements specify a locally linear trend with value of σ_η^2 fixed at 4. It also requests printing of filtered values of μ_t . The value of σ_ξ^2 , the disturbance variance in the slope equation, is estimated from the data.

```
level variance=4 noest print=filter;
slope;
```

You can specify the following *options*:

CHECKBREAK

turns on the checking of breaks in the level component.

NOEST

fixes the value of σ_η^2 to the value specified in the **VARIANCE=** option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(<FILTER> <SMOOTH>)

plots the filtered or smoothed estimate of the level component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

prints the filtered or smoothed estimate of the level component.

VARIANCE=*value*specifies an initial value for σ_{η}^2 , the disturbance variance in the μ_t equation at the start of the parameter estimation process. Any nonnegative value, including 0, is an acceptable starting value.

MODEL Statement

MODEL *dependent variable* <= *regressors* > ;

The MODEL statement specifies the response variable and, optionally, the predictor or regressor variables for the UCM model. This is a required statement in the UCM procedure. The predictors specified in the MODEL statement are assumed to have a linear and time-invariant relationship with the response. The predictors that have time-varying regression coefficients are specified separately in the [RANDOMREG](#) statement. Similarly, the predictors that have a nonlinear effect on the response variable are specified separately in the [SPLINEREG](#) statement. Only one MODEL statement can be specified.

NLOPTIONS Statement

NLOPTIONS < *options* > ;

PROC UCM uses the nonlinear optimization (NLO) subsystem to perform the nonlinear optimization of the likelihood function during the estimation of model parameters. You can use the NLOPTIONS statement to control different aspects of this optimization process. For most problems, the default settings of the optimization process are adequate. However, in some cases it might be useful to change the optimization technique or to change the maximum number of iterations. You can do this as follows by using the TECH= and MAXITER= options in the NLOPTIONS statement:

```
nloptions tech=dbldog maxiter=200;
```

This statement sets the maximum number of iterations to 200 and changes the optimization technique to DBLDOG rather than the default technique, TRUREG, that PROC UCM uses. For more information about the options that you can specify in the NLOPTIONS statement, see Chapter 6, “Nonlinear Optimization Methods” (*SAS/ETS User’s Guide*). In this version of PROC UCM, the user can specify only the TECH= and MAXITER= options; all other options remain at their default settings.

OUTLIER Statement

OUTLIER < options > ;

The OUTLIER statement enables you to control the reporting of the additive outliers (AO) and level shifts (LS) in the response series. The AOs are searched by default. You can search for LSs by using the [CHECKBREAK](#) option in the LEVEL statement.

You can specify the following *options*:

ALPHA=*significance-level*

specifies the significance level for reporting the outliers. By default, ALPHA=0.05.

MAXNUM=*number*

specifies the number of outliers to search for. By default, MAXNUM=5.

MAXPCT=*number*

is similar to the MAXNUM= option. The MAXPCT= option enables you to limit the number of outliers to search for according to a percentage of the series length. By default, MAXPCT=1.

NOTE: The number of outliers that are searched for is always the lower of the two numbers implied by the MAXNUM= and MAXPCT= options, regardless of whether they are explicitly specified or set to their defaults.

PRINT=SHORT | DETAIL

controls the printed output of the outlier search. The PRINT=SHORT option, which is the default, produces an outlier summary table that contains the most significant outliers, either AO or LS, that the outlier search finds. The PRINT=DETAIL option produces, in addition to the outlier summary table, separate tables that contain the AO and LS structural break chi-square statistics that are computed at each time point in the estimation span.

RANDOMREG Statement

RANDOMREG *regressors* < / options > ;

The RANDOMREG statement is used to specify regressors with time-varying regression coefficients. Each regression coefficient—for example, β_t —is assumed to evolve as a random walk:

$$\beta_t = \beta_{t-1} + \eta_t, \quad \eta_t \sim \text{iid } N(0, \sigma^2)$$

Of course, if the random walk disturbance variance σ^2 is 0, then the regression coefficient is not time-varying, and it reduces to the standard regression setting. There can be multiple RANDOMREG statements, and each statement can contain one or more regressors. The regressors in a given RANDOMREG statement form a group that is assumed to share the same disturbance variance parameter. The random walks associated with different regressors are assumed to be independent. For an example of using this statement, see [Example 30.4](#). For additional information about how estimates are reported for this type of regressors, see the section “Reporting Parameter Estimates for Random Regressors” on page 2170.

You can specify the following *options*:

NOEST

fixes the value of σ^2 to the value specified in the **VARIANCE=** option.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

plots the filtered or smoothed estimate of the time-varying regression coefficient.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

prints the filtered or smoothed estimate of the time-varying regression coefficient.

VARIANCE=*value*

specifies an initial value for σ^2 during the parameter estimation process. Any nonnegative value, including 0, is an acceptable starting value.

SEASON Statement

SEASON LENGTH=*integer* < *options* > ;

The SEASON or SEASONAL statement is used to specify a seasonal component, γ_t , in the model. A seasonal component can be one of the two types, DUMMY or TRIG. A DUMMY seasonal with season length s satisfies the following stochastic equation:

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \quad \omega_t \sim \text{iid } N(0, \sigma_\omega^2)$$

The equations for a TRIG (short for trigonometric) seasonal component are as follows

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if s is even and $(s-1)/2$ if it is odd. The sinusoids, also called harmonics, $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma_{j,t}^* \end{bmatrix} = \begin{bmatrix} \cos \lambda_j & \sin \lambda_j \\ -\sin \lambda_j & \cos \lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma_{j,t-1}^* \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega_{j,t}^* \end{bmatrix}$$

where the disturbances $\omega_{j,t}$ and $\omega_{j,t}^*$ are assumed to be independent and, for fixed j , $\omega_{j,t}$ and $\omega_{j,t}^* \sim N(0, \sigma_\omega^2)$. If s is even, then the equation for $\gamma_{s/2,t}^*$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

In the TRIG seasonal case, the option **KEEPPH=** or **DROPH=** can be used to obtain *subset trigonometric* seasonals that contain only a subset of the full set of harmonics $\gamma_{j,t}$, $j = 1, 2, \dots, [s/2]$. This is particularly useful when the season length s is large and the seasonal pattern is relatively smooth.

Note that whether the seasonal type is DUMMY or TRIG, there is only one parameter, the disturbance variance σ_ω^2 , in the seasonal model.

There can be more than one seasonal component in the model, necessarily with different season lengths if the seasons are full. You can have multiple *subset* season components with the same season length, if you need to use separate disturbance variances for different sets of harmonics. Each seasonal component is specified using a separate SEASON statement. A model with multiple seasonal components can easily become quite complex and might need a large amount of data and computing resources for its estimation and forecasting. The examples that follow illustrate the use of SEASON statement.

The following statement specifies a DUMMY type (default) seasonal component with a season length of four, corresponding to the quarterly seasonality. The disturbance variance σ_ω^2 is estimated from the data.

```
season length=4;
```

The following statement specifies a trigonometric seasonal with monthly seasonality. It also provides a starting value for σ_ω^2 .

```
season length=12 type=trig variance=4;
```

You must specify the following *option*:

LENGTH=*integer*

specifies the season length, s . The season length can be any integer greater than or equal to 2. Typical examples of season lengths are 12, corresponding to the monthly seasonality, or 4, corresponding to the quarterly seasonality.

You can also specify the following *options*:

DROPHARMONICS | **DROPH=***number-list* | **n TO m BY p**

enables you to drop some harmonics $\gamma_{j,t}$ from the full set of harmonics used to obtain a trigonometric seasonal. The drop list can include any integer between 1 and $[s/2]$, where s is the season length. For example, the following specification results in a specification of a trigonometric seasonal with a season length 12 that consists of only the first four harmonics $\gamma_{j,t}$, $j = 1, 2, 3, 4$:

```
season length=12 type=trig DROPH=5 6;
```

The last two *high*-frequency harmonics are dropped. The **DROPH=** option cannot be used with the **KEEPH=** option.

KEEPHARMONICS | **KEEPH=***number-list* | **n TO m BY p**

enables you to keep only the harmonics $\gamma_{j,t}$ listed in the option to obtain a trigonometric seasonal. The keep list can include any integer between 1 and $[s/2]$, where s is the season length. For example, the following specification results in a specification of a trigonometric seasonal with a season length of 12 that consists of all six harmonics $\gamma_{j,t}$, $j = 1, \dots, 6$:

```
season length=12 type=trig KEEPH=1 to 3;
season length=12 type=trig KEEPH=4 to 6;
```

However, these six harmonics are grouped into two groups, each having its own disturbance variance parameter. The **DROPH=** option cannot be used with the **KEEPH=** option.

NOEST

fixes the value of the disturbance variance parameter to the value specified in the **VARIANCE=** option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=F_ ANNUAL

PLOT=S_ ANNUAL

PLOT=(<plot-request> ... <plot-request>)

plots the season component. When you specify only one *plot-request*, you can omit the parentheses around it. You can use the **FILTER** and **SMOOTH** options to plot the filtered and smoothed estimates of the season component γ_t . You can use the **F_ ANNUAL** and **S_ ANNUAL** options to produce the plots of “annual” variation in the filtered and smoothed estimates of γ_t . The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here “month” and “year” are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years.

PRINT=HARMONICS

prints the summary of harmonics present in the seasonal component. This option is valid only for the trigonometric seasonal component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(<print-request> ... <print-request>)

prints the filtered or smoothed estimate of the seasonal component γ_t .

TYPE=DUMMY | TRIG

specifies the type of the seasonal component. By default, **TYPE=DUMMY**.

VARIANCE=value

specifies an initial value for the disturbance variance, σ_ω^2 , in the γ_t equation at the start of the parameter estimation process. Any nonnegative value, including 0, is an acceptable starting value.

SLOPE Statement

SLOPE <options> ;

The SLOPE statement is used to include a slope component in the model. The slope component cannot be used without the level component (see the **LEVEL** statement). The level and slope specifications jointly define the trend component of the model. A SLOPE statement without the accompanying LEVEL statement is ignored. The equations of the trend, defined jointly by the level μ_t and slope β_t , are as follows:

$$\begin{aligned}\mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim \text{iid } N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim \text{iid } N(0, \sigma_\xi^2)\end{aligned}$$

The SLOPE statement is used to specify the value of the disturbance variance, σ_ξ^2 , in the slope equation, and to request forecasts of β_t . The following examples illustrate this statement:

```
level;
slope;
```

The preceding statements fit a model with a locally linear trend. The disturbance variances σ_η^2 and σ_ξ^2 are estimated from the data. You can fit a locally linear trend with fixed slope by using the following statements:

```
level;
slope variance=0 noest;
```

You can specify the following *options*:

NOEST

fixes the value of the disturbance variance, σ_ξ^2 , to the value specified in the **VARIANCE=** option.

PLOT=FILTER

PLOT=SMOOTH

PLOT=(<FILTER> <SMOOTH>)

plots the filtered or smoothed estimate of the slope component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=(<FILTER> <SMOOTH>)

prints the filtered or smoothed estimate of the slope component β_t .

VARIANCE=value

specifies an initial value for the disturbance variance, σ_ξ^2 , in the β_t equation at the start of the parameter estimation process. Any nonnegative value, including 0, is an acceptable starting value.

SPLINEREG Statement

SPLINEREG *regressor* < *options* > ;

The SPLINEREG statement is used to specify a regressor that has a nonlinear relationship with the dependent series that can be approximated by a given B-spline. If the specified spline has degree d and is based on n internal knots, then it is known that it can be written as a linear combination of $(n + d + 1)$ regressors that are derived from the original regressor. The span of these $(n + d + 1)$ -derived regressors includes a constant; therefore, to avoid multicollinearity with the level component, one of these regressors is dropped. Specifying the SPLINEREG statement is equivalent to specifying a RANDOMREG statement with these derived regressors. You can specify multiple SPLINEREG statements. You must specify at least one interior knot, using either the NKNOTS= option or the KNOTS= option. For more information about splines, see Chapter 126, “The TRANSREG Procedure” (*SAS/STAT User’s Guide*). For an example of using this statement, see [Example 30.6](#). For additional information about how parameter estimates are reported for this type of regressors, see the section “[Reporting Parameter Estimates for Random Regressors](#)” on page 2170.

You can specify the following *options*:

DEGREE=*integer*

specifies the degree of the spline. It can be any integer larger than or equal to 0. By default, DEGREE=3. The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

KNOTS=*number-list* | *n* **TO** *m* **BY** *p*

specifies the interior knots or break points. The values in the knot list must be nondecreasing and must lie between the minimum and the maximum of the spline regressor values in the input data set. The first time you specify a value in the knot list, it indicates a discontinuity in the n th (from DEGREE= n) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the $(n - 1)$ th derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the [KNOTS=](#) option with the [NKNOTS=](#) option. You should keep the number of knots small.

NKNOTS=*m*

creates m knots, the first at the $100/(m + 1)$ percentile, the second at the $200/(m + 1)$ percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if NKNOTS=3, knots are placed at the 25th percentile, the median, and the 75th percentile. The value specified for the NKNOTS= option must be ≥ 1 . You cannot use the [NKNOTS=](#) option with the [KNOTS=](#) option.

NOTE: Specifying knots by using the NKNOTS= option can result in different sets of knots in the estimation and forecast stages if the distributions of regressor values in the estimation and forecast spans differ. The estimation span is based on the BACK= and SKIPFIRST= options in the [ESTIMATE](#) statement, and the forecast span is based on the BACK= and SKIPFIRST= options in the [FORECAST](#) statement.

NOEST

fixes the value of the regression coefficient random walk disturbance variance to the value specified in the **VARIANCE=** option.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

plots the filtered or smoothed estimate of the time-varying regression coefficient.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

prints the filtered or smoothed estimate of the time-varying regression coefficient.

VARIANCE=*value*

specifies an initial value for the regression coefficient random walk disturbance variance during the parameter estimation process. Any nonnegative value, including 0, is an acceptable starting value.

SPLINESEASON Statement

SPLINESEASON LENGTH=*integer* **KNOTS=***integer*₁ *integer*₂ ... **< options >** ;

The SPLINESEASON statement is used to specify a seasonal pattern that is to be approximated by a given B-spline. If the specified spline has degree d and is based on n internal knots, then it can be written as a linear combination of $(n + d)$ regressors that are derived from the seasonal dummy regressors. The SPLINESEASON specification is equivalent to specifying a RANDOMREG specification with these derived regressors. Such approximation is useful only if the season length is relatively large, at least larger than $(n + d)$. For additional information about splines, see Chapter 126, “The TRANSREG Procedure” (*SAS/STAT User's Guide*). For an example of using this statement, see [Example 30.3](#).

You must specify the following *options*:

LENGTH=*integer*

specifies the season length, s . The length can be any integer greater than or equal to 3.

KNOTS=*integer*₁ *integer*₂ ...

lists the *internal* knots. This list of values must be a nondecreasing sequence of integers within the range of 2 to $(s - 1)$, where s is the season length specified in the **LENGTH=** option.

You can also specify the following *options*:

DEGREE=*integer*

specifies the degree of the spline. It can be any integer greater than or equal to 0. By default, **DEGREE=3**.

NOEST

fixes the value of the regression coefficient random walk disturbance variance to the value specified in the **VARIANCE=** option.

OFFSET=integer

specifies the position of the first measurement within the season, if the first measurement is not at the start of the season. The **OFFSET=** value must be between one and the season length. The default value is one. The first measurement refers to the start of the estimation span and the forecast span. If these spans differ, their starting measurements must be separated by an integer multiple of the season length.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

plots the season component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the **FILTER** and **SMOOTH** options to plot the filtered and smoothed estimates of the season component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

prints the filtered or smoothed estimate of the spline season component.

RKNOTS=(knot, ..., knot) ... (knot, ..., knot)

specifies a grouping of knots such that the knots within the same group have identical seasonal values. The knots specified in this option must already be present in the list specified by the **KNOTS=** option. The knot groups must be non-overlapping and without any repeated knots.

VARIANCE=value

specifies an initial value for the regression coefficient random walk disturbance variance during the parameter estimation process. Any nonnegative value, including 0, is an acceptable starting value.

TF Statement

TF regressor < options > ;

The TF statement specifies a regressor that has a transfer-function relationship with the dependent series. A transfer function is useful for capturing the contributions from lagged values of the regressor. Box and Jenkins (1976) popularized ARIMA models that have transfer-function inputs. In the UCM procedure, you can specify a transfer function of the following type (assuming the regression variable is x):

$$\frac{(\gamma_0 + \gamma_1 B^{l1} + \gamma_2 B^{l2} + \dots) B^d}{(1 - \delta_1 B - \delta_2 B^2 - \dots - \delta_m B^m)(1 - \omega_1 B^s - \omega_2 B^{2s} - \dots - \omega_n B^{ns})} x_t$$

This transfer function is specified by using the ratio of polynomials in the backshift operator B . The numerator polynomial orders ($l1, l2, \dots$) are positive integers, possibly with gaps (for example, 1, 3). The numerator term B^d signifies the *delay* of order d . The denominator polynomial can have two factors: a nonseasonal factor, $(1 - \delta_1 B - \delta_2 B^2 - \dots - \delta_m B^m)$, and a seasonal factor whose season length is s , $(1 - \omega_1 B^s - \omega_2 B^{2s} - \dots - \omega_n B^{ns})$. The orders of the terms in the denominator factors cannot have gaps;

that is, if 5 is the maximum order of the nonseasonal factor, then all terms of orders 1 through 5 are present. By design, the denominator factors are restricted to be stable polynomials (their roots are strictly larger than 1 in absolute value). As an example, consider the following transfer function specification:

$$\frac{(\gamma_0 + \gamma_1 B^1 + \gamma_2 B^2) B^3}{(1 - \delta_1 B - \delta_2 B^2)(1 - \omega_1 B^4)} x_t$$

You can specify this transfer function as follows:

```
tf x num=(1 2) den=2 sden=1 s=4 delay=3;
```

Since the numerator polynomial orders do not have any gaps, the following simpler specification is also available:

```
tf x num=2 den=2 sden=1 s=4 delay=3;
```

Because the denominator factors do not permit gaps in their orders, only the maximum orders need to be provided in their specification.

A state space representation of a transfer-function relationship is described in the section “[State Space Form of a Transfer Function Relationship](#)” on page 2170. You can specify multiple TF statements, each one with a separate regressor. A regressor that is specified in any transfer function specification must not appear in any other regression specifications, such as in the right-hand side of the MODEL statement or in the RANDOMREG and SPLINEREG statements.

NOTE: The mathematical form of the transfer function considered by PROC UCM is similar to the one considered in the ARIMA procedure (Chapter 7, “ARIMA Procedure” ([SAS/ETS User’s Guide](#))). However, there are some differences:

- The sign convention of the coefficients of the nonzero-order terms in the numerator polynomial in the UCM procedure is opposite to that of the ARIMA procedure.
- The ARIMA procedure permits multiple polynomial factors in both the numerator and the denominator. The UCM procedure permits only one numerator factor and at most two denominator factors.
- The ARIMA procedure permits full control over the terms present in each of the polynomial factors. The UCM procedure does not permit such fine control over the terms in the polynomials.
- In the UCM procedure, you cannot fix the coefficients of the numerator polynomial. They are always estimated from the data.
- In the UCM procedure, if both nonseasonal and seasonal factors are present in the denominator, you must specify starting values for their coefficients either for both factors or for neither.

You can specify the following *options* in the TF statement:

DELAY=integer

specifies the delay order, which must be a positive integer. By default, DELAY=0.

DEN=integer

specifies the maximum order of the nonseasonal factor of the denominator polynomial. By default, DEN=0.

DENVAL=val1 val2 ...

specifies the starting values of the coefficients of the nonseasonal factor of the denominator polynomial. The number of values supplied in the DENVAL= option must match the value of the DEN= option. Moreover, the resulting polynomial must be stable.

NOEST

fixes the values of the denominator polynomial coefficients to those specified in the DENVAL= and SDENVAL= specifications.

NUM=argument

specifies the positive orders of the terms in the numerator polynomial. You can specify the *argument* in either of the following forms:

integer includes all orders from 1 to *integer*.

(*lag1*, *lag2*, ...) specifies a more general list of orders.

PLOT=FILTER**PLOT=SMOOTH****PLOT=(< FILTER > < SMOOTH >)**

plots the transfer-function component. When you specify only one plot request, you can omit the parentheses around it. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the transfer-function component.

PRINT=FILTER**PRINT=SMOOTH****PRINT=(< FILTER > < SMOOTH >)**

prints the filtered or smoothed estimate of the transfer-function component. When you specify only one print request, you can omit the parentheses around it. You can use the FILTER and SMOOTH options to print the filtered and smoothed estimates of the transfer-function component.

S=integer

specifies the season length that is used in the specification of the seasonal factor of the denominator polynomial. The season length can be any positive integer; for example, S=4 might be an appropriate value for a quarterly series. By default, S=1.

SDEN=integer

specifies the maximum order of the seasonal factor of the denominator polynomial. By default, SDEN=0.

SDENVAL=*val1 val2 ...*

specifies the starting values of the coefficients of the seasonal factor of the denominator polynomial. The number of values supplied in this option must match the value of the SDEN= option. Moreover, the resulting polynomial must be stable.

TFSTART=*value*

specifies the value of the transfer function at the start of the sample (the first time ID). By default, the value of this option is a missing value that is estimated from the data. This option is often used when the past values of the transfer function can be inferred because of the structure of the problem or when it is useful to set these values (usually to 0) to achieve identifiability of the overall model. For more information, see the section “[State Space Form of a Transfer Function Relationship](#)” on page 2170. See [Example 30.10](#) for an example of the use of this option.

Details: UCM Procedure

An Introduction to Unobserved Component Models

A UCM decomposes the response series into components such as trend, seasons, cycles, and the regression effects due to predictor series. The following model shows a possible scenario:

$$y_t = \mu_t + \gamma_t + \psi_t + \sum_{j=1}^m \beta_j x_{jt} + \epsilon_t$$

$$\epsilon_t \sim \text{iid } N(0, \sigma_\epsilon^2)$$

The terms μ_t , γ_t , and ψ_t represent the trend, seasonal, and cyclical components, respectively. In fact the model can contain multiple seasons and cycles, and the seasons can be of different types. For simplicity of discussion the preceding model contains only one of each of these components. The regression term, $\sum_{j=1}^m \beta_j x_{jt}$, includes contribution of regression variables with *fixed* regression coefficients. A model can also contain regression variables that have *time-varying* regression coefficients or that have a nonlinear or a transfer-function relationship with the dependent series (see “[Incorporating Predictors of Different Types](#)” on page 2169). The disturbance term ϵ_t , also called the *irregular* component, is usually assumed to be Gaussian white noise. In some cases it is useful to model the irregular component as a stationary ARMA process. For additional information, see the section “[Modeling the Irregular Component](#)” on page 2160.

By controlling the presence or absence of various terms and by choosing the proper flavor of the included terms, the UCMs can generate a rich variety of time series patterns. A UCM can be applied to variables after transforming them by transforms such as *log* and *difference*.

The components μ_t , γ_t , and ψ_t model structurally different aspects of the time series. For example, the trend μ_t models the natural tendency of the series in the absence of any other perturbing effects such as seasonality, cyclical components, and the effects of exogenous variables, while the seasonal component γ_t models the correction to the level due to the seasonal effects. These components are assumed to be statistically independent of each other and independent of the irregular component. All of the component models can be thought of as stochastic generalizations of the relevant deterministic patterns in time. This

way the deterministic cases emerge as special cases of the stochastic models. The different models available for these unobserved components are discussed next.

Modeling the Trend

As mentioned earlier, the trend in a series can be loosely defined as the natural tendency of the series in the absence of any other perturbing effects. The UCM procedure offers two ways to model the trend component μ_t . The first model, called the random walk (RW) model, implies that the trend remains roughly constant throughout the life of the series without any persistent upward or downward drift. In the second model the trend is modeled as a locally linear time trend (LLT). The RW model can be described as

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim \text{iid } N(0, \sigma_\eta^2)$$

Note that if $\sigma_\eta^2 = 0$, then the model becomes $\mu_t = \text{constant}$. In the LLT model the trend is locally linear, consisting of both the *level* and *slope*. The LLT model is

$$\begin{aligned} \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim \text{iid } N(0, \sigma_\eta^2) \\ \beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim \text{iid } N(0, \sigma_\xi^2) \end{aligned}$$

The disturbances η_t and ξ_t are assumed to be independent. There are some interesting special cases of this model obtained by setting one or both of the disturbance variances σ_η^2 and σ_ξ^2 equal to 0. If σ_ξ^2 is set equal to 0, then you get a linear trend model with fixed slope. If σ_η^2 is set to 0, then the resulting model usually has a smoother trend. If both the variances are set to 0, then the resulting model is the deterministic linear time trend: $\mu_t = \mu_0 + \beta_0 t$.

You can incorporate these trend patterns in your model by using the **LEVEL** and **SLOPE** statements.

Modeling a Cycle

A deterministic cycle ψ_t with frequency λ , $0 < \lambda < \pi$, can be written as

$$\psi_t = \alpha \cos(\lambda t) + \beta \sin(\lambda t)$$

If the argument t is measured on a continuous scale, then ψ_t is a periodic function with period $2\pi/\lambda$, amplitude $\gamma = (\alpha^2 + \beta^2)^{1/2}$, and phase $\phi = \tan^{-1}(\beta/\alpha)$. Equivalently, the cycle can be written in terms of the amplitude and phase as

$$\psi_t = \gamma \cos(\lambda t - \phi)$$

Note that when ψ_t is measured only at the integer values, it is not exactly periodic, unless $\lambda = (2\pi j)/k$ for some integers j and k . The cycles in their pure form are not used very often in practice. However, they are very useful as building blocks for more complex periodic patterns. It is well known that the periodic pattern of any complexity can be written as a sum of pure cycles of different frequencies and amplitudes. In time series situations it is useful to generalize this simple cyclical pattern to a stochastic cycle that has a fixed expected period but time-varying amplitude and phase. The stochastic cycle considered here is motivated by the following recursive formula for computing ψ_t ,

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix}$$

starting with $\psi_0 = \alpha$ and $\psi_0^* = \beta$. Note that ψ_t and ψ_t^* satisfy the relation

$$\psi_t^2 + \psi_t^{*2} = \alpha^2 + \beta^2 \quad \text{for all } t$$

A stochastic generalization of the cycle ψ_t can be obtained by adding random noise to this recursion and by introducing a damping factor, ρ , for additional modeling flexibility. This model can be described as follows,

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} \nu_t \\ \nu_t^* \end{bmatrix}$$

where $0 \leq \rho \leq 1$, and the disturbances ν_t and ν_t^* are independent $N(0, \sigma_\nu^2)$ variables. The resulting stochastic cycle has a fixed expected period but time-varying amplitude and phase. The stationarity properties of the random sequence ψ_t depend on the damping factor ρ . If $\rho < 1$, ψ_t has a stationary distribution with mean 0 and variance $\sigma_\nu^2/(1 - \rho^2)$. If $\rho = 1$, ψ_t is nonstationary.

You can incorporate a cycle in a UCM by specifying a **CYCLE** statement. You can include multiple cycles in the model by using separate **CYCLE** statements for each included cycle.

As mentioned before, the cycles are very useful as building blocks for constructing more complex periodic patterns. Periodic patterns of almost any complexity can be created by superimposing cycles of different periods and amplitudes. In particular, the seasonal patterns, general periodic patterns with integer periods, can be constructed as sums of cycles. This important topic of modeling the seasonal components is considered next.

Modeling Seasons

Seasonal fluctuations are a common source of variation in time series data. These fluctuations arise because of the regular changes in seasons or some other periodic events. The seasonal effects are regarded as corrections to the general trend of the series due to the seasonal variations, and these effects sum to 0 when summed over the full season cycle. Therefore the seasonal component γ_t is modeled as a stochastic periodic pattern of an integer period s such that the sum $\sum_{i=0}^{s-1} \gamma_{t-i}$ is always 0 in the mean. The period s is called the season length. Two different models for the seasonal component are considered here. The first model is called the *dummy* variable form of the seasonal component. It is described by the equation

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \quad \omega_t \sim \text{iid } N(0, \sigma_\omega^2)$$

The other model is called the *trigonometric* form of the seasonal component. In this case γ_t is modeled as a sum of cycles of different frequencies. This model is given by

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if s is even and $(s-1)/2$ if it is odd. The cycles $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma_{j,t}^* \end{bmatrix} = \begin{bmatrix} \cos \lambda_j & \sin \lambda_j \\ -\sin \lambda_j & \cos \lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma_{j,t-1}^* \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega_{j,t}^* \end{bmatrix}$$

where the disturbances $\omega_{j,t}$ and $\omega_{j,t}^*$ are assumed to be independent and, for fixed j , $\omega_{j,t}$ and $\omega_{j,t}^* \sim N(0, \sigma_\omega^2)$. If s is even, then the equation for $\gamma_{s/2,t}^*$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

The cycles $\gamma_{j,t}$ are called *harmonics*. If the seasonal component is deterministic, the decomposition of the seasonal effects into these harmonics is identical to its Fourier decomposition. In this case the sum of squares of the seasonal factors equals the sum of squares of the amplitudes of these harmonics. In many practical situations, the contribution of the high-frequency harmonics is negligible and can be ignored, giving rise to a simpler description of the seasonal. In the case of stochastic seasonals, the situation might not be so transparent; however, similar considerations still apply. Note that if the disturbance variance $\sigma_\omega^2 = 0$, then both the dummy and the trigonometric forms of seasonal components reduce to constant seasonal effects. That is, the seasonal component reduces to a deterministic function that is completely determined by its first $s - 1$ values.

In the UCM procedure you can specify a seasonal component in a variety of ways, the **SEASON** statement being the simplest of these. The dummy and the trigonometric seasonal components discussed so far can be considered as *saturated* seasonal components that put no restrictions on the $s - 1$ seasonal values. In some cases a more parsimonious representation of the seasonal might be more appropriate. This is particularly useful for seasonal components with large season lengths. In the UCM procedure you can obtain parsimonious representations of the seasonal components by one of the following ways:

- Use a *subset* trigonometric seasonal component obtained by deleting a few of the $[s/2]$ harmonics used in its sum. For example, a slightly smoother seasonal component of length 12, corresponding to the monthly seasonality, can be obtained by deleting the highest-frequency harmonic of period 2. That is, such a seasonal component will be a sum of five stochastic cycles that have periods 12, 6, 4, 3, and 2.4. You can specify such subset seasonal components by using the **KEEPH=** or **DROPH=** option in the **SEASON** statement.
- Approximate the seasonal pattern by a suitable spline approximation. You can do this by using the **SPLINESEASON** statement.
- A *block-seasonal* pattern is a seasonal pattern where the pattern is divided into a few blocks of equal length such that the season values within a block are the same—for example, a monthly seasonal pattern that has only four different values, one for each quarter. In some situations a long seasonal pattern can be approximated by the sum of block season and a simple season, the length of the simple season being equal to the block length of the block season. You can obtain such approximation by using a combination of **BLOCKSEASON** and **SEASON** statements.
- Consider a seasonal component of a large season length as a sum of two or more seasonal components that are each of much smaller season lengths. This can be done by specifying more than one **SEASON** statements.

Note that the preceding techniques of obtaining parsimonious seasonal components can also enable you to specify seasonal components that are more *general* than the simple saturated seasonal components. For example, you can specify a saturated trigonometric seasonal component that has some of its harmonics evolving according to one disturbance variance parameter while the others evolve with another disturbance variance parameter.

Modeling an Autoregression

An autoregression of order one can be thought of as a special case of a cycle when the frequency λ is either 0 or π . Modeling this special case separately helps interpretation and parameter estimation. The autoregression component r_t is modeled as

$$r_t = \rho r_{t-1} + v_t, \quad v_t \sim \text{iid } N(0, \sigma_v^2)$$

where $-1 \leq \rho < 1$. An autoregression can also provide an alternative to the **IRREGULAR** component when the model errors show some autocorrelation. You can incorporate an autoregression in your model by using the **AUTOREG** statement.

Modeling Regression Effects

A predictor variable can affect the response variable in a variety of ways. The UCM procedure enables you to model several different types of predictor-response relationships:

- The predictor-response relationship is *linear*, and the regression coefficient does not change with time. This is the simplest kind of relationship and such predictors are specified in the **MODEL** statement.
- The predictor-response relationship is *linear*, but the regression coefficient does change with time. Such predictors are specified in the **RANDOMREG** statement. Here the regression coefficient is assumed to evolve as a random walk.
- The predictor-response relationship is *nonlinear* and the relationship can change with time. This type of relationship can be approximated by an appropriate time-varying spline. Such predictors are specified in the **SPLINEREG** statement.
- The response depends on contemporaneous and lagged values of the predictor. This type of relationship is called transfer-function relationship, which can be specified in the **TF** statement.

A response variable can depend on its own past values—that is, lagged dependent values. Such a relationship can be specified in the **DEPLAG** statement.

Modeling the Irregular Component

The components—such as trend, seasonal and regression effects, and nonstationary cycles—are used to capture the structural dynamics of a response series. In contrast, the stationary cycles and the autoregression are used to capture the transient aspects of the response series that are important for its short-range prediction but have little impact on its long-term forecasts. The irregular component represents the residual variation remaining in the response series that is modeled using an appropriate selection of structural and transient effects. In most cases, the irregular component can be assumed to be simply Gaussian white noise. In some other cases, however, the residual variation can be more complicated. In such situations, it might be necessary to model the irregular component as a stationary ARMA process. Moreover, you can use the ARMA irregular component together with the dependent lag specification (see the **DEPLAG** statement) to specify an $\text{ARIMA}(p, d, q) \times (P, D, Q)_s$ model for the response series. For an explanation of the ARIMA notation, see the **IRREGULAR** statement. For an example of modeling a series by using an $\text{ARIMA}(0, 1, 1) \times (0, 1, 1)_{12}$ model, see [Example 30.8](#).

The Model Parameters

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression, and the regression coefficients in the regression terms. These parameters are estimated by maximizing the likelihood. It is possible to restrict the values of the model parameters to user-specified values.

Model Specification

A UCM is specified by describing the components in the model. For example, consider the model

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

consisting of the irregular, level, slope, and seasonal components. This model is called the basic structural model (BSM) by Harvey (1989). The syntax for a BSM with monthly seasonality of trigonometric type is as follows:

```
model y;
irregular;
level;
slope;
season length=12 type=trig;
```

Similarly, the following syntax specifies a BSM with a response variable y , a regressor x , and dummy-type monthly seasonality:

```
model y = x;
irregular;
level;
slope variance=0 noest;
season length=12 type=dummy;
```

Moreover, the disturbance variance of the slope component is restricted to 0, giving rise to a local linear trend with fixed slope.

A model can contain multiple cycle and seasonal components. In such cases the model syntax contains a separate statement for each of these multiple cycle or seasonal components; for example, the syntax for a model containing irregular and level components along with two cycle components could be as follows:

```
model y = x;
irregular;
level;
cycle;
cycle;
```

UCMs as State Space Models

The UCMs considered in PROC UCM are special cases of more general models, called (linear) state space models (SSMs). The section “[State Space Model and Notation](#)” on page 760 in Chapter 14, “[CSSM Procedure](#),” provides an elaborate notation for such models. However, for most of the UCMs considered in PROC UCM, much simpler notation suffices. This section describes a treatment of UCMs in terms of this simplified notation. At times the description and mathematical treatment (such as the expressions of likelihood) of state space models in PROC UCM and PROC SSM can appear different. However, these differences are only notational and the underlying mathematical quantities coincide. For example, the diffuse Kalman filter (DKF) described in this section is called the *exact initial* Kalman filter whereas the DKF described in the section “[Filtering, Smoothing, Likelihood, and Structural Break Detection](#)” on page 767 in Chapter 14, “[CSSM Procedure](#),” is called the *augmented* Kalman filter. Both of these algorithms produce the same final output (see Durbin and Koopman (2012, chap. 5) for more information).

An SSM can be described as follows:

$$\begin{aligned} y_t &= Z_t \alpha_t \\ \alpha_{t+1} &= T_t \alpha_t + \zeta_{t+1}, \quad \zeta_t \sim N(0, Q_t) \\ \alpha_1 &\sim N(0, P) \end{aligned}$$

The first equation, called the *observation equation*, relates the response series y_t to a state vector α_t that is usually unobserved. The second equation, called the *state equation*, describes the evolution of the state vector in time. The system matrices Z_t and T_t are of appropriate dimensions and are known, except possibly for some unknown elements that become part of the parameter vector of the model. The noise series ζ_t consists of independent, zero-mean, Gaussian vectors with covariance matrices Q_t . For most of the UCMs considered here, the system matrices Z_t and T_t , and the noise covariances Q_t , are time invariant—that is, they do not depend on time. In a few cases, however, some or all of them can depend on time. The initial state vector α_1 is assumed to be independent of the noise series, and its covariance matrix P can be partially diffuse. A random vector has a partially diffuse covariance matrix if it can be partitioned such that one part of the vector has a properly defined probability distribution, while the covariance matrix of the other part is infinite—that is, you have no prior information about this part of the vector. The covariance of the initial state α_1 is assumed to have the form

$$P = P_* + \kappa P_\infty$$

where P_* and P_∞ are nonnegative definite, symmetric matrices and κ is a constant that is assumed to be close to ∞ . In the case of UCMs considered here, P_∞ is always a diagonal matrix that consists of zeros and ones, and, if a particular diagonal element of P_∞ is one, then the corresponding row and column in P_* are 0.

The state space formulation of a UCM has many computational advantages. In this formulation there are convenient algorithms for estimating and forecasting the unobserved states $\{\alpha_t\}$ by using the observed series $\{y_t\}$. These algorithms also yield the in-sample and out-of-sample forecasts and the likelihood of $\{y_t\}$. The state space representation of a UCM does not need to be unique. In the representation used here, the unobserved components in the UCM often appear as elements of the state vector. This makes the elements of the state interpretable and, more important, the sample estimates and forecasts of these unobserved components are easily obtained. For additional information about the computational aspects of the state space modeling, see Durbin and Koopman (2012). Next, some notation is developed to describe the essential quantities computed during the analysis of the state space models.

Let $\{y_t, t = 1, \dots, n\}$ be the observed sample from a series that satisfies a state space model. Next, for $1 \leq t \leq n$, let the one-step-ahead forecasts of the series, the states, and their variances be defined as follows, using the usual notation to denote the conditional expectation and conditional variance:

$$\begin{aligned}\hat{\alpha}_t &= E(\alpha_t | y_1, y_2, \dots, y_{t-1}) \\ \Gamma_t &= \text{Var}(\alpha_t | y_1, y_2, \dots, y_{t-1}) \\ \hat{y}_t &= E(y_t | y_1, y_2, \dots, y_{t-1}) \\ F_t &= \text{Var}(y_t | y_1, y_2, \dots, y_{t-1})\end{aligned}$$

These are also called the *filtered* estimates of the series and the states. Similarly, for $t \geq 1$, let the following denote the full-sample estimates of the series and the state values at time t :

$$\begin{aligned}\tilde{\alpha}_t &= E(\alpha_t | y_1, y_2, \dots, y_n) \\ \Delta_t &= \text{Var}(\alpha_t | y_1, y_2, \dots, y_n) \\ \tilde{y}_t &= E(y_t | y_1, y_2, \dots, y_n) \\ G_t &= \text{Var}(y_t | y_1, y_2, \dots, y_n)\end{aligned}$$

If the time t is in the historical period—that is, if $1 \leq t \leq n$ —then the full-sample estimates are called the *smoothed* estimates, and if t lies in the future then they are called out-of-sample forecasts. Note that if $1 \leq t \leq n$, then $\tilde{y}_t = y_t$ and $G_t = 0$, unless y_t is missing.

All the filtered and smoothed estimates ($\hat{\alpha}_t, \tilde{\alpha}_t, \dots, G_t$, and so on) are computed by using the Kalman filtering and smoothing (KFS) algorithm, which is an iterative process. If the initial state is diffuse, as is often the case for the UCMs, its treatment requires modification of the traditional KFS, which is called the diffuse KFS (DKFS). The details of DKFS implemented in the UCM procedure can be found in De Jong and Chu-Chun-Lin (2003). Additional information on the state space models can be found in Durbin and Koopman (2012). The likelihood formulas described in this section are taken from the latter reference.

In the case of diffuse initial condition, the effect of the improper prior distribution of α_1 manifests itself in the first few filtering iterations. During these initial filtering iterations the distribution of the filtered quantities remains diffuse; that is, during these iterations the one-step-ahead series and state forecast variances F_t and Γ_t have the following form:

$$\begin{aligned}F_t &= F_{*t} + \kappa F_{\infty t} \\ \Gamma_t &= \Gamma_{*t} + \kappa \Gamma_{\infty t}\end{aligned}$$

The actual number of iterations—for example, I —affected by this improper prior depends on the nature of the vectors Z_t , the number of nonzero diagonal elements of P_∞ , and the pattern of missing values in the dependent series. After I iterations, $\Gamma_{\infty t}$ and $F_{\infty t}$ become 0 and the one-step-ahead series and state forecasts have proper distributions. These first I iterations constitute the *initialization* phase of the DKFS algorithm. The post-initialization phase of the DKFS and the traditional KFS is the same. In the state space modeling literature the pre-initialization and post-initialization phases are sometimes called *pre-collapse* and *post-collapse* phases of the diffuse Kalman filtering. In certain missing value patterns it is possible for I to exceed the sample size; that is, the sample information can be insufficient to create a proper prior for the filtering process. In these cases, parameter estimation and forecasting is done on the basis of this improper prior, and some or all of the series and component forecasts can have infinite variances (or zero precision).

The forecasts that have infinite variance are set to missing. The same situation can occur if the specified model contains components that are essentially multicollinear. In these situations no residual analysis is possible; in particular, no residuals-based goodness-of-fit statistics are produced.

The log likelihood of the sample (L_∞), which takes account of this diffuse initialization step, is computed by using the one-step-ahead series forecasts as follows,

$$L_\infty(y_1, \dots, y_n) = -\frac{(n-d)}{2} \log 2\pi - \frac{1}{2} \sum_{t=1}^I w_t - \frac{1}{2} \sum_{t=I+1}^n (\log F_t + \frac{v_t^2}{F_t})$$

where d is the number of diffuse elements in the initial state α_1 , $v_t = y_t - Z_t \hat{\alpha}_t$ are the one-step-ahead residuals, and

$$\begin{aligned} w_t &= \log F_{\infty t} && \text{if } F_{\infty t} > 0 \\ &= \log F_{*t} + \frac{v_t^2}{F_{*t}} && \text{if } F_{\infty t} = 0 \end{aligned}$$

If y_t is missing at some time t , then the corresponding summand in the log likelihood expression is deleted, and the constant term is adjusted suitably. Moreover, if the initialization step does not complete—that is, if I exceeds the sample size—then the value of d is reduced to the number of diffuse states that are successfully initialized.

The portion of the log likelihood that corresponds to the post-initialization period is called the nondiffuse log likelihood (L_0). The nondiffuse log likelihood is given by

$$L_0(y_1, \dots, y_n) = -\frac{1}{2} \sum_{t=I+1}^n (\log F_t + \frac{v_t^2}{F_t})$$

In the case of UCMs considered in PROC UCM, it often happens that the diffuse part of the likelihood, $\sum_{t=1}^I w_t$, does not depend on the model parameters, and in these cases the maximization of nondiffuse and diffuse likelihoods is equivalent. However, in some cases, such as when the model consists of dependent lags, the diffuse part does depend on the model parameters. In these cases the maximization of the diffuse and nondiffuse likelihood can produce different parameter estimates.

In some situations it is convenient to reparameterize the nondiffuse initial state covariance P_* as $\sigma^2 P_*$ and the state noise covariance Q_t as $\sigma^2 Q_t$ for some common scalar parameter σ^2 . In this case the preceding log-likelihood expression, up to a constant, can be written as

$$L_\infty(y_1, \dots, y_n) = -\frac{1}{2} \sum_{t=1}^I w_t - \frac{1}{2} \sum_{t=I+1}^n \log F_t - \frac{1}{2\sigma^2} \sum_{t=I+1}^n \frac{v_t^2}{F_t} - \frac{(n-d)}{2} \log \sigma^2$$

Solving analytically for the optimum, the maximum likelihood estimate of σ^2 can be shown to be

$$\hat{\sigma}^2 = \frac{1}{(n-d)} \sum_{t=I+1}^n \frac{v_t^2}{F_t}$$

When this expression of σ^2 is substituted back into the likelihood formula, an expression called the *profile likelihood* (L_{profile}) of the data is obtained:

$$-2L_{\text{profile}}(y_1, \dots, y_n) = \sum_{t=1}^I w_t + \sum_{t=I+1}^n \log F_t + (n-d) \log \left(\sum_{t=I+1}^n \frac{v_t^2}{F_t} \right)$$

In some situations the parameter estimation is done by optimizing the profile likelihood (see the section “[Parameter Estimation by Profile Likelihood Optimization](#)” on page 2174 and the [PROFILE](#) option in the ESTIMATE statement).

You can also request that parameter estimation be based on an alternate form of the likelihood, called the marginal likelihood ($L_m(\mathbf{Y}, \boldsymbol{\theta})$). You can switch to the marginal-likelihood-based parameter estimation by specifying [LIKE=MARGINAL](#) in the ESTIMATE statement. This alternate likelihood and two additional likelihoods are described in the section “[Likelihood Computation and Model-Fitting Phase](#)” on page 769 in Chapter 14, “[CSSM Procedure](#).” The diffuse likelihood, L_∞ , described in this section is equivalent to the diffuse likelihood, $L_d(\mathbf{Y}, \boldsymbol{\theta})$, described in that section. However, do not confuse the profile likelihood, L_{profile} , described in this section with the profile likelihood, $L_p(\mathbf{Y}, \boldsymbol{\theta})$, described in that section. The profiling in $L_p(\mathbf{Y}, \boldsymbol{\theta})$ refers to the profiling of the diffuse effects, whereas the profiling in L_{profile} refers to the profiling of a common scalar parameter σ^2 . For each of the three likelihoods—diffuse, marginal and profile—that are described in that section, it is possible to profile out (also called concentrate out) a common scalar parameter σ^2 and obtain expressions similar to the L_{profile} likelihood that is described in this section. In fact, when you request that parameter estimation be based on the marginal likelihood by specifying [LIKE=MARGINAL](#) in the ESTIMATE statement, the profile version of marginal likelihood ($L_m(\mathbf{Y}, \boldsymbol{\theta})$) is used if the [PROFILE](#) option is in effect (by default or when the [PROFILE](#) option is specified). The discussion in the section “[Parameter Estimation by Profile Likelihood Optimization](#)” on page 2174 also applies to marginal likelihood. As explained in the section “[Likelihood Computation and Model-Fitting Phase](#)” on page 769 in Chapter 14, “[CSSM Procedure](#),” the estimates that are based on marginal likelihood and the estimates that are based on diffuse likelihood coincide in many cases. In PROC UCM, estimates that are based on marginal likelihood and diffuse likelihood will differ only if at least one of the following conditions holds:

- The [DEPLAG](#) statement is present and the NOEST option is not specified.
- In a [TF](#) statement, at least one denominator factor is present and the NOEST option is not specified.
- In a [CYCLE](#) statement, RHO is fixed at 1 and the period is to be estimated—that is, $\text{RHO}=1$ and $\text{NOEST}=\text{RHO}$ or $\text{NOEST}=(\text{RHO VARIANCE})$.

Whenever you specify [LIKE=MARGINAL](#) in the ESTIMATE statement, the FitSummary table that displays the likelihood-based fit statistics includes fit statistics and information criteria that are based on the marginal likelihood in addition to fit statistics that are based on diffuse likelihood.

In the remainder of this section, the state space formulation of UCMs is further explained by using some particular UCMs as examples. The examples show that the state space formulation of the UCMs depends on the components in the model in a simple fashion; for example, the system matrix T is usually a block diagonal matrix with blocks that correspond to the components in the model. The only exception to this pattern is the UCMs that consist of the lags of dependent variable. This case is considered at the end of the section.

In what follows, $\text{Diag}[a, b, \dots]$ denotes a diagonal matrix with diagonal entries $[a, b, \dots]$, and the transpose of a matrix T is denoted as T' .

Locally Linear Trend Model

Recall that the dynamics of the locally linear trend model are

$$\begin{aligned} y_t &= \mu_t + \epsilon_t \\ \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t \\ \beta_t &= \beta_{t-1} + \xi_t \end{aligned}$$

Here y_t is the response series and ϵ_t , η_t , and ξ_t are independent, zero-mean Gaussian disturbance sequences with variances σ_ϵ^2 , σ_η^2 , and σ_ξ^2 , respectively. This model can be formulated as a state space model where the state vector $\alpha_t = [\epsilon_t \mu_t \beta_t]'$ and the state noise $\zeta_t = [\epsilon_t \eta_t \xi_t]'$. Note that the elements of the state vector are precisely the unobserved components in the model. The system matrices T and Z and the noise covariance Q corresponding to this choice of state and state noise vectors can be seen to be time invariant and are given by

$$Z = [1 \ 1 \ 0], \quad T = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix} \quad \text{and} \quad Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2]$$

The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1]$. The parameter vector θ consists of all the disturbance variances—that is, $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2)$.

Basic Structural Model

The basic structural model (BSM) is obtained by adding a seasonal component, γ_t , to the local level model. In order to economize on the space, the state space formulation of a BSM with a relatively short season length, season length = 4 (quarterly seasonality), is considered here. The pattern for longer season lengths such as 12 (monthly) and 52 (weekly) is easy to see.

Let us first consider the dummy form of seasonality. In this case the state and state noise vectors are $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{2,t} \gamma_{3,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_t 0 0]'$, respectively. The first three elements of the state vector are the irregular, level, and slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component γ_t . $\gamma_{1,t}$ corresponds to lag zero—that is, the same as γ_t , $\gamma_{2,t}$ to lag 1 and $\gamma_{3,t}$ to lag 2. The system matrices are

$$Z = [1 \ 1 \ 0 \ 1 \ 0 \ 0], \quad T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & -1 & -1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

and $Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, 0, 0]$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1]$.

In the case of the trigonometric type of seasonality, $\alpha_t = [\epsilon_t \mu_t \beta_t \gamma_{1,t} \gamma_{1,t}^* \gamma_{2,t}]'$ and $\zeta_t = [\epsilon_t \eta_t \xi_t \omega_{1,t} \omega_{1,t}^* \omega_{2,t}]'$. The disturbance sequences, $\omega_{j,t}$, $1 \leq j \leq 2$, and $\omega_{1,t}^*$, are independent, zero-

mean, Gaussian sequences with variance σ_ω^2 . The system matrices are

$$Z = [1 \ 1 \ 0 \ 1 \ 0 \ 1], \quad T = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cos \lambda_1 & \sin \lambda_1 & 0 \\ 0 & 0 & 0 & -\sin \lambda_1 & \cos \lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos \lambda_2 \end{bmatrix}$$

and $Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, \sigma_\omega^2, \sigma_\omega^2]$. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1]$. The parameter vector in both the cases is $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2)$.

Seasons with Blocked Seasonal Values

Block seasonals are special seasonal components that impose a special block structure on the seasonal effects. Let us consider a BSM with monthly seasonality that has a quarterly block structure—that is, months within the same quarter are assumed to have identical effects except for some random perturbation. Such a seasonal component is a block seasonal with block size m equal to 3 and the number of blocks k equal to 4. The state space structure for such a model with dummy-type seasonality is as follows: The state and state noise vectors are $\alpha_t = [\epsilon_t \ \mu_t \ \beta_t \ \gamma_{1,t} \ \gamma_{2,t} \ \gamma_{3,t}]'$ and $\zeta_t = [\epsilon_t \ \eta_t \ \xi_t \ \omega_t \ 0 \ 0]'$, respectively. The first three elements of the state vector are the irregular, level, and slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component γ_t . $\gamma_{1,t}$ corresponds to lag zero—that is, the same as γ_t , $\gamma_{2,t}$ to lag m and $\gamma_{3,t}$ to lag $2m$. All the system matrices are time invariant, except the matrix T . They can be seen to be $Z = [1 \ 1 \ 0 \ 1 \ 0 \ 0]$, $Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, 0, 0]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & -1 & -1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

when t is a multiple of the block size m , and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

otherwise. Note that when t is not a multiple of m , the portion of the T_t matrix corresponding to the seasonal is identity. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1]$.

Similarly, in the case of the trigonometric form of seasonality, $\alpha_t = [\epsilon_t \ \mu_t \ \beta_t \ \gamma_{1,t} \ \gamma_{1,t}^* \ \gamma_{2,t}]'$ and $\zeta_t = [\epsilon_t \ \eta_t \ \xi_t \ \omega_{1,t} \ \omega_{1,t}^* \ \omega_{2,t}]'$. The disturbance sequences, $\omega_{j,t}$, $1 \leq j \leq 2$, and $\omega_{1,t}^*$, are independent, zero-mean, Gaussian sequences with variance σ_ω^2 . $Z = [1 \ 1 \ 0 \ 1 \ 0 \ 1]$, $Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2, \sigma_\omega^2, \sigma_\omega^2]$,

and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & \cos \lambda_1 & \sin \lambda_1 & 0 \\ 0 & 0 & 0 & -\sin \lambda_1 & \cos \lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos \lambda_2 \end{bmatrix}$$

when t is a multiple of the block size m , and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

otherwise. As before, when t is not a multiple of m , the portion of the T_t matrix corresponding to the seasonal is identity. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1]$. The parameter vector in both the cases is $\theta = (\sigma_\epsilon^2, \sigma_\eta^2, \sigma_\xi^2, \sigma_\omega^2)$.

Cycles and Autoregression

The preceding examples have illustrated how to build a state space model corresponding to a UCM that includes components such as irregular, trend, and seasonal. There you can see that the state vector and the system matrices have a simple block structure with blocks corresponding to the components in the model. Therefore, here only a simple model consisting of a single cycle and an irregular component is considered. The state space form for more complex UCMs consisting of multiple cycles and other components can be easily deduced from this example.

Recall that a stochastic cycle ψ_t with frequency λ , $0 < \lambda < \pi$, and damping coefficient ρ can be modeled as

$$\begin{bmatrix} \psi_t \\ \psi_t^* \end{bmatrix} = \rho \begin{bmatrix} \cos \lambda & \sin \lambda \\ -\sin \lambda & \cos \lambda \end{bmatrix} \begin{bmatrix} \psi_{t-1} \\ \psi_{t-1}^* \end{bmatrix} + \begin{bmatrix} \nu_t \\ \nu_t^* \end{bmatrix}$$

where ν_t and ν_t^* are independent, zero-mean, Gaussian disturbances with variance σ_ν^2 . In what follows, a state space form for a model consisting of such a stochastic cycle and an irregular component is given.

The state vector $\alpha_t = [\epsilon_t \ \psi_t \ \psi_t^*]'$, and the state noise vector $\zeta_t = [\epsilon_t \ \nu_t \ \nu_t^*]'$. The system matrices are

$$Z = [1 \ 1 \ 0] \quad T = \begin{bmatrix} 0 & 0 & 0 \\ 0 & \rho \cos \lambda & \rho \sin \lambda \\ 0 & -\rho \sin \lambda & \rho \cos \lambda \end{bmatrix} \quad Q = \text{Diag}[\sigma_\epsilon^2, \sigma_\nu^2, \sigma_\nu^2]$$

The distribution of the initial state vector α_1 is proper, with $P_* = \text{Diag}[\sigma_\epsilon^2, \sigma_\psi^2, \sigma_\psi^2]$, where $\sigma_\psi^2 = \sigma_\nu^2(1 - \rho^2)^{-1}$. The parameter vector $\theta = (\sigma_\epsilon^2, \rho, \lambda, \sigma_\nu^2)$.

An autoregression r_t can be considered as a special case of cycle with frequency λ equal to 0 or π . In this case the equation for ψ_t^* is not needed. Therefore, for a UCM consisting of an autoregressive component and an irregular component, the state space model simplifies to the following form.

The state vector $\alpha_t = [\epsilon_t \ r_t]'$, and the state noise vector $\zeta_t = [\epsilon_t \ v_t]'$. The system matrices are

$$Z = [1 \ 1], \quad T = \begin{bmatrix} 0 & 0 \\ 0 & \rho \end{bmatrix} \quad \text{and} \quad Q = \text{Diag}[\sigma_\epsilon^2, \sigma_v^2]$$

The distribution of the initial state vector α_1 is proper, with $P_* = \text{Diag}[\sigma_\epsilon^2, \sigma_r^2]$, where $\sigma_r^2 = \sigma_v^2(1 - \rho^2)^{-1}$. The parameter vector $\theta = (\sigma_\epsilon^2, \rho, \sigma_v^2)$.

Incorporating Predictors of Different Types

In the UCM procedure, you can incorporate predictors in a UCM in a variety of ways: you can specify simple time-invariant linear predictors in the **MODEL** statement, you can specify predictors that have time-varying coefficients in the **RANDOMREG** statement, and you can specify predictors that have a nonlinear relationship with the response variable in the **SPLINEREG** statement. You can also specify a transfer-function relationship by using the **TF** statement. As with earlier examples, the first part of this section uses a simple special case to show how to obtain a state space form of a UCM that consists of a variety of predictors (except the transfer-function relationship). The state space form that is associated with a transfer-function relationship is described in the section “**State Space Form of a Transfer Function Relationship**” on page 2170.

Consider a random walk trend model that has predictors x , u_1 , u_2 , and v . Assume that x is a simple regressor that is specified in the **MODEL** statement, u_1 and u_2 are random regressors with time-varying regression coefficients that are specified in the same **RANDOMREG** statement, and v is a nonlinear regressor that is specified in a **SPLINEREG** statement. Further assume that the spline that is associated with v has degree one and is based on two internal knots. As explained in the section “**SPLINEREG Statement**” on page 2151, using v is equivalent to using $(n \text{ knots} + \text{degree}) = (2 + 1) = 3$ derived (random) regressors: for example, s_1, s_2, s_3 . There are $(1 + 2 + 3) = 6$ regressors in all, the first one being a simple regressor and the others being time-varying coefficient regressors. The time-varying regressors are in two groups: the first group consists of u_1 and u_2 , and the other group consists of s_1, s_2 , and s_3 . The dynamics of this model are as follows:

$$\begin{aligned} y_t &= \mu_t + \beta x_t + \kappa_{1t} u_{1t} + \kappa_{2t} u_{2t} + \sum_{i=1}^3 \gamma_{it} s_{it} + \epsilon_t \\ \mu_t &= \mu_{t-1} + \eta_t \\ \kappa_{1t} &= \kappa_{1(t-1)} + \xi_{1t} \\ \kappa_{2t} &= \kappa_{2(t-1)} + \xi_{2t} \\ \gamma_{1t} &= \gamma_{1(t-1)} + \zeta_{1t} \\ \gamma_{2t} &= \gamma_{2(t-1)} + \zeta_{2t} \\ \gamma_{3t} &= \gamma_{3(t-1)} + \zeta_{3t} \end{aligned}$$

All the disturbances $\epsilon_t, \eta_t, \xi_{1t}, \xi_{2t}, \zeta_{1t}, \zeta_{2t}$, and ζ_{3t} are independent, zero-mean, Gaussian variables, where ξ_{1t}, ξ_{2t} share a common variance parameter σ_ξ^2 and $\zeta_{1t}, \zeta_{2t}, \zeta_{3t}$ share a common variance σ_ζ^2 . These dynamics can be captured in the state space form by taking state $\alpha_t = [\epsilon_t \ \mu_t \ \beta \ \kappa_{1t} \ \kappa_{2t} \ \gamma_{1t} \ \gamma_{2t} \ \gamma_{3t}]'$, state disturbance $\zeta_t = [\epsilon_t \ \eta_t \ 0 \ \xi_{1t} \ \xi_{2t} \ \zeta_{1t} \ \zeta_{2t} \ \zeta_{3t}]'$, and the system matrices

$$\begin{aligned} Z_t &= [1 \ 1 \ x_t \ u_{1t} \ u_{2t} \ s_{1t} \ s_{2t} \ s_{3t}] \\ T &= \text{Diag}[0, 1, 1, 1, 1, 1, 1, 1] \\ Q &= \text{Diag}[\sigma_\epsilon^2, \sigma_\eta^2, 0, \sigma_\xi^2, \sigma_\xi^2, \sigma_\zeta^2, \sigma_\zeta^2, \sigma_\zeta^2] \end{aligned}$$

Note that the regression coefficients are elements of the state vector and that the system vector Z_t is not time-invariant. The distribution of the initial state vector α_1 is diffuse, with $P_* = \text{Diag}[\sigma_\epsilon^2, 0, 0, 0, 0, 0, 0, 0]$ and $P_\infty = \text{Diag}[0, 1, 1, 1, 1, 1, 1, 1]$. The parameters of this model are the disturbance variances, σ_ϵ^2 , σ_η^2 , σ_ξ^2 , and σ_ζ^2 , which are estimated by maximizing the likelihood. The regression coefficients, time-invariant β , and time-varying κ_{1t} , κ_{2t} , γ_{1t} , γ_{2t} and γ_{3t} are implicitly estimated during the state estimation (smoothing).

State Space Form of a Transfer Function Relationship

This section illustrates the state space form of a simple transfer-function relationship. The state space form of more complicated transfer-function relationships can be deduced using the same logic. Suppose that a predictor x enters the model for a response variable y as

$$\begin{aligned} y_t &= f_t + \epsilon_t \\ f_t &= \frac{(\gamma_0 + \gamma_1 B)}{(1 - \delta_1 B - \delta_2 B^2)} x_t \end{aligned}$$

where f_t is the transfer-function component and ϵ_t is a sequence of independent, zero-mean, Gaussian variables. In this description, the transfer-function component is described using the backward shift operator B . Alternatively, it can be described as follows:

$$f_t = \delta_1 f_{t-1} + \delta_2 f_{t-2} + \gamma_0 x_t + \gamma_1 x_{t-1}$$

This model can be easily put in a state space form by taking state $\alpha_t = (\epsilon_t \ f_t \ f_{t-1} \ \gamma_0 \ \gamma_1)'$, state disturbance $\zeta_t = (\epsilon_t \ 0 \ 0 \ 0 \ 0)'$, the system matrices $Z = [1 \ 1 \ 0 \ 0 \ 0]$, $Q = \text{Diag}[\sigma_\epsilon^2 \ 0 \ 0 \ 0 \ 0]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & \delta_1 & \delta_2 & x_{t+1} & x_t \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

The initial state α_1 is partially diffuse. The precise form of the initial state depends on the value of the **TFSTART=** option in the **TF** statement. If the **TFSTART=** option is not specified, all elements of α_1 except for the first element (ϵ_1) are treated as diffuse. On the other hand, if a value is specified in the **TFSTART=** option, the initial transfer function values (f_1 and f_0) in α_1 are fixed at that specified value. In this formulation of the model, the numerator coefficients of the transfer-function relationship (γ_0 and γ_1) are part of the state. They are implicitly estimated during the state estimation (smoothing). On the other hand, the denominator coefficients (δ_1 and δ_2) and the noise variance (σ_ϵ^2) are estimated by maximizing the likelihood.

Reporting Parameter Estimates for Random Regressors

If the random walk disturbance variance that is associated with a random regressor is held fixed at 0, then its coefficient is no longer time-varying. In the UCM procedure, the random regressor parameter estimates are reported differently if the random walk disturbance variance that is associated with a random regressor is held fixed at 0. The following points explain how the parameter estimates are reported in the parameter estimates table and in the **OUTEST=** data set:

- If the random walk disturbance variance that is associated with a random regressor is not held fixed, then its estimate is reported in the parameter estimates table and in the **OUTEST=** data set.

- If more than one random regressor is specified in a **RANDOMREG** statement, then the first regressor in the list is used as a representative of the list when the corresponding common variance parameter estimate is reported.
- If the random walk disturbance variance is held fixed at 0, then the parameter estimates table and the OUTEST= data set contain the corresponding regression parameter estimate rather than the variance parameter estimate.
- Similar considerations apply in the case of the derived random regressors that are associated with a spline regressor.

Forecasting with Predictor Variables

If regression effects are included in the model (in a **MODEL** statement or in one or more of the **RANDOMREG**, **SPLINEREG**, and **TF** statements) and the **FORECAST** statement is used to compute multistep forecasts, then future values of the predictor variables must be included in the **DATA=** data set for the forecast horizon that is defined by the **BACK=** and **LEAD=** options in the **FORECAST** statement. For more information about how the forecast horizon is defined, see the **FORECAST** statement.

ARMA Irregular Component

The state space form for the irregular component that follows an $\text{ARMA}(p, q) \times (P, Q)_s$ model is described in this section. The notation for ARMA models is explained in the **IRREGULAR** statement. A number of alternate state space forms are possible in this case; the one given here is based on Jones (1980). With slight abuse of notation, let $p = p + sP$ denote the effective autoregressive order and $q = q + sQ$ denote the effective moving average order of the model. Similarly, let ϕ be the effective autoregressive polynomial and θ be the effective moving average polynomial in the backshift operator with coefficients $\phi_1, \dots, \phi_p$ and $\theta_1, \dots, \theta_q$, obtained by multiplying the respective nonseasonal and seasonal factors. Then, a random sequence ϵ_t that follows an $\text{ARMA}(p, q) \times (P, Q)_s$ model with a white-noise sequence a_t has a state space form with state vector of size $m = \max(p, q + 1)$. The system matrices, which are time invariant, are as follows: $Z = [1 \ 0 \ \dots \ 0]$. The state transition matrix T , in a blocked form, is given by

$$T = \begin{bmatrix} 0 & I_{m-1} \\ \phi_m & \dots & \phi_1 \end{bmatrix}$$

where $\phi_i = 0$ if $i > p$ and I_{m-1} is an $(m - 1)$ dimensional identity matrix. The covariance of the state disturbance matrix $Q = \sigma^2 \psi \psi'$ where σ^2 is the variance of the white-noise sequence a_t and the vector $\psi = [\psi_0 \ \dots \ \psi_{m-1}]'$ contains the first m values of the impulse response function—that is, the first m coefficients in the expansion of the ratio θ/ϕ . Since ϵ_t is a stationary sequence, the initial state is nondiffuse and $P_\infty = 0$. The description of P_* , the covariance matrix of the initial state, is a little involved; the details are given in Jones (1980).

Models with Dependent Lags

The state space form of a UCM consisting of the lags of the dependent variable is quite different from the state space forms considered so far. Let us consider an example to illustrate this situation. Consider a model that has random walk trend, two simple time-invariant regressors, and that also includes a few—for example,

k —lags of the dependent variable. That is,

$$\begin{aligned} y_t &= \sum_{i=1}^k \phi_i y_{t-i} + \mu_t + \beta_1 x_{1t} + \beta_2 x_{2t} + \epsilon_t \\ \mu_t &= \mu_{t-1} + \eta_t \end{aligned}$$

The state space form of this augmented model can be described in terms of the state space form of a model that has random walk trend with two simple time-invariant regressors. A superscript dagger ($\dagger$) has been added to distinguish the augmented model state space entities from the corresponding entities of the state space form of the random walk with predictors model. With this notation, the state vector of the augmented model $\alpha_t^\dagger = [\alpha_t' y_t y_{t-1} \dots y_{t-k+1}]'$ and the new state noise vector $\zeta_t^\dagger = [\zeta_t' u_t 0 \dots 0]'$, where u_t is the matrix product $Z_t \zeta_t$. Note that the length of the new state vector is $k + \text{length}(\alpha_t) = k + 4$. The new system matrices, in block form, are

$$Z_t^\dagger = [0 \ 0 \ 0 \ 0 \ 1 \ \dots \ 0], \quad T_t^\dagger = \begin{bmatrix} T_t & 0 & \dots & 0 \\ Z_{t+1} T_t & \phi_1 & \dots & \phi_k \\ 0 & I_{k-1, k-1} & & 0 \end{bmatrix}$$

where $I_{k-1, k-1}$ is the $k - 1$ dimensional identity matrix and

$$Q_t^\dagger = \begin{bmatrix} Q_t & Q_t Z_t' & 0 \\ Z_t Q_t & Z_t Q_t Z_t' & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

Note that the T and Q matrices of the random walk with predictors model are time invariant, and in the expressions above their time indices are kept because they illustrate the pattern for more general models. The initial state vector is diffuse, with

$$P_*^\dagger = \begin{bmatrix} P_* & 0 \\ 0 & 0 \end{bmatrix}, \quad P_\infty^\dagger = \begin{bmatrix} P_\infty & 0 \\ 0 & I_{k, k} \end{bmatrix}$$

The parameters of this model are the disturbance variances σ_ϵ^2 and σ_η^2 , the lag coefficients $\phi_1, \phi_2, \dots, \phi_k$, and the regression coefficients β_1 and β_2 . As before, the regression coefficients get estimated during the state smoothing, and the other parameters are estimated by maximizing the likelihood.

Outlier Detection

In time series analysis it is often useful to detect changes over time in the characteristics of the response series. In the UCM procedure you can search for two types of changes, additive outliers (AO) and level shifts (LS). An additive outlier is an unusual value in the series, the cause of which might be a data recording error or a temporary shock to the series generation process. A level shift represents a permanent shift, either up or down, in the level of the series. You can control different aspects of the outlier search, such as the significance level of the reported outliers, by choosing different options in the **OUTLIER** statement. The search for AOs is done by default, whereas the **CHECKBREAK** option in the **LEVEL** statement must be used to turn on the search for LSs.

The outlier detection process implemented in the UCM procedure is based on De Jong and Penzer (1998). In this approach the fitted model is taken to be the *null* model, and the series values and level shifts that are

not adequately accounted for by the null model are flagged as outliers. The unusualness of a response series value at a particular time point t_0 , with respect to the fitted model, can be judged by estimating its value based on the rest of the data (that is, the series obtained by *deleting* the series value at t_0) and comparing the estimated value to the observed value. If the difference between the estimated and observed values is statistically significant, then such value can be regarded as an AO. Note that this difference between the estimated and observed values is also the regression coefficient of a *dummy* regressor that takes the value 1.0 at t_0 and is 0.0 elsewhere, assuming such a regressor is added to the null model. In this way the series value at t_0 is regarded as AO if the regression coefficient of this dummy regressor is significant. Similarly, you can say that a level shift has occurred at a time point t_0 if the regression coefficient of a regressor, which is 0.0 before t_0 and 1.0 at t_0 and thereafter, is statistically significant. De Jong and Penzer (1998) provide an efficient way to compute such AO and LS regression coefficients and their standard errors at all time points in the series. The outlier summary table, which is produced by default, simply lists the most statistically significant candidates among these.

Missing Values

Embedded missing values in the dependent variable usually cause no problems in UCM modeling. However, no missing values are allowed in the predictor variables. Certain patterns of missing values in the dependent variable can lead to failure of the initialization step of the diffuse Kalman filtering for some models. For example, if in a monthly series all values are missing for a certain month—such as May—then a BSM with monthly seasonality leads to such a situation. However, in this case the initialization step can complete successfully for a nonseasonal model such as local linear model.

Parameter Estimation

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression, the lag coefficients of the dependent lags, and the regression coefficients in the regression terms. The regression coefficients are always part of the state vector and are estimated by state smoothing. The remaining parameters are estimated by maximizing either the full diffuse likelihood or the nondiffuse likelihood. The decision to use the full diffuse likelihood or the nondiffuse likelihood depends on the presence or absence of the dependent lag coefficients in the parameter vector. If the parameter vector does not contain any dependent lag coefficients, then the full diffuse likelihood is used. If, on the other hand, the parameter vector does contain some dependent lag coefficients, then the parameters are estimated by maximizing the nondiffuse likelihood. The optimization of the full diffuse likelihood is often unstable when the parameter vector contains dependent lag coefficients. In this sense, when the parameter vector contains dependent lag coefficients, the parameter estimates are not true maximum likelihood estimates.

The optimization of the likelihood, either full or nondiffuse, is carried out using one of several nonlinear optimization algorithms. The user can control many aspects of the optimization process by using the **NLOPTIONS** statement and by providing the starting values of the parameters while specifying the corresponding components. However, in most cases the default settings work quite well. The optimization process is not guaranteed to converge to a maximum likelihood estimate. In most cases the difficulties in parameter estimation are associated with the specification of a model that is not appropriate for the series being modeled.

Parameter Estimation by Profile Likelihood Optimization

If a disturbance variance, such as the disturbance variance of the irregular component, is a part of the UCM and is a free parameter, then it can be profiled out of the likelihood. This means solving analytically for its optimum and plugging this expression back into the likelihood formula, giving rise to the so-called *profile* likelihood. The expression of the profile likelihood and the MLE of the profiled variance are given earlier in the section “[UCMs as State Space Models](#)” on page 2162, where the computation of the likelihood of the state space model is also discussed.

In some situations the optimization of the profile likelihood can be more efficient because the number of parameters to optimize is reduced by one; however, for a variety of reasons such gains might not always be observed. Moreover, in theory the estimates obtained by optimizing the profile likelihood and the usual likelihood should be the same, but in practice this might not hold because of numerical rounding and other conditions.

In the UCM procedure, by default the usual likelihood is optimized if any of the disturbance variance parameters is held fixed to a nonzero value by using the NOEST option in the corresponding component statement. In other cases the decision whether to optimize the profile likelihood or the usual likelihood is based on several factors that are difficult to document. You can choose which likelihood to optimize during parameter estimation by specifying the **PROFILE** option for the profile likelihood optimization or the **NOPROFILE** option for the usual likelihood optimization. In the presence of the **PROFILE** option, the disturbance variance to profile is checked in a specific order, so that if the irregular component disturbance variance is free then it is always chosen. The situation in other cases is more complicated.

Profiling in the Presence of Fixed Variance Parameters

Note that when the parameter estimation is done by optimizing the profile likelihood, the interpretation of the variance parameters that are held fixed to nonzero values changes. In the presence of the **PROFILE** option, the disturbance variances that are held at a fixed value by using the NOEST option in their respective component statements are interpreted as being restricted to be that fixed multiple of the profiled variance rather than being fixed at that nominal value. That is, implicitly, the parameter estimation is done under the restriction of holding the disturbance variance *ratio* fixed at a given value rather than the disturbance variance itself. For an example of this type of restriction to obtain a UC model that is equivalent to the famous Hodrick-Prescott filter, see [Example 30.5](#).

t Values

The *t* values reported in the table of parameter estimates are approximations whose accuracy depends on the validity of the model, the nature of the model, and the length of the observed series. The distributional properties of the maximum likelihood estimates of general unobserved components models have not been explored fully; therefore the probability values that correspond to a *t* distribution should be interpreted carefully, as they can be misleading. This is particularly true if the parameters in question are close to the boundary of the parameter space. The two sources by Harvey (1989, 2001) are good references for information about this topic. For some parameters, such as the cycle period, the reported *t* values are uninformative because comparison of the estimated parameter with 0 is never needed. In such cases the *t* values and the corresponding probability values should be ignored.

Computational Issues

Convergence Problems

As explained in the section “[Parameter Estimation](#)” on page 2173, the model parameters are estimated by nonlinear optimization of the likelihood. This process is not guaranteed to succeed. For some data sets, the optimization algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data. It is also possible for the algorithm to converge to a point that is not the global optimum of the likelihood.

If you experience convergence problems, the following points might be helpful:

- Data that are extremely large or extremely small can adversely affect results because of the internal tolerances used during the filtering steps of the likelihood calculation. Rescaling the data can improve stability.
- Examine your model for redundancies in the included components and regressors. If some of the included components or regressors are nearly collinear to each other, then the optimization process can become unstable.
- Experimenting with different options offered by the [NLOPTIONS](#) statement can help.
- Lack of convergence can indicate model misspecification or a violation of the normality assumption.

Computer Resource Requirements

The computing resources required for the UCM procedure depend on several factors. The memory requirement for the procedure is largely dependent on the number of observations to be processed and the size of the state vector underlying the specified model. If n denotes the sample size and m denotes the size of the state vector, the memory requirement for the smoothing stage of the Kalman filter is of the order of $6 \times 8 \times n \times m^2$ bytes, ignoring the lower-order terms. If the smoothed component estimates are not needed then the memory requirement is of the order of $6 \times 8 \times (m^2 + n)$ bytes. Besides m and n , the computing time for the parameter estimation depends on the type of components included in the model. For example, the parameter estimation is usually faster if the model parameter vector consists only of disturbance variances, because in this case there is an efficient way to compute the likelihood gradient.

Displayed Output

The default printed output produced by the UCM procedure is described in the following list:

- brief information about the input data set, including the data set name and label, and the name of the ID variable specified in the ID statement
- summary statistics for the data in the estimation and forecast spans, including the names of the variables in the model, their categorization as dependent or predictor, the index of the beginning and ending observations in the spans, the total number of observations and the number of missing observations, the smallest and largest measurements, and the mean and standard deviation

- information about the model parameters at the start of the model-fitting stage, including the fixed parameters in the model and the initial estimates of the free parameters in the model
- convergence status of the likelihood optimization process if any parameter estimation is done
- estimates of the free parameters at the end of the model fitting-stage, including the parameter estimates, their approximate standard errors, t statistics, and the approximate p -value
- the likelihood-based goodness-of-fit statistics, including the full likelihood, the portion of the likelihood corresponding to the diffuse initialization, the sum of squares of residuals normalized by their standard errors, and the information criteria: AIC, AICC, HQIC, BIC, and CAIC
- the fit statistics that are based on the raw residuals (observed minus predicted), including the mean squared error (MSE), the root mean squared error (RMSE), the mean absolute percentage error (MAPE), the maximum percentage error (MAXPE), the R-square, the adjusted R-square, the random walk R-square, and Amemiya's R-square
- the significance analysis of the components included in the model that is based on the estimation span
- brief information about the components included in the model
- additive outliers in the series, if any are detected
- the multistep series forecasts
- post-sample-prediction analysis table that compares the multistep forecasts with the observed series values, if the BACK= option is used in the FORECAST statement

Statistical Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, “Statistical Graphics Using ODS” (*SAS/STAT User's Guide*).

This section provides information about the basic ODS statistical graphics produced by the UCM procedure.

You can obtain most plots relevant to the specified model by using the global **PLOTS=** option in the PROC UCM statement. The plot of series forecasts in the forecast horizon is produced by default. You can further control the production of individual plots by using the **PLOT=** options in the different statements.

The main types of plots available are as follows:

- Time series plots of the component estimates, either filtered or smoothed, can be requested by using the **PLOT=** option in the respective component statements. For example, the use of **PLOT=SMOOTH** option in a CYCLE statement produces a plot of smoothed estimate of that cycle.
- Residual plots for model diagnostics can be obtained by using the **PLOT=** option in the ESTIMATE statement.
- Plots of series forecasts and model decompositions can be obtained by using the **PLOT=** option in the FORECAST statement.

The following example is a simple illustration of the available plot options.

Analysis of Sunspot Data: Illustration of ODS Graphics

In this example a well-known series, Wolfer's sunspot data (Anderson 1971), is considered. The data consist of yearly sunspot numbers recorded from 1749 to 1924. These sunspot numbers are known to have a cyclical pattern with a period of about eleven years. The following DATA step creates the input data set:

```
data sunspot;
    input year wolfer @@;
    year = mdy(1,1, year);
    format year year4.;
datalines;
1749  809 1750  834 1751  477 1752  478 1753  307 1754  122 1755   96
1756  102 1757  324 1758  476 1759  540 1760  629 1761  859 1762  612

... more lines ...

/* Load data into mylib */
data mylib.sunspot;
    set sunspot;
run;
```

The following statements specify a UCM that includes a cycle component and a random walk trend component:

```
proc ucm data=mylib.sunspot;
    id year interval=year;
    model wolfer;
    irregular;
    level ;
    cycle plot=(filter smooth);
    estimate back=24 plot=(loess panel cusum wn);
    forecast back=24 lead=24 plot=(forecasts decomp);
run;
```

The following subsections explain the graphics produced by the preceding statements.

Component Plots

The plots in Figure 30.8 and Figure 30.9, produced by specifying PLOT=(FILTER SMOOTH) in the CYCLE statement, show the filtered and smoothed estimates, respectively, of the cycle component in the model. Note that the smoothed estimate appears smoother than the filtered estimate. This is always true because the filtered estimate of a component at time t is based on the observations prior to time t —that is, it uses measurements from the first observation up to the $(t - 1)$ th observation. On the other hand, the corresponding smoothed estimate uses all the available observations—that is, all the measurements from the first observation to the last. This makes the smoothed estimate of the component more precise than the filtered estimate for the time points within historical period. In the forecast horizon, both filtered and smoothed estimates are identical, being based on the same set of observations.

Figure 30.8 Sunspots Series: Filtered Cycle

Figure 30.9 Sunspots Series: Smoothed Cycle**Residual Diagnostics**

If the fitted model is appropriate for the given data, then the corresponding one-step-ahead residuals should be approximately *white*—that is, uncorrelated—and approximately normal. Moreover, the residuals should not display any discernible pattern. You can detect departures from these conditions graphically. Different residual diagnostic plots can be requested by using the `PLOT=` option in the `ESTIMATE` statement.

The normality can be checked by examining the histogram and the normal quantile plot of residuals. The whiteness can be checked by examining the ACF and PACF plots that show the sample autocorrelation and sample partial-autocorrelation at different lags. The diagnostic panel shown in [Figure 30.10](#), produced by specifying `PLOT=PANEL`, contains these four plots.

Figure 30.10 Sunspots Series: Residual Diagnostics

The residual histogram and Q-Q plot show no serious violation of normality. The histogram appears reasonably symmetric and follows the overlaid normal density curve reasonably closely. Similarly, in the Q-Q plot the residuals follow the reference line fairly closely. The ACF and PACF plots also do not exhibit any violation of the whiteness assumption; the correlations at all nonzero lags seem to be insignificant.

The residual whiteness can also be formally tested by using the Ljung-Box portmanteau test. The plot in [Figure 30.11](#), produced by specifying `PLOT=WN`, shows the p -values of the Ljung-Box test statistics at different lags. In these plots the p -values for the first few lags, equal to the number of estimated parameters in the model, are not shown because they are always missing. This portion of the plot is shaded blue to indicate this fact. In the case of this model, five parameters are estimated so the p -values for the first five lags are not shown. The p -values are displayed on a log scale in such a way that higher bars imply more extreme test statistics. In this plot some early p -values appear extreme. However, these p -values are based on large sample theory, which suggests that these statistics should be examined for lags larger than the square root of sample size. In this example it means that the p -values for the first $\sqrt{154} \approx 12$ lags can be ignored. With this consideration, the plot shows no violation of whiteness since the p -values after the 12th lag do not appear extreme.

Figure 30.11 Sunspots Series: Ljung-Box Portmanteau Test

The plot in [Figure 30.12](#), produced by specifying PLOT=LOESS, shows the residuals plotted against time with an overlaid loess curve. This plot is useful for checking whether any discernible pattern remains in the residuals. Here again, no significant pattern appears to be present.

Figure 30.12 Sunspots Series: Residual Loess Plot

The plot in [Figure 30.13](#), produced by specifying `PLOT=CUSUM`, shows the cumulative residuals plotted against time. This plot is useful for checking structural breaks. Here, there appears to be no evidence of structural break since the cumulative residuals remain within the confidence band throughout the sample period. Similarly, you can request a plot of the squared cumulative residuals by specifying `PLOT=CUSUMSQ`.

Figure 30.13 Sunspots Series: CUSUM Plot

Brockwell and Davis (1991) can be consulted for additional information on diagnosing residuals. For more information about CUSUM and CUSUMSQ plots, you can consult Harvey (1989).

Forecast and Series Decomposition Plots

You can use the PLOT= option in the FORECAST statement to obtain the series forecast plot and the series decomposition plots. The series decomposition plots show the result of successively adding different components in the model starting with the trend component. The IRREGULAR component is left out of this process. The following two plots, produced by specifying PLOT=DECOMP, show the results of successive component addition for this example. The first plot, shown in Figure 30.14, shows the smoothed trend component and the second plot, shown in Figure 30.15, shows the sum of smoothed trend and cycle.

Figure 30.14 Sunspots Series: Smoothed Trend

Figure 30.15 Sunspots Series: Smoothed Trend plus Cycle

Finally, Figure 30.16 shows the forecast plot.

Figure 30.16 Sunspots Series: Series Forecasts

ODS Table Names

The UCM procedure assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 30.2](#).

Table 30.2 ODS Tables Produced by PROC UCM

ODS Table Name	Description	Statement	Option
Tables Summarizing the Estimation and Forecast Spans			
EstimationSpan	Estimation span summary information		Default
ForecastSpan	Forecast span summary information		Default

Table 30.2 *continued*

ODS Table Name	Description	Statement	Option
Tables Related to Model Parameters			
ConvergenceStatus	Convergence status of the estimation process		Default
FixedParameters	Fixed parameters in the model		Default
ParameterEstimates	Final estimates of the free parameters		Default
Tables Related to Model Information and Diagnostics			
BlockSeasonDescription	Information about the block seasonals in the model		Default
ComponentSignificance	Significance analysis of the components in the model		Default
CycleDescription	Information about the cycles in the model		Default
FitStatistics	Fit statistics based on the one-step-ahead predictions		Default
FitSummary	Likelihood-based fit statistics		Default
OutlierSummary	Summary table of the detected outliers		Default
AdditiveOutliers	AO statistics computed at each time point in the estimation span	OUTLIER	PRINT=DETAIL
LevelShifts	LS statistics computed at each time point in the estimation span	OUTLIER	PRINT=DETAIL
SeasonDescription	Information about the seasonals in the model		Default
SeasonHarmonics	Summary of harmonics in a trigonometric seasonal component	SEASON	PRINT=HARMONICS
SplineSeasonDescription	Information about the spline-seasonals in the model		Default
TrendInformation	Summary information of the level and slope components		Default
Tables Related to Filtered Component Estimates			
FilteredAutoReg	Filtered estimate of an autoreg component	AUTOREG	PRINT=FILTER
FilteredBlockSeason	Filtered estimate of a block seasonal component	BLOCKSEASON	PRINT=FILTER
FilteredCycle	Filtered estimate of a cycle component	CYCLE	PRINT=FILTER

Table 30.2 *continued*

ODS Table Name	Description	Statement	Option
FilteredIrregular	Filtered estimate of the irregular component	IRREGULAR	PRINT=FILTER
FilteredLevel	Filtered estimate of the level component	LEVEL	PRINT=FILTER
FilteredRandomReg	Filtered estimate of the time-varying random-regression coefficient	RANDOMREG	PRINT=FILTER
FilteredSeason	Filtered estimate of a seasonal component	SEASON	PRINT=FILTER
FilteredSlope	Filtered estimate of the slope component	SLOPE	PRINT=FILTER
FilteredSplineReg	Filtered estimate of the time-varying spline-regression coefficient	SPLINEREG	PRINT=FILTER
FilteredSplineSeason	Filtered estimate of a spline-seasonal component	SPLINESEASON	PRINT=FILTER
Tables Related to Smoothed Component Estimates			
SmoothedAutoReg	Smoothed estimate of an autoreg component	AUTOREG	PRINT=SMOOTH
SmoothedBlockSeason	Smoothed estimate of a block seasonal component	BLOCKSEASON	PRINT=SMOOTH
SmoothedCycle	Smoothed estimate of the cycle component	CYCLE	PRINT=SMOOTH
SmoothedIrregular	Smoothed estimate of the irregular component	IRREGULAR	PRINT=SMOOTH
SmoothedLevel	Smoothed estimate of the level component	LEVEL	PRINT=SMOOTH
SmoothedRandomReg	Smoothed estimate of the time-varying random-regression coefficient	RANDOMREG	PRINT=SMOOTH
SmoothedSeason	Smoothed estimate of a seasonal component	SEASON	PRINT=SMOOTH
SmoothedSlope	Smoothed estimate of the slope component	SLOPE	PRINT=SMOOTH
SmoothedSplineReg	Smoothed estimate of the time-varying spline-regression coefficient	SPLINEREG	PRINT=SMOOTH
SmoothedSplineSeason	Smoothed estimate of a spline-seasonal component	SPLINESEASON	PRINT=SMOOTH

Table 30.2 *continued*

ODS Table Name	Description	Statement	Option
Tables Related to Series Decomposition and Forecasting			
FilteredAllExceptIrreg	Filtered estimate of sum of all components except the irregular component	FORECAST	PRINT=FDECOMP
FilteredTrend	Filtered estimate of trend	FORECAST	PRINT= FDECOMP
FilteredTrendReg	Filtered estimate of trend plus regression	FORECAST	PRINT=FDECOMP
FilteredTrendRegCyc	Filtered estimate of trend plus regression plus cycles and autoreg	FORECAST	PRINT=FDECOMP
Forecasts	Dependent series forecasts		Default
PostSamplePrediction	Forecasting performance in the holdout period	FORECAST	BACK=
SmoothedAllExceptIrreg	Smoothed estimate of sum of all components except the irregular component	FORECAST	PRINT=DECOMP
SmoothedTrend	Smoothed estimate of trend	FORECAST	PRINT= DECOMP
SmoothedTrendReg	Smoothed estimate of trend plus regression	FORECAST	PRINT=DECOMP
SmoothedTrendRegCyc	Smoothed estimate of trend plus regression plus cycles and autoreg	FORECAST	PRINT=DECOMP

NOTE: The tables are related to a single series within a BY group. In the case of models that contain multiple cycles, seasonal components, or block seasonal components, the corresponding component estimate tables are sequentially numbered. For example, if a model contains two cycles and a seasonal component and the PRINT=SMOOTH option is used for each of them, the ODS tables containing the smoothed estimates will be named SmoothedCycle1, SmoothedCycle2, and SmoothedSeason. Note that the seasonal table is not numbered because there is only one seasonal component. There are some exceptions to this numbering rule: the tables, FilteredRandomReg, SmoothedRandomReg, FilteredSplineReg, and SmoothedSplineReg, are always numbered starting with 0.

ODS Graph Names

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 24, “Statistical Graphics Using ODS” (*SAS/STAT User’s Guide*).

You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC UCM generates are listed in Table 30.3, along with the required statements and options.

Table 30.3 ODS Graphics Produced by PROC UCM

ODS Graph Name	Description	Statement	Option
Plots Related to Residual Analysis			
ErrorACFPlot	Prediction error autocorrelation plot	ESTIMATE	PLOT=ACF
ErrorPACFPlot	Prediction error partial-autocorrelation plot	ESTIMATE	PLOT=PACF
ErrorHistogram	Prediction error histogram	ESTIMATE	PLOT=NORMAL

OUTFOR= Data Set

You can use the OUTFOR= option in the FORECAST statement to store the series and component forecasts produced by the procedure. This data set contains the following columns:

- the BY variables
- the ID variable. If an ID variable is not specified, then a numerical variable, `_ID_`, is created that contains the observation numbers from the input data set.
- the dependent series and the predictor series
- FORECAST, a numerical variable containing the one-step-ahead predicted values and the multistep forecasts
- RESIDUAL, a numerical variable containing the difference between the actual and forecast values
- STD, a numerical variable containing the standard error of prediction
- LCL and UCL, numerical variables containing the lower and upper forecast confidence limits
- S_SERIES and VS_SERIES, numerical variables containing the smoothed values of the dependent series and their variances
- S_IRREG and VS_IRREG, numerical variables containing the smoothed values of the irregular component and their variances. These variables are present only if the model has an irregular component.
- F_LEVEL, VF_LEVEL, S_LEVEL, and VS_LEVEL, numerical variables containing the filtered and smoothed values of the level component and the respective variances. These variables are present only if the model has a level component.
- F_SLOPE, VF_SLOPE, S_SLOPE, and VS_SLOPE, numerical variables containing the filtered and smoothed values of the slope component and the respective variances. These variables are present only if the model has a slope component.
- F_AUTOREG, VF_AUTOREG, S_AUTOREG, and VS_AUTOREG, numerical variables containing the filtered and smoothed values of the autoreg component and the respective variances. These variables are present only if the model has an autoreg component.
- F_CYCLE, VF_CYCLE, S_CYCLE, and VS_CYCLE, numerical variables containing the filtered and smoothed values of the cycle component and the respective variances. If there are multiple cycles in the model, these variables are sequentially numbered as `F_CYCLE1`, `F_CYCLE2`, and so on. These variables are present only if the model has at least one cycle component.
- F_SEASON, VF_SEASON, S_SEASON, and VS_SEASON, numerical variables containing the filtered and smoothed values of the season component and the respective variances. If there are multiple seasons in the model, these variables are sequentially numbered as `F_SEASON1`, `F_SEASON2`, and so on. These variables are present only if the model has at least one season component.
- F_BLKSEAS, VF_BLKSEAS, S_BLKSEAS, and VS_BLKSEAS, numerical variables containing the filtered and smoothed values of the blockseason component and the respective variances. If there are multiple block seasons in the model, these variables are sequentially numbered as `F_BLKSEAS1`, `F_BLKSEAS2`, and so on.

- F_SPLSEAS, VF_SPLSEAS, S_SPLSEAS, and VS_SPLSEAS, numerical variables containing the filtered and smoothed values of the splinesseason component and the respective variances. If there are multiple spline seasons in the model, these variables are sequentially numbered as F_SPLSEAS1, F_SPLSEAS2, and so on. These variables are present only if the model has at least one splinesseason component.
- Filtered and smoothed estimates, and their variances, of the time-varying regression coefficients of the variables that are specified in the RANDOMREG and SPLINEREG statements. A variable is not included if its coefficient is time-invariant, that is, if the associated disturbance variance is 0.
- F_TF, VF_TF, S_TF, and VS_TF, numerical variables that contain the filtered and smoothed values of the transfer-function component and their variances. If there are multiple transfer-function components in the model, these variables are sequentially numbered as F_TF1, F_TF2, and so on. These variables are present only if the model has at least one transfer-function component.
- S_TREG and VS_TREG, numerical variables containing the smoothed values of level plus regression component and their variances. These variables are present only if the model has at least one predictor variable or has dependent lags.
- S_TREGCYC and VS_TREGCYC, numerical variables containing the smoothed values of level plus regression plus cycle component and their variances. These variables are present only if the model has at least one cycle or an autoreg component.
- S_NOIRREG and VS_NOIRREG, numerical variables containing the smoothed values of the sum of all components except the irregular component and their variances. These variables are present only if the model has at least one seasonal or block seasonal component.

OUTEST= Data Set

You can use the OUTEST= option in the ESTIMATE statement to store the model parameters and the related estimation details. This data set contains the following columns:

- the BY variables
- COMPONENT, a character variable containing the name of the component corresponding to the parameter being described
- PARAMETER, a character variable containing the parameter name
- TYPE, a character variable indicating whether the parameter value was fixed by the user or estimated
- _STATUS_, a character variable indicating whether the parameter estimation process converged or failed or there was an error of some other kind
- ESTIMATE, a numerical variable containing the parameter estimate
- STD, a numerical variable containing the standard error of the parameter estimate. This has a missing value if the parameter value is fixed.

- TVALUE, a numerical variable containing the t -statistic. This has a missing value if the parameter value is fixed.
- PVALUE, a numerical variable containing the p -value. This has a missing value if the parameter value is fixed.

Statistics of Fit

This section explains the goodness-of-fit statistics reported to measure how well the specified model fits the data.

First the various statistics of fit that are computed using the prediction errors, $y_t - \hat{y}_t$, are considered. In these formulas, n is the number of nonmissing prediction errors and k is the number of fitted parameters in the model. Moreover, the sum of squared errors, $SSE = \sum (y_t - \hat{y}_t)^2$, and the total sum of squares for the series corrected for the mean, $SST = \sum (y_t - \bar{y})^2$, where $\bar{y}$ is the series mean, and the sums are over all the nonmissing prediction errors.

Mean Square Error

The mean square prediction error, $MSE = \frac{1}{n}SSE$

Root Mean Square Error

The root mean square error, $RMSE = \sqrt{MSE}$

Mean Absolute Percentage Error

The mean absolute percentage prediction error, $MAPE = \frac{100}{n} \sum_{t=1}^n |(y_t - \hat{y}_t)/y_t|$.

The summation ignores observations where $y_t = 0$.

R-Square

The R-square statistic, $R^2 = 1 - SSE/SST$.

If the model fits the series badly, the model error sum of squares, SSE, might be larger than SST and the R-square statistic will be negative.

Adjusted R-Square

The adjusted R-square statistic, $1 - (\frac{n-1}{n-k})(1 - R^2)$

Amemiya's Adjusted R-Square

Amemiya's adjusted R-square, $1 - (\frac{n+k}{n-k})(1 - R^2)$

Random Walk R-Square

The random walk R-square statistic (Harvey's R-square statistic that uses the random walk model for comparison), $1 - (\frac{n-1}{n})SSE/RWSSE$, where $RWSSE = \sum_{t=2}^n (y_t - y_{t-1} - \mu)^2$, and $\mu = \frac{1}{n-1} \sum_{t=2}^n (y_t - y_{t-1})$

Maximum Percentage Error

The largest percentage prediction error, $100 \max((y_t - \hat{y}_t)/y_t)$. In this computation the observations where $y_t = 0$ are ignored.

The likelihood-based fit statistics are reported separately (see the section “UCMs as State Space Models” on page 2162). They include the full log likelihood (L_∞), the diffuse part of the log likelihood, the normalized residual sum of squares, and several information criteria: AIC, AICC, HQIC, BIC, and CAIC. Let q denote the number of estimated parameters, n be the number of nonmissing measurements in the estimation span, and d

be the number of diffuse elements in the initial state vector that are successfully initialized during the Kalman filtering process. Moreover, let $n^* = (n - d)$. The reported information criteria, all in smaller-is-better form, are described in Table 30.4.

Table 30.4 Information Criteria

Criterion	Formula	Reference
AIC	$-2L_\infty + 2q$	Akaike (1974)
AICC	$-2L_\infty + 2qn^*/(n^* - q - 1)$	Hurvich and Tsai (1989)
HQIC	$-2L_\infty + 2q \log \log(n^*)$	Burnham and Anderson (1998)
BIC	$-2L_\infty + q \log(n^*)$	Hannan and Quinn (1979)
CAIC	$-2L_\infty + q(\log(n^*) + 1)$	Schwarz (1978)
		Bozdogan (1987)

Examples: UCM Procedure

Example 30.1: The Airline Series Revisited

The series in this example, the monthly airline passenger series, has already been discussed earlier; see the section “A Seasonal Series with Linear Trend” on page 2115. Recall that the series consists of monthly numbers of international airline travelers (from January 1949 to December 1960). Here additional output features of the UCM procedure are illustrated, such as how to use the ESTIMATE and FORECAST statements to limit the span of the data used in parameter estimation and forecasting. The following statements fit a basic structural model (BSM) to the logarithm of the airline passenger numbers. The disturbance variance for the slope component is held fixed at value 0; that is, the trend is locally linear with constant slope. In order to evaluate the performance of the fitted model on observed data, some of the observed data are withheld during parameter estimation and forecast computations. The observations in the last two years, 1959 and 1960, are not used in parameter estimation, while the observations in the last year, 1960, are not used in the forecasting computations. This is done using the BACK= option in the ESTIMATE and FORECAST statements. In addition, a panel of residual diagnostic plots is obtained using the PLOT= PANEL option in the ESTIMATE statement.

```
data seriesG;
  set sashelp.air;
  logair = log(air);
run;

/* Load data into mylib */
data mylib.seriesG;
  set seriesG;
run;
```

```

proc ucm data = mylib.seriesG;
  id date interval = month;
  model logair;
  irregular;
  level;
  slope var = 0 noest;
  season length = 12 type=trig;
  estimate back=24 plot=panel;
  forecast back=12 lead=24 print=forecasts;
run;

```

Output 30.1.1 and Output 30.1.2 display the summary of data used in estimation and forecasting, respectively. These tables provide simple summary statistics for the estimation and forecast spans; they include useful information such as the beginning and ending dates of the span, the number of nonmissing values, and so on.

Output 30.1.1 Observation Span Used in Parameter Estimation (Partial Output)

Variable	Type	First	Last	Nobs	Mean
logair	Dependent	JAN1949	DEC1958	120	5.43035

Output 30.1.2 Observation Span Used in Forecasting (Partial Output)

Variable	Type	First	Last	Nobs	Mean
logair	Dependent	JAN1949	DEC1959	132	5.48654

Output 30.1.3, and Output 30.1.4 display the fixed parameters in the model and the final estimates of the free parameters, respectively.

Output 30.1.3 Fixed Parameters in the Model

The UCM Procedure

Fixed Parameters in the Model		
Component	Parameter	Value
Slope	Error Variance	0

Output 30.1.4 Maximum Likelihood Estimates of the Free Parameters

The UCM Procedure

Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.00018686	0.0001	1.54	0.1233
Level	Error Variance	0.00040314	0.0002	2.57	0.0100
Season	Error Variance	0.00000350	0.0000	2.10	0.0354

Two types of goodness-of-fit statistics are reported after a model is fit to the series (see Output 30.1.5 and Output 30.1.6). The first type is the likelihood-based goodness-of-fit statistics, which include the full

likelihood of the data, the diffuse portion of the likelihood (see the section “[Details: UCM Procedure](#)” on page 2156), and the information criteria. The second type of statistics is based on the raw residuals: residual = observed – predicted. If the model is nonstationary, then one-step-ahead predictions are not available for some initial observations, and the number of values used in computing these fit statistics will be different from those used in computing the likelihood-based test statistics.

Output 30.1.5 Likelihood-Based Fit Statistics for the Airline Data

Likelihood Based Fit Statistics	
Statistic	Value
Diffuse Log Likelihood	180.63
Diffuse Part of Log Likelihood	-13.93
Non-Missing Observations Used	120
Estimated Parameters	3
Initialized Diffuse State Elements	13
Normalized Residual Sum of Squares	107
AIC (smaller is better)	-355.3
BIC (smaller is better)	-347.2
AICC (smaller is better)	-355
HQIC (smaller is better)	-352
CAIC (smaller is better)	-344.2

Output 30.1.6 Residuals-Based Fit Statistics for the Airline Data

Fit Statistics Based on Residuals	
Mean Squared Error	0.00156
Root Mean Squared Error	0.03944
Mean Absolute Percentage Error	0.57677
Maximum Percent Error	2.19396
R-Square	0.98705
Adjusted R-Square	0.98680
Random Walk R-Square	0.86370
Amemiya's Adjusted R-Square	0.98630
Number of non-missing residuals used for computing the fit statistics = 107	

The diagnostic plots based on the one-step-ahead residuals are shown in [Output 30.1.7](#). The residual histogram and the Q-Q plot show no reasons to question the approximate normality of the residual distribution. The remaining plots check for the *whiteness* of the residuals. The sample correlation plots, the autocorrelation function (ACF) and the partial autocorrelation function (PACF), also do not show any significant violations of the whiteness of the residuals. Therefore, on the whole, the model seems to fit the data well.

Output 30.1.7 Residual Diagnostics for the Airline Series Using a BSM

The forecasts are given in [Output 30.1.8](#). To save space, the upper and lower confidence limit columns are dropped from the output, and only the rows corresponding to the year 1960 are shown. Recall that the actual measurements in 1959 and 1960 were withheld during the parameter estimation, and the ones in 1960 were not used in the forecast computations.

Output 30.1.8 Forecasts for the Airline Data

date	Forecast	StdErr	logair	Residual
JAN60	6.050	0.038	6.033	-0.017
FEB60	5.996	0.044	5.969	-0.027

DEC60	6.121	0.077	6.068	-0.053

Output 30.1.9 shows the forecast plot. The forecasts in 1960 show that the model predictions were quite good.

Output 30.1.9 Forecast Plot of the Airline Series Using a BSM

Example 30.2: Variable Star Data

The series in this example is studied in detail in Bloomfield (2000). This series consists of brightness measurements (magnitude) of a variable star taken at midnight for 600 consecutive days. The data can be downloaded from a time series archive maintained by the University of York, England (<http://www.york.ac.uk/depts/maths/data/ts/welcome.htm> (series number 26)). The following DATA step statements read the data in a SAS data set:

```
data star;
    input magnitude @@;
    day = _n_;
    format day best4.;
datalines;
25 28 31 32 33 33 32 31 28 25 22 18
14 10 7 4 2 0 0 0 2 4 8 11
15 19 23 26 29 32 33 34 33 32 30 27
24 20 17 13 10 7 5 3 3 3 4 5
7 10 13 16 19 22 24 26 27 28 29 28

... more lines ...
```

The following statements use the TIMESERIES procedure to get a timeseries plot of the series (see [Output 30.2.1](#)):

```
proc timeseries data=star plot=series;
    var magnitude;
run;
```

Output 30.2.1 Plot of Star Brightness on Successive Days

The plot clearly shows the cyclic nature of the series. Bloomfield shows that the series is very well explained by a model that includes two deterministic cycles that have periods 29.0003 and 24.0001 days, a constant term, and a simple error term. He also mentions the difficulty involved in estimating the periods from the data (Bloomfield 2000, Chapter 3). In his case the cycle periods are estimated by least squares, and the sum of squares surface has multiple local optima and ridges. The following statements show how to use the UCM procedure to fit this two-cycle model to the series. The constant term in the model is specified by holding the variance parameter of the level component to 0.

```
/* Load data into mylib */
data mylib.star;
  set star;
run;

proc ucm data= mylib.star;
  id day interval=obs;
  model magnitude;
  irregular;
  level var=0 noest;
```

```

cycle;
cycle;
estimate;
run;

```

The final parameter estimates and the goodness-of-fit statistics are shown in [Output 30.2.2](#) and [Output 30.2.3](#), respectively. The model fit appears to be good.

Output 30.2.2 Two-Cycle Model: Parameter Estimates
The UCM Procedure

Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.09257	0.0054	17.19	<.0001
Cycle_1	Damping Factor	1.00000	0.0000	5519514	<.0001
Cycle_1	Period	29.00036	0.0023	12770.4	<.0001
Cycle_1	Error Variance	0.00000882	0.0000	1.67	0.0944
Cycle_2	Damping Factor	1.00000	0.0000	4718334	<.0001
Cycle_2	Period	24.00011	0.0019	12547.2	<.0001
Cycle_2	Error Variance	0.00000535	0.0000	1.50	0.1330

Output 30.2.3 Two-Cycle Model: Goodness of Fit

Fit Statistics Based on Residuals	
Mean Squared Error	0.12072
Root Mean Squared Error	0.34745
Mean Absolute Percentage Error	2.65141
Maximum Percent Error	36.38991
R-Square	0.99850
Adjusted R-Square	0.99849
Random Walk R-Square	0.97281
Amemiya's Adjusted R-Square	0.99847
Number of non-missing residuals used for computing the fit statistics = 599	

A summary of the cycles in the model is given in [Output 30.2.4](#).

Output 30.2.4 Two-Cycle Model: Summary

Name	Type	period	Rho	ErrorVar
Cycle_1	Stationary	29.00036	1.00000	0.00000882
Cycle_2	Stationary	24.00011	1.00000	0.00000535

Note that the estimated periods are the same as in Bloomfield's model, the damping factors are nearly equal to 1.0, and the disturbance variances are very close to 0, implying persistent deterministic cycles. In fact, this model is identical to Bloomfield's model.

Finally, [Output 30.2.5](#) shows the likely outlying observations that do not conform to the fitted model. The first outlier in this table, day 301, is also flagged by Bloomfield (according to his zero-based index system, it

is day 300).

Output 30.2.5 Two-Cycle Model: Outlier Summary

Outlier Summary						
		Standard				
day	Break Type	Estimate	Error	Chi-Square	DF	Pr > ChiSq
301	Additive Outlier	0.83088	0.3064	7.35	1	0.0067
407	Additive Outlier	0.82905	0.3065	7.32	1	0.0068
351	Additive Outlier	0.80169	0.3065	6.84	1	0.0089
119	Additive Outlier	0.80261	0.3069	6.84	1	0.0089
191	Additive Outlier	0.78733	0.3065	6.60	1	0.0102

Example 30.3: Modeling Long Seasonal Patterns

This example illustrates some of the techniques that you can use to model long seasonal patterns in a series. If the seasonal pattern is of moderate length and the underlying dynamics are simple, then it is easily modeled by using the basic settings of the SEASON statement, and these additional techniques are not needed. However, if the seasonal pattern has a long season length and/or has complex stochastic dynamics, then the techniques that are discussed here can be useful. You can obtain parsimonious models for a long seasonal pattern by using an appropriate subset of trigonometric harmonics, by using a suitable spline function, or by using a block-season pattern in combination with a much shorter seasonal component. You can also vary the disturbance variances of the subcomponents that combine to form the seasonal component.

The time series in this example consists of the number of calls that are received per shift at a call center. Each shift is six hours long, and the first shift of the day begins at midnight, resulting in four shifts per day. The observations are available from December 15, 1999, to April 30, 2000. This series is seasonal, with a season length of 28, which is moderate; in fact, there is no particular need to use pattern approximation techniques in this case. However, the series is adequate for demonstration purposes. This example proceeds as follows. First, an initial model with a full seasonal component is created. This model is used as a baseline for comparing alternative models created by the techniques that are being illustrated. In practice, any candidate model is first checked for adequacy by using various diagnostic procedures. In this example, the main focus is on the different ways that a long seasonal pattern can be modeled, and no model diagnostics are performed for the models that are being considered. The alternative models are compared by using the sum of absolute prediction errors in the holdout region.

The following DATA step statements create the input data set for this example:

```
data callCenter;
  input calls @@;
  label calls= "Number of Calls Received in a 6 Hour Shift";
  start = '15dec99:00:00'dt;
  datetime = INTNX( 'dthour6', start, _n_-1 );
  format datetime datetime10.;
datalines;
  18    122    244    128    19    113    230    119    17    112
  219    93    14    73    139    53    11    32    74    56
  15    137    289    153    20    125    227    106    16    101
```

```
... more lines ...
```

Initial exploration of the series clearly indicates that the series does not show any significant trend, and time of day and day of the week have a significant influence on the number of calls received. These considerations suggest a simple random walk trend model along with a seasonal component of season length 28, the total number of shifts in a week. The following statements specify this model. Note the PRINT=HARMONICS option in the SEASON statement, which produces a table that lists the full set of harmonics contributing to the seasonal along with the significance of their contribution. This table will be useful later in choosing a subset trigonometric model. The BACK=28 and LEAD=28 specifications in the FORECAST statement create a holdout region of 28 observations. The sum of absolute prediction errors (SAE) in this holdout region is used to compare the different models.

```
/* Load data into mylib */
data mylib.callCenter;
    set callCenter;
run;

proc ucm data= mylib.callCenter;
    id datetime interval=dthour6;
    model calls;
    irregular;
    level;
    season length=28 type=trig
        print=(harmonics);
    estimate back=28;
    forecast back=28 lead=28;
run;
```

The forecasting performance of this model in the holdout region is shown in [Output 30.3.1](#). The SAE is 516.22, which appears in the last row of the holdout analysis table.

Output 30.3.1 Predictions in the Holdout Region: Baseline Model

datetime	Actual	Forecast	Error	SAE
24APR00:00	12.000	-4.004	16.004	16.004

Now that a baseline model is created, the exploration for alternative models can begin. The review of the harmonic table in [Output 30.3.2](#) shows that all but the last three harmonics are significant, and deleting any of them to form a subset trigonometric seasonal component will lead to a poorer model. The last three harmonics, 12th, 13th, and 14th, with periods of 2.333, 2.15, and 2.0, respectively, do appear to be possible choices for deletion. Note that the disturbance variance of the seasonal component is not very insignificant (see [Output 30.3.3](#)); therefore the seasonal component is stochastic and the preceding logic, which is based on the final state estimate, provides only a rough guideline.

Output 30.3.2 Harmonic Analysis of the Season: Initial Model**The UCM Procedure**

Harmonic Analysis of Trigonometric Seasons (Based on the Final State)						
Season		Harmonic	Period	Chi-Square	DF	Pr > ChiSq
Name	Length					
Season	28	1	28.00000	234.19	2	<.0001

Output 30.3.3 Parameter Estimates: Initial Model**The UCM Procedure**

Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	92.14591	13.1099	7.03	<.0001
Level	Error Variance	44.83595	10.6547	4.21	<.0001
Season	Error Variance	0.01250	0.0065	1.92	0.0551

The following statements fit a subset trigonometric model formed by dropping the last three harmonics by specifying the DROPH= option in the SEASON statement:

```
proc ucm data=mylib.callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  season length=28 type=trig droph=12 13 14;
  estimate back=28;
  forecast back=28 lead=28;
run;
```

The last row of the holdout region prediction analysis table for the preceding model is shown in [Output 30.3.4](#). It shows that the subset trigonometric model has better prediction performance in the holdout region than the full trigonometric model; its SAE is 471.53, compared to an SAE of 516.22 for the full model.

Output 30.3.4 SAE for the Subset Trigonometric Model

datetime	Actual	Forecast	Error	SAE
30APR00:18	61.000	40.836	20.164	471.534

The following statements illustrate a spline approximation to this seasonal component. In the spline specification the knot placement is quite important, and usually some experimentation is needed. In the following model the knots are placed at the beginning and the middle of each day. Note that the knots at the beginning and end of the season, 1 and 28 in this case, should not be listed in the knot list because knots are always placed there anyway.

```
proc ucm data=mylib.callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  splinesseason length=28
    knots=3 5 7 9 11 13 15 17 19 21 23 25 27
    degree=3;
  estimate back=28;
  forecast back=28 lead=28;
run;
```

The spline season model takes about half the time to fit that the baseline model takes. The last row of the holdout region prediction analysis table for this model is shown in [Output 30.3.5](#), which shows that the spline season model performs even better than the previous two models in the holdout region; its SAE is 313.79, compared to an SAE of 471.53 for the previous model.

Output 30.3.5 SAE for the Spline Season Model

datetime	Actual	Forecast	Error	SAE
30APR00:18	61.000	23.350	37.650	313.792

The following statements illustrate yet another way to approximate a long seasonal component. Here a combination of BLOCKSEASON and SEASON statements results in a seasonal component that is a sum of two seasonal patterns: one seasonal pattern is simply a regular season with season length 4 that captures the *within-day* seasonal pattern, and the other seasonal pattern is a block seasonal pattern that remains constant during the day but varies from day to day within a week. Note the use of the NLOPTIONS statement to change the optimization technique during the parameter estimation to DBLDOG, which in this case performs better than the default technique, TRUREG.

```
proc ucm data=mylib.callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  season length=4 type=trig;
  blockseason nblocks=7 blocksize=4
    type=trig;
```

```

estimate back=28;
forecast back=28 lead=28;
nloptions tech=dbldog;
run;

```

This model also takes about half the time to fit that the baseline model takes. The last row of the holdout region prediction analysis table for this model is shown in [Output 30.3.6](#), which shows that the block season model does slightly better than the baseline model but not as well as the other two models; its SAE is 508.52, compared to an SAE of 516.22 for the baseline model.

Output 30.3.6 SAE for the Block Season Model

datetime	Actual	Forecast	Error	SAE
30APR00:18	61.000	39.339	21.661	508.522

This example showed a few different ways to model a long seasonal pattern. It showed that parsimonious models for long seasonal patterns can be useful, and in some cases even more effective than the full model. Moreover, for very long seasonal patterns the high memory requirements and long computing times might make full models impractical.

Example 30.4: Modeling Time-Varying Regression Effects

In April 1979, the Albuquerque Police Department began a special enforcement program aimed at reducing the number of DWI (driving while intoxicated) accidents. The program was administered by a squad of police officers, who used breath alcohol testing (BAT) devices and a van that houses a BAT device (Batmobile). These data were collected by the Division of Governmental Research of the University of New Mexico, under a contract with the National Highway Traffic Safety Administration of the U.S. Department of Transportation, to evaluate the Batmobile program. The first 29 observations are for a control period, and the next 23 observations are for the experimental (Batmobile) period. The data consist of two variables: ACC, which represents injuries and fatalities from Wednesday to Saturday nighttime accidents, and FUEL, which represents fuel consumption (millions of gallons) in Albuquerque. The variables are measured quarterly starting from the first quarter of 1972 up to the last quarter of 1984, covering the span of 13 years. The following DATA step statements create the input data set:

```

data bat;
  input ACC FUEL @@;
  batProgram = 0;
  if _n_ > 29 then batProgram = 1;
  date = INTNX( 'qtr', '1jan1972'd, _n_ - 1 );
  format date YYQC8.;
datalines;
192      32.592      238      37.250      232      40.032
246      35.852      185      38.226      274      38.711
266      43.139      196      40.434      170      35.898
234      37.111      272      38.944      234      37.717
210      37.861      280      42.524      246      43.965
248      41.976      269      42.918      326      49.789
342      48.454      257      45.056      280      49.385
290      42.524      356      51.224      295      48.562

```

279	48.167	330	51.362	354	54.646
331	53.398	291	50.584	377	51.320
327	50.810	301	46.272	269	48.664

230	47.961	304	46.039	311	55.683
292	52.263				

;

There are a number of ways to study these data and the question of the effectiveness of the BAT program. One possibility is to study the *before-after* difference in the injuries and fatalities per million gallons of fuel consumed, by regressing ACC on FUEL and the dummy variable BATPROGRAM, whose value is 0 before the program began and 1 while the program is in place. However, it is possible that the effect of the Batmobiles might well be cumulative, because as awareness of the program becomes dispersed, its effectiveness as a deterrent to driving while intoxicated increases. This suggests that the regression coefficient of the BATPROGRAM variable might be *time-varying*. The following program fits a model that incorporates these considerations. A seasonal component is included in the model since it is easy to see that the data show strong quarterly seasonality.

```
/* Load data into mylib */
data mylib.bat;
    set bat;
run;

proc ucm data=mylib.bat;
    model acc = fuel;
    id date interval=qtr;
    irregular;
    level var=0 noest;
    randomreg batProgram / plot=smooth;
    season length=4 var=0 noest plot=smooth;
    estimate plot=(panel residual);
    forecast plot=forecasts lead=0;
run;
```

The model seems to fit the data adequately. No data are withheld for model validation because the series is relatively short. The plot of the time-varying coefficient of BATPROGRAM is shown in [Output 30.4.1](#). As expected, it shows that the effectiveness of the program increases as awareness of the program becomes dispersed. The effectiveness eventually seems to level off. The residual diagnostic plots are shown in [Output 30.4.2](#) and [Output 30.4.3](#), the forecast plot is in [Output 30.4.4](#), the goodness-of-fit statistics are in [Output 30.4.5](#), and the parameter estimates are in [Output 30.4.6](#).

Example 30.5: Trend Removal Using the Hodrick-Prescott Filter

The Hodrick-Prescott filter (Hodrick and Prescott 1997) is a popular tool in macroeconomics for fitting a smooth trend to time series. It is well known that the trend computation according to this filter is equivalent to fitting the local linear trend plus irregular model with the level disturbance variance restricted to 0 and the slope disturbance variance restricted to be a suitable multiple of the irregular component variance. The multiple used depends on the frequency of the series; for example, for quarterly series the commonly recommended multiple is $1/1600 = 0.000625$. For other intervals there is no consensus, but a frequently suggested value for monthly series is $1/14400$ and the value for an annual series can range from $1/400 = 0.0025$ to $1/7 = 0.15$. The data set considered in this example consists of quarterly GNP values for the United States from 1960 to 1991.

In the UCM procedure statements that follow, the presence of the PROFILE option in the ESTIMATE statement implies that the restriction that the disturbance variance of the slope component be fixed at 0.000625 is interpreted differently: it implies that the disturbance variance of the slope component be restricted to be 0.000625 *times* the estimated irregular component variance, as needed for the Hodrick-Prescott filter. The plot of the fitted trend is shown in [Output 30.5.1](#), and the plot of the smoothed irregular component, which corresponds to the detrended series, is given in [Output 30.5.2](#). The detrended series can be further analyzed for business cycles.

```

/* Load data into mylib */
data mylib.gnp;
  set sashelp.gnp;
run;

proc ucm data=mylib.gnp;
  id date interval=qtr;
  model gnp;
  irregular plot=smooth;
  level var=0 noest plot=smooth;
  slope var=0.000625 noest;
  estimate PROFILE;
  forecast plot=(decomp);
run;

```

Output 30.5.1 Smoothed Trend for the GNP Series as per the Hodrick-Prescott Filter

Output 30.5.2 Detrended GNP Series

Example 30.6: Using Splines to Incorporate Nonlinear Effects

The data in this example are created to mirror the electricity demand and temperature data recorded at a utility company in the midwest region of the United States. The data set (not shown), `utility`, has three variables: `load`, `temp`, and `date`. The `load` column contains the daily electricity demand, the `temp` column has the average daily temperature readings, and the `date` column records the observation date.

The following statements produce a plot, shown in [Output 30.6.1](#), of electricity load versus temperature. Clearly the relationship is smooth but nonlinear: the load generally increases when the temperatures are higher or lower than the comfortable sixties.

```
proc sgplot data=utility;
  loess x=temp y=load / smooth=0.4;
run;
```

Output 30.6.1 Load versus Temperature Plot

The time series plot of the load (not shown) also shows that, apart from a day-of-the-week seasonal effect, there are no additional easily identifiable patterns in the series. The series has no apparent upward or downward trend. The following statements fit a UCM to the series that takes into account these observations. The particular choice of the model is a result of a little modeling exercise that compared a small number of competing models. The chosen model is adequate but by no means the best possible. The temperature effect is modeled by a deterministic three-degree spline with knots at 30, 40, 50, 60, and 75. The knot locations and the degree were chosen by visual inspection of the plot (Output 30.6.1). An autoregression component is used in place of the simple irregular component, which improved the residual analysis. The last 60 days of data are withheld for out-of-sample forecast evaluation (note the BACK= option in both the ESTIMATE and FORECAST statements). The OUTLIER statement is used to increase the number of outliers reported to 10. Since no CHECKBREAK option is used in the LEVEL statement, only the additive outliers are searched. In this example the use of the EXTRADIFFUSE= option in the ESTIMATE and FORECAST statements is useful for discarding some early one-step-ahead forecasts and residuals with large variance.

```
/* Load data into mylib */
data mylib.utility;
  set utility;
run;
```

```

proc ucm data=mylib.utility;
  id date interval=day;
  model load;
  autoreg;
  level plot=smooth;
  splinereg temp knots=30 40 50 65 75 degree=3
    variance=0 noest;
  season length=7 var=0 noest;
  estimate plot=panel back=60
    extradiffuse=50;
  outlier maxnum=10;
  forecast back=60 lead=60
    extradiffuse=50;
run;

```

The parameter estimates are given in [Output 30.6.2](#), and the residual goodness-of-fit statistics are shown in [Output 30.6.3](#). The residual diagnostic plots are shown in [Output 30.6.4](#). The ACF and PACF plots appear satisfactory, but the normality plots, particularly the Q-Q plot, show possible violations. It appears that, at least in part, this nonnormal behavior of the residuals might be attributable to the outliers in the series. The outlier summary table, [Output 30.6.5](#), shows the most likely outlying observations. Notice that most of these outliers are holidays, like July 4th, when the electricity load is lower than usual for that day of the week.

Output 30.6.2 Electricity Load: Parameter Estimates

The UCM Procedure

Output 30.6.6 Electricity Load: Forecast Evaluation of the Withheld Data

Example 30.7: Detection of Level Shift

The series in this example consists of the yearly water level readings of the Nile River recorded at Aswan, Egypt (Cobb 1978; De Jong and Penzer 1998). The readings are from the years 1871 to 1970. The series does not show any apparent trend or any other distinctive patterns; however, there is a shift in the water level starting at the year 1899. This shift could be attributed to the start of construction of a dam near Aswan in that year. A time series plot of this series is given in [Output 30.7.1](#). The following DATA step statements create the input data set:

```
data nile;
  input waterlevel @@;
  year = intnx( 'year', '1jan1871'd, _n_-1 );
  format year year4.;
datalines;
1120 1160 963 1210 1160 1160 813 1230 1370 1140

;

proc timeseries data=nile plot=series;
  id year interval=year;
  var waterlevel;
run;
```

Output 30.7.1 Nile Water Level

In this situation it is known that a shift in the water level occurred within the span of the series, and its effect can be easily taken into account by including an appropriate indicator variable as a regressor. However, in many situations such prior information is not available, and it is useful to detect such a shift by using data analysis. You can check for breaks in the level by using the [CHECKBREAK](#) option in the `LEVEL` statement. The following statements fit a simple locally constant level plus error model to the series:

```
/* Load data into mylib */
data mylib.nile;
  set nile;
run;

proc ucm data=mylib.nile;
  id year interval=year;
  model waterlevel;
  irregular;
  level plot=smooth checkbreak;
  estimate;
  forecast plot=decomp;
```

```
run;
```

The plot in [Output 30.7.2](#) shows a noticeable drop in the smoothed water level around 1899.

Output 30.7.2 Smoothed Trend without the Shift of 1899

The “Outlier Summary” table in [Output 30.7.3](#) shows the most likely types of breaks and their locations within the series span. The shift of 1899 is easily detected.

Output 30.7.3 Detection of Structural Breaks in the Nile River Level

Outlier Summary						
Break		Standard				
year	Type	Estimate	Error	Chi-Square	DF	Pr > ChiSq
1899	Level	-315.73791	97.6398	10.46	1	0.0012

The following statements specify a UCM that models the level of the river as a locally constant series with a shift in the year 1899, represented by a dummy regressor (SHIFT1899):

```
data mylib.nile;
  set nile;
  shift1899 = ( year >= '1jan1899'd );
run;
```

```
proc ucm data=mylib.nile;
  id year interval=year;
  model waterlevel = shift1899;
  irregular;
  level;
  estimate;
  forecast plot=decomp;
run;
```

The plot in [Output 30.7.4](#) shows the smoothed trend, including the correction due to the shift in the year 1899. Notice the simplicity in the shape of the smoothed curve after the incorporation of the shift information.

Output 30.7.4 Smoothed Trend Plus Shift of 1899

Example 30.8: ARIMA Modeling

This example shows how you can use the UCM procedure for ARIMA modeling. The parameter estimates and predictions for ARIMA models obtained by using PROC UCM will be close to those obtained by using PROC ARIMA (in the presence of the ML option in its ESTIMATE statement) if the model is stationary or if the model is nonstationary and there are no missing values in the data. For more information about the ARIMA procedure, see Chapter 7, “ARIMA Procedure” (*SAS/ETS User’s Guide*). However, if there are missing values in the data and the model is nonstationary, then the UCM and ARIMA procedures can produce significantly different parameter estimates and predictions. An article by Kohn and Ansley (1986) suggests a statistically sound method of estimation, prediction, and interpolation for nonstationary ARIMA models with missing data. This method is based on an algorithm that is equivalent to the Kalman filtering and smoothing algorithm used in the UCM procedure. The results of an illustrative example in their article are reproduced here using the UCM procedure. In this example an $ARIMA(0,1,1) \times (0,1,1)_{12}$ model is applied to the logarithm of the air series in the `sashelp.air` data set. Four different missing value patterns are considered to highlight different aspects of the problem:

- `mylib.Data1`. The full data set of 144 observations.
- `mylib.Data2`. The set of 78 observations that omit January through November in each of the last 6 years.
- `mylib.Data3`. The data set with the 5 observations July 1949, June, July, and August 1957, and July 1960 missing.
- `mylib.Data4`. The data set with all July observations missing and June and August 1957 also missing.

The following DATA steps create these data sets:

```
data mylib.Data1;
    set sashelp.air;
    logair = log(air);
run;

data mylib.Data2;
    set mylib.data1;
    if year(date) >= 1955 and month(date) < 12 then logair = .;
run;

data mylib.Data3;
    set mylib.data1;
    if (year(date) = 1949 and month(date) = 7) then logair = .;
    if ( year(date) = 1957 and
        (month(date) = 6 or month(date) = 7 or month(date) = 8))
        then logair = .;
    if (year(date) = 1960 and month(date) = 7) then logair = .;
run;

data mylib.Data4;
    set mylib.data1;
```

```

    if month(date) = 7 then logair = .;
    if year(date) = 1957 and (month(date) = 6 or month(date) = 8)
        then logair = .;
run;

```

The following statements specify the $\text{ARIMA}(0, 1, 1) \times (0, 1, 1)_{12}$ model for the logair series in the first data set (mylib.Data1):

```

proc ucm data=mylib.Data1;
    id date interval=month;
    model logair;
    irregular q=1 sq=1 s=12;
    deplag lags=(1)(12) phi=1 1 noest;
    estimate outest=mylib.est1;
    forecast outfor=mylib.for1;
run;

```

Note that the moving average part of the model is specified by using the Q=, SQ=, and S= options in the IRREGULAR statement and the differencing operator, $(1 - B)(1 - B^{12})$, is specified by using the DEPLAG statement. The model does not contain an intercept term; therefore no LEVEL statement is needed. The parameter estimates are saved in a data set EST1 by using the OUTEST= option in the ESTIMATE statement and the forecasts and the component estimates are saved in a data set FOR1 by using the OUTFOR= option in the FORECAST statement. The same analysis is performed on the other three data sets, but is not shown here.

Output 30.8.1 resembles Table 1 in Kohn and Ansley (1986). This table is generated by merging the parameter estimates from the four analyses. Only the moving average parameter estimates and their standard errors are reported. The columns EST1 and STD1 correspond to the estimates for mylib.Data1. The parameter estimates and their standard errors for other three data sets are similarly named. Note that the parameter estimates closely match the parameter estimates in the article. However, their standard errors differ slightly. This difference could be the result of different ways of computing the Hessian at the optimum. The white-noise error variance estimates are not reported here, but they agree quite closely with those in the article.

Output 30.8.1 Data Sets 1–4: Parameter Estimates and Standard Errors

parameter	est1	std1	est2	std2	est3	std3	est4	std4
MA_1	0.402	0.090	0.457	0.121	0.408	0.092	0.431	0.091
SMA_1	0.557	0.073	0.758	0.236	0.566	0.075	0.573	0.074

Output 30.8.2 resembles Table 2 in Kohn and Ansley (1986). It contains forecasts and their standard errors for the four data sets. The numbers are very close to those in the article.

Output 30.8.2 Data Sets 1–4: Forecasts and Standard Errors

DATE	for1	std1	for2	std2	for3	std3	for4	std4
JAN61	6.110	0.037	6.084	0.052	6.110	0.037	6.111	0.037
FEB61	6.054	0.043	6.091	0.058	6.054	0.043	6.055	0.043
MAR61	6.172	0.048	6.247	0.063	6.173	0.048	6.174	0.048
APR61	6.199	0.053	6.205	0.068	6.199	0.053	6.200	0.052
MAY61	6.233	0.057	6.199	0.072	6.232	0.058	6.233	0.056
JUN61	6.369	0.061	6.308	0.076	6.367	0.062	6.368	0.060
JUL61	6.507	0.065	6.409	0.079	6.497	0.067	.	.
AUG61	6.503	0.069	6.414	0.082	6.503	0.069	6.503	0.067
SEP61	6.325	0.072	6.299	0.085	6.325	0.072	6.326	0.071
OCT61	6.209	0.075	6.174	0.087	6.209	0.076	6.209	0.074
NOV61	6.063	0.079	6.043	0.089	6.064	0.079	6.064	0.077
DEC61	6.168	0.082	6.174	0.086	6.168	0.082	6.169	0.080

Output 30.8.3 is based on Data2. It resembles Table 3 in Kohn and Ansley (1986). The columns S_SERIES and VS_SERIES in the **OUTFOR=** data set contain the interpolated values of logair and their variances. The estimate column in **Output 30.8.3** reports interpolated values (which are the same as S_SERIES), and the std column reports their standard errors (which are computed as square root of VS_SERIES) for January–November 1957. The actual logair values for these months, which are missing in Data2, are also provided for comparison. The numbers are very close to those in the article.

Output 30.8.3 Data Set 2: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JAN57	5.753	5.733	0.045
FEB57	5.707	5.738	0.049
MAR57	5.875	5.893	0.052
APR57	5.852	5.850	0.054
MAY57	5.872	5.843	0.055
JUN57	6.045	5.951	0.055
JUL57	6.142	6.051	0.055
AUG57	6.146	6.055	0.054
SEP57	6.001	5.938	0.052
OCT57	5.849	5.812	0.049
NOV57	5.720	5.680	0.045

Output 30.8.4 resembles Table 4 in Kohn and Ansley (1986). These numbers are based on Data3, and they also are very close to those in the article.

Output 30.8.4 Data Set 3: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JUL49	4.997	5.013	0.031
JUN57	6.045	6.024	0.030
JUL57	6.142	6.147	0.031
AUG57	6.146	6.148	0.030
JUL60	6.433	6.409	0.031

Output 30.8.5 resembles Table 5 in Kohn and Ansley (1986). As before, the numbers are very close to those in the article.

Output 30.8.5 Data Set 4: Interpolated Values and Standard Errors

DATE	logair	estimate	std
JUN57	6.045	6.023	0.030
AUG57	6.146	6.147	0.030

The similarity between the outputs in this example and the results shown in Kohn and Ansley (1986) demonstrate that PROC UCM can be effectively used for nonstationary ARIMA models with missing data.

Example 30.9: Extracting a Business Cycle

The data set (not shown) `gdp` in this example has two variables: `date` dates the observations, and `lgdp` contains the quarterly readings of the US real GDP (in log scale). Pelagatti (2015, Example 3.3, Example 8.2) uses this quarterly time series (`lgdp`) to illustrate how you can adjust the smoothness of the estimated cycle by changing the order of the cycle in a trend-cycle decomposition,

$$\text{lgdp}_t = \mu_t + \psi_t + \epsilon_t$$

where μ_t is an integrated random walk trend, ψ_t is a cycle component, and ϵ_t is an irregular component.

```
/* Load data into mylib */
data mylib.gdp;
  set gdp;
run;
```

The following statements fit the model $\text{lgdp}_t = \mu_t + \psi_t + \epsilon_t$, where the cycle component has an order of 1 (default):

```
proc ucm data= mylib.gdp;
  where year(date) >= 1970;
  id date interval=quarter;
  model lgdp;
  irregular;
  level variance=0 noest plot=smooth;
  slope;
  cycle plot=smooth;
  estimate plot=panel;
  forecast plot=decomp outfor= mylib.for1;
run;
```

The following statements fit the same model, except that the cycle order is 2. Similarly, a model with a cycle order of 4 is also fit (not shown).

```

proc ucm data=mylib.gdp;
  where year(date) >= 1970;
  id date interval=quarter;
  model lgdp;
  irregular;
  level variance=0 noest plot=smooth;
  slope;
  cycle order=2 plot=smooth;
  estimate plot=panel;
  forecast plot=decomp outfor= mylib.for2;
run;

```

[Output 30.9.1](#) summarizes the features of the estimated cycles of different orders. The estimated periods of the first-order and second-order cycles, 31.59 and 45.18, are reasonable. However, the period of the fourth-order cycle seems quite unreasonable. Fortunately, Pelagatti (2015, Example 8.2) mentions that cycles of order 3 or higher are rarely needed when you are working with real economic series. Although they are not the same, the parameter estimates that the UCM procedure produces are reasonably close to those reported in Pelagatti (2015, Example 8.2).

Output 30.9.1 Cycles of Orders 1, 2, and 4: Summary

order	period	Frequency	Rho	ErrorVar
1	31.59294	0.19888	0.94371	0.00004873
2	45.18257	0.13906	0.76177	0.00000956
4	38877	0.00016162	0.52055	0.00000856

[Output 30.9.2](#) shows the plot of the first-order cycle, [Output 30.9.3](#) shows the plot of the second-order cycle, and [Output 30.9.4](#) shows the plot of the fourth-order cycle. You can see that although the overall form of the estimated cycle remains the same, the smoothness of the plot of the estimated cycle increases with the order.

Output 30.9.2 Estimated Cycle: Order = 1

Output 30.9.3 Estimated Cycle: Order = 2

Output 30.9.4 Estimated Cycle: Order = 4

Output 30.9.5 shows the three cycle estimates in the same plot. It shows that the estimates do not differ very much.

Output 30.9.5 Estimated Cycles of Orders 1, 2, and 4

Example 30.10: A Transfer-Function Model for the Italian Traffic Accident Data

This example is based on a case study described in Pelagatti (2015, chap. 9, sec. 1). In July 2003, Italy introduced a new traffic monitoring system with the aim of improving traffic safety. The case study tried to answer the question, “Was the monitoring system effective in reducing the number of traffic injuries?” The time series plot in [Output 30.10.1](#) shows monthly traffic injuries for the span of January 2001 to December 2013. Visual inspection of the plot clearly shows that the series is seasonal and has an overall downward trend, which appears to be more pronounced after the intervention.

Output 30.10.1 Monthly Traffic Injuries in Italy

Pelagatti (2015, chap. 9, sec. 1) suggests the following model for this series:

$$y_t = \mu_t + \psi_t + \text{shift03} \beta + \xi_t + \epsilon_t$$

Various terms in the right-hand side of this model are explained as follows:

- μ_t is the trend component, which is modeled as an integrated random walk.
- ψ_t is the trigonometric seasonal component, which accounts for the monthly seasonality.
- The effect of the introduction of the monitoring system is modeled using two terms:
 - One term captures a permanent shift, which is a regression effect that is associated with the dummy regressor `shift03`. The value of this regressor is 0 before July 2003 and 1 thereafter.
 - The other term captures a transient effect that rapidly decays to 0. The transient effect ξ_t is a transfer-function effect

$$\xi_t = \frac{\gamma_0 \text{pulse03}_t}{(1 - \delta B)}$$

where `pulse03` is a dummy regressor whose value is 1 at July 2003 and 0 otherwise. In this example, the value of the transfer function ξ_t is clearly 0 before July 2003.

- ϵ_t is the simple irregular component.

The following statements show how to fit this model to the data. The LIKE=MARGINAL option in the ESTIMATE statement causes the parameter estimation to be based on marginal likelihood rather than on diffuse likelihood, which is the default. Since the parameter vector of this model contains δ (the denominator coefficient of the transfer function), the parameter estimations that are based on marginal likelihood and diffuse likelihood can lead to different results. In this example, the results turn out to be similar; however, this is not necessarily the case in general. Generally, parameter estimation that is based on marginal likelihood is the preferred choice in such cases.

```
/* Load data into mylib */
data mylib.italy;
    set italy;
run;

proc ucm data=mylib.italy;
    id date interval=month;
    model Injured = shift03;
    irregular;
    level variance=0 noest;
    slope;
    season length=12 type=trig;
    tf pulse03 den=1 tfstart=0 plot=smooth;
    estimate plot=(panel residual) like=marginal;
    forecast plot=decomp;
run;
```

Output 30.10.3 shows the parameter estimates. It shows that soon after the introduction of the monitoring system in July 2003, the accident level decreased by about 5.22 thousand ($\hat{\beta} + \hat{\gamma}_0 = -(2.48 + 2.74)$). However, the permanent decrease was only about 2.48 thousand ($\hat{\beta} = -2.48$). The estimate of the decay parameter of the transfer function, δ , is 0.587.

Output 30.10.2 Estimates of the Model Parameters

The UCM Procedure

Final Estimates of the Free Parameters					
Component	Parameter	Estimate	Approx Std Error	t Value	Approx Pr > t
Irregular	Error Variance	0.55447	0.0923	6.01	<.0001
Slope	Error Variance	0.00064586	0.0005	1.43	0.1526
Season	Error Variance	0.00068803	0.0005	1.33	0.1849
shift03	Coefficient	-2.47939	0.7093	-3.50	0.0005
pulse03	Coefficient	-2.74316	0.9385	-2.92	0.0035
pulse03	DEN_1	0.58714	0.1780	3.30	0.0010

Output 30.10.3 shows the plot of smoothed estimate of the transfer function ξ_t , and Output 30.10.4 shows the plot of the estimate of the trend plus the total effect of the July 2003 intervention.

Output 30.10.3 Decaying Part of the July 2003 Intervention Effect (Smoothed Estimate of ξ_t)

Output 30.10.4 Smoothed Estimate of $\mu_t + \text{shift03 } \beta + \xi_t$ 

Finally, the [Output 30.10.5](#) shows the plot of the overall model fit.

Output 30.10.5 Sum of All Model Terms Except the Irregular

Overview

The time series analysis (TSA) package contains a set of time series analysis functions that can be used as part of the programming statements in the TSMODEL procedure. This package provides a flexible way to analyze time series within the procedure.

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS statement and the LIBNAME statement, see *SAS Cloud Analytic Services: User's Guide*. For general information about CAS and CAS sessions, see *SAS Cloud Analytic Services: Fundamentals*.

NOTE: The mylib.air data table that is used in the examples refers to SasHELP.AIR data.

CORR Class

CORR Object

The CORR class object functions perform the autocorrelation and autocovariance analysis of a time series array and output all the values and results.

Table 31.1 summarizes the methods that are associated with the CORR object.

Table 31.1 Methods of the CORR Object

Method	Description
GetResult	Get the analysis result
Initialize	Initialize the CORR object
Run	Run the analysis
SetNLags	Set the number of lags
SetNParms	Set the number of parameters
SetY	Set the input time series

Figure 31.1 diagrams the methods of the CORR object.

Figure 31.1 CORR Data Flow

CORR Synopsis

DECLARE OBJECT *obj* (CORR) ;

Method syntax, in order of typical usage:

```

rc=obj.Initialize () ;
rc=obj.SetY (YSeries) ;
rc=obj.SetNLags (Value) ;
rc=obj.SetNParms (Value) ;
rc=obj.Run () ;
rc=obj.GetResult ('Name',OutputArray) ;

```

CORR Methods

CORR.GetResult Method

```
rc=obj.GetResult ('Name',OutputArray) ;
```

Outputs the selected results to an array.

Input Arguments You must specify the following input arguments:

<i>Name</i>	specifies a string that identifies the result series to return. You can specify only one of the following values within single quotation marks:
<i>acov</i>	returns an array of covariance estimates, with <i>nlag</i> + 1 entries.
<i>acf</i>	returns an array of autocorrelation estimates, with <i>nlag</i> + 1 entries.
<i>acfstd</i>	returns an array of standard errors, with <i>nlag</i> + 1 entries.
<i>acf2std</i>	returns an array of twice standard errors, with <i>nlag</i> + 1 entries.
<i>acfnorm</i>	returns an array of normalized autocorrelation, with <i>nlag</i> + 1 entries.
<i>acfprob</i>	returns an array of autocorrelation probabilities, with <i>nlag</i> + 1 entries.
<i>acflprob</i>	returns an array of autocorrelation log probabilities, with <i>nlag</i> + 1 entries.
<i>pacf</i>	returns an array of partial autocorrelation estimates, with <i>nlag</i> + 1 entries.
<i>pacfstd</i>	returns an array of partial autocorrelation standard errors, with <i>nlag</i> + 1 entries.
<i>pacf2std</i>	returns an array of twice standard errors, with <i>nlag</i> + 1 entries.
<i>pacfnorm</i>	returns an array of normalized partial autocorrelation, with <i>nlag</i> + 1 entries.
<i>pacfprob</i>	returns an array of partial autocorrelation probabilities, with <i>nlag</i> + 1 entries.
<i>pacflprob</i>	returns an array of partial autocorrelation log probabilities, with <i>nlag</i> + 1 entries.
<i>iacf</i>	returns an array of inverse autocorrelation estimates, with <i>nlag</i> + 1 entries.
<i>iacfstd</i>	returns an array of inverse autocorrelation standard errors, with <i>nlag</i> + 1 entries.
<i>iacf2std</i>	returns an array of twice standard errors, with <i>nlag</i> + 1 entries.
<i>iacfnorm</i>	returns an array of normalized inverse autocorrelation, with <i>nlag</i> + 1 entries.
<i>iacfprob</i>	returns an array of inverse autocorrelation probabilities, with <i>nlag</i> + 1 entries.
<i>iacflprob</i>	returns an array of inverse autocorrelation log probabilities, with <i>nlag</i> + 1 entries.
<i>wn</i>	returns an array of Ljung-Box white noise tests, with <i>nlag</i> + 1 entries.
<i>wnprob</i>	returns white noise probabilities.
<i>wnlprob</i>	returns white noise log probabilities.

OutputArray specifies a numeric array to receive the result series.

CORR.Initialize Method

rc=obj.Initialize () ;

Initializes a CORR object to an empty state. This method must be called before the time series arrays and other attributes are specified for the CORR object.

Arguments There are no arguments associated with this method.

CORR.Run Method

```
rc=obj.Run () ;
```

Runs the CORR object to perform the autocorrelation and autocovariance analysis by using the time series array *YSeries* that has been specified for it. Upon successful completion, various results can be extracted from the CORR object.

CORR.SetNLags Method

```
rc=obj.SetNLags (Value) ;
```

Sets a named option for the CORR object.

Input Arguments You must specify the following input argument:

Value specifies the number of lags to use in the calculation. The default value is 24.

CORR.SetNParms Method

```
rc=obj.SetNParms (Value) ;
```

Sets a named option for the CORR object.

Input Arguments You must specify the following input argument:

Value specifies the degrees of freedom associated with the Ljung-Box statistics. The default value is 0.

CORR.SetY Method

```
rc=obj.SetY (YSeries) ;
```

Specifies the time series array (*YSeries*) for the CORR object.

Input Arguments You must specify the following input argument:

YSeries specifies a numeric array that contains the dependent series for the CORR object.

Arguments There are no arguments associated with this method.

OUTCORR Object

The OUTCORR object collects output from a CORR object.

Table 31.2 summarizes the methods that are associated with the OUTCORR object.

Table 31.2 Methods of the OUTCORR Object

Method	Description
Collect	Collect the results of a CORR object
nrows	Get the current row count from the OUTCORR object

Figure 31.2 diagrams the methods of the OUTCORR object.

Figure 31.2 OUTCORR Data Flow

OUTCORR Methods

OUTCORR.Collect Method

```
rc=obj.Collect (CORRObj) ;
```

Collects the results from a CORR object and saves them to a table.

Arguments You must specify the following input argument:

CORRObj is a character string that specifies the name of the CORR object to use as the source of the autocorrelation and autocovariance analysis results.

OUTCORR.nrows Attribute

`nrows=obj.nrows ()` ;

Gets the current row count from the OUTCORR object.

Arguments There are no arguments associated with this method.

Output Table Schema

The collector object, OUTCORR, collects the results of a CORR object.

OUTCORR collects the results of a CORR object. The output table contains the columns that are shown in Table 31.3.

Table 31.3 OUTCORR Output Table Contents

Column Name	Column Content	Statistics Used to Calculate Content
NAME	Name of target variable	N/A
LAG	Array of time lags	$h \in \{0, \dots, H\}$
N	Number of variance products	N_h , the number of observed products at lag h , ignoring missing values
MU	Mean value	Mean value
ACOV	Array of covariance estimates, with $nlag + 1$ entries	$\hat{\gamma}(h) = \frac{1}{T} \sum_{t=h+1}^T (y_t - \bar{y})(y_{t-h} - \bar{y})$, or $\hat{\gamma}(h) = \frac{1}{N_h} \sum_{t=h+1}^T (y_t - \bar{y})(y_{t-h} - \bar{y})$ when embedded missing values are present
ACF	Array of autocorrelation estimates, with $nlag + 1$ entries	$\hat{\rho}(h) = \hat{\gamma}(h) / \hat{\gamma}(0)$
ACFSTD	Array of standard errors, with $nlag + 1$ entries	$\text{Std}(\hat{\rho}(h)) = \sqrt{\frac{1}{T} \left(1 + 2 \sum_{j=1}^{h-1} \hat{\rho}(j)^2 \right)}$
ACF2STD	Array of twice standard errors, with $nlag + 1$ entries	$\text{Flag}(\hat{\rho}(h)) = \begin{cases} 1 & \hat{\rho}(h) > 2\text{Std}(\hat{\rho}(h)) \\ 0 & -2\text{Std}(\hat{\rho}(h)) < \hat{\rho}(h) < 2\text{Std}(\hat{\rho}(h)) \\ -1 & \hat{\rho}(h) < -2\text{Std}(\hat{\rho}(h)) \end{cases}$
ACFNORM	Array of normalized autocorrelation, with $nlag + 1$ entries	$\text{Norm}(\hat{\rho}(h)) = \hat{\rho}(h) / \text{Std}(\hat{\rho}(h))$

Table 31.3 *continued*

Column Name	Column Content	Statistics Used to Calculate Content
ACFPROB	Array of autocorrelation probabilities, with $nlag + 1$ entries	$\text{Prob}(\hat{\rho}(h)) = 2 (1 - \Phi(\text{Norm}(\hat{\rho}(h))))$
ACFLPROB	Array of autocorrelation log probabilities, with $nlag + 1$ entries	$\text{LogProb}(\hat{\rho}(h)) = -\log_{10}(\text{Prob}(\hat{\rho}(h)))$
PACF	Array of partial autocorrelation estimates, with $nlag + 1$ entries	$\hat{\varphi}(h) = \Gamma_{(0,h-1)}\{\gamma_j\}_{j=1}^h$
PACFSTD	Array of partial autocorrelation standard errors, with $nlag + 1$ entries	$\text{Std}(\hat{\varphi}(h)) = 1/\sqrt{N_0}$
PACF2STD	Array of twice standard errors, with $nlag + 1$ entries	$\text{Flag}(\hat{\varphi}(h)) = \begin{cases} 1 & \hat{\varphi}(h) > 2\text{Std}(\hat{\varphi}(h)) \\ 0 & -2\text{Std}(\hat{\varphi}(h)) < \hat{\varphi}(h) < 2\text{Std}(\hat{\varphi}(h)) \\ -1 & \hat{\varphi}(h) < -2\text{Std}(\hat{\varphi}(h)) \end{cases}$
PACFNORM	Array of normalized partial autocorrelation, with $nlag + 1$ entries	$\text{Norm}(\hat{\rho}(h)) = \hat{\rho}(h)/\text{Std}(\hat{\rho}(h))$
PACFPROB	Array of partial autocorrelation probabilities, with $nlag + 1$ entries	$\text{Prob}(\hat{\varphi}(h)) = 2 (1 - \Phi(\text{Norm}(\hat{\varphi}(h))))$
PACFLPROB	Array of partial autocorrelation log probabilities, with $nlag + 1$ entries	$\text{LogProb}(\hat{\varphi}(h)) = -\log_{10}(\text{Prob}(\hat{\varphi}(h)))$
IACF	Array of inverse autocorrelation estimates, with $nlag + 1$ entries	$\hat{\theta}(h)$
IACFSTD	Array of inverse autocorrelation standard errors, with $nlag + 1$ entries	$\text{Std}(\hat{\theta}(h)) = 1/\sqrt{N_0}$

Table 31.3 *continued*

Column Name	Column Content	Statistics Used to Calculate Content
IACF2STD	Array of twice standard errors, with $nlag + 1$ entries	$\text{Flag}(\hat{\theta}(h)) = \begin{cases} 1 & \hat{\theta}(h) > 2\text{Std}(\hat{\theta}(h)) \\ 0 & -2\text{Std}(\hat{\theta}(h)) < \hat{\theta}(h) < 2\text{Std}(\hat{\theta}(h)) \\ -1 & \hat{\theta}(h) < -2\text{Std}(\hat{\theta}(h)) \end{cases}$
IACFNORM	Array of normalized inverse autocorrelation, with $nlag + 1$ entries	$\text{Norm}(\hat{\theta}(h)) = \hat{\theta}(h)/\text{Std}(\hat{\theta}(h))$
IACFPROB	Array of inverse autocorrelation probabilities, with $nlag + 1$ entries	$\text{Prob}(\hat{\theta}(h)) = 2 \left(1 - \Phi \left(\text{Norm}(\hat{\theta}(h)) \right) \right)$
IACFLPROB	Array of inverse autocorrelation log probabilities, with $nlag + 1$ entries	$\text{LogProb}(\hat{\varphi}(h)) = -\log_{10}(\text{Prob}(\hat{\varphi}(h)))$
WN	Array of Ljung-Box white noise tests, with $nlag + 1$ entries	$Q(h) = T(T+2) \sum_{j=1}^h \rho(j)^2 / (T-j)$
WNPROB	White noise probabilities	$\text{Prob}(Q(h)) = \chi_{\max(1, h-p)}(Q(h))$
WNLPROB	White noise log probabilities	$\text{LogProb}(Q(h)) = -\log_{10}(\text{Prob}(Q(h)))$

CROSSCORR Class

CROSSCORR Object

The CROSSCORR class object functions perform the cross-correlation and cross-covariance analysis of two time series arrays and output all the values and results.

Table 31.4 summarizes the methods that are associated with the CROSSCORR object.

Table 31.4 Methods of the CROSSCORR Object

Method	Description
GetResult	Get the analysis result
Initialize	Initialize the CROSSCORR object
Run	Run the analysis
SetNLags	Set the number of lags
SetScale	Set the normalization
SetX	Set the cross time series array
SetY	Set the primary time series array

Figure 31.3 diagrams the methods of the CROSSCORR object.

Figure 31.3 CROSSCORR Data Flow

CROSSCORR Synopsis

DECLARE OBJECT *obj* (CROSSCORR) ;

Method syntax, in order of typical usage:

```

rc=obj.Initialize () ;
rc=obj.SetY (YSeries) ;
rc=obj.SetX (XSeries) ;
rc=obj.SetNLags (NLags) ;
rc=obj.SetScale (Adjscale) ;
rc=obj.Run () ;
rc=obj.GetResult ('Name',OutputArray) ;

```

CROSSCORR Methods

CROSSCORR.GetResult Method

```
rc=obj.GetResult ('Name',OutputArray) ;
```

Outputs the selected results to an array.

Input Arguments You must specify the following input arguments:

<i>Name</i>	specifies a string that identifies the result series to return. You can specify the following values within single quotation marks:
<i>ccov</i>	returns an array of cross-covariance estimates, with $2 \times nlag + 1$ entries.
<i>ccf</i>	returns an array of cross-correlation estimates, with $2 \times nlag + 1$ entries.
<i>ccfst</i>	returns an array of standard errors, with $2 \times nlag + 1$ entries.
<i>ccf2std</i>	returns an array of double standard errors, with $2 \times nlag + 1$ entries.
<i>ccfnorm</i>	returns an array of normalized cross-correlation, with $2 \times nlag + 1$ entries.
<i>ccfprob</i>	returns an array of probabilities, with $2 \times nlag + 1$ entries.
<i>ccflprob</i>	returns an array of log probabilities, with $2 \times nlag + 1$ entries.

OutputArray specifies a numeric array to receive the result series.

CROSSCORR.Initialize Method

```
rc=obj.Initialize () ;
```

Initializes an CROSSCORR object to an empty state. This method must be called before the time series arrays and other attributes are specified for the CROSSCORR object.

Arguments There are no arguments associated with this method.

CROSSCORR.Run Method

```
rc=obj.Run () ;
```

Runs the CROSSCORR object to perform the cross-correlation and cross-covariance analysis by using the time series arrays *YSeries* and *XSeries* that have been specified for it. Upon successful completion, various results can be extracted from the CROSSCORR object.

Arguments There are no arguments associated with this method.

CROSSCORR.SetNLags Method

```
rc=obj.SetNLags (Nlags) ;
```

Sets a named option for the CROSSCORR object.

Input Arguments You must specify the following input argument:

Nlags specifies the number of lags to use in the calculation. The default value is 24.

CROSSCORR.SetScale Method

rc=obj.SetScale (Adjscale) ;

Specifies the normalization setting for the CROSSCORR object.

Input Arguments You must specify the following input argument:

Adjscale specifies *Adjscale*, which controls the normalization of the cross-covariance and cross-correlation. You can specify the following numeric values:

- 0 specifies the default normalization.
- 1 specifies the unbiased normalization.
- 2 specifies the biased normalization.

For more information, see [Table 31.6](#).

CROSSCORR.SetX Method

rc=obj.SetX (XSeries) ;

Specifies the cross time series array (*XSeries*) for the CROSSCORR object.

Input Arguments You must specify the following input argument:

XSeries specifies a numeric array that contains the dependent series for the CROSSCORR object.

CROSSCORR.SetY Method

rc=obj.SetY (YSeries) ;

Specifies the primary time series array (*YSeries*) for the CROSSCORR object.

Input Arguments You must specify the following input argument:

YSeries specifies a numeric array that contains the dependent series for the CROSSCORR object.

OUTCROSSCORR Object

The OUTCROSSCORR object collects output from a CROSSCORR object.

Table 31.5 summarizes the methods that are associated with the OUTCROSSCORR object.

Table 31.5 Methods of the OUTCROSSCORR Object

Method	Description
Collect	Collect the results of a CROSSCORR object
nrows	Get the current row count from the OUTCROSSCORR object

Figure 31.4 diagrams the methods of the OUTCROSSCORR object.

Figure 31.4 OUTCROSSCORR Data Flow

OUTCROSSCORR Methods

OUTCROSSCORR.Collect Method

rc=obj.Collect (CROSSCORRObj) ;

Collects the results from a CROSSCORR object and saves them to a table.

Arguments You must specify the following input argument:

CROSSCORRObj is a character string that specifies the name of the CROSSCORR object to use as the source of the cross-correlation and cross-covariance analysis results.

OUTCROSSCORR.nrows Attribute

nrows=obj.nrows () ;

Gets the current row count from the OUTCROSSCORR object.

Arguments There are no arguments associated with this method.

Output Table Schema

The collector object, OUTCROSSCORR, collects the results of a CROSSCORR object.

OUTCROSSCORR collects the results of a CROSSCORR object. The output table contains the columns that are shown in [Table 31.6](#).

Table 31.6 OUTCROSSCORR Output Table Contents

Column Name	Column Content	Statistics Used to Calculate Content
NAME	Variable name	N/A
CROSS	Cross variable name	N/A
LAG	Array of time lags	$h \in \{-H, \dots, 0, \dots, H\}$
N	Number of variance products	N_h , the number of observed products at lag h , ignoring missing values
MEAN	Mean of variable	
CROSSMEAN	Mean of cross variable	
CCOV	Array of cross-covariance estimates, with $2 \times nlag + 1$ entries	$\hat{\gamma}_{x,y}(h) = \begin{cases} \frac{1}{N} \sum_{t=h+1}^T (x_t - \bar{x})(y_{t-h} - \bar{y}) & 0 \leq h < T \\ \frac{1}{N} \sum_{t= h +1}^T (x_{t- h } - \bar{x})(y_t - \bar{y}) & -T < h < 0 \end{cases}$ where $N = T$ if adjscale is 0, $N = N_h$ if adjscale is 1, and $N = T$ if adjscale is 2. Or $\hat{\gamma}_{x,y}(h) = \begin{cases} \frac{1}{N} \sum_{t=h+1}^T (x_t - \bar{x})(y_{t-h} - \bar{y}) & 0 \leq h < T \\ \frac{1}{N} \sum_{t= h +1}^T (x_{t- h } - \bar{x})(y_t - \bar{y}) & -T < h < 0 \end{cases}$ when embedded missing values are present, where $N = N_h$ if adjscale is 0, $N = N_h$ if adjscale is 1, and $N = T$ if adjscale is 2.
CCF	Array of cross-correlation estimates, with $2 \times nlag + 1$ entries	$\hat{\rho}_{x,y}(h) = \hat{\gamma}_{x,y}(h) / \sqrt{\hat{\gamma}_x(0)\hat{\gamma}_y(0)}$
CCFSTD	Array of cross-correlation standard errors, with $2 \times nlag + 1$ entries	$\text{Std}(\hat{\rho}_{x,y}(h)) = 1/\sqrt{N_0}$
CCF2STD	Array of indicators of sample cross-correlation outside 2 standard errors, with $2 \times nlag + 1$ entries	$\text{Flag}(\hat{\rho}_{x,y}(h)) = \begin{cases} 1 & \hat{\rho}_{x,y}(h) > 2\text{Std}(\hat{\rho}_{x,y}(h)) \\ 0 & -2\text{Std}(\hat{\rho}_{x,y}(h)) < \hat{\rho}_{x,y}(h) < 2\text{Std}(\hat{\rho}_{x,y}(h)) \\ -1 & \hat{\rho}_{x,y}(h) < -2\text{Std}(\hat{\rho}_{x,y}(h)) \end{cases}$
CCFNORM	Array of normalized cross-correlations, with $2 \times nlag + 1$ entries	$\text{Norm}(\hat{\rho}_{x,y}(h)) = \hat{\rho}_{x,y}(h) / \text{Std}(\hat{\rho}_{x,y}(h))$

Table 31.6 *continued*

Column Name	Column Content	Statistics Used to Calculate Content
CCFPROB	Array of cross-correlation probabilities, with $2 \times nlag + 1$ entries	$\text{Prob}(\hat{\rho}_{x,y}(h)) = 2 (1 - \Phi(\text{Norm}(\hat{\rho}_{x,y}(h))))$
CCFLPROB	Array of cross-correlation log probabilities, with $2 \times nlag + 1$ entries	$\text{LogProb}(\hat{\rho}_{x,y}(h)) = -\log_{10}(\text{Prob}(\hat{\rho}_{x,y}(h)))$

DECOMP Class

DECOMP Object

The DECOMP class object functions perform the seasonal decomposition or analysis of the time series arrays and output all the values and results.

Table 31.7 summarizes the methods that are associated with the DECOMP object.

Table 31.7 Methods of the DECOMP Object

Method	Description
GetResult	Get the analysis results
Initialize	Initialize the DECOMP object
Run	Run the analysis
SetLambda	Set the Hodrick-Prescott filter parameter for trend-cycle decomposition
SetMode	Set the type of decomposition
SetResults	Set the analysis results to be generated
SetSeasonality	Set the length of the seasonal cycles
SetY	Set the time series array

Figure 31.5 diagrams the methods of the DECOMP object.

Figure 31.5 DECOMP Data Flow

DECOMP Synopsis

DECLARE OBJECT *obj* (DECOMP) ;

Method syntax, in order of typical usage:

```

rc=obj.Initialize () ;
rc=obj.SetY (YSeries) ;
rc=obj.SetMode ('Name') ;
rc=obj.SetResults ('Name'<,'Name',... >) ;
rc=obj.SetSeasonality (Value) ;
rc=obj.SetLambda (Value) ;
rc=obj.Run () ;
rc=obj.GetResult ('Name',OutputArray) ;

```

DECOMP Methods

DECOMP.GetResult Method

```
rc=obj.GetResult ('Name',OutputArray) ;
```

Outputs the selected results to an array.

Input Arguments You must specify the following input arguments:

Name specifies a string that identifies the result series to return. You can specify the following values within single quotation marks:

<i>tcc</i>	returns the trend-cycle component.
<i>sic</i>	returns the seasonal-irregular component.
<i>sc</i>	returns the seasonal component.
<i>scstd</i>	returns the seasonal component standard errors.
<i>tcs</i>	returns the trend-cycle-seasonal component.
<i>ic</i>	returns the irregular component.
<i>sa</i>	returns the seasonally adjusted series.
<i>pcsa</i>	returns the percentage of change in seasonally adjusted series.
<i>tc</i>	returns the trend component.
<i>cc</i>	returns the cycle component.

OutputArray specifies a numeric array to receive the result series.

DECOMP.Initialize Method

```
rc=obj.Initialize () ;
```

Initializes a DECOMP object to an empty state. This method must be called before the time series array and other attributes are specified for the DECOMP object.

Arguments There are no arguments associated with this method.

DECOMP.Run Method

```
rc=obj.Run () ;
```

Runs the DECOMP object to perform the seasonal decomposition or analysis by using the time series array *YSeries* that has been specified for it. Upon successful completion, various results can be extracted from the DECOMP object.

Arguments There are no arguments associated with this method.

DECOMP.SetLambda Method

```
rc=obj.SetLambda (Value) ;
```

Sets the Hodrick-Prescott filter parameter for trend-cycle decomposition.

Input Arguments You must specify the following input argument:

Value specifies the length of the seasonal cycle. The default value is 1.

DECOMP.SetMode Method

rc=obj.SetMode (Value) ;

Sets the type of decomposition to be used to decompose the time series.

Input Arguments You can specify one of the following *Values*:

ADD | ADDITIVE specifies additive decomposition.
LOGADD | LOGADDITIVE specifies log-additive decomposition.
MULT | MULTIPLICATIVE specifies multiplicative decomposition.
MULTORADD specifies multiplicative or additive decomposition, depending on the data.
PSEUDOADD | PSEUDOADDITIVE specifies pseudo-additive decomposition.

DECOMP.SetResults Method

rc=obj.SetResults ('Name'<,'Name',... >) ;

Set a group of results to be generated in the DECOMP object.

Input Arguments You must specify the following input arguments:

Name specifies one or multiple strings that identify the result series to be generated. You can specify the following values within single quotation marks:

<i>tcc</i>	specifies the trend-cycle component.
<i>sic</i>	specifies the seasonal-irregular component.
<i>sc</i>	specifies the seasonal component.
<i>scstd</i>	specifies the seasonal component standard errors.
<i>tcs</i>	specifies the trend-cycle-seasonal component.
<i>ic</i>	specifies the irregular component.
<i>sa</i>	specifies the seasonally adjusted series.
<i>pcsa</i>	specifies the percentage of change in seasonally adjusted series.
<i>tc</i>	specifies the trend component.
<i>cc</i>	specifies the cycle component.

OutputArray specifies a numeric array to receive the result series.

DECOMP.SetSeasonality Method

rc=obj.SetSeasonality (Value) ;

Sets the length of seasonal cycles for the DECOMP object.

Input Arguments You must specify the following input argument:

Value specifies the length of the seasonal cycle, which must be either an integer greater than 1 or `_SEASONALITY_`. The predefined symbol `_SEASONALITY_` is the length of the seasonal cycle that is computed by using the seasonality or the time ID interval that you specify in a PROC TSMODEL step or a `runTimeCode` action call. For more information about predefined symbols, see the section “Predefined Symbols” in Chapter 16, “TSMODEL Procedure” (*SAS Visual Forecasting: Forecasting Procedures*). For more information about seasonality, see the section “Seasonality in Models” in Chapter 17, “Forecasting Details” (*SAS Visual Forecasting: Time Series Packages*). The default value is `_SEASONALITY_`.

DECOMP.SetY Method

`rc=obj.SetY (YSeries) ;`

Specifies the time series array (*YSeries*) for the DECOMP object.

Input Arguments You must specify the following input argument:

YSeries specifies a numeric array that contains the dependent series for the DECOMP object.

OUTDECOMP Object

The OUTDECOMP object collects output from DECOMP object.

Table 31.8 summarizes the methods that are associated with the OUTDECOMP object.

Table 31.8 Methods of the OUTDECOMP Object

Method	Description
Collect	Collect the results of a DECOMP object
nrows	Get the current row count from the OUTDECOMP object

Figure 31.6 diagrams the methods of the OUTDECOMP object.

Figure 31.6 OUTDECOMP Data Flow

OUTDECOMP Methods

OUTDECOMP.Collect Method

rc=obj.Collect (DECOMPObj) ;

Collects the results from a DECOMP object and saves them to a table.

Arguments You must specify the following input argument:

DECOMPObj is a character string that specifies the name of the DECOMP object to use as the source of the seasonal decomposition or analysis results.

OUTDECOMP.nrows Attribute

nrows=obj.nrows () ;

Gets the current row count from the OUTDECOMP object.

Arguments

There are no arguments associated with this method.

Output Table Schema

The collector object, OUTDECOMP, collects the results of a DECOMP object.

OUTDECOMP collects the results of a DECOMP object. The output table contains the columns that are shown in [Table 31.9](#).

Table 31.9 OUTDECOMP Output Table Contents

Column Name	Column Content
NAME	Variable name
MODE	Mode of decomposition
TIMEID	Time ID values
SEASON	Seasonal index
ORIGINAL	Original series
TCC	Trend-cycle component
SIC	Seasonal-irregular component
SC	Seasonal component
SCSTD	Seasonal component standard error
TCS	Trend-cycle-seasonal component
IC	Irregular component
SA	Seasonally adjusted series
PCSA	Percentage change in seasonally adjusted series
TC	Trend component
CC	Cycle component

For more information about each components, see [Table 31.12](#).

OUTDECOMP2 Object

The OUTDECOMP2 object collects output from DECOMP object. In this object, the time periods are recorded as the column names instead of decomposition components.

[Table 31.10](#) summarizes the methods that are associated with the OUTDECOMP2 object.

Table 31.10 Methods of the OUTDECOMP2 Object

Method	Description
Collect	Collect the results of a DECOMP object
nrows	Get the current row count from the OUTDECOMP2 object

[Figure 31.7](#) diagrams the methods of the OUTDECOMP2 object.

Figure 31.7 OUTDECOMP2 Data Flow

OUTDECOMP2 Methods

OUTDECOMP2.Collect Method

`rc=obj.Collect (DECOMPObj) ;`

Collects the results from a DECOMP object and saves them to a table.

Arguments You must specify the following input argument:

DECOMPObj is a character string that specifies the name of the DECOMP object to use as the source of the seasonal decomposition or analysis results.

OUTDECOMP2.nrows Attribute

`nrows=obj.nrows () ;`

Gets the current row count from the OUTDECOMP2 object.

Arguments

There are no arguments associated with this method.

Output Table Schema

The collector object, OUTDECOMP2, collects the results of a DECOMP object.

OUTDECOMP2 collects the results of a DECOMP object. The output table contains the columns that are shown in [Table 31.11](#).

Table 31.11 OUTDECOMP2 Output Table Contents

Column Name	Column Content
NAME	Variable name
MODE	Mode of decomposition
COMPONENT	Component Name
PERIOD	Period

Details

You can use the DECOMP object to perform seasonal decomposition (also called seasonal adjustment) on the working series. The DECOMP object uses classical decomposition. More complex seasonal decomposition or adjustment analysis can be performed by using the X11 or the X12 procedure of SAS/ETS.

The SetMode method determines the mode of the seasonal adjustment decomposition to be performed. There are four modes: multiplicative (MULT), additive (ADD), pseudo-additive (PSEUDOADD), and log-additive (LOGADD) decomposition (in which the components are exponentiated to the original metric). The default value for the SetMode method is MULTORADD, which uses multiplicative mode for series that are strictly positive, pseudo-additive mode for series that are nonnegative, and additive mode for series that are not nonnegative.

The SetLambda method specifies the Hodrick-Prescott filter parameter (Hodrick and Prescott 1980) for trend-cycle decomposition. The Hodrick-Prescott filter is used to decompose the trend-cycle component into the trend component and the cycle component in an additive fashion. The SetLambda method takes a single argument *Value*, which specifies the length of the seasonal cycle. A smaller *Value* assigns less significance to the cycle; that is, a value of 0 implies no cycle component. The default value is 1600.

Table 31.12 shows the notation and keywords that are associated with seasonal decomposition (adjustment) analysis.

Table 31.12 Seasonal Adjustment Formulas

Component	Input Argument	SetMode Value	Formula
Original series	original	MULT	$O_t = TC_t S_t I_t$
		ADD	$O_t = TC_t + S_t + I_t$
		LOGADD	$\log(O_t) = TC_t + S_t + I_t$
		PSEUDOADD	$O_t = TC_t (S_t + I_t - 1)$
Trend-cycle component	tcc	MULT	Centered moving average of O_t
		ADD	Centered moving average of O_t
		LOGADD	Centered moving average of $\log(O_t)$
		PSEUDOADD	Centered moving average of O_t
Seasonal-irregular component	sic	MULT	$SI_t = S_t I_t = O_t / TC_t$
		ADD	$SI_t = S_t + I_t = O_t - TC_t$
		LOGADD	$SI_t = S_t + I_t = \log(O_t) - TC_t$
		PSEUDOADD	$SI_t = S_t + I_t - 1 = O_t / TC_t$

Table 31.12 *continued*

Component	Keyword	MODE= Option	Formula
Seasonal component	sc	MULT	Seasonal averages of SI_t
		ADD	Seasonal averages of SI_t
		LOGADD	Seasonal averages of SI_t
		PSEUDOADD	Seasonal averages of SI_t
Irregular component	ic	MULT	$I_t = SI_t/S_t$
		ADD	$I_t = SI_t - S_t$
		LOGADD	$I_t = SI_t - S_t$
		PSEUDOADD	$I_t = SI_t - S_t + 1$
Trend-cycle-seasonal component	tcs	MULT	$TCS_t = TC_t S_t = O_t/I_t$
		ADD	$TCS_t = TC_t + S_t = O_t - I_t$
		LOGADD	$TCS_t = TC_t + S_t = O_t - I_t$
		PSEUDOADD	$TCS_t = TC_t S_t$
Trend component	tc	MULT	$T_t = TC_t - C_t$
		ADD	$T_t = TC_t - C_t$
		LOGADD	$T_t = TC_t - C_t$
		PSEUDOADD	$T_t = TC_t - C_t$
Cycle component	cc	MULT	$C_t = TC_t - T_t$
		ADD	$C_t = TC_t - T_t$
		LOGADD	$C_t = TC_t - T_t$
		PSEUDOADD	$C_t = TC_t - T_t$
Seasonally adjusted series	sa	MULT	$SA_t = O_t/S_t = TC_t I_t$
		ADD	$SA_t = O_t - S_t = TC_t + I_t$
		LOGADD	$SA_t = O_t/\exp(S_t) = \exp(TC_t + I_t)$
		PSEUDOADD	$SA_t = TC_t I_t$

When s is odd, the trend-cycle component is computed from the s -period-centered moving average as follows:

$$TC_t = \sum_{k=-\lfloor s/2 \rfloor}^{\lfloor s/2 \rfloor} y_{t+k}/s$$

When s is even, the trend-cycle component is computed from the s -period-centered moving average as follows:

$$TC_t = \sum_{k=-s/2}^{s/2-1} (y_{t+k} + y_{t+1+k})/2s$$

The seasonal component is obtained by averaging the seasonal-irregular component for each season,

$$S_{k+js} = \sum_{t=k \bmod s} \frac{SI_t}{T/s}$$

where $0 \leq j \leq T/s$ and $1 \leq k \leq s$. The seasonal components are normalized to sum to 1 (multiplicative) or 0 (additive).

DPF Class

DPF Object

The DPF class object functions take the output of the FREQ class object as input. The DPF class object performs count distribution analysis for a time series.

Table 31.13 summarizes the methods that are associated with the DPF object.

Table 31.13 Methods of the DPF Object

Method	Description
Initialize	Initialize the DPF object
Run	Run the analysis
SetOption	Set the specifications

Figure 31.8 diagrams the methods of the DPF object.

Figure 31.8 DPF Data Flow

DPF Synopsis

DECLARE OBJECT *obj* (DPF) ;

Method syntax, in order of typical usage:

```

rc=obj.Initialize (FREQObj) ;
rc=obj.SetOption ('Name',Value) ;
rc=obj.Run () ;

```

DPF Methods

DPF.Initialize Method

```
rc=obj.Initialize (FREQObj) ;
```

Specifies a FREQ object, which includes frequency analysis results. This method must be called before the time series arrays and other attributes are specified for the DPF object.

Input Arguments

You must specify a FREQ object, which includes frequency analysis results.

FREQObj specifies the FREQ object as input.

DPF.Run Method

```
rc=obj.Run () ;
```

Runs the DPF object to perform the count distribution analysis. Upon successful completion, various results can be extracted from the DPF object.

DPF.SetOption Method

```
rc=obj.SetOption ('Name', Value) ;
```

Sets a named option for the DPF object.

Input Arguments

You can specify one of the following for '*Name*' and its associated *Value*:

ALPHA	specifies the confidence level size, where alpha must be between 0 and 1. The default value is 0.05.								
CONVERGE	specifies the convergence criterion.								
MAXITER	specifies the maximum number of iterations, where <i>Value</i> is an integer.								
'SELECT'	takes a string <i>Value</i> that specifies the distribution selection criterion. You can specify one of the following <i>Values</i> : <table data-bbox="500 1394 1240 1528"> <tr> <td>AIC</td><td>specifies Akaike's information criterion.</td></tr> <tr> <td>BIC</td><td>specifies the Bayesian information criterion.</td></tr> <tr> <td>LOGLIK</td><td>specifies the log-likelihood.</td></tr> </table> The default value is LOGLIK.	AIC	specifies Akaike's information criterion.	BIC	specifies the Bayesian information criterion.	LOGLIK	specifies the log-likelihood.		
AIC	specifies Akaike's information criterion.								
BIC	specifies the Bayesian information criterion.								
LOGLIK	specifies the log-likelihood.								
'METHOD'	takes a string <i>Value</i> that specifies the candidate distribution to use in the analysis. You can specify one of the following <i>Values</i> : <table data-bbox="500 1701 1435 1913"> <tr> <td>BEST</td><td>specifies the best distribution, based on the value of the select argument.</td></tr> <tr> <td>BINOMIAL</td><td>specifies the binomial distribution.</td></tr> <tr> <td>GEOMETRIC</td><td>specifies the geometric distribution.</td></tr> <tr> <td>NEGBINOMIAL</td><td>specifies the negative binomial distribution.</td></tr> </table>	BEST	specifies the best distribution, based on the value of the select argument.	BINOMIAL	specifies the binomial distribution.	GEOMETRIC	specifies the geometric distribution.	NEGBINOMIAL	specifies the negative binomial distribution.
BEST	specifies the best distribution, based on the value of the select argument.								
BINOMIAL	specifies the binomial distribution.								
GEOMETRIC	specifies the geometric distribution.								
NEGBINOMIAL	specifies the negative binomial distribution.								

- POISSON** specifies the Poisson distribution.
- ZMBINOMIAL** specifies the zero-modified binomial distribution.
- ZMGEOMETRIC** specifies the zero-modified geometric distribution.
- ZMNEGBINOMIAL** specifies the zero-modified negative binomial distribution.
- ZMPOISSON** specifies the zero-modified Poisson distribution.

The default distribution is BEST.

OUTDPE Object

The OUTDPE object collects output from a DPF object.

Table 31.14 summarizes the methods that are associated with the OUTDPE object.

Table 31.14 Methods of the OUTDPE Object

Method	Description
<code>Collect</code>	Collect the results of a DPF object
<code>nrows</code>	Get the current row count from the OUTDPE object

Figure 31.9 diagrams the methods of the OUTDPF object.

Figure 31.9 OUTDPE Data Flow

OUTDPE Methods

OUTDPE.Collect Method

```
rc=obj.Collect (DPFObj) ;
```

Collects the results from a DPF object and saves them to a table.

Arguments You must specify the following input argument:

DPFObj is a character string that specifies the name of the DPF object to use as the source of the parameter estimation of the count distribution.

OUTDPE.nrows Attribute

```
nrows=obj.nrows () ;
```

Gets the current row count from the OUTDPE object.

Arguments There are no arguments associated with this method.

Output Table Schema

OUTDPE collects predictions using the count distribution that has the best fit. The output table contains the columns that are shown in [Table 31.15](#).

Table 31.15 OUTDPE Output Table Contents

Column Name	Column Content
NAME	Name of target variable
Distribution	Distribution
Parameter	Name of parameter
Estimate	Parameter estimate
StdErr	Standard error
Tvalue	<i>t</i> value
Probt	Approximate probability > <i>t</i>
Lower	Lower 95% of parameter estimate
Upper	Upper 95% of parameter estimate

OUTDPROB Object

The OUTDPROB object collects output from a DPF object.

Table 31.16 summarizes the methods that are associated with the OUTDPROB object.

Table 31.16 Methods of the OUTDPROB Object

Method	Description
Collect	Collect the results of a DPF object
nrows	Get the current row count from the OUTDPROB object

Figure 31.10 diagrams the methods of the OUTDPROB object.

Figure 31.10 OUTDPROB Data Flow

OUTDPROB Methods

OUTDPROB.Collect Method

rc=obj.Collect (DPFObj) ;

Collects the results from a DPF object and saves them to a table.

Arguments You must specify the following input argument:

DPFObj is a character string that specifies the name of the DPF object to use as the source of the prediction of the count distribution.

OUTDPROB.nrows Attribute

nrows=obj.nrows () ;

Gets the current row count from the OUTDPROB object.

Arguments There are no arguments associated with this method.

Output Table Schema

OUTDPROB collects predictions using the count distribution that has the best fit. The output table contains the columns that are shown in [Table 31.17](#).

Table 31.17 OUTDPROB Output Table Contents

Column Name	Column Content
<u>_NAME_</u>	Name of target variable
Index	Index
Value	Values
Observedzeros	Observed zeros
Expectedzeros	Expected zeros
Observed	Observed counts
Expected	Expected counts
Expectedlower	Expected lower confidence
Expectedupper	Expected upper confidence
Probability	Probability
Probabilitylower	Probability lower confidence
Probabilityupper	Probability upper confidence
Chisquare	Chi-square statistic
Chisquareprob	Chi-square probability
Chisquarelogprob	Chi-square log probability

Example

This example uses the TSMODEL procedure to analyze the frequency of the time series Air and then conducts a count distribution analysis.

The following DATA step loads the Sashelp.Air data set into the library. This DATA step assumes that your library is named mylib, but you can substitute any appropriately defined library.

```
data mylib.air (replace=yes);
    set Sashelp.air;
run;

proc tsmodel data=mylib.air outobj=(of=mylib.outfreq(replace=YES)
                                   odpe=mylib.dpe(replace=YES)
                                   odprob=mylib.dprob(replace=YES)
                                   );
    var air;
    id date interval=month;
    require tsa;
    submit;
        declare object f(FREQ);
        declare object of(OUTFREQ);
        declare object dpf(DPF);
        declare object odpe(OUTDPE);
        declare object odprob(OUTDPROB);
        rc = f.Initialize();
        rc = f.SetOption("SEASONALITY",12);
        rc = f.SetY(air);
        rc = f.Run();
        rc = of.Collect(f);

        rc = dpf.Initialize(f);
        rc = dpf.SetOption("SELECT","AIC","METHOD","POISSON");
        rc = dpf.Run();
        rc = odpe.Collect(dpf);
        rc = odprob.Collect(dpf);
    endsubmit;
run;
```

FREQ Class

FREQ Object

The FREQ class object function analyzes the frequency of a time series and outputs all unique values and corresponding counts for the time series.

Table 31.18 summarizes the methods that are associated with the FREQ object.

Table 31.18 Methods of the FREQ Object

Method	Description
GetResult	Get the analysis result
Initialize	Initialize the FREQ object
Nvalues	Return the number of unique values in the input series
Run	Run the analysis
SetOption	Set the specifications
SetY	Set the input time series

Figure 31.11 diagrams the methods of the FREQ object.

Figure 31.11 FREQ Data Flow

FREQ Synopsis

DECLARE OBJECT *obj* (FREQ) ;

Method syntax, in order of typical usage:

```

rc=obj.Initialize () ;
rc=obj.SetY (YSeries) ;
rc=obj.SetOption ('Name', Value) ;
rc=obj.Run () ;
rc=obj.GetResult ('Name', OutputArray) ;
rc=obj.Nvalues () ;

```

FREQ Methods

FREQ.GetResult Method

```
rc=obj.GetResult ('Name',OutputArray) ;
```

Outputs the selected results to an array.

Input Arguments You must specify the following input arguments:

Name specifies a string that identifies the result series to return. You can specify the following values within single quotation marks:

'VALUES'	retrieves a monotonically increasing list of the unique values that are found in the input series that is specified by using the SetY method.
'COUNTS'	retrieves the number of occurrences of each unique value.
'PCTS'	retrieves the percentage of total occurrences of each unique value.

OutputArray specifies a numeric array to receive the result series.

FREQ.Initialize Method

```
rc=obj.Initialize () ;
```

Initializes an FREQ object to an empty state. This method must be called before the time series arrays and other attributes are specified for the FREQ object.

Arguments There are no arguments associated with this method.

FREQ.Nvalues Method

```
rc=obj.Nvalues () ;
```

Returns the number of unique values in the input series to *rc*. This number is also the length of all result series that are returned by the GetResult method. It is set to a missing value if the Run method did not complete successfully.

Arguments There are no arguments associated with this method.

FREQ.Run Method

```
rc=obj.Run () ;
```

Runs the FREQ object to perform the autocorrelation and autocovariance analysis by using the time series array *YSeries* that has been specified for it. Upon successful completion, various results can be extracted from the FREQ object.

FREQ.SetOption Method

```
rc=obj.SetOption ('Name',Value) ;
```

Sets a named option for the FREQ object.

Input Arguments

You can specify the following for *'Name'* and its associated *Value*:

'SEASONALITY' specifies the seasonality of the time series, where *Value* is an integer. You can also specify `_SEASONALITY_`. The predefined symbol `_SEASONALITY_` is the length of the seasonal cycle that is computed by using the seasonality or the time ID interval that you specify in a PROC TSMODEL step or a **runTimeCode** action call. For more information about predefined symbols, see the section “Predefined Symbols” in Chapter 16, “TSMODEL Procedure” (*SAS Visual Forecasting: Forecasting Procedures*). For more information about seasonality, see the section “Seasonality in Models” in Chapter 17, “Forecasting Details” (*SAS Visual Forecasting: Time Series Packages*). The default value is 0.

FREQ.SetY Method

```
rc=obj.SetY (YSeries) ;
```

Specifies the time series array (*YSeries*) for the FREQ object.

Input Arguments You must specify the following input argument:

YSeries specifies the time series array to analyze.

OUTFREQ Object

The OUTFREQ object collects output from a FREQ object.

Table 31.19 summarizes the methods that are associated with the OUTFREQ object.

Table 31.19 Methods of the OUTFREQ Object

Method	Description
<code>Collect</code>	Collect the results of a FREQ object
<code>nrows</code>	Get the current row count from the OUTFREQ object

Figure 31.12 diagrams the methods of the OUTFREQ object.

Figure 31.12 OUTFREQ Data Flow

OUTFREQ Methods

OUTFREQ.Collect Method

`rc=obj.Collect (FREQObj) ;`

Collects the results from a FREQ object and saves them to a table.

Arguments You must specify the following input argument:

FREQObj is a character string that specifies the name of the FREQ object to use as the source of the frequency analysis.

OUTFREQ.nrows Attribute

`nrows=obj.nrows () ;`

Gets the current row count from the OUTFREQ object.

Arguments There are no arguments associated with this method.

Output Table Schema

The collector object, OUTFREQ, collects the results of frequency function.

OUTFREQ collects the results of frequency function. The output table contains the columns that are shown in [Table 31.20](#).

Table 31.20 OUTFREQ Output Table Contents

Column Name	Column Content
NAME	Name of target variable
Values	Array of series values
Counts	Array of frequency series counts
Percent	Percentage of total frequency

Example

This example uses the TSMODEL procedure to analyze the frequency of the time series Air:

```
proc tsmode1 data=mylib.air outobj=(of=mylib.outfreq(replace=YES));
  var air;
  id date interval=month;
  require tsa;
  submit;
  declare object f(FREQ);
  declare object of(OUTFREQ);
  rc = f.Initialize();
  rc = f.SetOption("SEASONALITY",12);
  rc = f.SetY(air);
  rc = f.Run();
  rc = of.Collect(f);
  endsubmit;
run;
```

SPECTRA Class

SPECTRA Object

The SPECTRA object performs the spectral analysis of a time series array and outputs the results.

Table 31.21 summarizes the methods that are associated with the SPECTRA object.

Table 31.21 Methods of the SPECTRA Object

Method	Description
Initialize	Initialize the SPECTRA object
Run	Run the analysis
SetKernel	Set the kernel
SetOption	Set the specifications
SetWeights	Set the weights
SetY	Set the input time series

Figure 31.13 diagrams the methods of the SPECTRA object.

Figure 31.13 SPECTRA Data Flow

SPECTRA Synopsis

DECLARE OBJECT *obj* (SPECTRA) ;

Method syntax, in order of typical usage:

```

rc=obj.Initialize () ;
rc=obj.SetY (YSeries) ;
rc=obj.SetOption ('Name',Value <,'Name',Value, ... > ) ;
rc=obj.SetKernel ('Kernel' < ,Value,Value> ) ;
rc=obj.SetWeights (NumericArray) ;
rc=obj.Run () ;

```

SPECTRA Methods

SPECTRA.Initialize Method

`rc=obj.Initialize () ;`

Initializes a SPECTRA object to an empty state. This method must be called before the time series arrays and other attributes for the SPECTRA object are specified.

Arguments

There are no arguments associated with this method.

SPECTRA.SetKernel Method

`rc=obj.SetKernel ('Kernel' < ,C,E>) ;`

Sets the kernel options for the SPECTRA object.

Input Arguments

You can specify one of the following input arguments for '*Kernel*':

'NONE'	uses no kernel.
'PARZEN'	uses a Parzen kernel.
'BARTLETT'	uses a Bartlett kernel.
'TUKEY'	uses a Tukey-Hanning kernel.
'TRUNC TRUNCAT'	uses a truncated kernel.
'QS QUADR'	uses a quadratic spectral kernel.

If neither WEIGHTS nor a kernel function is specified, the spectral density estimate is identical to the unmodified periodogram.

The *C* and *E* arguments are optional. You can specify them as follows:

<i>C</i>	specifies a positive scale coefficient for the kernel function. The specified value must be within the range 0 to 32,000.
<i>E</i>	specifies a positive exponent for the kernel function. The specified value must be within the range 0 to 1.

Kernel Option Details

You can further parameterize each of the kernel functions with a kernel scale factor by using the *C* and *E* arguments. Table 31.22 shows the default values of the kernel scale parameters *c* and *e* that are associated with each of the kernel functions together with their kernel scale factor values *M* for a series that has 100 periodogram ordinates. The formula that is used to generate the table entries is $M = cK^e$, where *K* is the number of Fourier component frequencies.

For example, to apply the truncated kernel by using default scale factor parameters in the frequency domain, you could specify the following:

Table 31.22 Default Kernel Scale Factor Parameters

Kernel	c	e	M
Bartlett	1/2	1/3	2.32
Parzen	1	1/5	2.51
Quadratic	1/2	1/5	1.26
Tukey-Hanning	2/3	1/5	1.67
Truncated	1/4	1/5	0.63

```
rc = SetKernel('TRUNCAT');
```

For more information about the kernel function parameterization, see the section “[Using Kernel Specifications](#)” on page 2290.

SPECTRA.SetOption Method

```
rc=obj.SetOption('Name', Value <,'Name', Value, ... > );
```

Sets a named option for the SPECTRA object.

Input Arguments

You can specify one of the following for '*Name*' and its associated *Value*:

'ADJUSTMEAN'

takes a string *Value* that specifies whether to adjust the series by its mean before performing the spectral analysis. You can specify one of the following *Values*:

TRUE | T | YES | Y adjusts the mean before performing spectral analysis.

FALSE | F | NO | N does not adjust the mean before performing spectral analysis.

The default is NO.

'DOMAIN'

takes a string *Value* that specifies how to interpret the smoothing function. You can specify one of the following *Values*:

FREQUENCY smooths the periodogram ordinate.

TIME applies the kernel as a filter to the time series autocovariance function.

The default is FREQUENCY. For more information about the DOMAIN option, see the section “[Using Kernel Specifications](#)” on page 2290.

'ALPHA'

specifies the width of a window that is drawn around the spectral density estimate in a spectral density versus frequency plot. Based on approximations proposed by Brockwell and Davis (1991), periodogram ordinates fall within this window with a confidence level of $1 - \alpha$. The value α must be between 0 and 1; the default is 0.5.

SPECTRA.SetWeights Method

```
rc=obj.SetWeights (NumericArray) ;
```

Sets the relative weights for the SPECTRA object.

Input Arguments

You must specify the following input argument:

NumericArray specifies a series of relative weights that are used to compute a spectral density estimate as the moving average smoothing of periodogram ordinates.

If neither WEIGHTS nor a kernel function is specified, the spectral density estimate is identical to the unmodified periodogram.

SPECTRA.SetY Method

```
rc=obj.SetY (YSeries) ;
```

Specifies the time series array (*YSeries*) for the SPECTRA object.

Input Arguments

You must specify the following input argument:

YSeries specifies a numeric array that contains the series for the SPECTRA object.

SPECTRA.Run Method

```
rc=obj.Run () ;
```

Runs the SPECTRA object to perform the spectral analysis by using the time series array *YSeries* that has been specified for it. Upon successful completion, various results can be extracted from the SPECTRA object.

Arguments

There are no arguments associated with this method.

OUTSPECTRA Object

The OUTSPECTRA object collects output from a SPECTRA object.

Table 31.23 summarizes the methods that are associated with the OUTSPECTRA object.

Table 31.23 Methods of the OUTSPECTRA Object

Method	Description
Collect	Collect the results of a SPECTRA object
nrows	Get the current row count from the OUTSPECTRA object

Figure 31.14 diagrams the methods of the OUTSPECTRA object.

Figure 31.14 OUTSPECTRA Data Flow

OUTSPECTRA Methods

OUTSPECTRA.Collect Method

rc=obj.Collect (SPECTRAObj) ;

Collects the results from a SPECTRA object and saves them to a table.

Arguments You must specify the following input argument:

SPECTRAObj is a character string that specifies the name of the SPECTRA object to use as the source of the spectral analysis.

OUTSPECTRA.nrows Attribute

nrows=obj.nrows () ;

Gets the current row count from the OUTSPECTRA object.

Arguments There are no arguments associated with this method.

Output Table Schema

OUTSPECTRA collects the results of a SPECTRA object. The output table contains the following columns:

Column Name	Column Content
NAME	Name of the variable
FREQ	Frequency in radians from 0 to π
PERIOD	Period or wavelength
COS	Cosine transform
SIN	Sine transform
P	Periodogram
S	Spectral density estimates
S_LOWER	Lower bound of confidence interval of spectral density
S_UPPER	Upper bound of confidence interval of spectral density

Details

The SPECTRA object uses the finite Fourier transform to decompose data series into a sum of sine and cosine terms of different amplitudes and wavelengths. The finite Fourier transform decomposition of the series x_t is

$$x_t = \frac{a_0}{2} + \sum_{k=1}^{K-1} f_k (a_k \cos \omega_k t + b_k \sin \omega_k t)$$

$$f_k = \begin{cases} 1/2 & \text{if } T \text{ is even and } k = K - 1 \\ 1 & \text{otherwise} \end{cases}$$

where

t	is the time subscript, $t = 0, 1, 2, \dots, T - 1$
x_t	are the equally spaced time series data
T	is the number of observations in the time series
K	is the number of frequencies in the Fourier decomposition: $K = \frac{T+2}{2}$ if T is even; $K = \frac{T+1}{2}$ if T is odd
k	is the frequency subscript, $k = 0, 1, 2, \dots, K - 1$
a_0	is the mean term: $a_0 = 2\bar{x}$
a_k	are the cosine coefficients
b_k	are the sine coefficients
ω_k	are the Fourier frequencies: $\omega_k = \frac{2\pi k}{T}$

Functions of the Fourier coefficients a_k and b_k can be plotted against frequency or against wavelength to form *periodograms*. The amplitude periodogram I_k is defined as

$$I_k = \frac{T}{2} (a_k^2 + b_k^2)$$

The periodogram I_k is an estimate at the discrete frequencies ω_k of the spectral density function that characterizes the series x_t . Smoothing the periodogram enables an improved spectral density estimate with

reduced variance and bias to be achieved at these points. Smoothing can be accomplished either by using a spectral window smoothing function or by applying a lag window filter to the series autocovariance function.

When the *Value* of the DOMAIN argument is FREQUENCY, the spectral density estimates are computed by using the following equation to smooth the periodogram ordinates:

$$S_k(M) = \sum_{\tau=K-T}^{K-1} w\left(\frac{\tau}{M}\right) I_{k+\tau}$$

where $w(\theta)$ is the spectral window function whose form is specified by either the SetKernel method or the SetWeights method; M is the kernel scale parameter, which acts as a frequency scaling factor in the spectral window smoothing function; and values of $I_{k+\tau}$ that fall outside $0 \leq k + \tau \leq K - 1$ are mapped to values inside this range by the equations presented previously.

When the *Value* of the DOMAIN argument is TIME, the spectral density values are estimated by applying a lag window filter, $\lambda(h, M)$, to the series autocovariance function. Then, the spectral density estimate can be computed from the filtered autocovariance function by using the following equation:

$$S_k(M) = \sum_{h=-(T-1)}^{T-1} \lambda(h, M) \hat{\gamma}(h) \cos h\omega_k$$

In this case, the kernel scale parameter, M , serves as a scale factor for the lag length, h , in the time domain. In the lag window formulation, the spectral density estimate is a consistent estimator as $T, M \rightarrow \infty$ under the conditions $\lambda(h, M) = 0$ for $|h| > M$ and $\lim_{T \rightarrow \infty} M/T = 0$. These conditions lead to the following parameterization of M :

$$M = cK^e$$

where the values $c > 0$ and $0 < e < 1$ satisfy the consistency conditions. To specify the kernel scale parameter explicitly, set c to the desired scale factor and set $e = 0$.

For uniformity and computational efficiency, all spectral density estimates are calculated using a spectral window weighting function, $w(\theta)$, which is applied to the periodogram ordinates. In the case where the *Value* of the DOMAIN argument is TIME, the effective spectral window weighting function is computed by the following equation:

$$w_{\text{TIME}}(\theta) = \sum_{h=-(T-1)}^{T-1} \lambda(h, M) \cos h\theta$$

Because the kernel scale parameter, M , serves as a lag scale factor in the time domain and as a bandwidth scale factor in the frequency domain, the impact of M on spectral density estimates depends on the *Value* of the DOMAIN argument. When the *Value* of the DOMAIN argument is specified to be FREQUENCY, increasing values of M decrease variance and increase bias in the spectral density estimates; when the *Value* of the DOMAIN argument is TIME, increasing values of M increase variance and decrease bias.

Using Kernel Specifications

You can specify one of 10 different kernel smoothing functions in the SPECTRA object. Five smoothing functions are available in the SetKernel method, and five complementary smoothing functions that correspond to lag window filters are available when the SetKernel method is used and the *Value* of the DOMAIN argument is TIME.

For example, a Parzen kernel with a support of 11 periodogram ordinates in the frequency domain can be specified using the SetKernel method:

```
rc = SetKernel('PARZEN', 5, 0);
```

The SPECTRA class of the TSA package supports the following spectral window kernel functions in the frequency domain, where $x = \tau/M$:

BARTLETT (Bartlett kernel):

$$w(x) = \begin{cases} 1 - |x| & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

PARZEN (Parzen kernel):

$$w(x) = \begin{cases} 1 - 6|x|^2 + 6|x|^3 & 0 \leq |x| \leq \frac{1}{2} \\ 2(1 - |x|)^3 & \frac{1}{2} \leq |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

QS (quadratic spectral kernel):

$$w(x) = \frac{3}{(2\pi x)^2} \left(\frac{\sin 2\pi x}{2\pi x} - \cos 2\pi x \right)$$

TUKEY (Tukey-Hanning kernel):

$$w(x) = \begin{cases} (1 + \cos(\pi x))/2 & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

TRUNCAT (truncated kernel):

$$w(x) = \begin{cases} 1 & |x| \leq 1 \\ 0 & \text{otherwise} \end{cases}$$

When the *Value* of the DOMAIN argument is TIME, the five preceding kernel functions are interpreted as lag window filters on the autocovariance function. The lag window kernel functions correspond to the following spectral window smoothing functions, where $\theta = 2\pi\tau/T$:

BARTLETT (Bartlett equivalent lag window filter):

$$w(\theta) = \frac{1}{2\pi M} \left(\frac{\sin(M\theta/2)}{\sin(\theta/2)} \right)^2$$

PARZEN (Parzen equivalent lag window filter):

$$w(\theta) = \frac{6}{\pi M^3} \left(\frac{\sin(M\theta/4)}{\sin(\theta/2)} \right)^4 \left(1 - \frac{2}{3} \sin^2(\theta/2) \right)$$

QS (quadratic spectral equivalent lag window filter):

$$w(\theta) = \begin{cases} \frac{3M}{4\pi} (1 - (M\theta/\pi)^2) & |\theta| \leq \pi/M \\ 0 & |\theta| > \pi/M \end{cases}$$

TUKEY (Tukey-Hanning equivalent lag window filter):

$$w(\theta) = \frac{1}{4} D_M(\theta - \pi/M) + \frac{1}{2} D_M(\theta) + \frac{1}{4} D_M(\theta + \pi/M)$$

$$D_M(\theta) = \frac{1}{2\pi} \frac{\sin[(M + 1/2)\theta]}{\sin(\theta/2)}$$

TRUNC (truncated equivalent lag window filter):

$$w(\theta) = D_M(\theta)$$

Using Specification of Weighting Constants

You can specify any number of weighting constants. The constants are interpreted symmetrically around the middle weight. The middle constant (or the constant to the right of the middle if an even number of weight constants is specified) is the relative weight of the current periodogram ordinate. The constant immediately to the right of the middle constant is the relative weight of the next periodogram ordinate, and so on. The actual weights that are used in the smoothing process are the weights that are specified in the `SetWeights` method, which are scaled so that they sum to 1.

The moving average calculation reflects at each end of the periodogram to accommodate the periodicity of the periodogram function when there are not enough periodogram ordinates.

For example, a simple triangular weighting can be specified using the following `WEIGHTS` option:

```
array group1[5]/nosymbols; group1[1]=1; group1[2]=2; group1[3]=3;
    group1[4]=2; group1[5]=1;
rc = spectra.SetWeights(group1);
```

Computational Method

If the number of observations, T , factors into prime integers that are less than or equal to 23 and the product of the square-free factors of T is less than 210, then the SPECTRA object uses the fast Fourier transform that was developed by Cooley and Tukey (1965) and implemented by Singleton (1969). If T cannot be factored in this way, then the SPECTRA object uses a Chirp-Z algorithm similar to that proposed by Monro and Branch (1977).

Missing Values

Missing values are replaced with an estimate of the mean to perform spectral analyses. This treatment of a series with missing values is consistent with the approach of Priestley (1981).

STATIONARITY Class

STATIONARITY Object

The STATIONARITY class object functions perform the stationarity tests on a time series and store all the results that you can retrieve later by using the OUTSTATIONARITY object.

Table 31.24 summarizes the methods that are associated with the STATIONARITY object.

Table 31.24 Methods of the STATIONARITY Object

Method	Description
Initialize	Initialize the STATIONARITY object
SetY	Set the input time series
SetOption	Set the specifications
SetLags	Set the number of lags
SetDiff	Set the differences of series
Run	Run the analysis

Figure 31.15 diagrams the methods of the STATIONARITY object.

Figure 31.15 STATIONARITY Data Flow

STATIONARITY Synopsis

DECLARE OBJECT *obj* (STATIONARITY) ;

Method syntax, in order of typical usage:

```

rc=obj.Initialize () ;
rc=obj.SetY ( YSeries ) ;
rc=obj.SetOption ('Name', Value < , 'Name', Value, ... > ) ;
rc=obj.SetLags ( Value ) ;
rc=obj.SetDiff ( Value ) ;
rc=obj.Run () ;

```

STATIONARITY Methods

STATIONARITY.Initialize Method

rc=obj.Initialize () ;

Initializes a STATIONARITY object to an empty state. This method must be called before the time series array and other attributes are specified for the STATIONARITY object.

Arguments There are no arguments associated with this method.

STATIONARITY.SetY Method

```
rc=obj.SetY (YSeries) ;
```

Specifies the time series array (*YSeries*) for the STATIONARITY object.

Input Arguments You must specify the following input argument:

YSeries specifies a numeric array that contains the time series for the STATIONARITY object to analyze.

STATIONARITY.SetOption Method

```
rc=obj.SetOption ('Name', Value < , 'Name', Value, ... > ) ;
```

Sets a named option for the STATIONARITY object.

Input Arguments

You must specify at least one of the following for '*Name*' and its associated *Value*:

'METHOD' takes a string *Value* that specifies the stationarity test method, which can be the augmented Dickey-Fuller (ADF) test, Phillips-Perron (PP) test, or random-walk-with-drift (RW) test. You can specify one of the following *Values*:

ADF | Dickey-Fuller specifies the augmented Dickey-Fuller test.

PP | Phillips-Perron specifies the Phillips-Perron test.

RW | Random-Walk specifies the random-walk-with-drift test.

The default is ADF.

'ORDER' | 'DLAG' takes an integer *Value* that specifies lags for the stationarity test method.

The *Value* must be a positive integer between 1 and 12 (inclusive), denoting the order that the STATIONARITY object uses for the test methods. If the value is between 2 and 12 (inclusive) and the method is ADF, the seasonal ADF test is performed. If the value is 1 and the method is ADF, the nonseasonal ADF test is performed. For the PP or RW method, values between 2 and 12 (inclusive) are discarded and the default order of 1 is used.

The default value is 1.

STATIONARITY.SetLags Method

```
rc=obj.SetLags (Value) ;
```

Sets the lags that the STATIONARITY object uses in the stationarity test calculation.

Input Arguments You must specify the following input argument:

Value specifies the number of lags to use in the calculation. The allowable value type is an array or a numeric scalar. Specifying a scalar *Value* is equivalent to specifying an array that contains consecutive numbers from 0 to *Value* (inclusive).

The default value is 2, which is equivalent to an array {0, 1, 2}.

STATIONARITY.SetDiff Method

```
rc=obj.SetDiff (Value) ;
```

Sets a differencing option for the STATIONARITY object.

Input Arguments You must specify the following input argument:

Value specifies a nonnegative integer scalar or an array of nonnegative integers. The STATIONARITY object differences the time series for each integer value in succession prior to performing the test calculations. For example, if you specify the array { 1, 3 }, then the object first takes the first-order difference and then applies a third-order difference to that first-order-differenced series.

The default value is 0.

STATIONARITY.Run Method

```
rc=obj.Run () ;
```

Runs the STATIONARITY object to perform various stationarity test calculations by using the time series array that you specify in the SetY method according to the options that you specify in other setter methods, such as SetOption. Upon successful completion, you can extract various results from the OUTSTATIONARITY object.

OUTSTATIONARITY Object

The OUTSTATIONARITY object collects output from a STATIONARITY object.

Table 31.25 summarizes the methods that are associated with the OUTSTATIONARITY object.

Table 31.25 Methods of the OUTSTATIONARITY Object

Method	Description
Collect	Collect the results of a STATIONARITY object
nrows	Get the current row count from the OUTSTATIONARITY object

Figure 31.16 diagrams the methods of the OUTSTATIONARITY object.

Figure 31.16 OUTSTATIONARITY Data Flow

OUTSTATIONARITY Methods

OUTSTATIONARITY.Collect Method

```
rc=obj.Collect (STATIONARITYObj) ;
```

Collects the results from a STATIONARITY object and saves them to a table.

Arguments You must specify the following input argument:

STATIONARITYObj is a character string that specifies the name of the STATIONARITY object to use as the source of the stationarity test analysis results.

OUTSTATIONARITY.nrows Attribute

```
nrows=obj.nrows () ;
```

Gets the current row count from the OUTSTATIONARITY object.

Arguments There are no arguments associated with this method.

Output Table Schema

The collector object, OUTSTATIONARITY, collects the results of a STATIONARITY object.

OUTSTATIONARITY The output table contains the columns shown in [Table 31.26](#).

Table 31.26 OUTSTATIONARITY Output Table Contents

Column	Description
Method	Unit root test method
MethodCode	Short code for the unit root test method
Type	Unit root test type
TypeCode	Short code for the unit root test type
Lags	Time lag
Rho	Regression test statistic. This column has missing values when the method is random walk with drift.
ProbRho	Regression test probability value. This column has missing values when the method is random walk with drift
Tau	Studentized test statistic
ProbTau	Studentized test probability value
F	<i>F</i> -test statistic. This column has missing values when the method is seasonal augmented Dickey-Fuller, random walk with drift, or Phillips-Perron. It also has missing values for the (nonseasonal) augmented Dickey-Fuller test when the test type is zero mean.
ProbF	<i>F</i> -test probability value. This column has missing values when the method is seasonal augmented Dickey-Fuller, random walk with drift, or Phillips-Perron. It also has missing values for the (nonseasonal) augmented Dickey-Fuller test when the test type is zero mean.

TSAOUTLIER Class

TSAOUTLIER Object

The TSAOUTLIER object detects outliers for time series data on the basis of the Hampel identifier and outputs the results.

Table 31.27 summarizes the methods that are associated with the TSAOUTLIER object.

Table 31.27 Methods of the TSAOUTLIER Object

Method	Description
Initialize	Initialize the TSAOUTLIER object
Run	Run the analysis
SetY	Set the input time series
SetHampel	Set outlier detection options for the Hampel-based method

Figure 31.17 diagrams the methods of the TSAOUTLIER object.

Figure 31.17 TSAOUTLIER Data Flow

TSAOUTLIER Synopsis

DECLARE OBJECT *obj* (TSAOUTLIER) ;

Method syntax, in order of typical usage:

```
rc=obj.Initialize () ;
rc=obj.SetY (YSeries) ;
rc=obj.SetHampel ('Name', Value < , 'Name', Value, ... >) ;
rc=obj.Run () ;
```

TSAOUTLIER Methods

TSAOUTLIER.Initialize Method

```
rc=obj.Initialize () ;
```

Initializes a TSAOUTLIER object to an empty state. You must call this method before you specify the time series arrays and other attributes for this object.

Arguments

There are no arguments associated with this method.

TSAOUTLIER.SetY Method

```
rc=obj.SetY (YSeries) ;
```

Specifies the time series array (*YSeries*) for the TSAOUTLIER object.

Input Arguments

You must specify the following input argument:

YSeries specifies a numeric array that contains the series for the TSAOUTLIER object. This object detects outliers by using the raw values of this series, which means that it keeps each missing value as-is while detecting outliers. The result is that missing values can be detected as outliers.

TSAOUTLIER.SetHampel Method

```
rc=obj.SetHampel (< 'Name', Value, 'Name', Value, ... >) ;
```

Specifies named options for the TSAOUTLIER object.

Input Arguments

You can specify one or more of the following '*Names*' and the associated *Value*:

'DISTRIBUTION' takes a string *Value* that specifies the data distribution that the TSAOUTLIER object uses to compute the threshold for detecting outliers. You can specify the following distribution *Values*:

EXP	specifies an exponential distribution.
LAPLACE	specifies a Laplace distribution.
LOGISTIC	specifies a logistic distribution.

	NORM	specifies a normal distribution. This is the default distribution.
	UNIFORM	specifies a uniform distribution.
'NUMSTD'		takes a positive numeric <i>Value</i> that specifies the number of standard deviations. The TSAOUTLIER object computes the outlier detection threshold by multiplying this <i>Value</i> by a scaling factor that corresponds to the distribution that you specify in the 'DISTRIBUTION' option. The default value is 3.
'THRESHOLD'		takes a positive numeric <i>Value</i> that specifies the threshold for detecting outliers. If you specify this option, then the 'DISTRIBUTION' and 'NUMSTD' options are ignored.
'WIDTH'		specifies a positive integer <i>Value</i> that determines the number of input observations to include in the sample window for outlier detection. If <i>Value</i> is equal to k , then a window of a maximum size of $2 \cdot k + 1$ is centered around each point of the time series, and outliers are detected by using the data in that window. The default value is 3.

TSAOUTLIER.Run Method

```
rc=obj.Run () ;
```

Runs the TSAOUTLIER object to perform the outlier analysis.

Arguments

There are no arguments associated with this method.

TSAOUTOUTLIER Object

The TSAOUTOUTLIER object collects output from a TSAOUTLIER object.

Table 31.28 summarizes the methods that are associated with the TSAOUTOUTLIER object.

Table 31.28 Methods of the TSAOUTOUTLIER Object

Method	Description
Collect	Collect the results of a TSAOUTLIER object
nrows	Get the current row count from the TSAOUTOUTLIER object

Figure 31.18 diagrams the methods of the TSAOUTOUTLIER object.

Figure 31.18 TSAOUTOUTLIER Data Flow

TSAOUTOUTLIER Methods

TSAOUTOUTLIER.Collect Method

rc=obj.Collect (TSAOUTLIERObj) ;

Collects the results from a TSAOUTLIER object and saves them to a table.

Arguments You must specify the following input argument:

TSAOUTLIERObj is a character string that specifies the name of the TSAOUTLIER object to use as the source of the outlier analysis.

TSAOUTOUTLIER.nrows Attribute

nrows=obj.nrows () ;

Gets the current row count from the TSAOUTOUTLIER object.

Arguments There are no arguments associated with this method.

Output Table Schema

The collector object, TSAOUTOUTLIER, collects the results of a TSAOUTLIER object.

Table 31.29 shows the contents of the TSAOUTOUTLIER object.

Table 31.29 Contents of the TSAOUTOUTLIER Object

Column	Type	Description
EVENT	String	Name of the outlier event
STATISTIC	Numeric	Values of the standardized distance from the median
TIMEID	Numeric	Time ID values for the series

Details

For more information about the TSAOUTLIER object, see the section “Hampel Method of Outlier Detection” (Chapter 2, *SAS Visual Forecasting: Time Series Packages*).

TSA Object

Functional Summary

NOTE: Each function in this section has a prefix of “TSA.”; however, the prefixes are omitted in descriptions for better readability.

Table 31.30 summarizes the functions in the TSA package.

Table 31.30 Functions in Time Series Analysis Package

TSA Function	Description
ACCUMULATE	Accumulates a univariate time series to a particular frequency
ACCUMULATE2	Accumulates a high-frequency time series to a lower frequency and expands the lower-frequency series to have the same length as the high-frequency series
ACF	Computes autocorrelation and autocovariance for a time series array
ARMAORDERS	Performs tests to tentatively identify the autoregressive and moving average orders of mixed autoregressive moving average models
CCF	Computes the cross-correlation and cross-covariance for two time series arrays
DPF Class Object	Performs count distribution analysis for time series
FREQ Class Object	Performs frequency analysis of a time series
INTERMITTENCYTEST	Tests for intermittency of a univariate time series
IACF	Computes the inverse autocorrelation for a time series array

Table 31.30 *continued*

TSA Function	Description
MOVINGSUMMARY	Computes statistics for a set of values within a moving time window
PACF	Computes the partial autocorrelation for a time series array
SCALE	Scales a time series between the minimum value and the maximum value of the original time series
SEASONALDECOMP	Computes the seasonal indices of a univariate time series using classical decomposition
SEASONALINDICES	Computes the seasonal indices of a univariate time series by using regression seasonal dummies
SEASONTTEST	Tests for seasonality of a univariate time series
SIMILARITY	Performs similarity analysis for time series
STATIONARITYTEST	Tests for stationarity of a univariate time series
TRANSFORM	Transforms time series according to the specified transformation type
UNBIASEDNESS	Tests whether a univariate time series is unbiased
WHITENOISE	Tests for white noise of a time series array

ACCUMULATE Method

`rc = TSA.ACCUMULATE (time, y, 'interval', id, z, <'accumulate'>, <'setmiss'>, <'zeromiss'>);`

The ACCUMULATE function accumulates a univariate time series to a particular frequency.

Required Arguments

You must specify the following arguments, separated by commas:

time specifies the time ID array for the time series.

y specifies the times series array to accumulate.

'interval' specifies the time interval.

You can specify any valid time interval name as a quoted string. Here are some typical intervals:

DAY specifies a seasonal cycle of length 7.

MONTH specifies a seasonal cycle of length 12.

QTR specifies a seasonal cycle of length 4.

YEAR specifies a seasonal cycle of length 1.

See Chapter 4, “Date Intervals, Formats, and Functions” (*SAS/ETS User’s Guide*), for other kinds of time intervals that you can specify.

Optional Arguments

You can also specify the following arguments, separated by commas. If you want to use a default value for any of these arguments, enter a space for it.

'accumulate' specifies the accumulation statistic.

You can specify the following values within single quotation marks:

AVERAGE AVG	specifies the average of the values in the time series.
CSS	specifies the corrected sum of squares of the values in the time series.
FIRST	specifies the first value of the time series.
LAST	specifies the last value of the time series.
MAXIMUM MAX	specifies the maximum value in the time series.
MEDIAN MED	specifies the median of the values in the time series.
MINIMUM MIN	specifies the minimum value in the time series.
N	specifies the number of nonmissing observations.
NMISS	specifies the number of missing observations.
NOBS	specifies the number of observations.
STDDEV STD	specifies the standard deviation of the values in the time series.
TOTAL	specifies the total sum of the values in the time series.
USS	specifies the uncorrected sum of squares of the values in the time series.

The default is TOTAL.

'setmiss' specifies the missing value interpretation.

You can specify the following values within single quotation marks:

AVERAGE AVG	specifies the accumulated average value.
FIRST	specifies the accumulated first nonmissing value.
MAXIMUM MAX	specifies the accumulated maximum value.
MEDIAN MED	specifies the accumulated median value.
MINIMUM MIN	specifies the accumulated minimum value.
MISSING	specifies a missing value.
NEXT	specifies the next period’s accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.
PREVIOUS PREV	specifies the previous period’s accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.

The default is MISSING.

'zeromiss' specifies the zero value interpretation.

You can specify the following values within single quotation marks:

- BOTH** sets both beginning and ending zeros to missing.
- LEFT** sets beginning zeros to missing.
- NONE** leaves beginning and ending zeros unchanged.
- RIGHT** sets ending zeros to missing.

The default is NONE.

Returned Values

The ACCUMULATE function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Success
< 0	Computational failure

- id* returns the time ID array for the accumulated time series.
- z* returns the accumulated time series array.

Example

This example uses the TSMODEL procedure to accumulate a time series:

```
proc tsmodel data=mylib.air outarray=mylib.outarray;
  id date interval=month;
  var air;
  outarrays qtravg new_id;
  require tsa;
  submit;
  declare object TSA(tsa);
  rc=TSA.ACCUMULATE(date, air, 'QTR', new_id, qtravg, 'AVERAGE', , );
  endsubmit;
run;
```

ACCUMULATE2 Method

```
rc = TSA.ACCUMULATE2 (time, y, 'interval', id, z, <'accumulate'>, <'setmiss'>, <'zeromiss'> ) ;
```

The ACCUMULATE2 function accumulates a high-frequency time series to a lower frequency and expands the lower-frequency time series to the same length as the high-frequency series.

Required Arguments

You must specify the following arguments, separated by commas:

time specifies the time ID array for the time series.

y specifies the times series array to accumulate.

'interval' specifies the time interval.

You can specify any valid time interval name as a quoted string. Here are some typical intervals:

DAY specifies a seasonal cycle of length 7.

MONTH specifies a seasonal cycle of length 12.

QTR specifies a seasonal cycle of length 4.

YEAR specifies a seasonal cycle of length 1.

See Chapter 4, “Date Intervals, Formats, and Functions” (*SAS/ETS User’s Guide*), for other kinds of time intervals that you can specify.

Optional Arguments

You can also specify the following arguments, separated by commas. If you want to use a default value for any of these arguments, enter a space for it.

'accumulate' specifies the accumulation statistic.

You can specify the following values within single quotation marks:

AVERAGE | AVG specifies the average of the values in the time series.

CSS specifies the corrected sum of squares of the values in the time series.

FIRST specifies the first value of the time series.

LAST specifies the last value of the time series.

MAXIMUM | MAX specifies the maximum value in the time series.

MEDIAN | MED specifies the median of the values in the time series.

MINIMUM | MIN specifies the minimum value in the time series.

N specifies the number of nonmissing observations.

NMISS specifies the number of missing observations.

NOBS specifies the number of observations.

STDDEV | STD specifies the standard deviation of the values in the time series.

TOTAL specifies the total sum of the values in the time series.

USS specifies the uncorrected sum of squares of the values in the time series.

The default is TOTAL.

'setmiss' specifies the missing value interpretation.

You can specify the following values within single quotation marks:

AVERAGE AVG	specifies the accumulated average value.
FIRST	specifies the accumulated first nonmissing value.
LAST	specifies the accumulated last nonmissing value.
MAXIMUM MAX	specifies the accumulated maximum value.
MEDIAN MED	specifies the accumulated median value.
MINIMUM MIN	specifies the accumulated minimum value.
MISSING	specifies a missing value.
NEXT	specifies the next period's accumulated nonmissing value. Missing values at the end of the accumulated series remain missing.
PREVIOUS PREV	specifies the previous period's accumulated nonmissing value. Missing values at the beginning of the accumulated series remain missing.

The default is MISSING.

'zeromiss' specifies the zero value interpretation.

You can specify the following values within single quotation marks:

BOTH	sets both beginning and ending zeros to missing.
LEFT	sets beginning zeros to missing.
NONE	leaves beginning and ending zeros unchanged.
RIGHT	sets ending zeros to missing.

The default is NONE.

Returned Values

The ACCUMULATE2 function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Success.
< 0	Computational failure.

id returns the time ID array for the accumulated time series.

z returns the accumulated time series array.

Example

This example uses the TSMODEL procedure to accumulate a monthly time series into a yearly time series:

```
proc tsmode1 data=mylib.air outarray=mylib.outarray;
  id date interval=month;
  var air;
  outarrays yearavg_expand yearid_expand;
  require tsa;
  submit;
  declare object TSA(tsa);
  rc=TSA.ACCUMULATE2(date, air, 'YEAR', yearid_expand, yearavg_expand,
                    'AVERAGE', , );
  endsubmit;
run;
```

ACF Method

```
rc = TSA.ACF (y, nlag, <lags>, <df>, <mu>, <acov>, <acf>, <acfstd>, <acf2std>, <acfnorm>,
              <acfprob> <acflprob>);
```

The ACF function computes autocorrelation and autocovariance for a time series array.

Required Arguments

You must specify the following arguments, separated by a comma:

y specifies the times series array.
nlag specifies the number of the lag to use in the calculation.

Returned Values

The ACF function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Success
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

lags returns the numbers of the lags that were used in the calculation.
df returns the number of observations used to compute *acov* and *acf*.

<i>mu</i>	returns the mean estimate.
<i>acov</i>	returns an array of covariance estimates, with <i>nlag</i> + 1 entries.
<i>acf</i>	returns an array of autocorrelation estimates, with <i>nlag</i> + 1 entries.
<i>acfstd</i>	returns an array of standard errors, with <i>nlag</i> + 1 entries.
<i>acf2std</i>	returns an array of twice standard errors, with <i>nlag</i> + 1 entries.
<i>acfnorm</i>	returns an array of normalized autocorrelation, with <i>nlag</i> + 1 entries.
<i>acfprob</i>	returns an array of autocorrelation probabilities, with <i>nlag</i> + 1 entries.
<i>acflprob</i>	returns an array of autocorrelation log probabilities, with <i>nlag</i> + 1 entries.

Example

This example uses the TSMODEL procedure to compute the autocorrelation of lag 3 of the time series Air:

```
proc tsmodel data=mylib.air outscalar=mylib.outscalars
      outarray=mylib.outarray;
  id date interval=month;
  var air;
  outscalars mu;
  outarrays acf acov lags df acfstd;
  require tsa;
  submit;
  declare object TSA(tsa);
  rc=TSA.ACF(air, 3, lags, df, mu, acov, acf, acfstd, , , , );
  endsubmit;
run;
```

ARMAORDERS Method

rc = TSA.ARMAORDERS (*y*, *dif*, <'method'>, <*p*>, <*q*>, <*perror*>, <*porders*>, <*qorders*>);

The ARMAORDERS function performs tests to tentatively identify the autoregressive and moving average orders of mixed autoregressive moving average models.

Required Arguments

You must specify the following argument:

<i>y</i>	specifies the times series array to test.
<i>dif</i>	specifies either an array of positive integers or a positive integer that is used for differencing. The default value is 0.

Optional Arguments

You can also specify the following arguments, separated by commas. If you want to use a default value for any of these arguments, enter a space for it.

'method' specifies the method of tentative order selection.
You can specify the following values within single quotation marks:

- ESACF** specifies the extended sample autocorrelation function.
- MINIC** specifies the minimum information criterion.
- SCAN** specifies the squared canonical correlations.

The default value is MINIC.

p specifies the autoregressive order range, where *p* is an array of two nonnegative integers that define the minimum and maximum values.
By default, *p* is the array [0,5].

q specifies the moving average order range, where *q* is an array of two nonnegative integers that define the minimum and maximum values.
By default, *q* is the array [0,5].

perror specifies the autoregressive orders used to estimate the error series for the MINIC method, where *perror* is an array of two nonnegative integers that define the minimum and maximum values.
By default, *perror* is the array [max(*p*), max(*p*)+max(*q*)].

Returned Values

The ARMAORDERS function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Success
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

- porders* returns the recommended autoregressive orders.
- qorders* returns the recommended moving average orders.

Example

This example uses the TSMODEL procedure to tentatively identify the autoregressive and moving average orders for the time series Air:

```
proc tsmodel data=mylib.air outscalar=mylib.outscalars;
  id date interval=month;
  var air;
  outscalars porders qorders;
  require tsa;
  submit;
  declare object TSA(tsa);
  porders = 0;
  qorders = 0;
  Array P[2]/nosymbols; P[1]=0; P[2]=5;
  Array Q[2]/nosymbols; Q[1]=0; Q[2]=5;
  rc=TSA.ARMAORDERS(air, 0, 'SCAN', P, Q, , porders, qorders);
  rc=TSA.ARMAORDERS(air, 1, 'ESACF', P, Q, , porders, qorders);
  rc=TSA.ARMAORDERS(air, 1, 'MINIC', P, Q, , porders, qorders);
  endsubmit;
run;
```

CCF Method

$rc = \text{TSA.CCF}(y, x, nlag, \langle lags \rangle, \langle df \rangle, \langle ymu \rangle, \langle xmu \rangle, \langle ccov \rangle, \langle ccf \rangle, \langle ccfstd \rangle, \langle ccf2std \rangle, \langle ccfnorm \rangle, \langle ccfprob \rangle, \langle ccflprob \rangle, \langle adjscale \rangle);$

The CCF function computes the cross-correlation and cross-covariance for two time series arrays.

Required Arguments

You must specify the following arguments, separated by commas:

- y* specifies one times series array.
- x* specifies the other time series array.
- nlag* specifies the number of the lag to compute.

Optional Arguments

You can also specify the following arguments, separated by commas. If you want to use a default value for any of these arguments, enter a space for it.

- adjscale* specifies *adjscale*, which controls the normalization of the cross-covariance and cross-correlation. You can specify the following numeric values:
 - 0 specifies the default normalization.
 - 1 specifies the unbiased normalization.
 - 2 specifies the biased normalization.

For more information, see [Table 31.6](#).

Returned Values

The CCF function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Success
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

<i>lags</i>	returns an array of lags that were computed, with $nlag + 1$ entries.
<i>df</i>	returns an array of number of products for which to compute the cross-correlation, with $nlag + 1$ entries.
<i>ymu</i>	returns the mean estimate of input time series <i>y</i> .
<i>xmu</i>	returns the mean estimate of input time series <i>x</i> .
<i>ccov</i>	returns an array of cross-covariance estimates, with $2 \times nlag + 1$ entries.
<i>ccf</i>	returns an array of cross-correlation estimates, with $2 \times nlag + 1$ entries.
<i>ccfstd</i>	returns an array of standard errors, with $2 \times nlag + 1$ entries.
<i>ccf2std</i>	returns an array of double standard errors, with $2 \times nlag + 1$ entries.
<i>ccfnorm</i>	returns an array of normalized cross-correlation, with $2 \times nlag + 1$ entries.
<i>ccfprob</i>	returns an array of probabilities, with $2 \times nlag + 1$ entries.
<i>ccflprob</i>	returns an array of log probabilities, with $2 \times nlag + 1$ entries.

Example

This example uses the TSMODEL procedure to compute the cross-correlation and cross-covariance of two time series arrays (Price and Sale) with lag 20:

```
data mylib.pricedata (replace=yes);
  set Sashelp.pricedata;
run;

proc tsmodel data=mylib.pricedata outarray=mylib.ccf_array
  outscalar=mylib.ccf_scalar;
  id date interval=month;
  var price sale;
  by region line product;
  outscalars ymu xmu;
  outarrays lags df ccov ccf ccfstd ccf2std ccfnorm ccfprob ccflprob;
  require tsa;
```

```

submit;
declare object TSA(tsa);
rc=TSA.CCF(price, sale, 20, lags, df, ymu, xmu, ccov, ccf,
           ccfst, ccf2std, ccfnorm, ccflprob, ccflprob);
endsubmit;
run;

```

IACF Method

`rc = TSA.IACF (y, nlag, <lags>, <df>, <mu>, <iacf>, <iacfstd>, <iacf2std>, <iacfnorm>, <iacfprob>, <iacflprob>);`

The IACF function computes the inverse autocorrelation for a time series array.

Required Arguments

You must specify the following arguments, separated by a comma:

y specifies the times series array.
nlag specifies the number of the lag to use in the calculation.

Returned Values

The IACF function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Success
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

lags returns the number of the lag that was used in the calculation.
df returns the number of observations used to compute *iacf*.
mu returns the mean estimate.
iacf returns an array of inverse autocorrelation estimates, with *nlag* + 1 entries.
iacfstd returns an array of inverse autocorrelation standard errors, with *nlag* + 1 entries.
iacf2std returns an array of twice standard errors, with *nlag* + 1 entries.
iacfnorm returns an array of normalized inverse autocorrelation, with *nlag* + 1 entries.
iacfprob returns an array of inverse autocorrelation probabilities, with *nlag* + 1 entries.
iacflprob returns an array of inverse autocorrelation log probabilities, with *nlag* + 1 entries.

Example

This example uses the TSMODEL procedure to compute the inverse autocorrelation of lag 3 of the time series Air:

```
proc tsmodel data=mylib.air outscalar=mylib.outscalars
      outarray=mylib.outarray;
  id date interval=month;
  var air;
  outscalars mu;
  outarrays iacf lags df iacfstd;
  require tsa;
  submit;
  declare object TSA(tsa);
  rc=TSA.IACF(air, 3, lags, df, mu, iacf, iacfstd, , , , );
  endsubmit;
run;
```

INTERMITTENCYTEST Method

rc = TSA.INTERMITTENCYTEST (*y*, <base>, <threshold>, <med>);

The INTERMITTENCYTEST function tests for intermittency of a univariate time series by computing the median of the length of contiguous constant periods (demand intervals).

Required Arguments

You must specify the following arguments, separated by commas:

y specifies the times series array to test. The test is applied to the last 100 values.

Optional Arguments

You can also specify the following arguments, separated by commas. If you want to use a default value for any of these arguments, enter a space for it.

base takes a numeric *Value* that specifies the base demand level. If you specify a missing value, the dependent series is analyzed to determine whether the base demand level can be set to one of the following values:

- 0
- the minimum value of the dependent series
- the maximum value of the dependent series
- the median value of the dependent series

First, the analysis determines whether the series is nearly constant by applying a threshold to the maximum (L_∞) norm of the nonmissing observations of the series. For nearly constant series, the base demand level is set to 0. Otherwise, analysis proceeds to compute the minimum, maximum, and median values of the series and assigns a score to each of those values. The

score of a value in this context is the number of observations that are sufficiently close to that value. If the number of missing values in the dependent series is higher than the scores for the minimum, maximum, and median, then the base demand level is set to 0. If scores for the minimum, maximum, and median are identical, then the base demand level is set to 0. Otherwise, the base demand level is set to the value that has the highest score among the minimum, maximum, and median.

threshold specifies the threshold value for intermittency. A value of 1 forces all series to be identified as intermittent, whereas a value of `.inf` (positive infinity) forces all series to be identified as nonintermittent. The default value is 2.

Returned Values

The INTERMITTENCYTEST function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Time series is not intermittent
1	Time series is intermittent
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

med returns the median length of the contiguous constant periods.

Example

This example uses the TSMODEL procedure to test the intermittency on the time series array *Air*:

```
proc tsmodel data=mylib.air outscalar=mylib.outscalars;
  id date interval=month;
  var air;
  outscalars intermittent;
  require tsa;
  submit;
  declare object TSA(tsa);
  intermittent=0;
  rc=TSA.INTERMITTENCYTEST(air, 0, 2, med);
  if rc>0 then intermittent= 1;
  endsubmit;
run;
```

MKTEST Method

```
rc = TSA.MKTEST (y, < seasonality > ,< alpha > , < sum > , < sigma > , < z > , < crit > , < pval > ) ;
```

The MKTEST function runs a Mann-Kendall test or a seasonal Mann-Kendall test.

Required Arguments

You must specify the following arguments, separated by commas:

y specifies the input time series array.

Optional Arguments

You can also specify the following arguments, separated by commas. If you want to use a default value for any of these arguments, enter a space for it.

seasonality specifies the seasonality of the series. You can specify an integer, or you can specify `_SEASONALITY_`. The predefined symbol `_SEASONALITY_` is the length of the seasonal cycle that is computed by using the seasonality or the time ID interval that you specify in a PROC TSMODEL step or a `runTimeCode` action call. For more information about predefined symbols, see the section “Predefined Symbols” in Chapter 16, “TSMODEL Procedure” (*SAS Visual Forecasting: Forecasting Procedures*). For more information about seasonality, see the section “Seasonality in Models” in Chapter 17, “Forecasting Details” (*SAS Visual Forecasting: Time Series Packages*). The default value is 1.

alpha specifies the significance level of the test. The default value is 0.05.

Returned Values

The MKTEST function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Test Result
1	Series has a monotonic trend
0	Series has no trend
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

sum returns the sum of the signs.

sigma returns the standard deviation of the sum of the signs.

z returns the Z-transformation of the sum of the signs.

crit returns the test critical value of the Z-transformation.
pval returns the p -value.

Details

When the specified seasonality is 1, the MKTEST function runs the Mann-Kendall test on a univariate time series and outputs the corresponding statistics. The Mann-Kendall test is a nonparametric test that is commonly used to detect monotonic trends in series. The null hypothesis, H_0 , is that the data come from a population that has independent realizations and the data are identically distributed. The alternative hypothesis, H_A , is that the data follow a monotonic trend. Given the series y_t , $t = 1, \dots, n$, the Mann-Kendall test statistic S is calculated as

$$S = \sum_{i=1}^{n-1} \sum_{j=i+1}^n \text{sgn}(y_j - y_i)$$

where

$$\text{sgn}(x) = \begin{cases} 1 & \text{if } x > 0 \\ 0 & \text{if } x = 0 \\ -1 & \text{if } x < 0 \end{cases}$$

Under the null hypothesis, the mean of S is $E(S) = 0$, and the variance σ^2 is

$$\sigma^2 = (n(n-1)(2n+5) - \sum_{k=1}^p n_k(n_k-1)(2n_k+5))/18$$

where p is the number of tied groups in the data set and n_k is the number of data points in the k th tied group.

When the specified seasonality is greater than 1, the MKTEST function runs a seasonal Mann-Kendall test on a univariate time series. The null hypothesis, H_0 , is that, for each season, the data come from a population that has independent realizations and the data are identically distributed. The alternative hypothesis, H_A , is that the data follow a monotonic trend in one or more seasons. For the g th season,

$$S_g = \sum_{i=1}^{n_g-1} \sum_{j=i+1}^{n_g} \text{sgn}(y_{jg} - y_{ig})$$

and the corresponding variance is

$$\sigma_g^2 = (n_g(n_g-1)(2n_g+5) - \sum_{k=1}^{p_g} n_{kg}(n_{kg}-1)(2n_{kg}+5))/18$$

where p_g is the number of tied groups in the data set and n_{kg} is the number of data points in the k th tied group. The seasonal Mann-Kendall statistic, S , for the entire series of m seasons is calculated according to

$$S = \sum_{g=1}^m S_g$$

The corresponding seasonal variance σ^2 is

$$\sigma^2 = \sum_{g=1}^m \sigma_g^2$$

The following Z-transformation of the statistic S approximately follows a standard normal distribution:

$$Z = \begin{cases} \frac{S-1}{\sigma} & \text{if } S > 0 \\ 0 & \text{if } S = 0 \\ \frac{S+1}{\sigma} & \text{if } S < 0 \end{cases}$$

The test result is obtained by comparing the Z-transformation to the critical value.

The Mann-Kendall test requires at least three nonmissing observations. The constant series is regarded as no trend by the Mann-Kendall test. If any season has fewer than three nonmissing observations, the seasonal Mann-Kendall test ignores it. If no season has enough nonmissing observations, the seasonal Mann-Kendall test cannot be performed. If any season has a constant series, this season is also ignored. If all seasons have constant series, the whole series is regarded as having no trend by the seasonal Mann-Kendall test.

Examples

This example uses the TSMODEL procedure to run the Mann-Kendall test on the time series array Air:

```
proc tsmodel data=mylib.air outscalar = mylib.scalars;
  id date interval=month;
  var air;
  outscalar rc sum sig z crit pval;
  require tsa;
  submit;
  declare object tsa(tsa);
  rc = tsa.mktest(air,1,0.05,sum,sig,z,crit,pval);
  endsubmit;
run;
```

MOVINGSUMMARY Method

```
rc = TSA.MOVINGSUMMARY (y, 'method', k, <lead>, <w>, <'setmiss'>, <'abs'>, x, <p>, <nmiss>)
                        ;
```

The MOVINGSUMMARY function computes statistics for a set of values within a moving time window.

Required Arguments

You must specify the following arguments, separated by commas:

- y specifies the input time series array.
- 'method' specifies the statistic to calculate for each output array, x_t , based on the elements of the y input array in the t window.
You can specify the following methods within single quotation marks:

EWMA	calculates the exponentially weighted moving average.
GMEAN	calculates the moving geometric mean.
MAX	calculates the maximum value.
MEAN	calculates the moving average.
MED	calculates the median value.
MIN	calculates the minimum value.
PROD	calculates the moving product.
RANGE	calculates the maximum value minus the minimum value.
SUM	calculates the moving sum.
TVALUE	calculates the standard deviation divided by the mean.
VAR	calculates the variance of the sample defined by the window around t .

k specifies the window size, where k is a positive integer. When the *method* is EWMA, k is always set to 1, and any other value that you specify is ignored. Defaults are used for all other arguments except w . For any other *method*, k is a required argument, and its value should not be less than 1.

Optional Arguments

You can also specify the following arguments, separated by commas. If you want to use a default value for any of these arguments, enter a space for it.

lead specifies the number of leading terms, where *lead* is a nonnegative integer less than k . You can specify the following values:

0	specifies the backward moving summary.
$k/2$	specifies the centered moving summary.
$k-1$	specifies the forward moving summary.

The default value is 0. When the *method* is EWMA, *lead* is set to 0.

w specifies an array of weights that has k elements when $k > 1$, or specifies a scalar value when $k = 1$. When the *method* is EWMA, this argument must be a scalar between 0 and 1, inclusive. If you omit this value, then by default, EWMA sets w to 1, and the MEAN, PROD, TVALUE, and VAR *methods* do not use any weight. This argument is ignored for the GMEAN, MED, MIN, RANGE, and SUM *methods*.

'*setmiss*' specifies how missing values are interpreted.

You can specify the following values within single quotation marks:

IGNORE	specifies that missing values have no effect on the summary.
MEAN	specifies that missing values are replaced with the mean of the remaining nonmissing values in the window. This value is supported only for the SUM <i>method</i> .

MISSING specifies that if the input window contains a missing value, the output value is also missing.

The default value is IGNORE. When the *method* is EWMA, 'setmiss' is always set to IGNORE, and any other value that you specify is ignored.

'abs' specifies how the series is transformed into nonnegative values prior to performing the moving summary.

You can specify the following values within single quotation marks:

OFF specifies no modification. This value is not supported for the GMEAN *method*, because the geometric mean is undefined for negative values in the series.

ON transforms each member of the series into its absolute value.

SQUARE transforms each member of the series into its square.

The default value is ON when the *method* is GMEAN and is OFF for any other *method*. When the *method* is EWMA, 'abs' is always set to OFF, and any other value that you specify is ignored.

Returned Values

The MOVINGSUMMARY function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
4	Warping limits relaxed
3	Expansion limits relaxed
2	Compression limits relaxed
1	Warping limits imposed
0	Success
< 0	Computational failure

x returns the transformed series.

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

p returns an array in which element *t* is the number of products that contributed to element *t* of *x*. The *p* argument is supported only when *method* is PROD or GMEAN.

nmiss returns the number of missing values that are generated.

Examples

This example uses the TSMODEL procedure to compute the five-period moving average of the time series array Air:

```
proc tsmodel data=mylib.air outscalar=mylib.scalars outarray=mylib.arrays;
  id date interval=month;
  var air;
  outarrays x p;
  outscalars rc nmiss;
  require tsa;
  submit;
  declare object TSA(tsa);
  rc=TSA.MOVINGSUMMARY(air, 'MEAN' , 5, 0 , , , , x, p, nmiss);
  endsubmit;
run;
```

This example uses the TSMODEL procedure to compute the five-period centered weighted moving product of the time series array Air:

```
proc tsmodel data=mylib.air outscalar=mylib.scalars outarray=mylib.arrays;
  id date interval=month;
  var air;
  outarrays x;
  outscalars rc;
  require tsa;
  submit;
  declare object TSA(tsa);
  Array w[5]/nosymbols; w[1]=0.3; w[2]=0.2; w[3]=0.25; w[4]=0.1; w[5]=0.15;
  rc=TSA.MOVINGSUMMARY(air, 'PROD' , 5, 2.5 , w, , , x, , );
  endsubmit;
run;
```

PACF Method

```
rc = TSA.PACF (y, nlag, <lags>, <df>, <mu>, <pacf>, <pacfstd>, <pacf2std>, <pacfnorm>,
               <pacfprob>, <pacflprob>);
```

The PACF function computes the partial autocorrelation for a time series array.

Required Arguments

You must specify the following arguments, separated by a comma:

- y* specifies the times series array.
- nlag* specifies the number of the lag to use in the calculation.

Returned Values

The PACF function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Success
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

lags returns the number of the lag that was used in the calculation.

df returns the number of observations used to compute *pacf*.

mu returns the mean estimate.

pacf returns an array of partial autocorrelation estimates, with $nlag + 1$ entries.

pacfst returns an array of partial autocorrelation standard errors, with $nlag + 1$ entries.

pacf2std returns an array of twice standard errors, with $nlag + 1$ entries.

pacfnorm returns an array of normalized partial autocorrelation, with $nlag + 1$ entries.

pacfprob returns an array of partial autocorrelation probabilities, with $nlag + 1$ entries.

pacflprob returns an array of partial autocorrelation log probabilities, with $nlag + 1$ entries.

Example

This example uses the TSMODEL procedure to compute the autocorrelation of lag 3 of the time series Air:

```
proc tsmodel data=mylib.air outscalar=mylib.outscalars
              outarray=mylib.outarray;
  id date interval=month;
  var air;
  outscalars mu;
  outarrays pacf lags df pacfst;
  require tsa;
  submit;
  declare object TSA(tsa);
  rc=TSA.PACF(air, 3, lags, df, mu, pacf, pacfst, , , , );
  endsubmit;
run;
```

SCALE Method

$rc = \text{TSA.SCALE}(y, min, max, nomiss, x, < nmiss >);$

The SCALE function scales a time series between a specified minimum value and a specified maximum value.

Required Arguments

You must specify the following arguments, separated by commas:

- y* specifies the input time series array.
- min* specifies the minimum value in the output array.
- max* specifies the maximum value in the output array.
- nomiss* specifies how missing values are treated. You can specify the following values:
 - 0** allows missing values in the input array.
 - 1** does not allow missing values in the input array. If missing values exist, the output array x_t becomes missing for all values of t .

The default is 0.

Returned Values

The SCALE function returns the following values:

- rc* returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
5	The input series is nearly constant
4	Missing values were found when the value 1 was specified for <i>nomiss</i>
3	One or more arguments are ignored
2	One or more arguments are set to the default value
1	The input series is all missing
-1	One or more arguments are not supported
-2	The minimum value of the transformed series is greater than its maximum value
-4	Extreme slope
-99	Bad arguments

- x* returns the transformed series.

Optional Returned Values

You can also specify the following argument to request an additional returned value:

nmiss returns the number of missing values that are generated.

Example

This example uses the TSMODEL procedure to scale the time series array *Air* between a minimum value of 0 and a maximum value of 100:

```
proc tsmodel data=mylib.air outarray=mylib.scale_array;
  id date interval=month;
  var air;
  outarrays t1;
  require tsa;
  submit;
  declare object TSA(tsa);
  rc=TSA.SCALE(air, 0, 100, , t1, );
  endsubmit;
run;
```

SEASONALDECOMP Method

```
rc = TSA.SEASONALDECOMP (y, s, 'mode', <lambda>, <tcc>, <sic>, <sc>, <scstd>, <tcs>,
                        <ic>, <sa>, <pcsa>, <tc>, <cc>);
```

The SEASONALDECOMP function performs the seasonal decomposition or analysis of the time series arrays, and it outputs the values and results.

Required Arguments

You must specify the following arguments, separated by commas:

y specifies the times series array to decompose.

s specifies the length of the seasonal cycle, where *s* must be either an integer greater than 1 or `_SEASONALITY_`. The predefined symbol `_SEASONALITY_` is the length of the seasonal cycle that is computed by using the seasonality or the time ID interval that you specify in a PROC TSMODEL step or a `runTimeCode` action call. For more information about predefined symbols, see the section “Predefined Symbols” in Chapter 16, “TSMODEL Procedure” (*SAS Visual Forecasting: Forecasting Procedures*). For more information about seasonality, see the section “Seasonality in Models” in Chapter 17, “Forecasting Details” (*SAS Visual Forecasting: Time Series Packages*).

'mode' specifies the type of decomposition to be used to decompose the time series.

You can specify the following values within single quotation marks:

ADD | ADDITIVE specifies additive decomposition.

LOGADD | LOGADDITIVE specifies log-additive decomposition.

- MULT | MULTIPLICATIVE** specifies multiplicative decomposition.
- MULTORADD** specifies multiplicative or additive decomposition, depending on data.
- PSEUDOADD | PSEUDOADDITIVE** specifies pseudo-additive decomposition.

Optional Arguments

You can also specify the following argument, separated by a comma from arguments that precede it. If you want to use a default value for this argument, enter a space for it.

lambda specifies the Hodrick-Prescott filter parameter for trend-cycle decomposition. The default value is 1,600. Filtering applies when the trend component or the cycle component is requested. If filtering is not specified, this option is ignored.

Returned Values

The SEASONALDECOMP function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Success
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

- tcc* specifies the trend-cycle component.
- sic* specifies the seasonal-irregular component.
- sc* specifies the seasonal component.
- scstd* specifies the seasonal component standard errors.
- tcs* specifies the trend-cycle-seasonal component.
- ic* specifies the irregular component.
- sa* specifies the seasonally adjusted series.
- pcsa* specifies the percentage of change in seasonally adjusted series.
- tc* specifies the trend component.
- cc* specifies the cycle component.

Example

This example uses the TSMODEL procedure to compute the seasonal indices on the time series array Air:

```
proc tsmode1 data=mylib.air outarray=mylib.outarray;
  id date interval=month;
  var air;
  outarrays ADJUSTED;
  require tsa;
  submit;
  declare object TSA(tsa);
  rc=TSA.SEASONALDECOMP(air, _SEASONALITY_, 'ADD', , , , , , , ADJUSTED, , , );
  endsubmit;
run;
```

SEASONALINDICES Method

```
rc = TSA.SEASONALINDICES (y, s, <'mode'>, <'term'>, <indices>);
```

The SEASONALINDICES function computes the seasonal indices of a univariate time series by using regression seasonal dummies.

Required Arguments

You must specify the following arguments, separated by a comma:

- y* specifies the times series array.
- s* specifies the seasonality to test, where *s* must be either a positive integer or `_SEASONALITY_`. The predefined symbol `_SEASONALITY_` is the length of the seasonal cycle that is computed by using the seasonality or the time ID interval that you specify in a PROC TSMODEL step or a `runTimeCode` action call. For more information about predefined symbols, see the section “Predefined Symbols” in Chapter 16, “TSMODEL Procedure” (*SAS Visual Forecasting: Forecasting Procedures*). For more information about seasonality, see the section “Seasonality in Models” in Chapter 17, “Forecasting Details” (*SAS Visual Forecasting: Time Series Packages*).

Optional Arguments

You can also specify the following arguments, separated by commas. If you want to use a default value for any of these arguments, enter a space for it.

- `'mode'` specifies the type of model to be used in the regression.
You can specify the following values within single quotation marks:

ADD ADDITIVE	uses an additive model.
MULT MULTIPLICATIVE	uses a multiplicative model.

The default method is ADD.

'term' specifies the type of terms to be used in the regression.

You can specify the following values within single quotation marks:

- S** uses only seasonal dummies terms.
- SC** uses only seasonal dummies and constant terms.
- ST** uses only seasonal dummies and trend terms.
- STC** uses seasonal dummies, trend, and constant terms.
- STQ** uses seasonal dummies, trend, and quadratic terms.
- STQC** uses seasonal dummies, trend, quadratic, and constant terms.

The default value is S. Quadratic values can be used only in the additive model.

Returned Values

The SEASONALINDICES function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Success
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

indices returns an array of seasonal indices.

Example

This example uses the TSMODEL procedure to compute the seasonal indices of the time series Air:

```
proc tsmode1 data=mylib.air outarray=mylib.outarray;
  id date interval=month;
  var air;
  outarrays sindices;
  require tsa;
  submit;
  declare object TSA(tsa);
  rc=TSA.SEASONALINDICES(air, _SEASONALITY_, 'ADD', 'STQC', sindices);
  endsubmit;
run;
```

SEASONTTEST Method

`rc = TSA.SEASONTTEST (y, s, < dif>, < p>, < alpha>, < aic>) ;`

The SEASONTTEST function tests whether a univariate time series is seasonal by comparing two time series models: one seasonal and one nonseasonal.

Required Arguments

You must specify the following arguments, separated by a comma:

- y* specifies the times series array to test.
- s* specifies the seasonality to test, where *s* must be either a positive integer or `_SEASONALITY_`. The predefined symbol `_SEASONALITY_` is the length of the seasonal cycle that is computed by using the seasonality or the time ID interval that you specify in a PROC TSMODEL step or a `runTimeCode` action call. For more information about predefined symbols, see the section “Predefined Symbols” in Chapter 16, “TSMODEL Procedure” (*SAS Visual Forecasting: Forecasting Procedures*). For more information about seasonality, see the section “Seasonality in Models” in Chapter 17, “Forecasting Details” (*SAS Visual Forecasting: Time Series Packages*).

Optional Arguments

You can also specify the following arguments, separated by commas. If you want to use a default value for any of these arguments, enter a space for it.

- dif* specifies an array of positive integers or a positive integer that is used for differencing. The default value is 0.
- p* specifies the autoregressive order (0 or 1). The default value is 0.
- alpha* specifies the significance level. The default value is 0.01.

Returned Values

The SEASONTTEST function returns the following values:

- rc* returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Time series is not seasonal
1	Time series is seasonal
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

aic returns an array of three values: Akaike's information criterion (AIC) for the nonseasonal model, AIC for seasonal model, and the p -value for the F test.

Details

The time series y is first predifferenced according to the specified *diff*. The predifferenced time series is fit by a nonseasonal autoregressive model of order p and a seasonal autoregressive model of order p . The AICs of both models and the F statistic of the seasonal model are calculated. If the seasonal model has a smaller AIC, and if the p -value of the F statistic is smaller than the significance level *alpha*, then the time series is identified as seasonal. Otherwise, the time series is identified as nonseasonal. The test is conducted only for series of at least two seasonal cycles. In general, seasonality is more difficult to identify in a series when the sample size is small because there are only a few seasonal cycles of data.

Example

The following example uses the TSMODEL procedure to test the seasonality of the time series array Air:

```
proc tsmodel data=mylib.air outscalar=mylib.outscalars
      outarray=mylib.outarray;
  id date interval=month;
  var air;
  outscalars seasonal;
  outarrays aic;
  require tsa;
  submit;
  declare object TSA(tsa);
  seasonal=0;
  rc=TSA.SEASONTTEST(air, _SEASONALITY_, 0, 1, , aic); /*- no detrending -*/
  if rc>0 then seasonal= 1;
  rc=TSA.SEASONTTEST(air, _SEASONALITY_, 1, 1, 0.05, ); /*- detrending -*/
  if rc>0 then seasonal= 1;
  endsubmit;
run;
```

SIMILARITY Method

`rc = TSA.SIMILARITY (x, y, <'type'>, <'scale'>, <expandpct>, <expandabs>, <compresspct>, <compressabs>, <measure>);`

The SIMILARITY function analyzes the similarity between two time series.

Required Arguments

You must specify the following arguments, separated by a comma:

- `x` specifies the input time series array to be compared to the target time series.
- `y` specifies the target time series array to be compared to the input time series.

Optional Arguments

You can also specify the following arguments, separated by commas. If you want to use a default value for any of these arguments, enter a space for it.

`'type'` specifies the similarity measure.

You can specify the following values within single quotation marks:

- ABSDEV** specifies the absolute deviation.
- MABSDEV** specifies the mean absolute deviation.
- MABSDEVINP** specifies the mean absolute deviation relative to the length of the input sequence.
- MABSDEVMAX** specifies the mean absolute deviation relative to the maximum valid path length.
- MABSDEVMIN** specifies the mean absolute deviation relative to the minimum valid path length.
- MABSDEVTAR** specifies the mean absolute deviation relative to the length of the target sequence.
- MSQRDEV** specifies the mean squared deviation.
- MSQRDEVINP** specifies the mean squared deviation relative to the length of the input sequence.
- MSQRDEVMAX** specifies the mean squared deviation relative to the maximum valid path length.
- MSQRDEVMIN** specifies the mean squared deviation relative to the minimum valid path length.
- MSQRDEVTAR** specifies the mean squared deviation relative to the length of the target sequence.
- SQRDEV** specifies the squared deviation.

The default value is `SQRDEV`.

'*scale*' specifies how the working input sequence is scaled with respect to the working target sequence. Scaling is performed after normalization.

You can specify the following values within single quotation marks:

ABS applies absolute scaling.
NONE applies no scaling.
STD applies standard scaling.

The default value is NONE.

expandpct specifies the warping expansion as a percentage of the length of the target sequence, where *expandpct* ranges from 0 to 100, 0 implies no compression, and 100 implies maximum allowable compression. The default value is 100.

expandabs specifies the absolute warping expansion, where *expandabs* is an integer that ranges from 0 to 10,000. The default is the maximum allowable absolute expansion.

compresspct specifies the warping compression as a percentage of the length of the target sequence, where *compresspct* ranges from 0 to 100, 0 implies no compression, and 100 implies maximum allowable compression. The default value is 100.

compressabs specifies the absolute warping compression, where *compressabs* is an integer that ranges from 0 to 10,000. The default is the maximum allowable absolute compression.

Returned Values

The SIMILARITY function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
4	Warping limits relaxed
3	Expansion limits relaxed
2	Compression limits relaxed
1	Warping limits imposed
0	Success
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

measure returns the similarity measure.

Example

This example uses the TSMODEL procedure to compute the similarity of two time series arrays: x and y.

```
data test;
  input i x1 x2 x3 y1 y2 y3 r;
  datalines;
  1 3 2 4 2 3 2 1
  2 5 4 5 4 5 3 1
  3 3 3 4 6 4 5 1
  4 3 6 6 7 6 7 1
  5 3 5 5 3 5 7 1
  6 6 6 6 8 8 8 1
  7 3 8 5 9 9 8 1
  8 8 9 8 3 7 3 1
  9 6 7 6 8 4 9 1
  10 7 9 8 9 6 7 1
;
run;

data mylib.testsim;
  set test;
run;

proc tsmodel data=mylib.testsim
  outscalar=mylib.sim_scalar
  nthreads=1;
  require tsa;
  id i interval=day;
  var x1 y1;
  outscalars measure;
  submit;
  declare object TSA(tsa);
  rc = TSA.SIMILARITY(x1, y1, 'absdev', 'NONE', , , , measure);
  endsubmit;
run;
```

STATIONARITYTEST Method

```
rc = TSA.STATIONARITYTEST (y, <dif>, <d>, <p>, <'type'>, <pvalue>);
```

The STATIONARITYTEST function tests for stationarity of a univariate time series.

Required Arguments

You must specify the following argument:

y specifies the times series array to test.

Optional Arguments

You can also specify the following arguments, separated by commas. If you want to use a default value for any of these arguments, enter a space for it.

- dif* specifies an array of positive integers or a positive integer that is used for differencing. The default value is 0.
- d* specifies the order of unit root ($d = 1, \dots, 12$). If the *type* is SSM, then $d = 1$. The default value is 1.
- p* specifies the autoregressive order, where *p* must be a nonnegative integer. The default value is 5.
- '*type*' specifies the type of test statistic used.

You can specify the following values within single quotation marks:

- SSM** specifies the studentized test statistic for the single mean (intercept) case.
- STR** specifies the studentized test statistic for the deterministic time trend case.
- SZM** specifies the studentized test statistic for the zero mean (no intercept) case. This value is allowed only when *d* has a value of 1.

The default value of *type* is SZM.

Returned Values

The STATIONARITYTEST function returns the following values:

- rc* returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Time series is stationary with the default significance level of 0.05
1	Time series is not stationary with the default significance level of 0.05
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

- pvalue* returns the probability value associated with the test.

Example

This example uses the TSMODEL procedure to test the stationarity on the time series array Air:

```
proc tsmode1 data=mylib.air outscalar=mylib.outscalars;
  id date interval=month;
  var air;
  outscalars stationary1 stationary2;
  require tsa;
  submit;
  declare object TSA(tsa);
  stationary1=1; stationary2=1;
  rc = TSA.STATIONARITYTEST(air,,,,,pvalue);
  *test with the default significant level=0.05;
  if rc =1 then stationary1 = 0;
  *test with significant level = 0.1;
  if pvalue > 0.1 then stationary2 = 0;
  endsubmit;
run;
```

TRANSFORM Method

```
rc = TSA.TRANSFORM (y, <'type'>, <inverse>, <c>, <x>);
```

The TRANSFORM function transforms a time series to another form.

Required Arguments

You must specify the following arguments:

y specifies an input time series array.

Optional Arguments

You can also specify the following arguments, separated by commas. If you want to use a default value for any of these arguments, enter a space for it.

type specifies the type of transformation. You can specify the following values within single quotation marks:

LOG	specifies logarithmic transformation.
SQRT	specifies square root transformation.
LOGIT	specifies logit transformation.
BOXCOX	specifies Box-Cox transformation.
NONE	requests that no transformation be performed.

The default value is NONE.

inverse specifies whether to perform an inverse transformation. You can specify the following values:

- 0** does not perform an inverse transformation.
- 1** returns the inverse of the specified transformation method.

The default value is 0.

- c*** specifies a parameter to be used in the transformation. Its use depends on the transformation method as follows:
- For log transformation, ***c*** is bias: $x = \log(y + c)$. The default value is 0.
 - For square root transformation, ***c*** is bias: $x = \sqrt{y + c}$. The default value is 0.
 - For logit transformation, ***c*** is scaling: $x = \log(c \times y / (1 - (c \times y)))$. The default value is 1.
 - For the Box-Cox transformation, ***c*** is λ : $x = c^2 + (y^c - 1)/c$. If ***c*** is not specified, $x=y$.

Returned Values

The TRANSFORM function returns the following values:

- rc*** returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Success
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

- x*** returns the transformed series.

Example

This example uses the TSMODEL procedure to take the log transform of the time series array **Air**:

```
proc tsmode1 data=mylib.air outarray=mylib.trans_array;
  id date interval=month;
  var air;
  outarrays t1;
  require tsa;
  submit;
  declare object TSA(tsa);
  rc=TSA.TRANSFORM(air, 'LOG', 0, 0, t1);
  endsubmit;
run;
```

UNBIASEDNESS Method

***rc* = TSA.UNBIASEDNESS (*y*, *predict*, < *siglevel*>, *intercept*, *scale*, *fvalue*, *pvalue*) ;**

The UNBIASEDNESS function tests whether a univariate time series is unbiased.

Required Arguments

You must specify the following arguments, separated by a comma:

y specifies the input time series array.
predict specifies an input array of predicted time series.

Optional Arguments

You can also specify the following argument. If you want to use a default value for this argument, enter a space for it.

siglevel specifies the significance level.

Returned Values

The UNBIASEDNESS function returns the following values:

rc returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
1	Biased predictions
0	Unbiased predictions
-1	Degree of freedom error
-2	Singular system
-3	Extreme value

intercept returns the constant parameter.

scale returns the scale parameter.

fvalue returns the test statistic for the *F* test.

pvalue returns the *p*-value for the *F* test.

Example

This example uses the TSMODEL procedure to test whether the series Actual is unbiased:

```
proc hpf data=sashelp.air out=_null_ outfor=outfor;
  id date interval=month;
  forecast air;
run;

proc reg data=outfor;
  model actual=predict;
  test intercept=0, predict=1;
run;
quit;
data mylib.outfor;
  set outfor;
run;

proc tsmodel data=mylib.outfor outscalar=mylib.bias_scalar outarray=mylib.bias_array;
  id date interval=month;
  var ACTUAL PREDICT;
  outscalars intercept scale fvalue pvalue;
  require tsa;
  submit;
  declare object TSA(tsa);
  rc=TSA.UNBIASEDNESS(ACTUAL, PREDICT, 0.05, intercept, scale, fvalue, pvalue);
  endsubmit;
run;
```

WHITENOISE Method

`rc = TSA.WHITENOISE (y, nlag, <lags>, <df>, <wn>, <wnprob>, <wnlprob>);`

The WHITENOISE function tests for white noise in a time series array.

Required Arguments

You must specify the following arguments, separated by a comma:

- y* specifies the times series array to compute.
- nlag* specifies the number of the lag to use in the calculation.

Returned Values

The WHITENOISE function returns the following values:

- rc* returns one of the following scalar return codes:

<i>rc</i>	Termination Reason
0	Success
< 0	Computational failure

Optional Returned Values

You can also specify the following arguments, separated by commas, to request additional returned values. If you do not want the value to be returned, enter a space for it.

<i>lags</i>	returns the number of the lag that was used in the calculation.
<i>df</i>	returns the number of observations that were used to test white noise.
<i>wn</i>	returns an array of Ljung-Box white noise tests, with <i>nlag</i> + 1 entries.
<i>wnprob</i>	returns white noise probabilities.
<i>wnlprob</i>	returns white noise log probabilities.

Example

This example uses the TSMODEL procedure to perform the white noise test of lag 3 of the time series Air:

```
proc tsmodel data=mylib.air outarray=mylib.outarray;
  id date interval=month;
  var air;
  outarrays lags df wn wnprob wnlprob;
  require tsa;
  submit;
  declare object TSA(tsa);
  rc=TSA.WHITENOISE(air, 3, lags, df, wn, wnprob, wnlprob);
  endsubmit;
run;
```

Overview: TSM Package

The time series model (TSM) package contains a set of time series modeling objects that provide a flexible way to model and forecast time series. For more information about the statistical methodology that underlies this package, see relevant chapters in *SAS/ETS User's Guide* and *SAS Forecast Server Procedures: User's Guide*.

TSM Package Summary

Table 32.1 lists the objects that are contained in the TSM package. These objects are designed to provide access to various univariate time series model families.

Table 32.1 Objects in the Time Series Model Package

Object	Description
Central Objects	
TSM	Time series model object (Note 1)
CFC	Combine Forecasts object (Note 2)
Time Series Model Specification Objects (Note 3)	
ARIMASPEC	Autoregressive integrated moving average model specification object
ESMSPEC	Exponential smoothing model specification object
EXMSPEC	External model specification object
IDMSPEC	Intermittent demand model specification object
RNNSPEC	Recurrent neural network (RNN) specification object
UCMSPEC	Unobserved component model (UCM) specification object
Time Series Model Collector Objects (Note 4)	
TSMFOR	Time series model forecast collector object
TSMOUTOPT	Time series RNN model optimization history collector object
TSMPEST	Time series model parameter estimates collector object
TSMRNNSTAT	Time series RNN model fit statistics collector object
TSMSPEC	Time series model specification collector object
TSMSTAT	Time series model fit statistics collector object
Time Series Model Repeater Objects (Note 5)	
TSMINEST	Time series model input parameter estimates repeater object
TSMINSPEC	Time series model input specification repeater object

NOTE:

1. The TSM object is the central hub that interacts with all other objects. It executes and encapsulates the computational services for all univariate time series models.
2. The Combine Forecasts (CFC) object allows you to perform forecast combinations.
3. The time series model specification objects enable you to specify the characteristics of a time series model to be executed by a TSM object.

4. The time series model collector objects operate on TSM objects to collect and save various results from the time series model execution (fit statistics, forecasts, parameter estimates, model specifications, and so on).
5. The time series model repeater objects act as conduits to replay collected model specifications and model parameter estimates as input to other TSM objects.

Figure 32.1 diagrams the relationships among the objects in the TSM package.

Figure 32.1 TSM Object Data Flow

Using the TSM Package

The following steps provide a general outline of how to use each type of object in the TSM package. Subsequent sections describe each step in greater detail.

- 1 Configure a model specification object.
- 2 Use the TSM object with the model specification object to generate a forecast.
- 3 Use TSM collector objects to extract results and parameter estimates from the TSM object.
- 4 Use TSM repeater objects to replay collected parameters and specifications to another TSM object.

Step 1: Configure a Model Specification Object

Model specification objects define the time series model characteristics that you want to be applied to the TSM object, which then performs the model execution. Model specification objects use **Open** and **Close** methods to initialize and finalize model specifications. The basic execution pattern follows this sequence of operations:

- 1 **Declare:** Create the model specification object by using the object declaration statement. The object declaration assigns a default model specification to the specification objects.
- 2 **Open:** Initialize the specification object to a default state that is ready to accept configuration methods that shape the model and define its characteristics.
- 3 **Configure:** Use object-specific model specification methods to configure the model. For example, in an ESMSPEC, you might specify the smoothing method or model to be used, specify a functional transformation for the dependent variable to force the use of specific smoothing parameters, or specify bounds on the estimated parameters. For an ARIMASPEC, you might specify a set of autoregressive or moving average backshift operator polynomial factors, specify differencing operators, add simple and complex transfer functions, or specify a functional transformation for the dependent variable.
- 4 **Close:** Declare the model specification object to be complete and ready for use.
- 5 **Use:** Use the completed model specification object with a TSM object to directly perform the specified time series model fit and forecast computations. You can also use model specification objects with the automatic time series modeling (ATSM) package to include custom models into its automatic time series forecasting process. For more information about this use, see Chapter 2, “Automatic Time Series Modeling Package” (*SAS Visual Forecasting: Time Series Packages*).

Step 2: Use a TSM Object with a Model Specification Object

The TSM object executes the time series model. The TSM object is configured with a time series model from one of the model specification objects. Then the TSM object applies that configuration to the time series data to produce a forecast. The basic execution pattern follows this sequence of operations:

- 1 Declare:** Create the TSM object by using the object declaration statement.
- 2 Initialize:** Add a model specification object to the TSM object.
- 3 Specify variables:** Specify the dependent series (Y) and any independent series (X) variables.
- 4 Specify options:** Specify other options and properties as appropriate.
- 5 Run:** Execute the model in the TSM object to produce its forecast.
- 6 Extract:** Extract the results by using collector objects.

Various properties (attributes) of the executed TSM object can be queried directly and saved into declared variables, or the results can be collected by the TSM collector objects for presentation and storage.

Step 3: Use the TSM Collector Objects

Collector objects enable you to create a snapshot of results from TSM objects and store those results in tables. Each collector object defines a table schema that is determined by the collector object's design. The TSM collector objects follow a common pattern. The basic execution follows this sequence of operations:

- 1 Declare:** Create the collector object using the object declaration statement.
- 2 Collect:** Use the Collect method with a TSM object passed in as an argument to collect results from the TSM object. For example, the TSMPEST object collects parameter estimates from a TSM object, and the TSMSPEC object collects from a model specification's XML. Rows that are collected are automatically appended to the collector's associated table at the end of each BY group, and the collector object's saved row set is automatically reset. Rows that are added to the table are qualified by the values of the corresponding values of the BY variable. This enables repeater objects to locate the rows that are relevant to each BY group and correctly replay that information into a TSM object. The **nrows** attribute returns the current row count in the collector. A missing value is returned if nothing has been collected. The data can now be used for reports or used by a repeater object on another model.

Step 4: Use the TSM Repeater Objects

Repeater objects read rows from a table and convert their contents back into useful information that can be used by other TSM objects. This is the inverse function of the collector objects. Each repeater object defines a table schema that is determined by its counterpart collector object's design. Repeater objects must be associated with an existing table that has the table schema that is required by the repeater object. The basic execution follows this sequence of events:

- 1 Declare:** Create the repeater object by using the object declaration statement.

- 2 Replay:** Use the `TSM.Replay` method on a TSM object with the repeater object passed in as an argument to execute a new time series model. The replayed TSM object generates the forecast data that was produced by the new time series model. Then the data can be collected by using a collector object as described in Step 3.

Return Codes

Table 32.2 shows the return code (designated by *rc* in method statements) status values that are used in this package. These status code values are returned after a method that is associated with an object is called; they can help determine whether the method executed successfully.

Table 32.2 Return Codes

Status	Meaning
< 0	An unrecoverable error occurred. No result was produced.
= 0	Unconditional success. The requested action was completed, and a normal result was produced.
> 0	Conditional success or warning. A result was produced subject to conditions.

TSM Object

The TSM object generates forecasts of univariate time series.

Table 32.3 lists the time series model families that are supported.

Table 32.3 Model Families for the TSM Object

Family	Object	Description
ARIMA	ARIMASPEC	ARIMAX models
ESM	ESMSPEC	Exponential smoothing models
EXM	EXMSPEC	External model (external forecast)
IDM	IDMSPEC	Intermittent demand models (Croston's/average demand (ADEM))
RNN	RNNSPEC	Recurrent neural network models
UCM	UCMSPEC	Unobserved component models

Table 32.4 summarizes the methods that are associated with the TSM object.

Table 32.4 Methods of the TSM Object

Method	Description
AddX	Add an independent time series array (<i>XSeries</i>) for the TSM object
AddExternal	Add external forecast component series for the TSM object
criterion	Return the final fit statistic over a specified forecast region
GetForecast	Get the forecast series
Initialize	Initialize the TSM object
nfor	Return the forecast series length
Replay	Replay the restored model and parameter estimates
Run	Run the TSM object
SetOption	Specify the named option for the TSM object
SetY	Specify the dependent time series array (<i>YSeries</i>) for the TSM object

The basic execution pattern for using a TSM object follows this sequence of operations:

- 1 Declare:** The object declaration statement creates a new TSM object.
- 2 Initialize:** The TSM.Initialize method takes a model specification object as its argument and initializes the TSM object for that specified time series model. If no model specification object is provided, the TSM object is initialized as an exponential smoothing method (ESM) that uses the best suited exponential smoothing model. This is equivalent to initializing the TSM object with an ESMSPEC object that has default option values.
- 3 SetY:** The TSM.SetY method defines the dependent time series for the TSM object.
- 4 AddX:** The TSM.AddX method defines any independent time series for the TSM object. Each call defines one predictor series. Repeat as needed for each predictor series.
- 5 SetOption:** The TSM.SetOption method specifies any options that affect the running of the model. Each call defines an option. Repeat as needed to specify all options that are required.
- 6 Run:** The TSM.Run method uses its currently configured X and Y time series data to execute the time series model that is defined by the TSM object's model specification. At completion, the model has estimated the parameters and produced a final forecast based on these parameters.

TSM Synopsis

DECLARE OBJECT *obj* (TSM) ;

Method syntax, in order of typical usage:

```
rc=obj.Initialize (< ModelSpec >) ;
rc=obj.SetY (YSeries) ;
rc=obj.AddX (XSeries < ,Required,NoDiff,ModelSymbol >) ;
rc=obj.AddExternal (Series < ,Role >) ;
rc=obj.SetOption ('Name', Value < , 'Name', Value, ... >) ;

nfor=obj.nfor () ;
criterion=obj.criterion (Region) ;
```

TSM Methods

TSM.AddExternal Method

```
rc=obj.AddExternal (Series < ,Role >) ;
```

Adds a time series array, *Series*, for use in external model computations when the TSM object is initialized from an external model specification (EXMSPEC) object. Calling this method when the TSM object is not configured with an EXMSPEC results in a nonzero return code and no further action. However, the specified parameters are saved so that you can configure the TSM object with an EXMSPEC by using the TSM.Replay method. In that case, the parameters that you specify in this TSM.AddExternal call are processed when you call the Run method. For more information about external model support, see the section “EXMSPEC Object” on page 2380.

No default role mapping is implied by the name of the *Series* variable that you specify in the method. Each call to the AddExternal method adds the specified series to the TSM object according to its role in the external model. That role association happens in one of the following ways:

- You specify the *Role* argument in the method call. This takes precedence over any role mapping that is defined in the EXMSPEC that was used in the TSM.Initialize method. If you specify an invalid *Role* value, an error occurs.
- You specify a *Series* variable that matches a role mapping in the EXMSPEC object that was used in the TSM.Initialize method. If you specify a *Series* variable that fails to match a role mapping in the EXMSPEC, an error occurs.

This method can be called as many times as needed to specify all of the external series that are required to run the external model. In all cases, if the series that you specify to add fails to resolve to a role in the EXMSPEC object, an error occurs without the series being included in the TSM object. Such failures do not cause subsequent TSM.AddExternal method calls to fail.

Input Arguments

You must specify the following input arguments:

<i>Series</i>	specifies a numeric array that contains an external forecast series for the TSM object.
<i>Role</i>	is a case-sensitive character string that specifies the role of the external forecast series in the external model. You can specify one of the following values:
ERROR	returns prediction errors.
LOWER	returns a lower confidence limit series.
STDERR	returns a prediction standard error series.
PREDICT	returns a prediction series.
UPPER	returns an upper confidence limit series.

TSM.AddX Method

```
rc=obj.AddX (XSeries < ,Required,NoDiff,ModelSymbol> ) ;
```

Adds an independent time series array (*XSeries*) for the TSM object. Each call of the TSM.AddX method adds the specified *XSeries* array variable to the TSM object. This method can be called as many times as needed to specify all the independent variables. By default, the name of the *XSeries* variable must match the name of an input symbol in the model specification that is used to configure the TSM object. You can specify a symbol name, *ModelSymbol*, to associate an *XSeries* array with an input symbol in the model specification. ARIMA, RNN, and UCM models support *XSeries* predictors, but RNN models ignore the optional arguments.

If you add multiple independent series, you must not use the same *XSeries* array variable for more than one series. For example, if you retrieve the values of independent variables by using the GetSeries method of the Time Series Data Frame (TSDF) object in the Automatic Time Series Modeling (ATSM) package, then you must use different arrays to store their values. The following programming statements illustrate this requirement by storing values of two independent variables, x1 and x2, in the arrays xarr1 and xarr2, respectively:

```
/* Create an instance of the TSDF object */
declare object df(tsdf);
rc = df.Initialize();
rc = df.AddY(sale);
rc = df.AddX(x1);
rc = df.AddX(x2);
rc = df.SetOption('lead',12);

/* Create an instance of the model object */
declare object ucm(ucmspec);
rc = ucm.Open();
rc = ucm.AddComponent('level',0,1);
rc = ucm.AddComponent('slope',0,1);
rc = ucm.AddComponent('irregular',.,0);
rc = ucm.AddInput('x1');
rc = ucm.AddInput('x2');
rc = ucm.Close();
```

```

/* Create an instance of the TSM object */
declare object tsm(tsm);
rc = tsm.Initialize(ucm);
rc = tsm.SetY(sale);

/* Store x1 and x2 values in separate arrays xarr1 and xarr2 */
array xarr1[1] / nosymbols;
call dynamic_array(xarr1, _LENGTH_);
rc = d.GetSeries('x1',xarr1,'adjust','yes');

array xarr2[1] / nosymbols;
call dynamic_array(xarr2, _LENGTH_);
rc = d.GetSeries('x2',xarr2,'adjust','yes');

/* Add x1 and x2 as independent variables to TSM instance */
rc = tsm.AddX(xarr1,0,0,'x1');
rc = tsm.AddX(xarr2,0,0,'x2');

/* Run the model */
rc = tsm.run();

```

Input Arguments

You must specify the following input argument:

XSeries specifies a numeric array that contains an independent series for the TSM object.

You can also specify the following input arguments:

<i>Required</i>	takes a Boolean value (0 or 1) that, when set to 1, specifies that the <i>XSeries</i> variable is required to be in the model. This might cause the model estimation to fail if the <i>XSeries</i> array variable is deemed inadmissible for inclusion in the underlying model. The default value is 0.
<i>NoDiff</i>	takes a Boolean value (0 or 1) that, when set to 1, specifies that the <i>XSeries</i> variable does not automatically follow the <i>XSeries</i> variable differencing. The default value is 0.
<i>ModelSymbol</i>	takes a character variable that specifies the name of an input symbol in the model specification to be associated with the <i>XSeries</i> variable when the model is run. By default, the TSM.AddX method adds <i>XSeries</i> variables to a model specification if they are not already referenced as an input symbol. Specification of <i>ModelSymbol</i> defines a way to include the <i>XSeries</i> variable if the model specification object includes a symbol that matches the <i>ModelSymbol</i> argument.

TSM.criterion Method

*criterion=*obj.criterion (*Region*) ;

Returns the fit statistic value over the specified forecast *Region* for the TSM object. The criterion is set via the 'CRITERION' argument in the “TSM.SetOption Method” on page 2353. A missing value indicates that the TSM object instance has not produced a successful forecast.

Input Arguments

You must specify the following input argument:

<i>Region</i>	is a case-insensitive character string that specifies the forecast region over which the fit statistic is computed. You can specify one of the following values:
BACK	returns the fit statistic over the time region that is subsequent to the FIT region and that did not contribute any data for estimating model parameters (that is, the model forecast region).
FIT	returns the fit statistic over the time region that supplied observations for estimating model parameters (that is, the model fit region).

TSM.GetForecast Method

*rc=*obj.GetForecast (*Which*, *Result*) ;

Gets the specified forecast series (*Which*) from the TSM object and stores it in the specified numeric array (*Result*).

Input Arguments

You must specify the following input argument:

<i>Which</i>	is a case-insensitive character string that specifies the type of forecast series to return. You can specify one of the following values:
ERROR	returns prediction errors.
LOWER	returns a lower confidence limit series.
STDERR	returns a prediction standard error series.
PREDICT	returns a prediction series.
UPPER	returns an upper confidence limit series.

Output Arguments

You must specify the following output argument:

<i>Result</i>	specifies a numeric array to receive the forecast series.
---------------	---

TSM.Initialize Method

```
rc=obj.Initialize (< ModelSpec>) ;
```

Initializes a TSM object to use the specified *ModelSpec*. This method must be called before the time series arrays (*XSeries* and *YSeries*) and other attributes for the TSM object are specified. If no *ModelSpec* object is specified, the TSM object is initialized to use the default ESM specification. This is equivalent to initializing the TSM object with an ESMSPEC object that has default option values.

Input Arguments

You can specify the following input argument:

ModelSpec specifies an optional name for a TSM model specification object that is used to configure the TSM object.

TSM.nfor Method

```
nfor=obj.nfor () ;
```

Returns the length (observation count) of the forecast series for the TSM object. A missing value indicates that the TSM object has not produced a successful forecast.

Arguments

There are no arguments associated with this method.

TSM.Replay Method

```
rc=obj.Replay (TSMINSPECObj< ,TSMINESTObj>) ;
```

Uses a previously saved model specification from a *TSMINSPECObj* as input to another TSM object. Optionally, restored parameter estimates from *TSMINESTObj* are applied to the model specification.

Input Arguments

You must specify the following input argument:

TSMINSPECObj specifies the TSMINSPEC object to supply the model specification.

You can also specify the following input argument:

TSMINESTObj specifies the TSMINEST object to supply the model's parameter estimates.

TSM.Run Method

```
rc=obj.Run () ;
```

Runs the TSM object to estimate and forecast the time series model by using the specified dependent (*YSeries*) and independent (*XSeries*) series. Upon successful completion, various results can be extracted from the TSM object. The Run method also attempts to process any TSM.AddExternal calls that were deferred because of the TSM object not being configured with an EXMSPEC. An error occurs at this point if the TSM object is still not configured with an EXMSPEC but you had specified TSM.AddExternal method calls.

Arguments

There are no arguments associated with this method.

TSM.SetOption Method

```
rc=obj.SetOption ('Name', Value < , 'Name', Value, ... > ) ;
```

Specifies the named options for the TSM object. When you invoke this method, the previous forecast produced by the [TSM.Run](#) method is discarded. You must then rerun the [TSM.Run](#) method in order to produce a new forecast using the updated configuration options.

Input Arguments

You must specify at least one of the following *'Names'* and its associated *Value*:

'ALPHA'	takes a numeric <i>Value</i> between 0 and 1, exclusive, that specifies the significance level for forecast confidence bands. The default value is 0.05.
'BACK'	takes a nonnegative integer <i>Value</i> that specifies the back region for model performance. If <i>'BACK'=n</i> and the number of observations is <i>T</i> , then the first $T - n$ observations are used to diagnose a series. The default is value 0.
'CRITERION'	takes a string <i>Value</i> that specifies the model selection criterion (statistic of fit) to be used to select from several candidate models. You can specify one of the following <i>Values</i> :
AADJRSQ	specifies Amemiya's adjusted R-square.
ADJRSQ	specifies the adjusted R-square.
AIC	specifies Akaike's information criterion.
AICC	specifies the finite-sample corrected AIC.
APC	specifies Amemiya's prediction criterion.
GMAPE	specifies the geometric mean absolute percentage error.
GMAPES	specifies the geometric mean absolute error as a percentage of standard deviation.
GMAPPE	specifies the geometric mean absolute predictive percentage error.
GMASPE	specifies the geometric mean absolute symmetric percentage error.
GMRAE	specifies the geometric mean relative absolute error.
IMASE	specifies the in-sample mean absolute scaled error.
MAE	specifies the mean absolute error.
MAPE	specifies the mean absolute percentage error.
MAPES	specifies the mean absolute error as a percentage of standard deviation.
MAPPE	specifies the symmetric mean absolute predictive percentage error.
MASE	specifies the mean absolute scaled error.
MAXERR	specifies the maximum error.
MAXPE	specifies the maximum percentage error.
MAXPPE	specifies the maximum predictive percentage error.

MAXRE	specifies the maximum relative error.
MAXSPE	specifies the maximum symmetric percentage error.
MDAPE	specifies the median absolute percentage error.
MDAPES	specifies the median absolute error as a percentage of standard deviation.
MDAPPE	specifies the median absolute predictive percentage error.
MDRAE	specifies the median relative absolute error.
MDASPE	specifies median absolute symmetric percentage error.
ME	specifies the mean error.
MINERR	specifies the minimum error.
MINPE	specifies the minimum percentage error.
MINPPE	specifies the minimum predictive percentage error.
MINRE	specifies the minimum relative error.
MINSPE	specifies the minimum symmetric percentage error.
MPE	specifies the mean percentage error.
MPPE	specifies the mean predictive percentage error.
MRAE	specifies the mean relative absolute error.
MRE	specifies the mean error.
MSE	specifies the mean square error.
MSPE	specifies the mean symmetric percentage error.
RMSE	specifies the root mean square error.
RMSSE	specifies the root mean square scaled error.
RSQUARE	specifies the R-square.
RWRSQ	specifies the random walk R-square.
SMAPE	specifies the symmetric mean absolute percentage error.
SBC	specifies the Schwarz Bayesian information criterion.
SSE	specifies the sum of square error.
UMSE	specifies the unbiased mean square error.
URMSE	specifies the unbiased root mean square error.

The default value is RMSE.

'HOLDOUT' takes a nonnegative integer *Value* that specifies the holdout region for model selection. The holdout sample is a subset of dependent series (which you specify by using the `TSM.SetY` method) that ends at the last nonmissing observation. This option is relevant only when a TSM instance has been initialized via the [Initialize](#) method by using a model specification that requires model selection. Currently, this applies only to a model specification that is created by an [ESMSPEC](#) object and whose 'METHOD' option is set to either 'BEST', 'BESTN', or 'BESTS' via the [ESMSPEC.SetOption](#) method. The default value is 0.

'HORIZON'	takes a numeric <i>Value</i> that specifies the forecast horizon reference time. When set to a missing value, the forecast horizon reference time is automatically set as the first time period that follows the last nonmissing observation of the dependent series. The default value is a missing value. Currently, this option does not apply to a model specification that is created by an RNNSPEC object.
'LEAD'	takes a nonnegative integer <i>Value</i> that specifies the forecast lead. The default value is the value specified in the PROC TSMODEL statement (LEAD= option). If LEAD= is not specified in the PROC TSMODEL statement, the default value of LEAD=0.
'VERBOSE'	takes a Boolean <i>Value</i> (0 or 1) that, when set to 1, enables the TSM.Run method to generate additional log messages when issues occur during the process of fitting a specified model to the input data. These additional messages can help you identify the cause of model fitting failures, such as the specification of invalid weight bounds for model parameters. The default is 0 (no additional log messages are generated).

TSM.SetY Method

```
rc=obj.SetY (YSeries) ;
```

Specifies the dependent time series array (*YSeries*) for the TSM object.

Input Arguments

You must specify the following input argument:

YSeries specifies a numeric array that contains the dependent series for the TSM object.

CFC Object

The CFC object creates optimized combinations of time series model forecasts. The performance of combined model forecasts tends to improve over that of individual models. You can specify the model forecasts to be combined either as arbitrary time series arrays or as instances of the TSM object that have been previously run. [Table 32.5](#) summarizes the methods that are associated with the CFC object.

Table 32.5 Methods of the CFC Object

Method	Description
AddModel	Add a forecast series from an instance of the TSM object
AddPredict	Add a time series array as a forecast series
criterion	Return the final fit statistic over a specified forecast region
GetForecast	Get the forecast series
Initialize	Initialize the CFC object
nfor	Return the forecast series length
Run	Run the CFC object to generate a combined forecast
SetOption	Specify the named option for the CFC object
SetY	Specify the dependent time series array (<i>YSeries</i>) for the CFC object

The basic execution pattern for using a CFC object follows this sequence of operations:

- 1 Declare:** The object declaration statement creates a new instance of the CFC object.
- 2 Initialize:** The [CFC.Initialize](#) method resets the object in preparation for a new run.
- 3 SetY:** The [CFC.SetY](#) method defines the dependent time series for the CFC object.
- 4 AddModel:** The [CFC.AddModel](#) method adds the forecast series that was produced by an instance of the TSM object. Each call adds one model forecast series to the combination. Repeat as needed for each model forecast series to be combined. Also, if you invoke this method prior to invoking the [CFC.SetY](#) method, then this method will use the dependent series of the TSM object as the dependent series of the CFC object.
- 5 AddPredict:** The [CFC.AddPredict](#) method adds a forecast series to the combination that is specified as a numeric array. Each call adds one forecast series to the combination. Repeat as needed for each forecast series to be combined.
- 6 SetOption:** The [CFC.SetOption](#) method specifies any options that affect the generation of the combined model forecast. Each call defines an option. Repeat as needed to specify all options that are required.
- 7 Run:** The [CFC.Run](#) method uses its currently configured dependent and forecast series data to generate a combined forecast.

Figure 32.2 illustrates the data flow through the CFC object and its relationship with other components of the TSM package.

Figure 32.2 CFC Object Data Flow

CFC Synopsis

DECLARE OBJECT *obj* (CFC) ;

Method syntax, in order of typical usage:

```
rc=obj.Initialize () ;
rc=obj.SetY (YSeries) ;
rc=obj.AddModel (ModelObj < , ModelName >) ;
rc=obj.AddPredict (Predict, PredictSE < ,ModelName, Nparms > ) ;
rc=obj.SetOption ('Name', Value < , 'Name', Value,... >) ;
rc=obj.Run () ;
rc=obj.GetForecast (Which, Result) ;
nfor=obj.nfor () ;
criterion=obj.criterion (Region) ;
```

CFC Methods

CFC.AddModel Method

```
rc=obj.AddModel (ModelObj < , ModelName >) ;
```

Adds the forecast model series that were produced by an instance of the TSM object to the forecast combination process. This includes both the predicted and standard error series that were produced by the TSM object during the forecasting process. By default, the CFC object uses the name of the TSM object instance to identify the forecast component associated with its forecast series. However, you can optionally specify the forecast component via the *ModelName* argument.

Input Arguments

You must specify the following input argument:

ModelObj specifies the TSM object to use as a source of forecast model series.

You can also specify the following input argument:

ModelName is a character string that specifies the name of the forecast component that is used to identify the model forecast series in the combination. The default is the name of the TSM object instance that is used as the source of forecast model series.

CFC.AddPredict Method

```
rc=obj.AddPredict (Predict, PredictSE < , ModelName, Nparms > ) ;
```

Adds a forecast series to be included in the forecast combination for the CFC object. This includes both the *Predict* predicted series and the *PredictSE* standard errors series as numeric arrays. You can optionally specify the name of the forecast component in the combination via the *ModelName* argument. Each call to the AddPredict method adds the specified *Predict* and *PredictSE* series to the CFC object to be included in the combination process. The arrays that are used to specify the *Predict* and *PredictSE* series do not need to be unique, but the forecast component names that are specified in the *ModelName* argument must be unique if you specify them. You can call the AddPredict method repeatedly to specify multiple forecast series.

Input Arguments

You must specify the following input arguments:

- Predict* specifies a numeric array that contains the predicted series.
- PredictSE* specifies a numeric array that contains the standard errors of the predicted series.

You can also specify the following input arguments:

- ModelName* is a character string that specifies the name of the forecast component that is used to identify the model forecast series in the combination. The default is a unique name that is autogenerated by the CFC object.
- Nparms* takes a numeric value that specifies the number of parameters used by the model that generated the forecast series. Valid values are integers greater than or equal to 0. The default value is 0.

CFC.criterion Method

criterion=obj.criterion (Region) ;

Returns the fit statistic value over the specified forecast *Region* for the CFC object. The criterion is set via the 'CRITERION' argument in the CFC.SetOption method. A missing value indicates that the CFC object instance has not produced a successful forecast.

Input Arguments

You must specify the following input argument:

- Region* is a case-insensitive character string that specifies the forecast region over which the fit statistic is computed. You can specify one of the following values:
- | | |
|-------------|--|
| BACK | returns the fit statistic over the time region that is subsequent to the FIT region and that did not contribute any data to the process of estimating combination weights for the specified model forecast series. |
| FIT | returns the fit statistic over the time region that supplied observations for the process of estimating combination weights for the specified model forecast series. |

CFC.GetForecast Method

rc=obj.GetForecast (Which, Result) ;

Gets the specified forecast series (*Which*) from the CFC object and stores it in the specified numeric array (*Result*).

Input Arguments

You must specify the following input argument:

- Which* is a case-insensitive character string that specifies the type of forecast series to return. You can specify one of the following values:

ERROR	returns prediction errors.
LOWER	returns a lower confidence limit series.
STDERR	returns a prediction standard error series.
PREDICT	returns a prediction series.
UPPER	returns an upper confidence limit series.

Output Arguments

You must specify the following output argument:

Result specifies a numeric array to receive the forecast series.

CFC.Initialize Method

```
rc=obj.Initialize ();
```

Initializes a CFC object by discarding a previous forecast and resetting the object's configuration to the default values. This method must be called before any other attributes for the CFC object are specified.

Arguments

There are no arguments associated with this method.

CFC.nfor Method

```
nfor=obj.nfor ();
```

Returns the length (observation count) of the forecast series for the CFC object. A missing value indicates that the CFC object has not produced a successful forecast.

Arguments

There are no arguments associated with this method.

CFC.Run Method

```
rc=obj.Run ();
```

Runs the CFC object to perform the forecast combination process by using the dependent (*YSeries*) and candidate forecast series that have been specified for it. Upon successful completion, various results can be extracted from the CFC object.

Arguments

There are no arguments associated with this method.

CFC.SetOption Method

```
rc=obj.SetOption ('Name', Value <, 'Name', Value, ... >) ;
```

Specifies the named options for the CFC object. When you invoke this method, the previous forecast combination produced by the [CFC.Run](#) method is discarded. You must then rerun the [CFC.Run](#) method in order to produce a new forecast combination using the updated configuration options.

Input Arguments

You must specify at least one of the following 'Names' and its associated *Value*:

'BACK'	takes a nonnegative integer <i>Value</i> that specifies the back region for model performance. If 'BACK'= n and the number of observations is T , then the first $T - n$ observations are used to diagnose a series. The default value is 0.						
'CRITERION'	takes a string <i>Value</i> that specifies the fit statistic to be computed for the final forecast. The default value is RMSE. For a list of valid values, see the 'CRITERION' argument in the "TSM.SetOption Method" on page 2353.						
'ENCALPHA'	takes a numeric <i>Value</i> between 0 and 1, inclusive, that specifies the significance level of the encompassing test. The default value is 0.05.						
'ENCTEST'	takes a string <i>Value</i> that specifies the encompassing test type. The encompassing test attempts to eliminate from consideration any forecasts that fail to add significant information to the final forecast. For a detailed description of the encompassing test, see the chapter "Forecast Combination Computational Details" in <i>SAS Forecast Server Procedures: User's Guide</i> . You can specify the following <i>Values</i> : <table data-bbox="406 1081 1443 1585"> <tr> <td>HLN</td><td>uses the Harvey-Leybourne-Newbold (HLN) test to estimate pairwise encompassing between candidate forecasts. Candidates are ranked from best to worst using the 'CRITERION' option. Iterating from best to worst, inferior candidates are tested together with the best of the untested candidates for retention in the combined set. The significance level for the test is given by the 'ENCALPHA' argument.</td></tr> <tr> <td>NONE</td><td>performs no encompassing tests.</td></tr> <tr> <td>OLS</td><td>uses an OLS-based regression test to estimate pairwise encompassing between candidate forecasts. Candidates are ranked from best to worst using the 'CRITERION' option. Iterating from best to worst, inferior candidates are tested together with the best of the untested candidates for retention in the combined set. The significance level for the test is given by the 'ENCALPHA' argument.</td></tr> </table>	HLN	uses the Harvey-Leybourne-Newbold (HLN) test to estimate pairwise encompassing between candidate forecasts. Candidates are ranked from best to worst using the 'CRITERION' option. Iterating from best to worst, inferior candidates are tested together with the best of the untested candidates for retention in the combined set. The significance level for the test is given by the 'ENCALPHA' argument.	NONE	performs no encompassing tests.	OLS	uses an OLS-based regression test to estimate pairwise encompassing between candidate forecasts. Candidates are ranked from best to worst using the 'CRITERION' option. Iterating from best to worst, inferior candidates are tested together with the best of the untested candidates for retention in the combined set. The significance level for the test is given by the 'ENCALPHA' argument.
HLN	uses the Harvey-Leybourne-Newbold (HLN) test to estimate pairwise encompassing between candidate forecasts. Candidates are ranked from best to worst using the 'CRITERION' option. Iterating from best to worst, inferior candidates are tested together with the best of the untested candidates for retention in the combined set. The significance level for the test is given by the 'ENCALPHA' argument.						
NONE	performs no encompassing tests.						
OLS	uses an OLS-based regression test to estimate pairwise encompassing between candidate forecasts. Candidates are ranked from best to worst using the 'CRITERION' option. Iterating from best to worst, inferior candidates are tested together with the best of the untested candidates for retention in the combined set. The significance level for the test is given by the 'ENCALPHA' argument.						
	The default is NONE.						
'HMISSPCT'	takes a numeric <i>Value</i> between 0 and 100 that specifies a threshold for the percentage of missing forecast values in the combination horizon. This threshold is used to exclude a candidate forecast from consideration in the final combination. By default, no horizon missing percentage test is performed on candidate forecasts. The forecast horizon is the region of time in which multistep forecasts are generated.						
'LEAD'	takes a nonnegative integer <i>Value</i> that specifies the forecast lead. The default is the value that is specified in the PROC TSMODEL statement (LEAD= option). If the LEAD=						

option is not specified in the PROC TSMODEL statement, the default value of LEAD=0 is used.

'MISSMODE' takes a string *Value* that specifies a method for treating missing values in the forecast combination. In a particular time slice across the combination ensemble, one or more combination contributors can have a missing value. This setting determines the treatment of those contributors in the final combination for such time indices. You can specify the following *Values*:

MISSING generates a missing combined forecast at each time index with one or more missing contributors.

RESCALE rescales the combination weights for the nonmissing contributors at each time index to sum to 1. You cannot specify RESCALE when the value of the 'WEIGHT' argument is OLS or NRLS.

The default value depends on the combination weight method that is specified by the 'WEIGHT' argument. RESCALE is the default for simple average, user-specified weights, ranked user weights, ranked weights, and RMSE weights. MISSING is the default for all other methods.

'MISSPCT' takes a numeric *Value* between 0 and 100 that specifies a threshold for the percentage of missing forecast values in the combination estimation region. This threshold is used to exclude a candidate forecast from consideration in the final combination. By default, no missing percentage test is performed on candidate forecasts.

'RANKING' takes a string *Value* that specifies the fit statistic to be used for ranking forecast candidates. This option is used in conjunction with the 'ENCTEST' and 'WEIGHT' (when *Value* is set to RANKWGT) arguments. For a list of valid values, see the 'CRITERION' argument in the “[TSM.SetOption Method](#)” on page 2353. The default value is RMSE.

'SEMODE' takes a string *Value* that specifies the method for computing the prediction error variance series. This series is used to compute the prediction standard error, which in turn is used to compute confidence bands on the combined forecast. You can specify the following *Values*:

DIAG computes the prediction error variance by assuming that the forecast errors at time t are uncorrelated so that the simple diagonal form of Σ_t is used.

ESTCORR computes the prediction error variance by using estimates of $\rho_{i,j,t}$, the sample cross-correlation between $e_{i,t}$ and $e_{j,t}$ over the time span $t = 1, \dots, T$, where t denotes the last time index of the actual series y_t . This *Value* implies that the error series $e_{i,t}$ and $e_{j,t}$ are assumed to be jointly stationary.

The default is DIAG.

'USERWEIGHTS' takes a numeric array *Value* that specifies the combination weights to be used when the value of the 'WEIGHT' argument is RANKWGT or USERDEF. If the specified weights do not sum to 1, then the weights are automatically normalized to sum to 1 and a warning message is issued. For more information, see the 'WEIGHT' argument.

'WEIGHT' takes a string *Value* that specifies the method for determining the combination weights that are used in the weighted average of the candidate model forecasts. You can specify the following *Values*:

AICC	computes the combination weights on the basis of corrected AIC weights. By default, all AICC scored candidate forecasts are combined.
AVERAGE	computes the simple average of the forecasts that are selected for combination.
ERLS	computes the combination weights on the basis of a constrained least squares problem to minimize the ℓ_2 norm of the combined forecast residuals subject to the constraint that the weights sum to 1.
LAD	computes the weights on the basis of a least absolute deviations (LAD) measure of fit for the combined forecast. A linear program is formulated in which an objective function to be minimized is expressed in terms of the absolute values of a loss series subject to constraints that the weights sum to 1 and be nonnegative.
NERLS	computes the combination weights on the basis of a constrained least squares problem to minimize the ℓ_2 norm of the combined forecast residuals subject to the constraints that the weights sum to 1 and be nonnegative.
NRLS	is equivalent to NERLS, except that the resulting combination weights are not constrained to summing to 1.
OLS	computes the combination weights that result from the ordinary least squares problem to minimize the ℓ_2 norm of the combined forecast residuals.
RANKWGT	assigns weights by using the rank of the candidate forecasts at the time the combination is performed. You can optionally specify the weights in the 'USERWEIGHTS' argument, where the number of specified values must match the number of model forecasts that are specified in the current instance of the CFC object. The weights are assigned by ranking the candidate forecasts from best to worst on the basis of the fit statistic specified in the 'RANKING' argument. The best candidate uses the first weight, W1, and so on. If you do not specify the weights in the 'USERWEIGHTS' argument, then the weight of each candidate forecast is set to the inverse value of its rank. The set of weights that is used is normalized to account for candidate forecasts that are omitted from the final combination.
RMSEWGT	computes the combination weights on the basis of the RMSE statistic of fit for the forecast contributors. The weights are normalized to sum to 1.
USERDEF	assigns weights by using the list of user-specified values. You must specify the weights in the 'USERWEIGHTS' argument, where the number of specified values must match the number of model forecasts that are specified in the current instance of the CFC object. The weights correspond to the order of specification of the model forecasts. The set of weights that is used is normalized to account for candidates that are omitted from the final combination.

The default is AVERAGE.

CFC.SetY Method

```
rc=obj.SetY (YSeries) ;
```

Specifies the dependent time series array (*YSeries*) for the CFC object.

Input Arguments

You must specify the following input argument:

YSeries specifies a numeric array that contains the dependent series for the CFC object.

ESMSPEC Object

The ESMSPEC object defines an exponential smoothing model specification for use with the TSM object. The basic execution pattern for defining an ESMSPEC follows this sequence of operations:

- 1 Declare:** The object declaration statement creates a new ESMSPEC object. By default, it is an ESMSPEC with METHOD=BEST.
- 2 Open:** The ESMSPEC.Open method initializes the default ESMSPEC object for a new configuration.
- 3 Configure:** The various ESMSPEC.Set methods configure the ESMSPEC object.
- 4 Close:** The ESMSPEC.Close method finalizes the ESMSPEC object.
- 5 Apply:** Add the ESMSPEC to a TSM object using the TSM.Initialize method.

Table 32.6 summarizes the methods that are associated with the ESMSPEC object.

Table 32.6 Methods of the ESMSPEC Object

Method	Description
Close	Close ESM model specification
GetLabel	Retrieve label of specified ESM model
Open	Open ESM model specification
SetOption	Set option for ESM model
SetParm	Set parameters for ESM model
SetTransform	Set transform for ESM model

You can also store the XML representation of the ESMSPEC object in an output table. For more information, see the section “[TSM SPEC Object](#)” on page 2410.

Figure 32.3 illustrates the data flow through the ESMSPEC object.

Figure 32.3 ESMSPEC Object Data Flow

ESMSPEC Synopsis

DECLARE OBJECT *obj* (ESMSPEC) ;

Method syntax, in order of typical usage:

```

rc=obj.Open () ;
rc=obj.SetTransform ('Type' <,'Option',Parm>) ;
rc=obj.SetParm ('CompName' < , Parm, LRest, URest>) ;
rc=obj.SetOption ('Name', Value <,'Name',Value,... >) ;
rc=obj.GetLabel () ;
rc=obj.Close () ;
  
```

ESMSPEC Methods

ESMSPEC.Close Method

```
rc=obj.Close () ;
```

Finalizes the ESMSPEC object to prepare the ESM model to be used in a TSM object or to be imported to a TMSPEC object for printing or for storage in a model repository catalog.

Arguments

There are no arguments associated with this method.

ESMSPEC.GetLabel Method

```
rc=obj.GetLabel () ;
```

Retrieves the label of the specified ESM model and stores it in the return variable, *rc*.

Arguments

There are no arguments associated with this method.

ESMSPEC.Open Method

```
rc=obj.Open () ;
```

Opens the ESMSPEC object.

Arguments

There are no arguments associated with this method.

ESMSPEC.SetOption Method

```
rc=obj.SetOption ('Name', Value <, 'Name', Value, ... >) ;
```

Specifies ESM options.

Input Arguments

You must specify at least one of the following *'Names'* and its associated *Value*:

'CRITERION' takes a string *Value* that specifies the model selection criterion (statistic of fit) to be used to select from several candidate models. For a list of valid values, see the **'CRITERION'** argument in the “[TSM.SetOption Method](#)” on page 2353. The default value is RMSE.

'METHOD' takes a string *Value* that specifies the ESM method. You can specify the following values:

ADDWINTERS requests the Winters additive method.

BEST uses seasonal properties of the data to choose between the BESTN and BESTS methods. If the data consist of a single seasonal cycle, the BESTN method is used. Otherwise, a seasonality test is performed on both the original data and the original data after one

nonseasonal difference is taken. If seasonality is present in either the original or differenced series, the series is considered to be seasonal. If the data are seasonal, the BESTS method is used. If neither seasonality test indicates seasonality, the BESTN method is used. The results of the seasonality test are summarized in [Table 32.7](#). The significance level for the seasonality test is 0.05. For more information about the seasonality test, see the SEASONTTEST function of the time series analysis (TSA) package.

BESTN	requests the best candidate nonseasonal smoothing model among the SIMPLE, LINEAR, and DAMPTREND methods.
BESTS	requests the best candidate seasonal smoothing model among the SEASONAL, ADDWINTERS, and WINTERS methods.
DAMPTREND	requests damped trend exponential smoothing.
DOUBLE	requests second order exponential smoothing.
LINEAR	requests linear (Holt) exponential smoothing.
MULTSEASONAL	requests multiplicative seasonal exponential smoothing.
SEASONAL	requests additive seasonal exponential smoothing.
SIMPLE	requests simple (single) exponential smoothing.
WINTERS	requests the Winters multiplicative method.

By default, METHOD=BEST.

'NOSTABLE'	takes a Boolean <i>Value</i> (0 or 1) that, when set to 1, requests that the smoothing model parameter estimates not be restricted to the additive invertible region of the parameter space. The default is 0 (parameter estimates are restricted).
'NOEST'	takes a Boolean <i>Value</i> that indicates whether the smoothing model parameters are fixed values. By default, the smoothing model parameters are optimized. 'NOEST' requires all of the exponential smoothing model parameters to be explicitly specified via calls to the ESMSPEC.SetParm method. This argument is ignored if any of the model parameters is not specified.

Table 32.7 Results of BEST Method of the ESMSPEC.SetOption Method

Number of Seasonal Cycles	Result of Seasonality Test	Method Used
< 2	Test is not performed	BESTN
≥ 2	Test indicates seasonality	BESTS
≥ 2	Test does not indicate seasonality	BESTN

ESMSPEC.SetParm Method

```
rc=obj.SetParm ('CompName' < , Parm, LRest, URest>);
```

Specifies parameter values and restrictions for the specified ESM component. Optional bounds, *LRest* and *URest*, can be specified to restrict the weight value for the specified ESM component during parameter optimization. Parameter values and restrictions must be in the range from -1 to 2 .

Input Arguments

You must specify the following input argument:

<i>'CompName'</i>	specifies a character variable that indicates the ESM component context. You can specify the following values:
DAMP	specifies that <i>Parm</i> is the initial value of a damping weight parameter.
LEVEL	specifies that <i>Parm</i> is the initial value of a level weight parameter.
SEASON	specifies that <i>Parm</i> is the initial value of a season weight parameter.
TREND	specifies that <i>Parm</i> is the initial value of a trend weight parameter.

You can also specify the following input arguments:

<i>Parm</i>	takes a numeric value that specifies the initial value of the smoothing component weight. The default value is a missing value, which causes the optimizer to use a grid search to find an appropriate initial value.
<i>LRest</i>	is a numeric variable that specifies a lower bound on the smoothing weight. The default value of the level, season, and trend weight parameters is 0.001 . The default value of the damping weight parameter is 0.8 .
<i>URest</i>	is a numeric variable that specifies an upper bound on the smoothing weight. The default value is 0.999 for all smoothing weights.

ESMSPEC.SetTransform Method

```
rc=obj.SetTransform ('Type' < , 'Option', Parm>);
```

Specifies the functional transform, *'Type'*, to be used by the ESM model. The optional arguments *Option* and *Parm* offer greater control over the transform.

Input Arguments

You must specify the following input argument:

<i>'Type'</i>	takes one of the following string values:
AUTO	automatically chooses between NONE and LOG based on model selection criteria.
BOXCOX	requests Box-Cox transformation. You can specify the control parameter for the transformation by using the optional <i>Parm</i> argument, whose value must be between -5 and 5 . The default value of <i>Parm</i> is 1 .

LOG	requests logarithmic transformation.
LOGIT LOGISTIC	requests logistic transformation.
NONE	does not apply a transformation.
SQRT	requests square-root transformation.

The default is NONE.

You can also specify the following input arguments:

<i>'Option'</i>	takes one of the following string values that specifies prediction semantics for the inverse transform: <table><tr><td>MEAN</td><td>requests that the inverse transform produce mean forecasts.</td></tr><tr><td>MEDIAN</td><td>requests that the inverse transform produce median forecasts.</td></tr></table> The default is MEAN.	MEAN	requests that the inverse transform produce mean forecasts.	MEDIAN	requests that the inverse transform produce median forecasts.
MEAN	requests that the inverse transform produce mean forecasts.				
MEDIAN	requests that the inverse transform produce median forecasts.				
<i>Parm</i>	takes a numeric value between −5 and 5 that specifies a control parameter. This parameter is allowed only for Box-Cox transformations. The default is 1.				

ARIMASPEC Object

The ARIMASPEC object generates autoregressive integrated moving average (ARIMA) model specifications for use with a TSM object.

Table 32.8 summarizes the methods that are associated with the TSM.ARIMASPEC method.

Table 32.8 Methods of the ARIMASPEC Object

Method	Description
AddARPoly	Add an autoregressive polynomial factor to the ARIMA model
AddMAPoly	Add a moving average polynomial factor to the ARIMA model
AddTF	Add a transfer function to the ARIMA model
AddTFDenPoly	Add a transfer function denominator factors to the ARIMA model
AddTFNumPoly	Add a transfer function numerator factors to the ARIMA model
Close	Close the ARIMA model specification
GetLabel	Retrieve the label of the specified ARIMA model
Open	Open the ARIMA model specification
SetDiff	Add differencing to the ARIMA model
SetOption	Specify the ARIMA option
SetTFTransform	Specify the transfer function transform
SetTransform	Specify transform

The basic execution pattern for using an ARIMASPEC object follows this sequence of operations:

- 1 Declare:** The object declaration statement creates a new ARIMASPEC object. At creation, its default state is ARIMA(0,1,0) with intercept (random walk with drift).
- 2 Open:** The ARIMASPEC.Open method readies the default ARIMASPEC object for new configuration.
- 3 Configure:** The various ARIMASPEC.Set methods configure the ARIMASPEC object.
- 4 Close:** The ARIMASPEC.Close method finalizes the ARIMASPEC object.
- 5 Apply:** The TSM.Initialize method adds the ARIMASPEC to a TSM object.

You can also store the XML representation of the ARIMA model in a table. For more information, see the section “[TSMSPC Object](#)” on page 2410. [Figure 32.4](#) illustrates the data flow through the ARIMASPEC object.

Figure 32.4 ARIMASPEC Object Data Flow

You can include series transforms such as log or Box-Cox in the specification. Deferred seasonality wildcards for seasonal ARIMA polynomial factors and seasonal differencing lags are also supported. The following list summarizes where these features can be used. For more information, see the method descriptions.

- `ARIMASPEC.SetDiff` supports a seasonal wildcard lag in the `DiffArray`.
- `ARIMASPEC.AddARPoly` and `ARIMASPEC.AddMAPoly` support addition of seasonal ARIMA polynomial factors.
- `ARIMASPEC.AddTF` supports a seasonal wildcard lag in the `DiffArray`.
- `ARIMASPEC.AddTFNumPoly` and `ARIMASPEC.AddTFDenPoly` support addition of seasonal ARIMA polynomial factors for the transfer function numerator and denominator, respectively.
- `ARIMASPEC.SetTransform` applies transforms such as log, square root, logistic, or Box-Cox to the model.

When you specify ARIMA model coefficient values for any model components, you must specify them for all model components without regard to the value of the NOEST argument in the [ARIMASPEC.SetOption](#) method. Failing to specify a complete set of ARIMA model parameters results in an error when you call [ARIMASPEC.Close](#), and the accumulated ARIMA model specification is reset.

ARIMASPEC Synopsis

DECLARE OBJECT *obj* (**ARIMASPEC**) ;

Method syntax, in order of typical usage:

```
rc=obj.Open () ;
rc=obj.SetTransform ('Type' <,'Option', Parm>) ;
rc=obj.SetDiff (DiffArray <,NDiff>) ;
rc=obj.AddARPoly (OrderArray <,NOrder,Seasonal,CoeffArray>) ;
rc=obj.AddMAPoly (OrderArray <,NOrder,Seasonal,CoeffArray>) ;
rc=obj.AddTF (XName, < Delay,DifArray,NDiff,ConstCoeff>) ;
rc=obj.AddTFNumPoly (XName, NumArray <,NNum,Seasonal,CoeffArray>) ;
rc=obj.AddTFDenPoly (XName, DenArray <,NDen,Seasonal,CoeffArray>) ;
rc=obj.SetTFTransform (XName, 'Type', < Parm>) ;
rc=obj.SetOption ('Name', Value <,'Name',Value,... >) ;
rc=obj.GetLabel () ;
rc=obj.Close () ;
```

ARIMASPEC Methods

ARIMASPEC.AddARPoly Method

rc=obj.AddARPoly (OrderArray <, NOrder, Seasonal, CoeffArray>) ;

Adds an autoregressive (AR) polynomial factor to ARIMA model. Additional AR polynomial factors can be added to the ARIMA model with subsequent calls to this method.

Input Arguments

You must specify the following input argument:

OrderArray is a numeric array that specifies AR polynomial lags. Valid values are integers greater than or equal to 1.

You can also specify the following input arguments:

<i>NOrder</i>	takes a numeric variable that specifies the number of <i>OrderArray</i> values to use. If you do not specify <i>NOrder</i> , or if you specify no value or a missing value for it, it is set to the length of <i>OrderArray</i> —that is, all values in <i>OrderArray</i> are used.
<i>Seasonal</i>	takes a Boolean value (0 or 1) that, when set to 1, specifies that the AR polynomial is seasonal. By default, the AR polynomial is not seasonal and the lags of the AR polynomial are simple.

CoeffArray is a numeric array that specifies the initial values of AR polynomial coefficients. If you set the 'NOEST' option to 1 by using the [ARIMASPEC.SetOption](#) method, then these initial values are also the final values of the coefficients. If you specify this argument, then you must also complete all the following tasks:

- Ensure that the cardinality of *CoeffArray* is at least *NOrder*.
- If you call [ARIMASPEC.AddTF](#) method, then specify the *ConstCoeff* argument in that call.
- If you call any of the following methods, then specify the *CoeffArray* argument in that method call: [ARIMASPEC.AddMAPoly](#), [ARIMASPEC.AddTFDenPoly](#), or [ARIMASPEC.AddTFNumPoly](#).
- If you do not set 'NOINT' to 1 by using the [ARIMASPEC.SetOption](#) method, then specify 'MU' by using the [ARIMASPEC.SetOption](#) method.

ARIMASPEC.AddMAPoly Method

```
rc=obj.AddMAPoly (OrderArray < , NOrder, Seasonal, CoeffArray> ) ;
```

Adds a moving average (MA) polynomial factor to ARIMA model. More MA polynomial factors can be added to the ARIMA model by subsequent calls to the this method.

Input Arguments

You must specify the following input argument:

OrderArray is a numeric array that specifies MA polynomial lags. Valid values are integers greater than or equal to 1.

You can also specify the following input arguments:

NOrder takes a numeric variable that specifies the number of *OrderArray* values to use. If you do not specify *NOrder*, or if you specify no value or a missing value for it, it is set to the length of *OrderArray*—that is, all values in *OrderArray* are used.

Seasonal takes a Boolean value (0 or 1) that, when set to 1, specifies that the MA polynomial is seasonal. By default, the MA polynomial is not seasonal and the lags of the MA polynomial are simple.

CoeffArray is a numeric array that specifies the initial values of MA polynomial coefficients. If you set the 'NOEST' option to 1 by using the [ARIMASPEC.SetOption](#) method, then these initial values are also the final values of the coefficients. If you specify this argument, then you must also complete all the following tasks:

- Ensure that the cardinality of *CoeffArray* is at least *NOrder*.
- If you call [ARIMASPEC.AddTF](#) method, then specify the *ConstCoeff* argument in that call.
- If you call any of the following methods, then specify the *CoeffArray* argument in that method call: [ARIMASPEC.AddARPoly](#), [ARIMASPEC.AddTFDenPoly](#), or [ARIMASPEC.AddTFNumPoly](#).
- If you do not set 'NOINT' to 1 by using the [ARIMASPEC.SetOption](#) method, then specify 'MU' by using the [ARIMASPEC.SetOption](#) method.

ARIMASPEC.AddTF Method

```
rc=obj.AddTF (XName < , Delay, DifArray, NDiff, ConstCoeff>) ;
```

Adds a transfer function to the ARIMA model for the specified *XName* variable. This method adds the variable as a simple scale effect subject to any specified lag and differencing that might be applied.

Input Arguments

You must specify the following input argument:

XName is a character string that specifies the name of the X variable.

You can also specify the following input arguments:

Delay takes a numeric value that specifies the simple delay for the predictor. The default value is 0.

DifArray is a numeric array that specifies differencing orders for the X variable. Valid values are integers greater than or equal to 1. If you do not specify *DifArray*, or if you specify no value for it, then no differencing is applied. Values in *DifArray* are interpreted as follows:

- Negative values are not allowed and result in an error condition.
- Nonnegative values represent differencing orders.
- An .S missing value is interpreted to include seasonal difference order.
- Any other missing value is ignored.

NDiff takes a numeric value that specifies the number of *DifArray* values to use. If you do not specify *NDiff*, or if you specify no value or a missing value for it, then all the values in *DifArray* are used.

ConstCoeff takes a numeric value that specifies the initial value of the scale parameter—that is, the zero-degree coefficient of the numerator. If you set the 'NOEST' option to 1 by using the [ARIMASPEC.SetOption](#) method, then this initial value is also the final value of the coefficient. If you specify this argument, then you must also complete the following tasks:

- If you call any of the following methods, then you must also specify the *CoeffArray* argument in that method call: [ARIMASPEC.AddARPoly](#), [ARIMASPEC.AddMAPoly](#), [ARIMASPEC.AddTFDenPoly](#), or [ARIMASPEC.AddTFNumPoly](#).
- If you do not set 'NOINT' to 1 by using the [ARIMASPEC.SetOption](#) method, then specify 'MU' by using the [ARIMASPEC.SetOption](#) method.

ARIMASPEC.AddTFDenPoly Method

```
rc=obj.AddTFDenPoly (XName, DenArray < , NDen, Seasonal, CoeffArray>) ;
```

Adds a transfer function denominator polynomial factor for the specified *XName* variable. More polynomials can be added by subsequent calls to the [ARIMASPEC.AddTFNumPoly](#) method.

Input Arguments

You must specify the following input argument:

<i>XName</i>	is a character string that specifies the name of the X variable.
<i>DenArray</i>	is a numeric array that specifies denominator polynomial lags for the X variable. Valid values are integers greater than 0.

You can also specify the following input arguments:

<i>NDen</i>	takes a numeric value that specifies the number of <i>DenArray</i> values to use. Valid values are integers greater than 0. If you do not specify <i>NDen</i> , or if you specify no value or a missing value for it, it is set to the length of <i>DenArray</i> —that is, all values in <i>DenArray</i> are used.
<i>Seasonal</i>	takes a Boolean value (0 or 1) that, when set to 1, specifies that the denominator polynomial is seasonal. By default, the denominator polynomial is not seasonal and the lags of the denominator polynomial are simple.
<i>CoeffArray</i>	is a numeric array that specifies the initial values of denominator polynomial coefficients. If you set the 'NOEST' option to 1 by using the ARIMASPEC.SetOption method, then these initial values are also the final values of the coefficients. If you specify this argument, then you must also complete all the following tasks: • Ensure that the cardinality of <i>CoeffArray</i> is at least <i>NDen</i>. • Specify the <i>ConstCoeff</i> argument in the ARIMASPEC.AddTF method. • If you call any of the following methods, then specify the <i>CoeffArray</i> argument in that method call: ARIMASPEC.AddARPoly, ARIMASPEC.AddMAPoly, or ARIMASPEC.AddTFNumPoly. • If you do not set 'NOINT' to 1 by using the ARIMASPEC.SetOption method, then specify 'MU' by using the ARIMASPEC.SetOption method.

ARIMASPEC.AddTFNumPoly Method

```
rc=obj.AddTFNumPoly (XName, NumArray < , NNum, Seasonal, CoeffArray> ) ;
```

Adds a transfer function numerator polynomial factor for the specified *XName* variable. More polynomials can be added by subsequent calls to the [ARIMASPEC.AddTFNumPoly](#) method.

Input Arguments

You must specify the following input argument:

<i>XName</i>	is a character string that specifies the name of the X variable.
<i>NumArray</i>	is a numeric array that specifies numerator polynomial lags for the X variable. Valid values are integers greater than 0.

You can also specify the following input arguments:

<i>NNum</i>	takes a numeric value that specifies the number of <i>NumArray</i> values to use. If you do not specify <i>NNum</i> , or if you specify no value or a missing value for it, it is set to the length of <i>NumArray</i> —that is, all values in <i>NumArray</i> are used.
<i>Seasonal</i>	takes a Boolean value (0 or 1) that, when set to 1, specifies that the numerator polynomial is seasonal. By default, the numerator polynomial is not seasonal and the lags of the numerator polynomial are simple.

CoeffArray is a numeric array that specifies the initial values of numerator polynomial coefficients. If you set the 'NOEST' option to 1 by using the [ARIMASPEC.SetOption](#) method, then these initial values are also the final values of the coefficients. If you specify this argument, then you must also complete all the following tasks:

- Ensure that the cardinality of *CoeffArray* is at least *NNum*.
- Specify the *ConstCoeff* argument in the [ARIMASPEC.AddTF](#) method.
- If you call any of the following methods, then specify the *CoeffArray* argument in that method call: [ARIMASPEC.AddARPoly](#), [ARIMASPEC.AddMAPoly](#), or [ARIMASPEC.AddTFDenPoly](#).
- If you do not set 'NOINT' to 1 by using the [ARIMASPEC.SetOption](#) method, then specify 'MU' by using the [ARIMASPEC.SetOption](#) method.

ARIMASPEC.Close Method

```
rc=obj.Close () ;
```

Finalizes the ARIMASPEC object to prepare the ARIMA model to be used in a TSM object or to be imported to a TSMSPEC object for printing or for storage in a model repository.

Arguments

There are no arguments associated with this method.

ARIMASPEC.GetLabel Method

```
rc=obj.GetLabel () ;
```

Retrieves the label of the specified ARIMA model and stores it in the return variable, *rc*.

Arguments

There are no arguments associated with this method.

ARIMASPEC.Open Method

```
rc=obj.Open () ;
```

Initializes an empty ARIMASPEC object for configuration.

Arguments

There are no arguments associated with this method.

ARIMASPEC.SetDiff Method

```
rc=obj.SetDiff (DiffArray < , NDiff>) ;
```

Adds differencing to the ARIMA model.

Input Arguments

You must specify the following input argument:

DiffArray is a numeric array that specifies differencing orders, where each order must be an integer greater than or equal to 1. Values in *DiffArray* are interpreted as follows:

- Negative values are not allowed and result in an error condition.
- Nonnegative integer values represent differencing orders.
- An .S missing value is interpreted to include seasonal difference order.
- Any other missing value is ignored.

You can also specify the following input argument:

NDiff takes a numeric value that specifies the number of *DiffArray* values to use. The default is to use all elements of *DiffArray*.

ARIMASPEC.SetOption Method

```
rc=obj.SetOption ('Name', Value <, 'Name', Value, ... >) ;
```

Specifies ARIMA model options. Options are ('Name',Value) pairs where 'Name' is a case-insensitive character string and Value depends on the 'Name'.

Input Arguments

You must specify at least one of the following 'Names' and its associated Value:

'CONVERGE' takes a numeric Value between 0 and 1, exclusive, that specifies the convergence criterion. Convergence is assumed when the largest change in the estimate for any parameter is less than the specified Value. If the absolute value of the parameter estimate is greater than 0.01, the relative change is used; otherwise, the absolute change in the estimate is used. The default is 0.001.

'DELTA' takes a numeric Value between 0 and 1, exclusive, that specifies the perturbation value for computing numerical derivatives. The default is 0.001.

'MAXITER' takes a positive integer Value that specifies the maximum number of iterations allowed. The default is 50.

'METHOD' takes a string Value that specifies the estimation method to use. You can specify one of the following Values:

CLS specifies the conditional least squares method.

ML specifies the maximum likelihood method.

ULS specifies the unconditional least squares method.

The default is CLS.

'MU' takes a numeric Value that specifies a constant term for the ARIMA model. The default is 0.

'NOEST'	takes a Boolean <i>Value</i> (0 or 1) that, when set to 1, specifies that no estimation is performed. The default is 0 (estimation is performed).
'NOINT'	takes a Boolean <i>Value</i> (0 or 1) that, when set to 1, specifies that the model should not have an intercept. This suppresses the fitting of a constant (or intercept) parameter in the model, and the 'MU' <i>Value</i> that you specify is ignored. The default is 0 (model has an intercept).
'NOSTABLE'	takes a Boolean <i>Value</i> (0 or 1) that, when set to 1, requests that the autoregressive and moving average parameter estimates for the noise part of the model not be restricted to the stationary and invertible regions, respectively. The default is 0 (parameter estimates for the noise part of the model are restricted).
'SINGULAR'	takes a numeric <i>Value</i> between 0 and 1, exclusive, that specifies the criterion for checking singularity. If a pivot of a sweep operation is less than <i>Value</i> , the matrix is deemed singular. Sweep operations are performed on the Jacobian matrix during final estimation and on the covariance matrix when preliminary estimates are obtained. The default is 1E-7.

ARIMASPEC.SetTFTTransform Method

rc=obj.SetTFTTransform (XName, 'Type', < Parm >) ;

Specifies a functional transform for specified *XName* variable.

Input Arguments

You must specify the following input arguments:

<i>XName</i>	is a character string that specifies the name of the X variable.
<i>'Type'</i>	takes a string value that specifies the functional transform to use. You can specify the following values:
BOXCOX	requests Box-Cox transformation. You can specify the control parameter for the transformation by using the optional <i>Parm</i> argument, whose value must be between -5 and 5. The default value of <i>Parm</i> is 1.
LOG	requests logarithmic transformation.
LOGIT LOGISTIC	requests logistic transformation.
NONE	does not apply a transformation.
SQRT	specifies square-root transformation.

The default is NONE.

You can also specify the following input argument:

<i>Parm</i>	takes a numeric value between -5 and 5 that specifies a control parameter. This parameter is allowed only for Box-Cox transformations. The default is 1.
-------------	--

ARIMASPEC.SetTransform Method

```
rc=obj.SetTransform ('Type' < ','Option',Parm>);
```

Specifies the functional transform '*Type*' to be used by the ARIMA model. Optional arguments *Option* and *Parm* offer greater control over the transform.

Input Arguments

You must specify the following input argument:

'Type'	takes a string value that specifies the functional transform to use. You can specify the following values:
BOXCOX	requests Box-Cox transformation. You can specify the control parameter for the transformation by using the optional <i>Parm</i> argument, whose value must be between -5 and 5 . The default value of <i>Parm</i> is 1 .
LOG	requests logarithmic transformation.
LOGIT LOGISTIC	requests logistic transformation.
NONE	does not apply a transformation.
SQRT	specifies square-root transformation.

The default is NONE.

You can also specify the following input arguments:

'Option'	takes a string value that specifies prediction semantics for the inverse transform. You can specify the following values:
MEAN	requests that the inverse transform produce mean forecasts.
MEDIAN	requests that the inverse transform produce median forecasts.
	The default is MEAN.
Parm	takes a numeric value between -5 and 5 that specifies a control parameter. This parameter is allowed only for Box-Cox transformations. The default is 1 .

EXMSPEC Object

The EXMSPEC object generates an external model (EXM) specification for use with the TSM object, or with the automatic time series modeling (ATSM) package for automatic forecasting services.

Table 32.9 summarizes the methods that are associated with the EXMSPEC object.

Table 32.9 Methods of the EXMSPEC Object

Method	Description
Close	Close EXM model specification
GetLabel	Retrieve label of specified EXM model
Open	Open EXM model specification
SetOption	Set options for EXM model specification
SetTransform	Set transform for EXM model specification

Figure 32.5 illustrates the data flow through the EXMSPEC object.

Figure 32.5 EXMSPEC Object Data Flow

The basic execution pattern for using an EXMSPEC object follows this sequence of operations:

- 1 Declare:** The object declaration statement creates a new EXMSPEC object.
- 2 Open:** The EXMSPEC.Open method readies the default EXMSPEC object for new configuration.
- 3 Configure:** The various EXMSPEC.Set methods configure the EXMSPEC object.
- 4 Close:** The EXMSPEC.Close method finalizes the EXMSPEC object.
- 5 Apply:** The EXMSPEC object is applied to a TSM object using the TSM.Initialize method or is used with the ATSM package. For more information about using the EXMSPEC object, see the section “[TSM Object](#)” on page 2346 or Chapter 2, “Automatic Time Series Modeling Package” (*SAS Visual Forecasting: Time Series Packages*).

NOTE:

1. You can also store the XML representation of the EXMSPEC object in an output table. For more information, see the section “[TSM Object](#)” on page 2410.
2. To run the EXMSPEC object in a TSM object, time series variables for the forecast series roles must be added to the TSM object via the TSM.AddExternal method. For more information, see the section “[TSM.AddExternal Method](#)” on page 2348.
3. To run the EXMSPEC object in an ATSM:FORENG object, time series variables for the forecast series roles must be added to the ATSM:TSDf object that is used to specify the time series data for the ATSM:FORENG object. When the EXMSPEC object is used with the ATSM package, more sophisticated persistence mechanisms are available. For more information, see Chapter 2, “Automatic Time Series Modeling Package” (*SAS Visual Forecasting: Time Series Packages*).

EXMSPEC Synopsis

DECLARE OBJECT *obj* (EXMSPEC) ;

Method syntax, in order of typical usage:

```
rc=obj.Open () ;
rc=obj.SetTransform ('Type' < ,Option,Parm>) ;
rc=obj.SetOption ('Name', Value < ,'Name',Value,... >) ;
rc=obj.GetLabel () ;
rc=obj.Close () ;
```

EXMSPEC Methods

EXMSPEC.Close Method

```
rc=obj.Close () ;
```

Finalizes the EXM model in the EXMSPEC object. This prepares the EXM model for use in a TSM object or to be imported to a TSMSPEC object for printing or storage in a model repository catalog.

Arguments

There are no arguments associated with this method.

EXMSPEC.GetLabel Method

```
rc=obj.GetLabel () ;
```

Retrieves the label of the specified EXM model and stores it in the return variable, *rc*.

Arguments

There are no arguments associated with this method.

EXMSPEC.Open Method

```
rc=obj.Open () ;
```

Initializes an EXMSPEC object for configuration.

Arguments

There are no arguments associated with this method.

EXMSPEC.SetOption Method

```
rc=obj.SetOption ('Name', Value < , 'Name', Value, ... >) ;
```

Specifies the options for the EXMSPEC object.

Input Arguments

You must specify at least one of the following '*Names*' and its associated *Value*:

'ERROR'	takes a string <i>Value</i> that specifies the variable name for ERROR series.
'LOWER'	takes a string <i>Value</i> that specifies the variable name for LOWER series.
'METHOD'	takes a string <i>Value</i> that specifies the method to approximate prediction STDERR series. You can specify one of the following values:
ACF	Autocorrelation is used.
ERRORACF	Prediction error autocorrelation is used.
NONE	No prediction error autocorrelation is used.
PERFECT	Perfect autocorrelation is assumed.

	WN	Prediction error autocorrelation is white noise.
		The default is PERFECT.
'NLAGPCT'		takes a numeric <i>Value</i> between 0 and 100 that specifies the percentage of error series count for ACF computations. The default is 25 (25%).
'NPARMS'		takes a nonnegative integer <i>Value</i> that specifies the number of parameters for the external forecast. The default is 0.
'PREDICT'		takes a string <i>Value</i> that specifies the variable name for PREDICT series.
'SIGMA'		takes a numeric <i>Value</i> that specifies the prediction standard error for the external model. If left unspecified, then the prediction mean square error is computed from the prediction errors by using the 'NPARMS' argument. The default is missing value.
'STDERR'		takes a string <i>Value</i> that specifies the variable name for STDERR series.
'UPPER'		takes a string <i>Value</i> that specifies the variable name for UPPER series.

EXMSPEC.SetTransform Method

rc=obj.SetTransform ('Type' < ,Option,Parm>) ;

Specifies the functional transform to be used by the EXM model.

Input Arguments

You must specify the following input argument:

'Type'	takes one of the following string values:
BOXCOX	requests Box-Cox transformation. You can specify the control parameter for the transformation by using the optional <i>Parm</i> argument, whose value must be between −5 and 5. The default value of <i>Parm</i> is 1.
LOG	requests logarithmic transformation.
LOGIT LOGISTIC	requests logistic transformation.
NONE	does not apply a transformation.
SQRT	requests square-root transformation.

The default is NONE.

You can also specify the following input arguments:

'Option'	takes one of the following string values that specifies prediction semantics for the inverse transform:
MEAN	requests that the inverse transform produce mean forecasts.
MEDIAN	requests that the inverse transform produce median forecasts.
	The default is MEAN.
<i>Parm</i>	takes a numeric value between −5 and 5 that specifies a control parameter. This parameter is allowed only for Box-Cox transformations. The default is 1.

IDMSPEC Object

The IDMSPEC object generates intermittent demand models for use with the TSM object. You open the IDMSPEC object to begin defining a new IDM model. You call the IDMSPEC methods to configure the object with the desired settings to define the model characteristics of interest, and then you close the IDMSPEC object to ready it for use in a TSM object. For more information, see the section “[TSM.Initialize Method](#)” on page 2352. You can also store the XML representation of the IDM in an output table. For more information, see the section “[TSMSPEC Object](#)” on page 2410.

[Table 32.10](#) the methods that are associated with the IDMSPEC object.

Table 32.10 Methods of the IDMSPEC Object

Method	Description
Close	Close IDM model specification
GetLabel	Retrieve label of specified IDM model
Open	Open IDM model specification
SetMethod	Set component smoothing method
SetOption	Set options for IDM model specification
SetParm	Set component parameters
SetTransform	Set component transform

[Figure 32.6](#) illustrates the data flow through the IDMSPEC object.

Figure 32.6 IDMSPEC Object Data Flow

IDMSPEC Synopsis

DECLARE OBJECT *obj* (IDMSPEC) ;

Method syntax, in order of typical usage:

```

rc=obj.Open () ;
rc=obj.SetOption ('Name', Value <,'Name',Value,... >) ;
rc=obj.SetTransform ('IDMComp', 'Type' <,'Option',Parm>) ;
rc=obj.SetMethod ('IDMComp', 'Method') ;
rc=obj.SetParm ('IDMComp', 'ESMComp' < , Parm, Noest, LRest, URest>) ;
rc=obj.GetLabel () ;
rc=obj.Close () ;
  
```

IDMSPEC Methods

IDMSPEC.Close Method

```
rc=obj.Close () ;
```

Finalizes the IDM model in the IDMSPEC object and prepares the IDM model for use in a TSM object or to be imported to a TSMSPEC object for printing or storage in a model repository catalog.

Arguments

There are no arguments associated with this method.

IDMSPEC.GetLabel Method

```
rc=obj.GetLabel () ;
```

Retrieves the label of the specified IDM model and stores it in the return variable, *rc*.

Arguments

There are no arguments associated with this method.

IDMSPEC.Open Method

```
rc=obj.Open () ;
```

Opens the IDMSPEC object for configuration and initializes it with default options. The default options specify that the best IDM model from among the average demand and Croston's model be selected based on the RMSE criterion (see the value BEST for the '**MODEL**' argument in the SetOption method). The smoothing model for the individual components of both models is selected from among the best candidate nonseasonal smoothing method (see value BESTN for the '*Method*' argument in the SetMethod method). In addition, by default, all component transformations are automatically chosen between NONE and LOG based on the model selection criterion (see the value AUTO for the '*Type*' argument in the SetTransform method).

Arguments

There are no arguments associated with this method.

IDMSPEC.SetMethod Method

```
rc=obj.SetMethod ('IDMComp', 'Method') ;
```

Sets a smoothing method for IDM model component.

Input Arguments

You must specify the following input arguments:

'IDMComp' is a character string that specifies the IDM component model. You can specify one of the following values:

AVERAGE specifies the average demand model.

INTERVAL specifies demand interval model.

SIZE specifies demand size model.

'Method' takes a string value that specifies the name of the smoothing method. You can specify one of the following values:

BESTN requests the best candidate nonseasonal smoothing model among the SIMPLE, LINEAR, or DAMPTREND methods.

DAMPTREND requests damped trend exponential smoothing.

LINEAR requests linear (Holt) exponential smoothing.

NONE disables the use of a smoothing model for the specified component.

SIMPLE requests simple (single) exponential smoothing.

The default is BESTN.

IDMSPEC.SetOption Method

```
rc=obj.SetOption ('Name', Value < , 'Name', Value, ... > ) ;
```

Specifies the options for the IDMSPEC object.

Input Arguments

You must specify at least one of the following *'Names'* and its associated *Value*:

'BASE' takes a numeric *Value* that specifies the base demand level. If you specify a missing value, the dependent series is analyzed to determine whether the base demand level can be set to one of the following values:

- 0
- the minimum value of the dependent series
- the maximum value of the dependent series
- the median value of the dependent series

First, the analysis determines whether the series is nearly constant by applying a threshold to the maximum (L_∞) norm of the nonmissing observations of the series. For nearly constant series, the base demand level is set to 0. Otherwise, analysis proceeds to compute the minimum, maximum, and median values of the series and assigns a score to each of those values. The score of a value in this context is the number of observations that are sufficiently close to that value. If the number of missing values in the dependent series is higher than the scores for the minimum, maximum, and median, then the base demand level is set to 0. If scores for the minimum, maximum, and median are identical, then the base demand level is set to 0. Otherwise, the base demand level is set to the value that has the highest score among the minimum, maximum, and median.

'CRITERION' takes a string *Value* that specifies the model selection criterion (statistic of fit) to be used to select from several candidate models. For a list of valid values, see the 'CRITERION' argument in the “[TSM.SetOption Method](#)” on page 2353. The default value is RMSE.

'MODEL' is a character string that specifies a mnemonic for the IDM model to use. You can specify the following *Values*:

- AVERAGE** uses the single smoothing model to fit the average demand component.
- BEST** requests the best IDM model from among the AVERAGE and CROSTON models.
- CROSTON** uses the two smoothing models to fit the demand interval component and the demand size component.

The default is BEST.

IDMSPEC.SetParm Method

```
rc=obj.SetParm ('IDMComp', 'ESMComp' < , Parm, Noest, LRest, URest>);
```

Sets parameter value and restrictions for the ESM component in the IDM component model. The ESM method-specific bounds are employed to limit or filter the smoothing method weight values.

Input Arguments

You must specify the following input arguments:

'IDMComp' is a character string that specifies the IDM component model. You can specify one of the following values:

- AVERAGE** specifies the average demand model.
- INTERVAL** specifies demand interval model.
- SIZE** specifies demand size model.

'ESMComp' is a character string that specifies the ESM component of the IDM component. You can specify one of the following values:

- DAMP** specifies that *Parm* is the initial value of a damping weight parameter.
- LEVEL** specifies that *Parm* is the initial value of a level weight parameter.
- TREND** specifies that *Parm* is the initial value of a trend weight parameter.

You can also specify the following input arguments:

- Parm* takes a numeric value that specifies the smoothing component weight.
- Noest* takes a Boolean value (0 or 1) that, when set to 1, specifies that the *Parm* argument is fixed. The default value is 0 (initial).
- LRest* takes a numeric value between –1 and 2 that specifies a lower bound restriction on the ESM weight. The default value of the level and trend weight parameters is 0.001. The default value of the damping weight parameter is 0.8.
- URest* takes a numeric value between –1 and 2 that specifies an upper bound restriction on the ESM weight. The default value is 0.999 for all smoothing weights.

IDMSPEC.SetTransform Method

```
rc=obj.SetTransform ('IDMComp', 'Type' <','Option',Parm>) ;
```

Sets the functional transform to be used by the IDM model component.

Input Arguments

You must specify the following input arguments:

'IDMComp' is a character string that specifies the IDM component model. You can specify one of the following values:

AVERAGE specifies the average demand model.

INTERVAL specifies demand interval model.

SIZE specifies demand size model.

'Type' takes a string value that specifies the transform to use. You can specify one of the following values:

AUTO automatically chooses between NONE and LOG based on model selection criteria.

BOXCOX requests Box-Cox transformation. You can specify the control parameter for the transformation by using the optional *Parm* argument, whose value must be between –5 and 5. The default value of *Parm* is 1.

LOG requests logarithmic transformation.

LOGIT | LOGISTIC requests logistic transformation.

NONE does not apply a transformation.

SQRT requests square-root transformation.

The default is AUTO.

You can also specify the following input arguments:

'Option' takes a string value that specifies prediction semantics for the inverse transform. You can specify the following values:

MEAN requests that the inverse transform produce mean forecasts.

MEDIAN requests that the inverse transform produce median forecasts.

The default is MEAN.

Parm takes a numeric value between –5 and 5 that specifies a control parameter. This parameter is allowed only for Box-Cox transformations. The default is 1.

RNNSPEC Object

The RNNSPEC object generates time series recurrent neural network (RNN) model specifications for use with a TSM object.

Table 32.11 summarizes the methods that are associated with the TSM.RNNSPEC method.

Table 32.11 Methods of the RNNSPEC Object

Method	Description
AddTF	Add a transfer function to the RNN model
Close	Close the RNN model specification
GetLabel	Retrieve the label of the specified RNN model
Open	Open the RNN model specification
SetOptimizer	Specify optimizer options
SetOption	Specify the RNN model options

The basic execution pattern for using an RNNSPEC object follows this sequence of operations:

- 1 Declare:** The object declaration statement creates a new RNNSPEC object.
- 2 Open:** The RNNSPEC.Open method prepares the default RNNSPEC object for a new configuration.
- 3 Configure:** The various RNNSPEC.Set methods configure the RNNSPEC object.
- 4 Close:** The RNNSPEC.Close method finalizes the RNNSPEC object.
- 5 Apply:** The TSM.Initialize method adds the RNNSPEC to a TSM object.

You can also store the XML representation of the RNN model in an output table. For more information, see the section “TSMSPEC Object” on page 2410. Figure 32.7 illustrates the data flow through the RNNSPEC object.

Figure 32.7 RNNSPEC Object Data Flow

RNNSPEC Synopsis

DECLARE OBJECT *obj* (RNNSPEC) ;

Method syntax, in order of typical usage:

```

rc=obj.Open () ;
rc=obj.AddTF (XName) ;
rc=obj.SetOption ('Name', Value <,'Name',Value,... >) ;
rc=obj.SetOptimizer ('Name', Value <,'Name',Value,... >) ;
rc=obj.GetLabel () ;
rc=obj.Close () ;
  
```

RNNSPEC Methods

RNNSPEC.AddTF Method

```
rc = obj.AddTF (XName) ;
```

This option adds a transfer function to the RNN model for the specified *XName* variable. Unlike the ARIMASPEC object, all other parameters except the variable name in AddTF are disabled. The RNNSPEC AddTF method provides a basic transfer function, which is described in the TNF package.

Input Arguments

You must specify the following input argument:

XName is a character string that specifies the name of the X variable.

RNNSPEC.Close Method

```
rc=obj.Close () ;
```

Finalizes the RNNSPEC object to prepare the RNN model to be used in a TSM object or to be imported to a TSMSPEC object for printing or for storage in a model repository.

Arguments

There are no arguments associated with this method.

RNNSPEC.GetLabel Method

```
rc=obj.GetLabel () ;
```

Retrieves the label of the specified RNN model and stores it in the return variable, *rc*.

Arguments

There are no arguments associated with this method.

RNNSPEC.Open Method

```
rc=obj.Open () ;
```

Initializes an empty RNNSPEC object for configuration.

Arguments

There are no arguments associated with this method.

RNNSPEC.SetOption Method

```
rc=obj.SetOption ('Name', Value < , 'Name', Value, ... > ) ;
```

Specifies RNN model options. Options are ('Name', Value) pairs, where 'Name' is a case-insensitive character string and Value depends on the 'Name'.

Input Arguments

You must specify at least one of the following 'Names' and its associated Value:

'BATCHSELECTION'	takes a string Value that specifies how to make a minibatch data set for training networks. You can specify one of the following values: RANDOM RAN selects the minibatch data set randomly. SEQUENCE SEQ selects the minibatch data set sequentially according to the order of observations in the training data. SHUFFLE SHUF selects the minibatch data set sequentially after shuffling the training data. The default is SHUFFLE.
'FCSTLOWERBOUND'	takes a numeric Value that specifies a lower bound for the forecast. Forecast values that are below the specified value are truncated to the Value. A missing value indicates that no lower-bound truncation should occur. The default is a missing value.
'FCSTUPPERBOUND'	takes a numeric Value that specifies an upper bound for the forecast. Forecast values that are above the specified value are truncated to the Value. A missing value indicates that no upper-bound truncation should occur. The default is a missing value.
'NINPUT'	takes a positive integer Value that specifies the length of input series for the network. It is the length of the sampled subsequence for the input layer. The default is 6.
'NLAYER'	takes a positive integer Value that specifies the number of neural network layers. The first layer is the input layer, and the last layer is the output layer. The default is 3, which means that the neural network has one hidden layer.
'NNEURONH'	takes a positive integer Value that specifies the number of neurons for each hidden node. The default is 10.
'NORMALIZE'	takes a string Value that specifies a normalization method for the input sequence and the target sequence. You can specify one of the following values: MIDRANGE uses the midrange normalization, which scales variables so that the midrange is 0 and the half-range is 1. The result is that variables have a minimum value of -1 and a maximum value of 1. NONE means that variables are not modified.

STD uses the normal standardization, which scales variables so that the mean is 0 and the standard deviation is 1.

The default is STD.

'NVALIDATION' takes a nonnegative integer *Value* that specifies the number of validation samples. The validation sample is used to validate models. The default is 0. When the value is set to 0, the training error is used for model validation.

'OUTPUTINITBIAS' takes a numeric *Value* that specifies the initial bias for the output layer. The default is 0.

'POSTTRAIN' takes a string *Value* that specifies whether the optimization will run on the validation samples after the training process ends. You can specify one of the following values:

NO means that the post-training process is not performed.

YES means that the post-training process is performed.

The default is YES if the size of the validation sample is greater than 0. Otherwise, the default is NO.

'RECURRENTINITBIAS' takes a numeric *Value* that specifies the initial bias for the recurrent layers. The default is 0.

'RNNTYPE' takes a string *Value* that specifies a recurrent network type for the hidden layers. You can specify one of the following values:

GRU uses the gated recurrent unit.

LSTM uses the long short-term memory unit.

RNN uses the original recurrent neural network.

The default is LSTM.

'SEED' takes a nonnegative integer *Value* that specifies the seed to generate random numbers for the optimization process and data shuffling of mini-batch selection. When the value is 0, the seed is generated by using the time of day from the computer's clock. The default is 12345.

'USEERRORACF' takes a string *Value* that specifies whether to use the autocorrelation (ACF) to calculate forecast standard errors for forecast confidence intervals.

NO means that the standard error of the h -step forecast is calculated by the residual standard deviation multiplied by the square root of h .

YES means that the standard error of the h -step forecast is calculated by the residual standard deviation multiplied by the square root of the cumulative ACF up to the h lag.

The default is YES.

'WEIGHTINIT'

takes a string *Value* that specifies the weight initialization function for the neurons in each hidden layer. You can specify one of the following values:

CAUCHY	initializes weights so that the median is 0 and the scale is 1.
NORMAL	initializes weights so that the mean is 0 and the standard deviation is 1.
UNIFORM	initializes weights so that the mean is 0 and the half-range is 1.
XAVIER	initializes weights according to the method of Glorot and Bengio (2010) for a normal distribution.

The default is XAVIER.

RNNSPEC.SetOptimizer Method

```
rc=obj.SetOptimizer ('Name', Value <,'Name',Value,... > ) ;
```

Specifies optimizer options for the RNNSPEC object.

Input Arguments

You must specify at least one of the following '*Names*' and its associated *Value*:

'ALGORITHM'

takes a string *Value* that specifies one of the following stochastic gradient descent (SGD) optimization algorithms:

ADAM	uses adaptive moment estimation, which computes adaptive learning rates for each parameter.
MOMENTUM	uses an exponential smoothing model to accelerate SGD in the relevant direction and to dampen oscillation.
VANILLA	uses the plain stochastic gradient descent method.

The default is ADAM.

'BETA1'

takes a positive numeric *Value* that specifies the exponential decay rate for the first moment in the Adam learning algorithm. The value should be between 0 (inclusive) and 1 (exclusive). The default is 0.9.

'BETA2'

takes a positive numeric *Value* that specifies the exponential decay rate for the second moment in the Adam learning algorithm. The value should be between 0 (inclusive) and 1 (exclusive). The default is 0.999.

'CLIPGRADMAX'

takes a positive numeric *Value* that specifies the maximum gradient value. All gradient values that exceed the specified maximum value are set to the specified maximum value. The default is 1,000. When you specify the missing value, it means that there is no restriction on the gradient values.

'CLIPGRADMIN'	takes a negative numeric <i>Value</i> that specifies the minimum gradient value. All gradient values that are less than the specified minimum value are set to the specified minimum value. The default is -1,000. When you specify the missing value, it means that there is no restriction on the gradient values.
'DROPOUT'	takes a numeric <i>Value</i> that specifies the probability that the output of a neuron in a fully connected layer will be set to 0 during training. The specified probability is recalculated each time an observation is processed. The value should be between 0 (inclusive) and 1 (exclusive). The default is 0.
'DROPOUTINPUT'	takes a numeric <i>Value</i> that specifies the probability that an input variable will be set to 0 during training. The specified probability is recalculated each time an observation is processed. The value should be between 0 (inclusive) and 1 (exclusive). The default is 0.
'DROPOUTTYPE'	takes a string <i>Value</i> that specifies one of the following dropout types: INVERTED uses the inverted dropout. STANDARD uses the standard dropout. The default is STANDARD.
'EPSILON'	takes a positive numeric <i>Value</i> that specifies a very small number to prevent any division by zero in the Adam learning algorithm. The default is 1E-08.
'GAMMA'	takes a positive numeric <i>Value</i> that specifies the gamma parameter for the learning rate policy. The value should be between 0 and 1, inclusive. The default is 0.1.
'LEARNINGPOLICY'	takes a string <i>Value</i> that specifies one of the following learning rate policies: FIXED specifies a fixed learning rate. INV sets the learning rate parameter value after each epoch, according to the initial learning rate, the value of the gamma parameter, and the value of the power parameter. The rate is calculated as $\text{LEARNINGRATE} * (1 + \text{GAMMA} * \text{currentEpoch})^{-\text{POWER}}$ POLY sets the learning rate parameter value after each epoch, according to the initial learning rate, the maximum number of epochs, and the value of the power parameter. The rate is calculated as $\text{LEARNINGRATE} * \left(1 - \frac{\text{currentEpoch}}{\text{MAXEPOCHS}}\right)^{-\text{POWER}}$ STEP sets the learning rate parameter by multiplying the current learning rate value by the gamma parameter value. The

number of steps is specified in the `stepSize` parameter. The learning rate is recalculated for each group of epochs according to the step size. The rate is calculated as

$$\text{LEARNINGRATE} * \text{GAMMA}$$

The default is `FIXED`.

'LEARNINGRATE'	takes a positive numeric <i>Value</i> that specifies the learning rate for stochastic gradient descent. The default is 0.001.
'MAXEPOCHS'	takes a positive integer <i>Value</i> that specifies the maximum number of epochs. The default is 100.
'MINIBATCHSIZE'	takes a positive integer <i>Value</i> that specifies the number of observations per thread in a minibatch. The default is 1.
'MOMENTUM'	takes a numeric <i>Value</i> that specifies the momentum parameter value for stochastic gradient descent. The value should be between 0 and 1, inclusive. The default is 0.9.
'NMINIBATCH'	takes a positive integer <i>Value</i> that specifies the maximum number of minibatch sets. The default is the maximum number of 64-bit signed integers.
'POWER'	takes a nonnegative numeric <i>Value</i> that specifies the power for the learning rate policy. The default is 0.75.
'REGL1'	takes a nonnegative numeric <i>Value</i> that specifies the weight for the L1 regularization term. The default is 0, which means that the L1 regularization is not performed. It is suggested that the weight parameter begin with a small value, such as 1E-6. L1 regularization can be combined with L2 regularization.
'REGL2'	takes a nonnegative numeric <i>Value</i> that specifies the weight for the L2 regularization term. The default is 0, which means that the L2 regularization is not performed. It is suggested that the weight parameter begin with a small value, such as 1E-3. L2 regularization can be combined with L1 regularization.
'STAGNATION'	takes a nonnegative integer <i>Value</i> that specifies the number of successive training errors when a validation set is not given or the number of successive validation errors without improvement that will cause early termination. The default is 20. A value of 0 means that no stagnation early stopping is applied.
'STEPSIZE'	takes a positive integer <i>Value</i> that specifies the step size when the learning rate policy is set to <code>STEP</code> . The default is 10.
'THRESHOLD'	takes a nonnegative numeric value that specifies the threshold that is used to determine whether the validation score is improving or stagnating. When

$$\text{abs}(\text{currentScore} - \text{previousScore}) \leq \text{abs}(\text{currentScore}) * \text{THRESHOLD}$$

the current iteration does not improve the optimization and the stagnation counter is incremented. Otherwise, the stagnation counter is set to 0. When a validation (holdout) data set is not available, the training score is used. The default value is 1E-08, and the minimum value is 0.

'WARMUPEPOCHS'

takes a nonnegative integer *Value* that specifies the number of epochs for the learning rate warmup. The number should not exceed the maximum number of epochs. The default is 0, which means that there is no warmup.

UCMSPEC Object

The unobserved component model (UCM) specification object generates UCM models for use with the TSM object. You open the UCMSPEC object to begin defining a new UCM model. You call the UCMSPEC methods to define the model characteristics, and then you close the UCMSPEC object to ready it for use in a TSM object. For more information, see the section “[TSM.Initialize Method](#)” on page 2352. You can also store the XML representation of the UCM in an output table. For more information, see the section “[TSMSPEC Object](#)” on page 2410. Note that the UCMSPEC object is equivalent to the HPFUCMSPEC procedure in *SAS Forecast Server Procedures: User’s Guide*.

Table 32.12 lists the methods that are associated with the UCMSPEC object.

Table 32.12 Methods of the UCMSPEC Object

Method	Description
AddAutoreg	Add an autoregressive component to a UCM model
AddBlockSeason	Add a block-season component to a UCM model
AddComponent	Add a fundamental component to a UCM model
AddCycle	Add a cycle component to a UCM model
AddDeplag	Add a deplag component to a UCM model
AddInput	Add an input component to a UCM model
AddSeason	Add a seasonal component to a UCM model
Close	Close the UCM model specification
GetLabel	Retrieve the label of the specified UCM model
Open	Open the UCM model specification
SetTransform	Specify the transform

Figure 32.8 illustrates the data flow through the UCMSPEC object.

Figure 32.8 UCMSPEC Object Data Flow

UCMSPEC Synopsis

DECLARE OBJECT *obj* (UCMSPEC) ;

Method syntax, in order of typical usage:

```

rc=obj.Open () ;
rc=obj.AddAutoreg (< Rho, NoestRho, Variance, Noest>) ;
rc=obj.AddBlockSeason (BlockSize, NBlocks, <'Type', Offset, Variance, Noest>) ;
rc=obj.AddComponent (Comp, < Variance, Noest>) ;
rc=obj.AddCycle (< Period, NoestPeriod, Rho, NoestRho, Variance, Noest>) ;
rc=obj.AddDeplag (LagArray, < NLag, CoeffArray, Noest>) ;
rc=obj.AddInput (XName, < Delay, DiffArray, NDiff, Transform, TransParm>) ;
rc=obj.AddSeason (Length, <'Type', Variance, Noest>) ;
rc=obj.SetTransform (XName, < Delay, DiffArray, NDiff, 'Type', TransParm>) ;
rc=obj.GetLabel () ;
rc=obj.Close () ;

```

UCMSPEC Methods

UCMSPEC.AddAutoreg Method

`rc=obj.AddAutoreg (< Rho, NoestRho, Variance, Noest>) ;`

Adds an autoregressive component to a UCM model specification. You can add at most one autoregressive component to a UCM model specification.

Input Arguments

You can specify the following input arguments:

<i>Rho</i>	takes a numeric value that specifies the starting value for the AR(1) coefficient during the parameter estimation process. The value of <i>Rho</i> must be in the interval $[-1, 1)$, which includes -1 but excludes 1 . The default is a missing value.
<i>NoestRho</i>	takes a Boolean value that specifies whether the AR(1) coefficient is to be estimated (0) or fixed (1) at the specified starting value. If the value of <i>NoestRho</i> is 1, you must specify a valid nonmissing <i>Rho</i> value. The default value is 0.
<i>Variance</i>	specifies an initial value for the disturbance variance during the parameter estimation process. If you specify this argument, then any nonnegative value, including 0, is acceptable. If you omit this argument or specify a missing value, then the estimation process computes a reasonable initial value.
<i>Noest</i>	takes a Boolean value that specifies whether the variance of the AR(1) noise process is to be estimated (0) or fixed (1). If the value of <i>Noest</i> is 1, you must specify a valid nonmissing <i>Variance</i> value. The default value is 0.

UCMSPEC.AddBlockSeason Method

`rc=obj.AddBlockSeason (BlockSize, NBlocks, <'Type', Offset, Variance, Noest>) ;`

Adds a block-season component to a UCM model specification. You can use this method repeatedly to add more block-season components to a UCM model specification.

Input Arguments

You must specify the following input arguments:

<i>BlockSize</i>	takes a numeric value that specifies the block size, where the value of <i>BlockSize</i> can be any integer greater than or equal to 2. Typical examples of block sizes are 24 (which corresponds to the hours of the day when a day is used as a block in hourly data) or 60 (which corresponds to the minutes in an hour when an hour is used as a block in data that are recorded by minutes).
<i>NBlocks</i>	takes a numeric value that specifies the number of blocks, where the value of <i>NBlocks</i> can be any integer greater than or equal to 2.

You can also specify the following input arguments:

'Type'	is a character string that specifies the type of the seasonal component. You can specify one of the following values: DUMMY specifies a dummy-type seasonal component. TRIG specifies a trigonometric seasonal component. The default is DUMMY.
Offset	takes a numeric value that specifies the offset (the position of the first measurement within the block, if the first measurement is not at the start of a block). The <i>Offset</i> value must be an integer between 1 and <i>BlockSize</i> . The default value is 1.
Variance	specifies an initial value for the disturbance variance during the parameter estimation process. If you specify this argument, then any nonnegative value, including 0, is acceptable. If you omit this argument or specify a missing value, then the estimation process computes a reasonable initial value.
Noest	takes a Boolean value that specifies whether the disturbance variance is to be estimated (0) or fixed (1). If the value of <i>Noest</i> is 1, you must specify a valid nonmissing <i>Variance</i> value. The default value is 0.

UCMSPEC.AddComponent Method

rc=obj.AddComponent (Comp, < Variance, Noest>);

Adds a fundamental component (such as LEVEL, SLOPE, or IRREGULAR) to a UCM model specification. This method must be called separately to add each of these fundamental components. A UCM model specification cannot contain more than one instance of these fundamental components.

Input Arguments

You must specify the following input argument:

Comp	is a character string that specifies the UCM component model. You can specify one of the following values: IRREGULAR includes an irregular component in the model that corresponds to the overall random error in the model. LEVEL includes a level component in the model. The level component, either by itself or together with a slope component, forms the trend component. If the slope component is absent, the resulting trend is a random walk (RW). If the slope component is present, then a locally linear trend (LLT) is obtained. SLOPE includes a slope component in the model. If you specify this value, you must call the method again with the value LEVEL for the <i>Comp</i> argument.
-------------	---

You can also specify the following input arguments:

Variance	specifies an initial value for the disturbance variance during the parameter estimation process. If you specify this argument, then any nonnegative value, including 0, is acceptable. If you omit this argument or specify a missing value, then the estimation process computes a reasonable initial value.
-----------------	---

Noest takes a Boolean value that specifies whether the disturbance variance is to be estimated (0) or fixed (1). If the value of *Noest* is 1, you must specify a valid nonmissing *Variance* value. The default value is 0.

UCMSPEC.AddCycle Method

rc=obj.AddCycle (< *Period*, *NoestPeriod*, *Rho*, *NoestRho*, *Variance*, *Noest*>) ;

Adds a cycle component to a UCM model specification. You can add multiple cycle components to a UCM model specification.

Input Arguments

You can specify the following input arguments:

Period specifies a numeric value as a starting value for the cycle period during the parameter estimation process, where the value of *Period* can be any number greater than 2. The default is a missing value.

NoestPeriod takes a Boolean value that specifies whether the cycle period is to be estimated (0) or fixed (1) at the specified starting value. If the value of *NoestPeriod* is 1, you must specify a valid nonmissing *Period* value. The default value is 0.

Rho takes a numeric value that specifies the starting value for the AR(1) coefficient during the parameter estimation process. The value of *Rho* must be in the interval (0, 1], which includes 1 but excludes 0. The default is a missing value.

NoestRho takes a Boolean value that specifies whether the AR(1) coefficient is to be estimated (0) or fixed (1) at the specified starting value. If the value of *NoestRho* is 1, you must specify a valid nonmissing *Rho* value. The default value is 0.

Variance specifies an initial value for the disturbance variance during the parameter estimation process. If you specify this argument, then any nonnegative value, including 0, is acceptable. If you omit this argument or specify a missing value, then the estimation process computes a reasonable initial value.

Noest takes a Boolean value that specifies whether the disturbance variance is to be estimated (0) or fixed (1). If the value of *Noest* is 1, you must specify a valid nonmissing *Variance* value. The default value is 0.

UCMSPEC.AddDeplag Method

rc=obj.AddDeplag (*LagArray*, < *NLag*, *CoeffArray*, *Noest*>) ;

Adds the lags of the dependent variable as predictors in the UCM specification.

Input Arguments

You must specify the following input argument:

LagArray specifies an integer array that defines a factor of lags of the dependent variable to be included in the deplag component of the UCM specification. The array must contain lags in ascending order.

You can also specify the following input arguments:

<i>NLag</i>	takes an integer that specifies the number of <i>LagArray</i> values to use. The default is all <i>LagArray</i> values.
<i>CoeffArray</i>	is a numeric array that specifies initial coefficients for the lagged dependent variables. This array must include initial values for all lag coefficients. The range of values of the lag coefficients are not constrained to lie in any region. If you specify this argument in the first invocation of the UCMSPEC.AddDeplag method, then you must also specify it in all subsequent invocations of the method. That is, you must either specify initial values for all lag coefficients across all factors of lags or specify initial values for none. By default, the estimation process computes a reasonable initial value for all coefficients.
<i>Noest</i>	takes a Boolean value that specifies whether lag coefficients are to be estimated (0) or fixed (1). The value of <i>Noest</i> must match across all subsequent invocations of the UCMSPEC.AddDeplag method. That is, lag coefficients across all factors of lags are either fixed or estimated from the data. If the value of <i>Noest</i> is 1, then the lag coefficients are fixed to the values that you specify in <i>CoeffArray</i> . Therefore, in this case, you must also specify the <i>CoeffArray</i> argument in all subsequent invocations of the UCMSPEC.AddDeplag method. The default value of <i>Noest</i> is 0.

Details

You can specify the lags of the dependent variable in the UCM specification as a set of polynomial factors. One call to the UCMSPEC.AddDeplag method adds one such polynomial factor. For each polynomial, you can specify the lags to include in the *LagArray* list. Each lag corresponds to the exponent of a backward shift operator that is included as an additive term in the corresponding polynomial factor. When the corresponding UCM is fitted, the polynomial factors of all UCMSPEC.AddDeplag calls are expanded, and the terms of the resulting polynomial correspond to lags of the dependent variable that are added as predictors to the fitted UCM.

This is best illustrated by an example. The following statements add to the UCM specification the simplest polynomial factor that includes only the first lag of the dependent variable as a predictor in the fitted model:

```
/* Create an instance of the UCM specification object */
DECLARE OBJECT obj(UCMSPEC);

/* Initialize an empty UCM specification */
rc = obj.open();

/* A UCM specification must have at least one stochastic component */
rc = obj.AddComponent('IRREGULAR');

/* Specify a polynomial factor that includes a single lag of */
/* the dependent variable as a predictor in the fitted UCM */
ARRAY lags1[1] / NOSYMBOLS;
lags1[1] = 1;

/* Specify the lag coefficient */
ARRAY coeff1[1] / NOSYMBOLS;
coeff1[1] = 0.1;

/* Add a new polynomial factor to the UCM specification */
rc = obj.AddDeplag(lags1, 1, coeff1, 1);
```

In particular, the preceding statements specify that the polynomial $(1 - \phi_{1,1}B)$ be included in the UCM specification and that the coefficient of the first lag in this polynomial (that is, $\phi_{1,1}$) be fixed at 0.1. Also, because the value of the *Noest* argument is 1, all subsequent calls to the UCMSPEC.AddDeplag method must also specify the value of *Noest* as 1 and supply lag coefficients in the *CoeffArray* argument. You can submit the following code to add more factors to the polynomial:

```
/* Specify a polynomial factor that includes three lags of */
/* the dependent variable as predictors in the fitted UCM */
ARRAY lags2[3] / NOSYMBOLS;
lags2[1] = 2;
lags2[2] = 12;
lags2[3] = 18;

/* Specify the coefficients for lags 2, 12, and 18 */
ARRAY coeff2[3] / NOSYMBOLS;
coeff2[1] = 0.3;
coeff2[2] = -1.2;
coeff2[3] = 0.7;

/* Specify a polynomial factor that includes two lags of */
/* the dependent variable as predictors in the fitted UCM */
ARRAY lags3[2] / NOSYMBOLS;
lags3[1] = 4;
lags3[2] = 24;

/* Specify the coefficients for lags 4 and 24 */
ARRAY coeff3[2] / NOSYMBOLS;
coeff3[1] = 0.2;
coeff3[2] = 0.5;

/* Add two more polynomial factors to the UCM specification */
rc = obj.AddDeplag(lags2, 3, coeff2, 1);
rc = obj.AddDeplag(lags3, 2, coeff3, 1);

/* Finalize the UCM specification (prepare it to be fitted) */
rc = obj.close();
```

The preceding statements, when you combine them with the first UCMSPEC.AddDeplag method call, specify that the polynomial $(1 - \phi_{1,1}B)(1 - \phi_{2,1}B^2 - \phi_{2,2}B^{12} - \phi_{2,3}B^{18})(1 - \phi_{3,1}B^4 - \phi_{3,2}B^{24})$ be included in the UCM specification. In addition, the statements specify that the coefficients of the 2nd, 4th, 12th, 18th, and 24th lags in this polynomial be fixed at 0.3, 0.2, -1.2, 0.7, and 0.5, respectively.

You can replace the last call to the UCMSPEC.AddDeplag method with the following statement in order to include only the first element of the lags3 array in the polynomial factor (that is, the 4th lag) and to specify that its coefficient be fixed at 0.2 and not be estimated:

```
rc = obj.AddDeplag(lags3, 1, coeff3, 1);
```

If you want to estimate the lag coefficient values from the data rather than specifying fixed ones, you can just specify the *LagArray* argument and replace all previous UCMSPEC.AddDeplag calls with the following:

```
rc = obj.AddDeplag(lags1);
rc = obj.AddDeplag(lags2);
rc = obj.AddDeplag(lags3);
```

For more information about the structure of the deplag component of a UCM specification, see the DEPLAG statement of PROC HPFUCMSPEC in *SAS Forecast Server Procedures: User's Guide*.

UCMSPEC.AddInput Method

```
rc=obj.AddInput (XName, < Delay, DiffArray, NDiff, Transform, TransParm>);
```

Adds an input (predictor variable) to a UCM model specification. You can add multiple inputs to a UCM model specification.

If you use the UCM specification to initialize a Time Series Model (TSM) object, then for each input that you add by using this AddInput method, you must also add that input to the TSM object by using the TSM.AddX method. Otherwise, the TSM object's model preparation fails when you run the TSM object.

Input Arguments

You must specify the following input argument:

XName is a character variable that specifies the name of the X-variable symbol.

You can also specify the following input arguments:

Delay takes a nonnegative integer value that specifies the lag of the X-variable in the model. If not specified, the *Delay* is 0.

DiffArray is numeric array of nonnegative integers that specifies differencing orders for the X-variable. If not specified, no differencing is applied to the predictor series.

NDiff takes a numeric variable that specifies the number of *DiffArray* values to use. If not specified, the cardinality of *DiffArray* is used.

Transform is character variable that specifies the name of a functional transform. You can specify one of the following values:

BOXCOX requests Box-Cox transformation. You can specify the control parameter for the transformation by using the optional *TransParm* argument, whose value must be between –5 and 5. The default value of *TransParm* is 1.

LOG requests logarithmic transformation.

LOGIT | LOGISTIC requests logistic transformation.

NONE does not apply a transformation.

SQRT requests square-root transformation.

The default is NONE.

TransParm takes a numeric value between –5 and 5 that specifies a transform parameter. This parameter is allowed only for Box-Cox transformations. The default is 1.

UCMSPEC.AddSeason Method

```
rc=obj.AddSeason (Length, <'Type', Variance, Noest>) ;
```

Adds a seasonal component to a UCM model specification. You can add multiple seasonal component to a UCM model specification.

Input Arguments

You must specify the following input argument:

Length is a numeric variable that specifies the length of a seasonal cycle.

You can also specify the following input arguments:

'Type' is a character string that specifies the type of the seasonal component. You can specify one of the following values:

DUMMY specifies a dummy type seasonal component.

TRIG specifies a trigonometric seasonal component.

The default is DUMMY.

Variance specifies an initial value for the disturbance variance during the parameter estimation process. If you specify this argument, then any nonnegative value, including 0, is acceptable. If you omit this argument or specify a missing value, then the estimation process computes a reasonable initial value.

Noest takes a Boolean value that specifies whether the disturbance variance is to be estimated (0) or fixed (1). If the value of *Noest* is 1, you must specify a valid nonmissing *Variance* value. The default value is 0.

UCMSPEC.Close Method

```
rc=obj.Close () ;
```

Finalizes the UCM model in the UCMSPEC object. This method prepares the UCM model for use in a TSM object or to be imported to a TSMSPEC object for printing or storage in a model repository catalog.

Arguments

There are no arguments associated with this method.

UCMSPEC.GetLabel Method

```
rc=obj.GetLabel () ;
```

Retrieves the label of the specified UCM model and stores it in the return variable, *rc*.

Arguments

There are no arguments associated with this method.

UCMSPEC.Open Method

```
rc=obj.Open () ;
```

Opens the UCMSPEC object for configuration. This method initializes an empty UCM model.

Arguments

There are no arguments associated with this method.

UCMSPEC.SetTransform Method

```
rc=obj.SetTransform ('Type' <','Option',Parm>) ;
```

Specifies the functional transform to be used by the UCM model.

Input Arguments

You must specify the following input argument:

'Type'	takes a string value that specifies the transform to use. You can specify one of the following values:
BOXCOX	requests Box-Cox transformation. You can specify the control parameter for the transformation by using the optional <i>Parm</i> argument, whose value must be between -5 and 5 . The default value of <i>Parm</i> is 1 .
LOG	requests logarithmic transformation.
LOGIT LOGISTIC	requests logistic transformation.
NONE	does not apply a transformation.
SQRT	requests square-root transformation.
The default is NONE.	
'Option'	takes a string value that specifies prediction semantics for the inverse transform. You can specify the following values:
MEAN	requests that the inverse transform produce mean forecasts.
MEDIAN	requests that the inverse transform produce median forecasts.
The default is MEAN.	
<i>Parm</i>	takes a numeric value between -5 and 5 that specifies a control parameter. This parameter is allowed only for Box-Cox transformations. The default is 1 .

TSMPEST Object

The time series model parameter estimates (TSMPEST) collector object collects parameter estimates from a TSM object and stores them in an output table for printing or archiving or for use by a repeater object on another TSM object.

Table 32.13 summarizes the methods that are associated with the TSMPEST object.

Table 32.13 Methods of the TSMPEST Object

Method	Description
Collect	Collect parameter estimates from TSM objects
nrows	Return the number of rows that are collected
SetOption	Set options for the TSMPEST collector object

Figure 32.9 illustrates the data flow through the TSMPEST object.

Figure 32.9 TSMPEST Object Data Flow

TSMPEST Synopsis

DECLARE OBJECT *obj* (TSMPEST) ;

Method syntax, in order of typical usage:

```
rc=obj.SetOption ('Name', Value < , 'Name', Value, ... >) ;
rc=obj.Collect (TSMObj) ;
nrows=obj.nrows () ;
```

TSMPEST Methods

TSMPEST.Collect Method

```
rc=obj.Collect (TSMObj) ;
```

Collects time series model parameter estimates from a TSM object, *TSMObj*, and stores them in an output table.

Input Arguments

You must specify the following input argument:

TSMObj specifies the TSM object to use as the source of time series model parameter estimates.

TSMPEST.nrows Method

```
nrows=obj.nrows () ;
```

Returns the number of rows that have been collected and stored in the table.

Arguments

There are no arguments associated with this method.

TSMPEST.SetOption Method

```
rc=obj.SetOption ('Name', Value < , 'Name', Value, ... >) ;
```

Specifies the options for the TSMPEST object.

Input Arguments

You must specify at least one of the following '*Names*' and its associated '*Value*':

- | | |
|-------------------------|---|
| 'MODELNAME' | takes a string <i>Value</i> that specifies the name of the model to be stored in the output table along with the parameter estimates of the model. By default, the model name is the name of the TSM object instance that is collected by the TSMPEST.Collect method. |
| 'FORCEMODELNAME' | takes a Boolean <i>Value</i> that specifies whether the model name should be stored in the output table even when the model failed to run. You can specify one of the following values: |

DISABLE|NO|N|FALSE|F|OFF does not store the model name in the output table if the model failed to run.

ENABLE|YES|Y|TRUE|T|ON always stores the model in the table.

The default is DISABLE.

TSMSPEC Object

The time series model specification (TSMSPEC) collector object collects the model specification from a TSM object, *TSMObj*, and stores it in an output table for printing or archiving or for use by a repeater object on another TSM object.

Table 32.14 summarizes the methods that are associated with the TSMSPEC object.

Table 32.14 Methods of the TSMSPEC Object

Method	Description
Collect	Collect model specification from TSM objects
nrows	Return the number of rows that are collected

Figure 32.10 illustrates the data flow through the TSMSPEC object.

Figure 32.10 TSMSPEC Object Data Flow

TSMSPEC Synopsis

DECLARE OBJECT *obj* (TSMSPEC) ;

Method syntax, in order of typical usage:

```
rc=obj.Collect (TSMObj) ;
nrows=obj.nrows () ;
```

TSMSPEC Methods

TSMSPEC.Collect Method

```
rc=obj.Collect (TSMObj) ;
```

Collects time series model specifications from a TSM object, *TSMObj*, and stores them in an output table.

Input Arguments

You must specify the following input argument:

TSMObj specifies the TSM object to use as the source of time series model parameter estimates.

TSMSPEC.nrows Method

```
nrows=obj.nrows () ;
```

Returns the number of rows that have been collected and stored in the table.

Arguments

There are no arguments associated with this method.

TSMFOR Object

The TSMFOR object collects forecast series from a TSM object, *TSMObj*, and stores them in an output table. The table schema that is used for storing the set of forecast series variables is compatible with the schema that the HPFENGINE procedure uses for the data set that is specified in the TSMFOR= option. Alternatively, the TSMFOR object can be configured to collect from a TSM object the smoothed (imputed) values for the dependent series and their associated standard errors and confidence limits.

Table 32.15 shows the contents of the TSMFOR object.

Table 32.15 Contents of the TSMFOR Object

Column	Type	Description
NAME	String	Name of the dependent variable
MODEL	String	(Optional) Model name
TIMEID	Numeric	Uniform time ID values for series
ACTUAL	Numeric	Accumulated values of dependent variable
ERROR	Numeric	Residuals
LOWER	Numeric	Lower confidence limit
PREDICT	Numeric	Forecasts of the dependent variable
STD	Numeric	Prediction standard error
UPPER	Numeric	Upper confidence limit

Table 32.16 summarizes the methods that are associated with the TSMFOR object.

Table 32.16 Methods of the TSMFOR Object

Method	Description
Collect	Collect forecasts estimates from the TSM object
nrows	Return the number of rows collected
SetOption	Specifies options for the TSMFOR instance

Figure 32.11 illustrates the data flow through the TSMFOR object.

Figure 32.11 TSMFOR Object Data Flow

TSMFOR Synopsis

DECLARE OBJECT *obj* (TSMFOR <('Name', Value)>) ;

Method syntax, in order of typical usage:

```

rc=obj.SetOption (Name, Value) ;
rc=obj.Collect (ModelObj <,Region>) ;
rc=obj.nrows () ;

```

Input Arguments

You can optionally specify one or more of the following '*Names*' and its associated *Value*:

'MODELNAME' takes a string *Value* that specifies whether to add a model name column to the output table. The default model name is the TSM instance name. You can override the default model name via the 'MODELNAME' option of the [SetOption](#) method. You can specify one of the following *Values*:

YES	includes a model name column in the output table.
NO	does not include a model name column in the output table.

The default is NO.

'SMOOTH'	takes a string <i>Value</i> that specifies whether to output the smoothed (imputed) dependent series values and their associated standard errors and confidence limits. If you set this option to 'YES', the PREDICT column holds the values of the smoothed dependent series instead of the forecast series. You can specify one of the following <i>Values</i> :
YES	stores the smoothed dependent series and its associated statistics from a TSM instance in an output table.
NO	stores the forecast series and its associated statistics from a TSM instance in an output table.

The default is NO.

TSMFOR Methods

TSMFOR.Collect Method

```
rc=obj.Collect (ModelObj< ,Region> ) ;
```

Collects the forecast series from a TSM object, *ModelObj*. An optional *Region* argument can be specified to indicate the forecast region to be collected. If you specify the 'SMOOTH' option in the declaration of the TSMFOR instance, then the smoothed (imputed) dependent series is collected instead.

Input Arguments

You must specify the following input argument:

<i>ModelObj</i>	is a character string that specifies the name of the TSM object to use as the source of time series model forecasts.
-----------------	--

You can also specify the following input argument:

<i>Region</i>	specifies the time region over which to collect the forecast series. You can specify the following values for <i>Region</i> :
<i>string</i>	specifies the collection region. You can specify the following <i>strings</i> :
ALL	collects over the entire time span of the available data.
FIT	collects over the time region that supplied observations to estimate model parameters (that is, the model fit region).
FORECAST	collects over the time region that is subsequent to the FIT region and that did not contribute any data to the model parameter estimation process (that is, the model forecast region).

The default is ALL.

numeric is a two-valued numeric array, in which the first value specifies the starting time ID and the second value specifies the ending time ID of the time region over which the forecast series are to be collected. Either the starting time ID or the ending time ID can be a missing value. If both are missing values, then the default value ALL is used.

TSMFOR.nrows Method

```
rc=obj.nrows () ;
```

Returns the number of rows that have been collected and stored in the table.

Arguments

There are no arguments associated with this method.

TSMFOR.SetOption Method

```
rc=obj.SetOption ('Name', Value) ;
```

Specifies the named options for the TSMFOR instance.

Input Arguments

You must specify the following *'Name'* and its associated *Value*:

'MODELNAME' takes a string *Value* that is copied to the `_MODEL_` column of the output table. This option is relevant only if you set the 'MODELNAME' option to 'YES' in the declaration of the TSMFOR instance. The default value is the TSM instance name.

TSMSTAT Object

The TSMSTAT object collects model statistics of fit from a TSM object, *TSMObj*, and stores them in an output table. This information is useful for evaluating how well the model fits the dependent series. For more information about forecast fit statistics, see the section “Statistics of Fit” in Chapter 17, “Forecasting Details” (*SAS Visual Forecasting: Time Series Packages*).

Table 32.17 shows the contents of the TSMSTAT object.

Table 32.17 Contents of the TSMSTAT Object

Column	Type	Description
NAME	String	Name of the dependent variable
REGION	String	Region in which the fit statistics are calculated. You can specify the following values: FIT indicates that fit statistics were calculated over the fit region. FORECAST indicates that fit statistics were calculated over the forecast (back) region. HOLDOUT indicates that fit statistics were calculated over the holdout region.
MODEL	String	Model name
AADJRSQ	Numeric	Amemiya's adjusted R-square
ADJRSQ	Numeric	Adjusted R-square
AIC	Numeric	Akaike's information criterion
AICC	Numeric	Finite sample corrected AIC
APC	Numeric	Amemiya's prediction criterion
DFE	Numeric	Degrees of freedom error
GMAPE	Numeric	Geometric mean absolute percentage error
GMAPES	Numeric	Geometric mean absolute error as a percentage of standard deviation
GMAPPE	Numeric	Geometric mean absolute predictive percentage error
GMRAE	Numeric	Geometric mean relative absolute error
GMASPE	Numeric	Geometric mean absolute symmetric percentage error
IMASE	Numeric	In-sample mean absolute scaled error
MAE	Numeric	Mean absolute error
MAPE	Numeric	Mean absolute percentage error
MAPES	Numeric	Mean absolute error as a percentage of standard deviation
MAPPE	Numeric	Mean absolute predictive percentage error
MASE	Numeric	Mean absolute scaled error
MAXAPES	Numeric	Maximum absolute error as a percentage of standard deviation
MAXERR	Numeric	Maximum error

Table 32.17 *continued*

Column	Type	Description
MAXPE	Numeric	Maximum percentage error
MAXPPE	Numeric	Maximum predictive percentage error
MAXRE	Numeric	Maximum relative error
MAXSPE	Numeric	Maximum symmetric percentage error
MDAPE	Numeric	Median absolute percentage error
MDAPES	Numeric	Median absolute error as a percentage of standard deviation
MDAPPE	Numeric	Median absolute predictive percentage error
MDASPE	Numeric	Median absolute symmetric percentage error
MDRAE	Numeric	Median relative absolute error
ME	Numeric	Mean error
MINAPES	Numeric	Minimum absolute error as a percentage of standard deviation
MINERR	Numeric	Minimum error
MINPE	Numeric	Minimum percentage error
MINPPE	Numeric	Minimum predictive percentage error
MINRE	Numeric	Minimum relative error
MINSPE	Numeric	Minimum symmetric percentage error
MPE	Numeric	Mean percentage error
MPPE	Numeric	Mean predictive percentage error
MRAE	Numeric	Mean relative absolute error
MRE	Numeric	Mean relative error
MSE	Numeric	Mean square error
MSPE	Numeric	Mean symmetric percentage error
N	Numeric	Number of observations that were used. This is the number of observations in the block of observations from the first to the last nonmissing error, which includes any embedded missing errors.
NMISSA	Numeric	Number of missing actual values
NMISSP	Numeric	Number of missing predicted values
NOBS	Numeric	Number of observations
NPARMS	Numeric	Number of parameters

Table 32.17 *continued*

Column	Type	Description
RMSE	Numeric	Root mean square error
RMSSE	Numeric	Root mean square scaled error
RSQUARE	Numeric	R-square
RWRSQ	Numeric	Random walk R-square
SBC	Numeric	Schwarz Bayesian information criterion
SMAPE	Numeric	Symmetric mean absolute percentage error
SSE	Numeric	Sum of square error
SST	Numeric	Corrected total sum of squares
TSS	Numeric	Total sum of squares
UMSE	Numeric	Unbiased mean square error
URMSE	Numeric	Unbiased root mean square error

Table 32.18 summarizes the methods that are associated with the TSMSTAT object.

Table 32.18 Methods of the TSMSTAT Object

Method	Description
Collect	Collect model statistics of fit from the TSM object
nrows	Return the number of rows collected
SetOption	Set options for the TSMSTAT collector object

Figure 32.12 illustrates the data flow through the TSMSTAT object.

Figure 32.12 TSMSTAT Object Data Flow

TSMSTAT Synopsis

DECLARE OBJECT *obj* (TSMSTAT) ;

Method syntax, in order of typical usage:

```

rc=obj.SetOption ('Name', Value <,'Name',Value,... >) ;
rc=obj.Collect (TSMObj) ;
nrows=obj.nrows () ;

```

TSMSTAT Methods

TSMSTAT.Collect Method

```
rc=obj.Collect (TSMObj) ;
```

Collects model statistics of fit from a TSM object, *TSMObj*, and stores them in an output table.

Input Arguments

You must specify the following input argument:

TSMObj specifies the TSM object to use as the source of model fit statistics.

TSMSTAT.nrows Method

```
nrows=obj.nrows () ;
```

Returns the number of rows that have been collected and stored in the table.

Arguments

There are no arguments associated with this method.

TSMSTAT.SetOption Method

```
rc=obj.SetOption ('Name', Value <,'Name',Value,... >) ;
```

Specifies the options for the TSMSTAT object.

Input Arguments

You must specify at least one of the following '*Names*' and its associated *Value*:

'MODELNAME' takes a string *Value* that specifies the name of the model to be stored to the output table along with the parameter estimates of the model. By default, the model name is the name of the TSM object instance that is collected by the [TSMSTAT.Collect](#) method.

'FORCEMODELNAME' takes a Boolean *Value* that specifies whether the model name should be stored in the output table even when the model failed to run. You can specify one of the following values:

DISABLE|NO|N|FALSE|F|OFF does not store the model name in the output table if the model failed to run.

ENABLE|YES|Y|TRUE|T|ON always stores the model in the output table.

The default is DISABLE.

TSMINEST Object

The time series model input estimates (TSMINEST) repeater object imports parameter estimates from a table for use in a TSM object. The TSMINEST table schema that is required for the parameter estimates is compatible with that used by the TSMPEST collector object. The TSMINEST object must be used in conjunction with a TSMINSPEC specification object and a TSM model object to replay a model by using its saved parameters (for an example, see [Example 32.3](#)).

Table 32.19 summarizes the methods of the TSMINEST object.

Table 32.19 Methods of the TSMINEST Object

Method	Description
<code>nrows</code>	Return number of rows in the TSMINEST object

TSMINEST Synopsis

```
DECLARE OBJECT obj (TSMINEST) ;
```

Method syntax:

```
rc=obj.nrows () ;
```

TSMINEST Methods

TSMINEST.nrows Method

```
rc=obj.nrows () ;
```

Returns the number of rows in the TSMINEST object, *obj*. A returned missing value indicates that the object has not been successfully configured.

Arguments

There are no arguments associated with this method.

TSMINSPEC Object

The time series model input specification (TSMINSPEC) repeater object imports model specifications from a table for use in a TSM object. The TSMINSPEC table schema that is required for the model specification is compatible with that used by the TSMSPEC collector object.

Table 32.20 summarizes the methods of the TSMINSPEC object.

Table 32.20 Methods of the TSMINSPEC Object

Method	Description
<code>nrows</code>	Return number of rows in TSMINSPEC object

TSMINSPEC Synopsis

DECLARE OBJECT *obj* (TSMINSPEC) ;

Method syntax:

rc obj.nrows () ;

TSMINSPEC Methods

TSMINSPEC.nrows Method

rc=obj.nrows () ;

Returns the number of rows that have been collected and stored in the table. A returned missing value indicates that the TSMINSPEC object has not been successfully configured.

Arguments

There are no arguments associated with this method.

TSMOUTOPT Object

The TSMOUTOPT object collects the optimization history, which contains training and validation errors, from a TSM object, *TSMObj*, and stores them in an output table. This information is useful for evaluating how well the model fits the dependent series. This object is available only for the RNNSPEC object.

Table 32.21 shows the contents of the TSMOUTOPT object.

Table 32.21 Contents of the TSMOUTOPT Object

Column	Type	Description
Epoch	Numeric	Epoch number
Train Error	Numeric	Training error
Valid Error	Numeric	Validation error

Table 32.22 summarizes the methods that are associated with the TSMOUTOPT object.

Table 32.22 Methods of the TSMOUTOPT Object

Figure 32.13 TSMOUTOPT Object Data Flow

TSMOUTOPT Synopsis

DECLARE OBJECT *obj* (TSMOUTOPT) ;

Method syntax, in order of typical usage:

rc=obj.Collect (TSMObj) ;

TSMOUTOPT Methods

TSMOUTOPT.Collect Method

rc=obj.Collect (TSMObj) ;

Collects the optimization history from the TSM object, *TSMObj*, and stores it in an output table.

Input Arguments

You must specify the following input argument:

TSMObj specifies the TSM object to use as the source of the optimization history.

TSMRNNSTAT Object

The TSMRNNSTAT object collects RNN model statistics of fit from a TSM object, *TSMObj*, and stores them in an output table. This information is useful for evaluating how well the model fits the dependent series. This object is available only for the RNNSPEC object.

Table 32.23 shows the contents of the TSMRNNSTAT object.

Table 32.23 Contents of the TSMRNNSTAT Object

Column	Type	Description
NAME	String	Name of the dependent variable
OPTEPOCH	Numeric	Epoch number of the best model selected
PTVLDERROR	Numeric	Post-training validation error
TRNERROR	Numeric	Training error
VLDERROR	Numeric	Validation error

Table 32.24 summarizes the methods that are associated with the TSMRNNSTAT object.

Table 32.24 Methods of the TSMRNNSTAT Object

Method	Description
Collect	Collect model statistics of fit from the TSM object

TSMRNNSTAT Synopsis

DECLARE OBJECT *obj* (TSMRNNSTAT) ;

Method syntax, in order of typical usage:

*rc=***obj.Collect** (TSMObj) ;

Methods of the RNNSPEC Object

TSMRNNSTAT Methods

TSMRNNSTAT.Collect Method

*rc=***obj.Collect** (TSMObj) ;

Collects RNN model statistics of fit from a TSM object, *TSMObj*, and stores them in an output table.

Input Arguments

You must specify the following input argument:

TSMObj specifies the TSM object to use as the source of model fit statistics.

Examples: TSM Package

Throughout this section, it is assumed that you have already started a CAS session and the data tables that are used in this section are stored in mylib, a CAS library that you have the necessary permissions to work with. This section assumes that you are familiar with the general workings of the TSMODEL procedure; for more information, see Chapter 16, “TSMODEL Procedure” (*SAS Visual Forecasting: Forecasting Procedures*).

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```
proc options option=(CASHOST CASPORT);
run;
```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named mysess, and the LIBNAME statement creates the mylib CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the mysess session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS statement and the LIBNAME statement, see *SAS Cloud Analytic Services: User's Guide*. For general information about CAS and CAS sessions, see *SAS Cloud Analytic Services: Fundamentals*.

Example 32.1: Fitting and Forecasting with ARIMA and ESM Models

The airline passenger data, given as Series G in Box and Jenkins (1976), have been used in time series analysis literature as an example of a nonstationary seasonal time series; for more information about ARIMA modeling of Series G, see “Example 7.2 Seasonal Model for the Airline Series” in the ARIMA chapter of *SAS/ETS User’s Guide*.

This example shows how you can use the objects in the TSM package to fit the airline model, $ARIMA(0,1,1) \times (0,1,1)_{12}$ NOINT and to fit the Winters exponential smoothing model to the airline series. In particular, it shows how you can do the following:

1. Create ARIMA and ESM specifications by using the ARIMASPEC and ESMSPEC specification objects.
2. Use these specification objects to initialize the TSM model objects.
3. Use these TSM model objects to fit the airline model and Winters model to the airline series, and to forecast the series according to these models.
4. Postprocess the forecast results to compute an ad hoc statistic.
5. Output the computed results to tables.

The broad outline of the code in this example is as follows:

1. The PROC TSMODEL statement specifies the input data set (mylib.air), a variety of output tables (mylib.airFor, mylib.airEst, and so on), and the forecast lead (12).
2. The ID statement specifies date as the time index variable, and the INTERVAL= option indicates that the data are monthly.
3. The VAR statement specifies the input data set variable, air, which contains the airline series.
4. The OUTARRAYS and OUTSCALARS statements declare some output arrays and scalars that are used to store the analysis results, which are subsequently saved as tables.
5. The REQUIRE statement specifies the TSM package, which is needed for the analysis.
6. The statements between the SUBMIT and ENDSUBMIT statements use the TSM package objects to perform the actual analysis in your CAS session.
7. These statements are grouped in three sections:
 - The first section does the specification, fitting, and forecasting according to the airline model. The airSpec object contains the airline specification, and the airModel object is a TSM model object that is initialized by using airSpec. After the airModel is run, the parameter estimates are collected in airEst and the forecasts are collected in airFor. The model residuals are stored in the airErr array for later processing.

- The second section does the specification, fitting, and forecasting according to the Winters exponential smoothing model. The `esmSpec` object contains the Winters specification, and the `esmModel` object is a TSM model object that is initialized by using `esmSpec`. The `esmModel` is run, and the model residuals are stored in the `esmErr` array for later processing.
- The third section computes an ad hoc statistic called `nbetter`, which counts the number of times the airline model residuals are smaller (in absolute size) than the Winters model. This section is included to illustrate how you can write your own custom postprocessing code to analyze the results that are produced by the TSM objects.

```
proc tsmodel data=mylib.air
    outobj=(airFor=mylib.airFor airEst=mylib.airEst)
    outscalar=mylib.nbetter outarray=mylib.out lead=12;

Example 32.2: Fitting a Transfer Function Model

This example uses the gas furnace data from Box and Jenkins (1976). The data, called Series J by Box and Jenkins, contain sequentially recorded measurements of two variables: x , the input gas rate, and y , the output CO_2 . The data also include an index variable, time, which keeps track of the sequence number of each observation (essentially the row index). The TSMODEL procedure requires an ID variable that has a valid time interval associated with it to index the observations. In order to satisfy this requirement, the time variable is assigned as the time ID variable in the ID statement and its interval is specified as SECOND using the INTERVAL= option. The value INTERVAL=SECOND is one of the simplest interval types for sequential indexing. As shown in “Example 7.3 Model for Series J Data from Box and Jenkins” in the ARIMA chapter of *SAS/ETS User’s Guide*, a reasonable ARIMAX model for y turns out to be $y = \text{TFinput}(x) + \text{AR}(2)$, where $\text{TFinput}(x)$ is a transfer function term in x with a delay of 3, numerator polynomial of order 2, and

denominator polynomial of order 1, and where AR(2) is an error term of autoregressive order 2. The following statements show how to fit this model by using the objects in the TSM package:

```
proc tsmodel data=mylib.seriesj
  outobj=(jEst=mylib.jEst);
  id time interval=second;
  var x y;
  require tsm;
  submit;

  *** Transfer function modeling for seriesJ ***;
  declare object jModel(tsm);
  declare object jSpec(arimaspec);
  declare object jEst(tsmpest);

  array num[2]/nosymbols;
  array den[1]/nosymbols;
  array ar[2]/nosymbols;

  *** Set up the transfer function model spec: ***;
  rc = jSpec.Open( );

  *** Specify AR orders: p = (1 2) ***;
  ar[1] = 1;
  ar[2] = 2;
  rc = jSpec.AddARPoly(ar);

  rc = jSpec.AddTF('x', 3); *delay=3;
  num[1] = 1;
  num[2] = 2;
  rc = jSpec.AddTFNumPoly('x', num);
  den[1] = 1;
  rc = jSpec.AddTFDenPoly('x', den);
  *** done setting up ARIMA model ***;
  rc = jSpec.Close( );

  *** Set up and run the TSM object ***;
  rc = jModel.Initialize(jSpec);
  rc = jModel.SetY(y);
  rc = jModel.AddX(x);
  rc = jModel.Run( );

  *** output gas furnace model forecasts and estimates ***;
  rc = jEst.Collect(jModel);
endsubmit;
quit;
```

Output 32.2.1 shows the parameter estimates for the transfer function model.

Output 32.2.1 Parameter Estimates for the Transfer Function Model (Partial Output)

Example 32.3: Replaying a Previously Fitted Model

In some cases, it is useful to save the model specification and parameter estimates that are computed during an analysis for later use. For example, you can use the saved model specification and parameter estimates to produce model forecasts at a later stage (possibly with new measurements appended to the original data). This example shows how you can do the following:

1. Save the model specification and parameter estimates for later use by using the Collect method of the TSMSPEC and TSMPEST objects, respectively.
2. Reuse the previously saved model specification and parameter estimates to configure a TSM object by using the Replay method.
3. Produce the model forecasts by using this TSM object.

The following statements fit the airline model to the airline series (see [Example 32.1](#) for more information about the airline series and the airline model). The model specification and parameter estimates are stored in the tables mylib.airOSpec and mylib.airEst, respectively.

```
proc tsmmodel data=mylib.air
  outobj=(airEst=mylib.airEst airOSpec=mylib.airOSpec) ;
  id date interval=month;
  var air;
  require tsm;
  submit;

  *** Analysis based on airline model ***;
  declare object airModel(tsm);
  declare object airSpec(arimaspec);
  declare object airEst(tsmpest);
  declare object airOSpec(tsmspec);

  array diff[2]/nosymbols;
  array ma[1]/nosymbols;

  *** Set up the airline model spec:   ***;
  ** Model: log(air) ~ (0,1,1) (0,1,1)12 noint ***;
  rc = airSpec.Open();
```

```

*** Specify differencing orders ***;
diff[1] = 1;
diff[2] = 12;
rc = airSpec.SetDiff(diff,2);
*** Specify moving average orders: q = (1)(12) ***;
*** Use AddMAPoly twice for the two factors ***;
ma[1] = 1;
rc = airSpec.AddMAPoly(ma);
ma[1] = 12;
rc = airSpec.AddMAPoly(ma);
*** Specify NOINT ***;
rc = airSpec.SetOption('noint',1);
*** Specify the log transform ***;
rc = airSpec.SetTransform('log');
*** Done setting up the ARIMA model ***;
rc = airSpec.Close();

*** Set up and run the TSM object ***;
rc = airModel.Initialize(airSpec);
rc = airModel.SetY(Air);
rc = airModel.SetOption('lead',12);
rc = airModel.Run();

*** Output airline model spec and estimates ***;
rc = airEst.Collect(airModel);
rc = airOSpec.Collect(airModel);
endsubmit;
quit;

```

Output 32.3.1 shows the parameter estimates that are saved in mylib.airEst.

Example 32.4: Performing Time Series Imputation Using an ARIMA Model

Time series imputation is the process of replacing missing values in a time series with reasonable values that reflect the existing pattern in the available data (such as trend, seasonal variations, or long-term cyclical variations). It is a popular technique that is used across various domains of science. This example shows how you can do the following:

- Fit an ARIMA model to a time series that contains missing values by using a TSM object.
- Store the imputed values of the time series in a table.

For the purposes of this example, the following statements introduce two artificial missing values into the airline series (see [Example 32.1](#) for more information about the airline series and the airline model). The modified series is stored in the `mylib.airMiss` table. These statements assume that your engine libref is named `mylib`, but you can substitute any appropriately defined engine libref.

```

data mylib.airmiss;
  set mylib.air;
  airmiss = air;
  if date = '01JUL1955'd then airmiss = .;
  if date = '01AUG1955'd then airmiss = .;
run;

```

The following statements plot the modified airline series along with the two artificial missing values that were introduced. The results are shown in [Output 32.4.1](#).

```

proc sort data=mylib.airmiss out=airmiss;
  by date;
run;

proc sgplot data=airmiss;
  series x=date y = airmiss / break lineattrs=(color=blue thickness=3);
  series x=date y = air / lineattrs=(thickness=2 pattern=dot color=blue);
run;

```

In [Output 32.4.1](#), the solid blue line represents all the nonmissing data values in the modified airline series. The dotted blue line between the years 1955 and 1956 represents the two actual values that were set to missing values.

Output 32.4.1 Airline Passenger Time Series with Artificial Missing Values

The following statements fit the airline model to the modified airline series and store the imputed time series in the mylib.airImpute table:

```

proc tsmodel data=mylib.airmiss
  outobj=(airImpute=mylib.airImpute) ;
  id date interval=month;
  var airmiss;
  require tsm;
  submit;

  *** Analysis based on airline model ***;
  declare object airModel(tsm);
  declare object airSpec(arimaspec);
  declare object airImpute(tsmfor('SMOOTH','YES'));

  array diff[2]/nosymbols;
  array ma[1]/nosymbols;

  *** Set up the airline model spec: ***;
  ** Model: log(air) ~ (0,1,1)(0,1,1)12 noint ***;
  rc = airSpec.Open();
  *** Specify differencing orders ***;
  diff[1] = 1;
  diff[2] = 12;
  rc = airSpec.SetDiff(diff,2);
  *** Specify moving average orders: q = (1)(12) ***;
  *** Use AddMAPoly twice for the two factors ***;
  ma[1] = 1;
  rc = airSpec.AddMAPoly(ma);
  ma[1] = 12;
  rc = airSpec.AddMAPoly(ma);
  *** Specify NOINT ***;
  rc = airSpec.SetOption('noint',1);
  *** Specify the log transform ***;
  rc = airSpec.SetTransform('log');
  *** Done setting up the ARIMA model ***;
  rc = airSpec.Close();

  *** Set up and run the TSM object ***;
  rc = airModel.Initialize(airSpec);
  rc = airModel.SetY(Airmiss);
  rc = airModel.Run();

  *** Output the imputed airline time series ***;
  rc = airImpute.Collect(airModel);
endsubmit;
quit;

```

The following statements plot the modified airline series along with its imputed version. The results are shown in [Output 32.4.2](#).

```

data mylib.airimpute;
  merge mylib.airimpute mylib.airmiss;
  by date;
run;

```

```

proc sort data=mylib.airimpute out=airimpute;
  by date;
run;

proc sgplot data=airimpute;
  series x=date y = actual / break lineattrs=(thickness=3 color=blue);
  series x=date y = air / lineattrs=(thickness=2 pattern=dot color=blue);
  series x=date y = predict / lineattrs=(thickness=1 color=red);
  where year(date) >= 1954 and year(date) <= 1956;
run;

```

In [Output 32.4.2](#), the thick blue line represents the modified airline series, and the thin red line represents its imputed version. The time axis range is restricted to the dates between the years 1954 and 1956 in order to facilitate the visualization. Notice how the thin red line (imputed values) closely mimics the dotted blue line (original actual values) over the region between the years 1955 and 1956 where the artificial missing values were introduced.

Output 32.4.2 Imputed Airline Passenger Time Series

Example 32.5: Combining Forecasts

This example shows how you can use the objects in the TSM package to combine multiple model forecasts to generate an improved forecast. In particular, it shows how you can do the following:

1. Fit the airline model, $\text{ARIMA}(0,1,1) \times (0,1,1)_{12}$ NOINT, to the airline series.
2. Fit the Winters exponential smoothing model to the airline series.
3. Use the CFC object to produce a combined forecast that is more accurate than the individual forecasts.
4. Store fit statistics for all models in an output table for later comparison.

```
proc tsmodel data=mylib.air outobj=(fitstats=mylib.fitstats) lead=12;
  id date interval=month;
  var air;
  require tsm;
  submit;

```

Output 32.5.1 shows the value of the root mean square error (RMSE) fit statistic for the airline, ESM, and forecast combination models over both the fit and forecast regions. Lower RMSE values indicate a more accurate model. Notice how the combined model forecast improves in accuracy over both of the independent forecasts in both the fit and forecast regions.

Output 32.5.1 Fit Statistics for the Airline, ESM, and Forecast Combination Models**Root Mean Square Error (RMSE) Statistic**

<u>_MODEL_</u>	<u>_REGION_</u>	<u>RMSE</u>
airModel	FIT	10.7047
airModel	FORECAST	8.7732
esmModel	FIT	10.5826
esmModel	FORECAST	10.6018
airCFC	FIT	10.3719
airCFC	FORECAST	8.6551

Example 32.6: Recurrent Neural Network Forecasting

This example illustrates how to use the RNNSPEC object to fit a recurrent neural network forecasting model to the airline passenger data (see [Example 32.1](#) for more information about the airline series).

The following statements perform forecasting by using the LSTM recurrent neural network on the example data set. Specifying the value 12 for the 'NINPUT' argument means that the length of the input subsequence is 12. The value, 12, of the 'NVALIDATION' argument corresponds to the range of the validation period. The STD normalization is imposed. SetY specifies the AIR variable as the target variable. The number of layers is 4, which means that the neural network consists of one input layer, two hidden layers, and one output layer. The number of neurons in each hidden node is 30. When you specify 'ADAM' in the 'ALGORITHM' optimizer option, the stochastic gradient descent method uses the Adam optimization algorithm.

Overview: UTL Package

This chapter describes the various utility object classes that the utility (UTL) package contains. The UTL package provides a set of multipurpose tools that simplify the development of time series analysis programs for the TSMODEL procedure. The following types of computation are currently supported by the UTL package:

- computing prediction standard errors and confidence limits for specified actual and predicted time series
- computing and storing model forecast fit statistics in tables for specified actual and predicted time series
- storing ad hoc numeric variables that are defined in a user program in tables
- timing the execution of arbitrary portions of the time series analysis program that you submit as input to the TSMODEL procedure

The UTL package is object-oriented. To use the UTL package, you must declare instances of the object classes that the package contains. Declaring an object instance is the object-oriented equivalent of declaring a program variable. As with simple program variables, the declaration assigns the instance a name of your choosing and assigns a type, which is defined by the object's class. Unlike simple program variables, the object instance requires a different syntax for interacting with it and offers different functions (methods) that are contextual to the object. The object can offer highly sophisticated capabilities with a simple-to-use interface.

UTL Package Summary

Table 33.1 summarizes the objects in the UTL package.

Table 33.1 Objects in the UTL Package

Object	Description
CLIMITS	Object that computes prediction standard errors and confidence limits for specified actual and predicted time series
OUTNVP	Ad hoc name, value pair collector object for storing numeric scalar or array variables that are found in a user program in a table
UTL	Object that provides miscellaneous, stateless utility functions
UTLSTAT	Collector object for computing forecast fit statistics for specified actual and predicted time series and storing those statistics in a table

Using the UTL Package

The objects in the UTL package are divided into three categories:

- stateful computational objects (CLIMITS object)
- collector objects (OUTNVP and UTLSTAT objects)
- stateless functions (UTL object)

Collector objects provide a mechanism to create a snapshot of results (either from stateful objects or from plain program variables) and store those results in tables. Each collector object defines a table schema that is determined by the collector object's design. The collector objects in the UTL package (OUTNVP and UTLSTAT) follow a common method pattern. The basic execution follows this sequence of operations:

1. **Declare:** Create the collector object by using the object declaration statement.
2. **Collect:** Use the Collect method to store results in a table. The input arguments of the Collect method are specific to the collector object. For example, the UTLSTAT collector object's Collect method requires an actual and predicted time series as arguments. It then uses the specified series to compute forecast fit statistics and stores the results in a table. In contrast, the OUTNVP collector object's Collect method takes an ad hoc numerical scalar or array variable from the user program and stores it in a table. Rows that are collected are automatically appended to the collector's associated table at the end of each BY group, and the collector object's saved row set is automatically reset. The Nrows attribute returns the current row count in the collector. A missing value is returned if nothing has been collected. The data, now stored in tables, can then be used to produce reports or for further computations.

Common Argument Types

Table 33.2 defines the common argument types that are used in this chapter. The symbol *x* corresponds to the variable name.

Table 33.2 Common Argument Types

SAS Data Type	Declaration Syntax
Numeric	<i>x</i> or LENGTH <i>x</i> 8;
Numeric array	ARRAY <i>x</i> [<i>n</i>]/NOSYMBOLS;
Status	<i>x</i> or LENGTH <i>x</i> 8;
String	LENGTH <i>x</i> \$ <i>n</i> ;

Return Codes

Table 33.3 shows the return code (*rc* in method statements) status values that are used in this package. These status code values are returned after a method that is associated with an object is called; they can help determine whether the method executed successfully.

Table 33.3 Return Codes

Status	Meaning
< 0	An unrecoverable error occurred. No result was produced.
= 0	Unconditional success. The requested action completed and a normal result was produced.
> 0	Conditional success or warning. A result was produced subject to conditions.

Upon returning a negative status code, most methods in the UTL package objects also write a message to the output log that explains the causes of the related failure. These messages provide useful information during the process of debugging a user program. In the TSMODEL procedure, the output log is stored in the table that is specified in the OUTLOG= option in the PROC TSMODEL statement. For more information about how to enable and configure logging and about how to access the output log after an invocation of the TSMODEL procedure, see Chapter 16, “TSMODEL Procedure” (*SAS Visual Forecasting: Forecasting Procedures*).

CLIMITS Object

The CLIMITS object provides a mechanism for computing both the prediction standard errors and confidence limits of an *external model* (that is, a user-defined model) forecast, which is described by a pair of actual and predicted time series. The first stage of the computational process involves validating both input series. This validation is accomplished by ascertaining that the actual and predicted series have nonmissing observation values under at least one matching index. In addition, the predicted series is checked for the presence of extreme values. Next, the prediction standard errors are computed from the prediction errors (that is, the model residuals). Finally, the confidence limits are computed from the prediction standard errors. You can optionally supply the value of the confidence level that is used to compute the confidence limits. Note that the CLIMITS object retains all computed results in its internal memory. Individual forecast series can be queried via the [GetForecast](#) method, which is a method in the CLIMITS object.

Table 33.4 summarizes the methods that are associated with the CLIMITS object.

Table 33.4 Methods of the CLIMITS Object

Method	Description
Compute	Compute the prediction standard errors and confidence limits for specified actual and predicted time series
GetForecast	Retrieve a computed forecast series by name

CLIMITS Synopsis

DECLARE OBJECT *obj* (CLIMITS) ;

Method syntax, in order of typical usage:

rc=obj.Compute (*Actual,Predicted,< Alpha>,< NParms>,< Method>,< NlagPct>,< HorizonStart>*
);

rc=obj.GetForecast (*Which,Result*);

Figure 33.1 outlines the programmatic data flow through the CLIMITS object; each arrow represents a different object method.

Figure 33.1 CLIMITS Object Data Flow

CLIMITS Methods

CLIMITS.Compute Method

`rc=obj.Compute (Actual, Predicted,< Alpha>,< NParms>, < Method>,< NlagPct>, < HorizonStart> ) ;`

Computes the prediction standard errors and confidence limits for specified actual and predicted time series. Both input series are validated by ascertaining the presence of nonmissing observation values under at least one matching index. Also, the predicted series is checked for the presence of extreme values. The computed forecast series are stored in the object's internal memory and can be individually queried via the [GetForecast](#) method into a numeric array defined in the user program. A negative return code indicates that the validation of an input series failed (for example, the predicted series has extreme values or all missing values), you specified an out-of-range *Alpha* argument value, or a computational failure occurred (for example, an out-of-memory error).

Input Arguments

You must specify the following input arguments:

- Actual* specifies a numeric array that corresponds to the actual time series.
- Predicted* specifies a numeric array that corresponds to the predicted time series.

You can also specify the following input arguments:

- Alpha* takes a numeric value between 0 and 1, exclusive, that specifies the significance level for forecast confidence bands. The default value is 0.05.

- HorizonStart* takes a SAS date, datetime, or time value that specifies the start of the forecast horizon. When you specify this argument, the effective forecast horizon for any particular BY group might differ from another because of differences in the lengths of the historical data across the BY groups, but all forecasts will start at the same date as determined by the *HorizonStart* value. When you specify a missing value (.), the start of the forecast horizon is automatically set as the first time period following the last nonmissing observation of the dependent series. The default value is a missing value.

- Method* takes a string that specifies the external model to be used to approximate the prediction standard errors. You can specify one of the following values:

- ACF** indicates that autocorrelation is used.
- ERRORACF** indicates that prediction error autocorrelation is used.
- NONE** indicates that no prediction error autocorrelation is used.
- PERFECT** indicates that perfect autocorrelation is assumed.
- WN** indicates that the prediction error autocorrelation is white noise.

The default value is PERFECT.

- NlagPct* takes a numeric value between 0 and 100 that specifies the percentage of error series count for autocorrelation computations. The default value is 25 (25%).

- NParms* takes a nonnegative integer value that specifies the number of parameters that the external model uses to generate the forecasts. The default value is 0.

CLIMITS.GetForecast Method

```
rc=obj.GetForecast (Which,Result) ;
```

Places the specified forecast series (*Which*) from the CLIMITS object into the specified numeric array (*Result*). Forecast series have the same length as the predicted series that is supplied to the [Compute](#) method via its *Predicted* argument. The GetForecast method returns a negative status code if the [Compute](#) method returned a nonzero value or if it was not yet executed (that is, no results exist to be queried).

Input Arguments

You must specify the following input argument:

Which is a case-insensitive character string that specifies the type of forecast series to return. You can specify one of the following values:

LOWER returns a lower confidence limit series.
STDERR returns a prediction standard error series.
UPPER returns an upper confidence limit series.

Output Arguments

You must specify the following output argument:

Result specifies a numeric array to receive the forecast series. If the array length is longer than the requested series, it is padded with missing values.

OUTNVP Object

The OUTNVP object collects any ad hoc numeric variables that are defined in the user program into tables. The OUTNVP collector object accepts any of the following numeric types: scalar literal, scalar variable, and array variable.

Table 33.5 shows the contents of the OUTNVP object.

Table 33.5 Contents of the OUTNVP Object

Column	Type	Description
NAME	String	Name of the dependent variable
CALL	Numeric	Call count within the BY group
UTAG	Numeric	User-defined numeric tag
VIX	Numeric	Value index (1-based) for the row
VALUE	Numeric	Actual value for variable's row

Table 33.6 summarizes the methods that are associated with the OUTNVP object.

Table 33.6 Methods of the OUTNVP Object

Method	Description
<code>Collect</code>	Collect value for numeric data type
<code>nrows</code>	Get the OUTNVP instance row count

OUTNVP Synopsis

DECLARE OBJECT *obj* (OUTNVP) ;

Method syntax, in order of typical usage:

```
rc=obj.Collect ( Variable,< Utag> ) ;  
nrows=obj.nrows () ;
```

Figure 33.2 outlines the programmatic data flow through the OUTNVP object.

Figure 33.2 OUTNVP Object Data Flow

OUTNVP Methods

OUTNVP.Collect Method

```
rc=obj.Collect ( Variable,< Utag> ) ;
```

Stores a numeric type, either scalar literal or variable or array variable in the OUTNVP table. When the *Variable* parameter is a numeric scalar literal or variable, this method collects a single row into the OUTNVP table. When the *Variable* parameter is a numeric array variable, this method collects a sequence of rows for the span of indices in the array. If the optional parameter *Utag* is specified, its value is included in the `_UTAG_` column of each collected OUTNVP row. The name of the collected variable is also included in the `_NAME_` column of each collected OUTNVP row. Similarly, the value of a counter that counts the number of calls to this method that are made within a BY group is also included in column `_CALL_` of each OUTNVP row. A negative return value indicates that an error occurred while storing results into a table.

Input Arguments

You must specify the following input arguments:

Variable specifies a numeric array to be collected into the OUTNVP table.

You can also specify the following input argument:

Utag takes a numeric value that is included in the _UTAG_ column of the OUTNVP table. The default value is a missing value.

OUTNVP.nrows Method

```
nrows=obj.nrows () ;
```

Returns the number of rows that have been collected and stored in the table.

Arguments

There are no arguments associated with this method.

UTLSTAT Object

The UTLSTAT object conveniently computes a number of forecast fit statistics for an ad hoc pair of user-specified actual and predicted time series. The computed forecast fit statistics are automatically stored in a table. For each ad hoc pair of actual and predicted time series that is input into a UTLSTAT collector object, a single row of forecast fit statistics is added to the underlying table. [Table 33.7](#) shows the contents of the UTLSTAT object. For more information about forecast fit statistics, see the section “Statistics of Fit” in Chapter 17, “Forecasting Details” (*SAS Visual Forecasting: Time Series Packages*).

Table 33.7 Contents of the UTLSTAT Object

Column	Type	Description
NAME	String	Variable name of actual series
MODEL	String	Variable name of predicted series
AADJRSQ	Numeric	Amemiya’s adjusted R-square
ADJRSQ	Numeric	Adjusted R-square
AIC	Numeric	Akaike’s information criterion
AICC	Numeric	Finite sample corrected AIC
APC	Numeric	Amemiya’s prediction criterion
DFE	Numeric	Degrees of freedom error
GMAPE	Numeric	Geometric mean absolute percentage error

Table 33.7 *continued*

Column	Type	Description
GMAPES	Numeric	Geometric mean absolute error as a percentage of standard deviation
GMAPPE	Numeric	Geometric mean absolute predictive percentage error
GMRAE	Numeric	Geometric mean relative absolute error
GMASPE	Numeric	Geometric mean absolute symmetric percentage error
IMASE	Numeric	In-sample mean absolute scaled error
MAE	Numeric	Mean absolute error
MAPE	Numeric	Mean absolute percentage error
MAPES	Numeric	Mean absolute error as a percentage of standard deviation
MAPPE	Numeric	Mean absolute predictive percentage error
MASE	Numeric	Mean absolute scaled error
MAXAPES	Numeric	Maximum absolute error as a percentage of standard deviation
MAXERR	Numeric	Maximum error
MAXPE	Numeric	Maximum percentage error
MAXPPE	Numeric	Maximum predictive percentage error
MAXRE	Numeric	Maximum relative error
MAXSPE	Numeric	Maximum symmetric percentage error
MDAPE	Numeric	Median absolute percentage error
MDAPES	Numeric	Median absolute error as a percentage of standard deviation
MDAPPE	Numeric	Median absolute predictive percentage error
MDASPE	Numeric	Median absolute symmetric percentage error
MDRAE	Numeric	Median relative absolute error
ME	Numeric	Mean error
MINAPES	Numeric	Minimum absolute error as a percentage of standard deviation
MINERR	Numeric	Minimum error
MINPE	Numeric	Minimum percentage error
MINPPE	Numeric	Minimum predictive percentage error
MINRE	Numeric	Minimum relative error
MINSPE	Numeric	Minimum symmetric percentage error

Table 33.7 *continued*

Column	Type	Description
MPE	Numeric	Mean percentage error
MPPE	Numeric	Mean predictive percentage error
MRAE	Numeric	Mean relative absolute error
MRE	Numeric	Mean relative error
MSE	Numeric	Mean square error
MSPE	Numeric	Mean symmetric percentage error
N	Numeric	Number of observations that were used. This is the number of observations in the block of observations from the first to the last nonmissing error, which includes any embedded missing errors.
NMISSA	Numeric	Number of missing actual values
NMISSP	Numeric	Number of missing predicted values
NOBS	Numeric	Number of observations
NPARMS	Numeric	Number of parameters
RMSE	Numeric	Root mean square error
RMSSE	Numeric	Root mean square scaled error
RSQUARE	Numeric	R-square
RWRSQ	Numeric	Random walk R-square
SBC	Numeric	Schwarz Bayesian information criterion
SMAPE	Numeric	Symmetric mean absolute percentage error
SSE	Numeric	Sum of square error
SST	Numeric	Corrected total sum of squares
TSS	Numeric	Total sum of squares
UMSE	Numeric	Unbiased mean square error
URMSE	Numeric	Unbiased root mean square error

Table 33.8 summarizes the methods that are associated with the UTLSTAT object.

Table 33.8 Methods of the UTLSTAT Object

Method	Description
<code>Collect</code>	Compute and collect forecast fit statistics for a specified ad hoc pair of actual and predicted time series.
<code>nrows</code>	Get the UTLSTAT instance row count

UTLSTAT Synopsis

DECLARE OBJECT *obj* (UTLSTAT) ;

Method syntax, in order of typical usage:

```
rc=obj.Collect (Actual, Predicted, < Nparms > ) ;
nrows=obj.nrows () ;
```

Figure 33.3 outlines the programmatic data flow through the UTLSTAT object.

Figure 33.3 UTLSTAT Object Data Flow

UTLSTAT Methods

UTLSTAT.Collect Method

```
rc=obj.Collect (Actual, Predicted < , Nparms < , Back < , ModelName>>>) ;
```

Computes and collects forecast fit statistics for an ad hoc pair of specified actual time series and predicted time series. Each call collects up to two rows and saves them in the UTLSTAT table; these two rows contain the forecast fit statistics that are listed in Table 33.7. A negative return value indicates that an error occurred either during the computation of the forecast fit statistics or during storage of the results in a table. The values of the forecast fit statistics that are computed and the number of rows that are collected by this method depend on the values of the optional arguments *Nparms* and *Back*.

Input Arguments

You must specify the following input arguments:

- Actual* specifies a numeric array that corresponds to the actual time series.
- Predicted* specifies a numeric array that corresponds to the predicted time series.

You can also specify the following optional input arguments, in the order shown:

- Nparms* takes a numeric value that specifies the number of parameters used by the model that generated the predicted time series. The default value is 0.
- Back* takes a nonnegative integer value that specifies the number of time periods to use for computing out-of-sample statistics.

If you specify the value *B* for *Back*, then the UTLSTAT object computes and writes two sets of statistics to the UTLSTAT table. The first set is referred to as in-sample statistics and corresponds to time periods 1 to $L - B$, where L is the length of the series. The second set is referred to as out-of-sample statistics and corresponds to time periods $L - B + 1$ to L . The variable `_REGION_` in the UTLSTAT table identifies each set. The `_REGION_='FIT'` row contains in-sample statistics, and the `_REGION_='FORECAST'` row contains out-of-sample statistics. If $B = 0$, then only in-sample statistics are computed and collected, and the UTLSTAT table contains only the `_REGION_='FIT'` row. If $B > L$, then the object does not write any statistics to the UTLSTAT table, and if you have specified an OUTLOG table, it writes an appropriate error message to that table.

If you omit this value or specify a missing value, the default value is 0.

- ModelName* takes a string value that specifies the name of the model that generated the predicted time series. The object writes this name to the variable `_MODEL_` in the collected UTLSTAT table. If you omit this value or specify a missing value, the default value is the name that you specify for the *Predicted* array.

UTLSTAT.nrows Method

```
nrows=obj.nrows () ;
```

Returns the number of rows that have been collected and stored in the table.

Arguments

There are no arguments associated with this method.

UTL Object

The UTL object provides a method that enables you to measure the execution time of arbitrary portions of the time series analysis program that you submit as input to the TSMODEL procedure. [Table 33.9](#) summarizes this method.

Table 33.9 Method of the UTL Object

Method	Description
GetTime	Get the current time

UTL Synopsis

```
DECLARE OBJECT obj (UTL) ;
```

Method syntax:

```
currentTime=obj.GetTime () ;
```

UTL Methods

UTL.GetTime Method

```
currentTime=obj.GetTime () ;
```

Returns the time (in seconds) relative to the start of the execution of the TSMODEL procedure.

Arguments

There are no arguments associated with this method.

Details

You can use this method to measure the execution time of arbitrary portions of your time series analysis program. If you invoke this method twice and subtract the resulting *currentTime* values, then you can compute a time difference that has a precision of approximately 10 microseconds. The following statements illustrate this functionality:

```

/* Create an instance of the UTL object */
DECLARE OBJECT pkgObj(UTL);

/* Get the current time prior to performing some work */
tStartSecs = pkgObj.GetTime();

/* Perform some arbitrary work */
...

/* Get the current time after performing the work */
tEndSecs = pkgObj.GetTime();

/* Compute the amount of time (in seconds) taken to perform the work */
tDiffSecs = tEndSecs - tStartSecs;

/* Print the time difference in the log */
put tDiffSecs;

```

In particular, the preceding statements store in `tDiffSecs` the measured execution time of an arbitrary amount of work and then print the execution time in the log by passing `tDiffSecs` as the argument to the `PUT` statement. For information about how to log the output of the `PUT` statement, see the `OUTLOG=`, `LOGCONTROL=`, and `PUTTOLOG=` options in the `PROC TSMODEL` statement in Chapter 16, “TSMODEL Procedure” (*SAS Visual Forecasting: Forecasting Procedures*).

Examples: UTL Package

Throughout this section, it is assumed that you have already started a CAS session and that the data tables that are used in this section are in `mylib`, a CAS library that you have the necessary permissions to work with. This section assumes that you are familiar with the general workings of the `TSMODEL` procedure; for more information, see Chapter 16, “TSMODEL Procedure” (*SAS Visual Forecasting: Forecasting Procedures*).

Using CAS Sessions and CAS Engine Librefs

SAS Cloud Analytic Services (CAS) is the analytic server and associated cloud services in SAS Viya. This section describes how to create a CAS session and set up a CAS engine libref that you can use to connect to the CAS session. It assumes that you have a CAS server already available; contact your system administrator if you need help starting and terminating a server. This CAS server is identified by specifying the host on which it runs and the port on which it listens for communications. To simplify your interactions with this CAS server, the host information and port information for the server are stored as SAS option values that are retrieved automatically whenever this CAS server needs to be accessed. You can examine the host and port values for the server at your site by using the following statements:

```

proc options option=(CASHOST CASPORT);
run;

```

In addition to starting a CAS server, your system administrator might also have created a CAS session and a CAS engine libref for your use. You can define your own sessions and CAS engine librefs that connect to the CAS server as shown in the following statements:

```
cas mysess;
libname mylib cas sessref=mysess;
```

The CAS statement creates the CAS session named `mysess`, and the LIBNAME statement creates the `mylib` CAS engine libref that you use to connect to this session. It is not necessary to explicitly name the CASHOST and CASPORT of the CAS server in the CAS statement, because these values are retrieved from the corresponding SAS option values.

If you have created the `mysess` session, you can terminate it by using the TERMINATE option in the CAS statement as follows:

```
cas mysess terminate;
```

For more information about the CAS statement and the LIBNAME statement, see *SAS Cloud Analytic Services: User's Guide*. For general information about CAS and CAS sessions, see *SAS Cloud Analytic Services: Fundamentals*.

Example 33.1: Collecting Forecast Fit Statistics and Ad Hoc Numeric Variables into Tables

This example demonstrates the capabilities of the UTLSTAT and OUTNVP collector objects from the UTL package. The UTLSTAT collector object is used to compute and collect forecast fit statistics for a specified pair of actual and predicted time series. In contrast, the OUTNVP collector object is used to store ad hoc numeric variables that are found in the user-defined program into tables. The example starts by using a DATA step to load a sample time series data set called `Sashelp.Air` into a table. The TSMODEL procedure is then invoked and the Time Series Model (TSM) object (available in the TSM package) is used to generate a model for the Air series in the `Sashelp.Air` data set. Next, both the actual Air series and its predicted counterpart (generated by the TSM object) are input into the UTLSTAT object to compute and collect numerous forecast fit statistics (see [Table 33.7](#)) into a table. Because this example processes only a single time series (the Air series) and a single BY group, a single row of output is stored in the UTLSTAT table. The example then uses the OUTNVP collector object to store into a table various forecast series that are retrieved from the TSM object. Each forecast series is first queried into a numeric array via the GetForecast method in the TSM object. Each array is then input directly, one by one, into the OUTNVP collector object. Finally, some results are retrieved from the resulting UTLSTAT and OUTNVP tables, sorted, and printed for further inspection.

The following DATA step loads the `Sashelp.Air` data set onto the CAS server. This DATA step assumes that your CAS engine libref is named `mylib`, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.air (replace=yes);
  set Sashelp.Air;
run;
```

The following statements use the TSMODEL procedure to perform time series modeling on a single BY group. Because no ACCUMULATE= option is specified in the ID or VAR statements, its default value of TOTAL is used, which accumulates observations within a time period as a total sum of the nonmissing values.

```

proc tsmmodel data=mylib.air
  outarray = mylib.outarray (replace=yes)
  outscalar = mylib.outscalar (replace=yes)
  outobj=(
    utlstatobj = mylib.utlstat (replace = YES)
    outnvpmodelobj = mylib.outnvpmodel (replace = YES)
  )
  outlog = mylib.outlog (replace=yes)
  lead=12;
id date interval=month start='01jan1949'd end='01dec1960'd;
outarray predict error stderr lcl ucl;
outscalar rc1 rc2 rc3 rc4 rc5 rc6 rc7 rc8;
var air;
require tsm utl;
submit;
  /* Declare the "Time Series Model" (TSM) object and perform fit */
  declare object esm(tsm);
  rc1 = esm.Initialize();
  if rc1 < 0 then do; stop; end;
  rc1 = esm.SetY(air);
  if rc1 < 0 then do; stop; end;
  rc1 = esm.Run();
  if rc1 < 0 then do; stop; end;

  /* Retrieve forecast series computed internally by the TSM object */
  rc2 = esm.GetForecast('predict',predict); /*Predicted series*/
  if rc2 < 0 then do; stop; end;
  rc2 = esm.GetForecast('error',error);      /*Forecast error series*/
  if rc2 < 0 then do; stop; end;
  rc2 = esm.GetForecast('stderr',stderr);    /*Prediction std. errors series*/
  if rc2 < 0 then do; stop; end;
  rc2 = esm.GetForecast('lower',lcl);        /*Lower conf. limits series*/
  if rc2 < 0 then do; stop; end;
  rc2 = esm.GetForecast('upper',ucl);        /*Upper conf. limits series*/
  if rc2 < 0 then do; stop; end;

  /* Collect forecast series computed by the TSM object into a table */
  declare object outnvpmodelobj(outnvp);
  rc3 = outnvpmodelobj.Collect(air,_SERIES_);
  if rc3 < 0 then do; stop; end;
  rc3 = outnvpmodelobj.Collect(predict,_SERIES_);
  if rc3 < 0 then do; stop; end;
  rc3 = outnvpmodelobj.Collect(error,_SERIES_);
  if rc3 < 0 then do; stop; end;
  rc3 = outnvpmodelobj.Collect(stderr,_SERIES_);
  if rc3 < 0 then do; stop; end;
  rc3 = outnvpmodelobj.Collect(lcl,_SERIES_);
  if rc3 < 0 then do; stop; end;
  rc3 = outnvpmodelobj.Collect(ucl,_SERIES_);
  if rc3 < 0 then do; stop; end;

  /* Compute and collect a vast number of forecast fit statistics */
  declare object utlstatobj(utlstat);

```

```

rc4 = utlstatobj.Collect(air, predict);
if rc4 < 0 then do; stop; end;
endsubmit;
run;

```

You can use the PRINT procedure to display a small subset of the 55 different forecast fit statistics that are collected by the UTLSTAT object. PROC PRINT can access CAS tables directly; thus, there is no need to retrieve the UTLSTAT table from CAS and save it in a local data set prior to display.

```

/* Print a few forecast fit statistics for the single BY group */
proc print data=mylib.utlstat;
  var _NAME_ _MODEL_ NOBS RMSE MAPE MAE RSQUARE AIC;
run;

```

Output 33.1.1 shows that a single row of data was collected. This row corresponds to the forecast fit statistics that were collected for a single forecast (that is, one pair of actual and predicted series) within the single BY group that was processed by the TSMODEL procedure call.

Output 33.1.1 Sample of the Forecast Fit Statistics Computed and Collected by the UTLSTAT Object

Obs	_NAME_	_MODEL_	NOBS	RMSE	MAPE	MAE	RSQUARE	AIC
1	AIR	predict	144	10.579085435	3.0845016398	8.0064787209	0.9921692375	679.35714621

You can use the PRINT procedure again to display a small subset of observations from the following six different series that were collected by the OUTNVP object into the mylib.outnvpmodel table:

- The actual series (that is, the Air series).
- The predicted series that was generated by the TSM object.
- The forecast error series that was generated by the TSM object.
- The prediction standard errors series that was generated by the TSM object.
- The lower confidence limits series that was generated by the TSM object.
- The upper confidence limits series that was generated by the TSM object.

You can print in sequence the values of the first three observations in each of these six series, for a total of 18 rows. To accomplish this, you must sort the mylib.outnvpmodel table in a manner that sequentially aligns all rows that correspond to each unique observation index in all collected series (that is, all rows that correspond to the first observation in all six series, followed by all rows that correspond to the second observation in all six series, and so on). You can use the SORT procedure to simultaneously sort a table and store the results in a local data set as follows:

```

/* Sort OUTNVP table by "row index" and "BY group Collect() call count" */
/* (that is, _VIX_ and _CALL_ columns). */
proc sort data=mylib.outnvpmodel out=outnvpmodel;
  by _VIX_ _CALL_;
run;

/* Print the values of the first 18 rows, which correspond to the values */

```

```

/* of the first 3 observations in the six collected series. These 18 rows */
/* correspond to the condition "1 <= _VIX_ <= 3" in the table called */
/* "mylib.OUTNVPMODEL". */
proc print data=outnvpmodel (obs=18);
run;

```

Output 33.1.2 Sample of the Six Ad Hoc Series Collected by the OUTNVP Object

Obs	_VAR_	_CALL_	_UTAG_	_VIX_	_VALUE_
1	AIR	1	0	1	112
2	predict	2	0	1	111.44700541
3	error	3	0	1	0.5529945856
4	stderr	4	0	1	10.691036547
5	lcl	5	0	1	90.492958825
6	ucl	6	0	1	132.401052
7	AIR	1	0	2	118
8	predict	2	0	2	119.94581467
9	error	3	0	2	-1.945814668
10	stderr	4	0	2	10.691036547
11	lcl	5	0	2	98.991768079
12	ucl	6	0	2	140.89986126
13	AIR	1	0	3	132
14	predict	2	0	3	135.17351431
15	error	3	0	3	-3.173514311
16	stderr	4	0	3	10.691036547
17	lcl	5	0	3	114.21946772
18	ucl	6	0	3	156.1275609

The sequence that is displayed in [Output 33.1.2](#) was obtained by using the SORT procedure to sort the data in the OUTNVP table in increasing order of the columns `_VIX_` (series row index) and `_CALL_` (that is, the OUTNVP object's Collect method call count within BY group). For example, rows 1–6 contain the values of the first observation in each of the six collected series, which correspond to the rows in the `mylib.outnvpmodel` table where column `_VIX_` = 1: row 1 is the value of the first observation in the Air series (that is, column `_VAR_` = 'AIR') and rows 2–6 are the values of the first observations in the Predict, Error, StdErr, LCL, and UCL forecast series that were retrieved from the TSM object via its GetForecast method. The same applies for the second observation in each of the six collected series as described by rows 7–12 (that is, rows where column `_VIX_` = 2) and for the third observation in each of the six collected series as described by rows 13–18 (rows where column `_VIX_` = 3).

Example 33.2: Computing Prediction Standard Errors and Confidence Limits for an Ad Hoc External Forecast

This example uses the TSMODEL procedure to compute the prediction standard errors and confidence limits of an ad hoc forecast that includes an actual and predicted time series. The example starts by using a DATA step to create a synthetic data set called ExternalModel. The synthetic data set contains three time series that make up an ad hoc *external model* (that is, a user-defined model) forecast: an actual series called Air, a simulated forecast error series called Error, and a simulated predicted series called Predict. This synthetic, ad hoc external forecast lacks the prediction standard errors and confidence limits, which will be computed by the CLIMITS object. Notice from the DATA step code that the actual time series is simply a copy of the Air series taken from the Sashelp.Air data set. The predicted time series is generated by simply adding a small amount of noise to the actual Air series. The added noise corresponds to random samples taken of the uniform distribution (which ranges from 0.0 to 1.0) multiplied by a factor of 10. Thus, the added noise samples range from 0.0 to 10.0 and have an expected value of 5.0. This expected value is important because it corresponds to the average forecast error of the simulated predicted series, a value that over many samples should approximate the prediction standard errors that will be computed by the CLIMITS object for this synthetic, ad hoc external forecast. Next, the synthetic data set is uploaded to a table and the TSMODEL procedure is invoked. The actual and predicted time series are input to the CLIMITS object's **Compute** method to compute the prediction standard errors and confidence limits of the ad hoc external forecast. The CLIMITS object's **GetForecast** method is then used to retrieve the resulting three forecast series into numeric arrays that are defined in the user program. Finally, the OUTNVP collector object collects a total of six series into a table: the actual Air series, the simulated predicted and forecast error series, and the three forecast series that were computed by the CLIMITS object. This was similarly done in [Example 33.1](#) to store into a table the actual series plus the five forecast series that were retrieved from the TSM object via its own GetForecast method. Finally, some results are retrieved from tables, sorted, and printed for further inspection:

The following DATA step creates a synthetic data set that contains actual and simulated predicted time series:

```
data ExternalModel (replace=yes);
    set Sashelp.Air;                /* The actual series: Sashelp.Air */
    error = floor(10*ranuni(246));  /* Simulated forecast error series */
    predict = air + error;          /* Simulated predicted series */
run;
```

The following DATA step loads the ExternalModel data set onto the CAS server. This DATA step assumes that your CAS engine libref is named mylib, but you can substitute any appropriately defined CAS engine libref.

```
data mylib.ExternalModel;
    set ExternalModel;
run;
```

The following statements use the TSMODEL procedure to compute the prediction standard errors and confidence limits of the ad hoc external forecast that resides in the synthetic data set:

```
proc tsmodel data = mylib.externalmodel
    outarray = mylib.outarray (replace=yes)
    outscalar = mylib.outscalar (replace=yes)
    outlog = mylib.outlog (replace=yes)
    outobj=( outnvpmodelobj = mylib.outnvpmodel (replace = YES) );
```

```

id date interval=month start='01jan1949'd end='01dec1960'd;
var air predict error;
outarrays stderr lcl ucl;
outscalar rc1 rc2 rc3;
require utl;
submit;
    /* Compute the prediction standard errors and confidence limits */
    declare object clim(CLIMITS);
    rc1 = clim.Compute(air,predict,0.05); /* Confidence level: 0.05 */
    if rc1 < 0 then do; stop; end;

    /* Retrieve the forecast series stored internally in the CLIMITS object */
    rc2 = clim.GetForecast('stderr',stderr); /* Prediction sdt. errors series */
    if rc2 < 0 then do; stop; end;
    rc2 = clim.GetForecast('lower',lcl);      /* Lower conf. limits series */
    if rc2 < 0 then do; stop; end;
    rc2 = clim.GetForecast('upper',ucl);      /* Upper conf. limits series */
    if rc2 < 0 then do; stop; end;

    /* Collect the actual, predicted, and forecast error series, in addition */
    /* to the forecast series computed by the CLIMITS object into a table*/
    declare object outnvpmodelobj(outnvp);
    rc3 = outnvpmodelobj.Collect(air,_SERIES_);
    if rc3 < 0 then do; stop; end;
    rc3 = outnvpmodelobj.Collect(predict,_SERIES_);
    if rc3 < 0 then do; stop; end;
    rc3 = outnvpmodelobj.Collect(error,_SERIES_);
    if rc3 < 0 then do; stop; end;
    rc3 = outnvpmodelobj.Collect(stderr,_SERIES_);
    if rc3 < 0 then do; stop; end;
    rc3 = outnvpmodelobj.Collect(lcl,_SERIES_);
    if rc3 < 0 then do; stop; end;
    rc3 = outnvpmodelobj.Collect(ucl,_SERIES_);
    if rc3 < 0 then do; stop; end;
endsubmit;
run;

```

Following what was done in [Example 33.1](#), you can use the PRINT procedure to display a small subset of observations from the following six different series that were collected by the OUTNVP object into the mylib.outnvpmodel table:

- The actual series (Air series) of the ad hoc external forecast.
- The simulated predicted series of the ad hoc external forecast.
- The simulated forecast error series of the ad hoc external forecast.
- The prediction standard errors series that were computed by the CLIMITS object for the ad hoc external forecast.
- The lower confidence limits series that were computed by the CLIMITS object for the ad hoc external forecast.
- The upper confidence limits series that were computed by the CLIMITS object for the ad hoc external forecast.

You can print in sequence the values of the first three observations in each of these six series, for a total of 18 rows. To accomplish this, you must sort the `mylib.outnvpmodel` table in a manner that sequentially aligns all rows that correspond to each unique observation index in all collected series (all rows that correspond to the first observation in all six series, followed by all rows that correspond to the second observation in all six series, and so on). You can use the SORT procedure to simultaneously sort a table and store the results in a local data set as follows:

```
/* Sort OUTNVP table by "row index" and "BY group Collect() call count" */
/* (that is, _VIX_ and _CALL_ columns). */
proc sort data=mylib.outnvpmodel out=outnvpmodel;
    by _VIX_ _CALL_;
run;

/* Print the value of the first 18 rows, which corresponds to the values */
/* of the first 3 observations in the six collected series. These 18 rows */
/* correspond to the condition "1 <= _VIX_ <= 3" in the table called */
/* "mylib.OUTNVPMODEL". */
proc print data=outnvpmodel (obs=18);
run;
```

Output 33.2.1 Sample of the Six Ad Hoc Series Collected by the OUTNVP Object

Obs	_VAR_	_CALL_	_UTAG_	_VIX_	_VALUE_
1	AIR	1	0	1	112
2	predict	2	0	1	117
3	error	3	0	1	5
4	stderr	4	0	1	5.0408057116
5	lcl	5	0	1	107.12020235
6	ucl	6	0	1	126.87979765
7	AIR	1	0	2	118
8	predict	2	0	2	124
9	error	3	0	2	6
10	stderr	4	0	2	5.0408057116
11	lcl	5	0	2	114.12020235
12	ucl	6	0	2	133.87979765
13	AIR	1	0	3	132
14	predict	2	0	3	135
15	error	3	0	3	3
16	stderr	4	0	3	5.0408057116
17	lcl	5	0	3	125.12020235
18	ucl	6	0	3	144.87979765

The sequence displayed in [Output 33.2.1](#) was obtained by using the SORT procedure to sort the data in the OUTNVP table in increasing order of the columns `_VIX_` (that is, the series row index) and `_CALL_` (that is, the OUTNVP object's Collect method call count within BY group). For example, rows 1–6 contain the values of the first observation in each of the six collected series, which correspond to the rows in the `mylib.outnvpmodel` table where column `_VIX_` = 1: row 1 is the value of the first observation in the actual Air series (that is, column `_VAR_` = 'AIR'), rows 2–3 are the values of the first observations in the simulated Predict and Error series of the ad hoc external forecast, and rows 4–6 are the values of the first observations in the StdErr, LCL, and UCL forecast series that were computed by the CLIMITS object for the ad hoc external forecast and retrieved via its [GetForecast](#) method. The same applies for the second observation in each of

the six collected series as described by rows 7–12 (that is, rows where column `_VIX_` = 2) and for the third observation in each of the six collected series as described by rows 13–18 (rows where column `_VIX_` = 3).

Notice also in [Output 33.2.1](#) the value of 5.0408057116, which is reported for the first three observations of the prediction standard errors series, as shown by rows where column `_VAR_` = 'stderr'. This reported value should be close to the expected value of the simulated forecast error of the synthetic external forecast (5.0).
